USE = ПОЛЬЗОВАНИЕ (или ИСПОЛЬЗОВАНИЕ) – (1) Use:- in medieval English property law, the right of one person to take the profits of land belonging to another. It involved at least two and usually three persons. One man (A) would convey or enfeoff land to another (B) on the condition that the latter would use it not for his own benefit but for the benefit of a third man (C) – who could be A himself. C (or A), thus, had the profits – that is, the use – of the land and could treat the land as he pleased. This legal institution, which arose as early as the XI century, came to be employed not only as a legitimate method of providing for property management and for conveyancing but also as a method of defrauding creditors, depriving feudal landlords of their dues, and permitting religious institutions to derive the benefit of land that they could not own directly. Originally, carrying out the use depended on the conscience of the person entrusted with the property, because there was no writ by which the common-law courts could enforce it. Toward the end of the XIV century, however, the equity courts began to issue decrees for its enforcement. Whereas common-law courts had considered B to be the full owner, equity courts viewed him as merely the nominal owner and considered C the true, or 'equitable', owner and rendered judgments on that basis. By 1535 the use had become so objectionable because of its frequent employment for improper and illegal objects – particularly for avoiding dues or taxes – that Parliament enacted the Statute of Uses, which abolished many forms of the use. The uses that survived were called trusts, and they constitute the foundation on which the modern law of trusts exists.

(2) Use (all categories and General Technology Note):- operation, installation (including on-site installation), maintenance (checking), repair, overhaul and refurbishing.

USE–BASED APPLICATION = ПРИМЕНЕНИЕ, ОСНОВАННОЕ НА ИСПОЛЬЗОВАНИИ – Use-Based Application:- in the US patent law, there are 4 filing bases on which an application may be based. One filing basis is use of the mark in commerce (the other three are filing based on an intent-to-use the mark in commerce, filing based on a pending foreign application, and filing based on a foreign registration). Applicants who file based on use in commerce must be using the mark they wish to register with the goods or services in the application prior to or at the time of filing the application. To base the application on the applicant's use of the mark in commerce, the applicant must submit the following four items:- (i) a statement that the mark is in use in commerce, as defined by 15 USC §1127, and was in use in such commerce on or in connection with the goods or services listed in the application on the application filing date; (ii) the date of the applicant's first use of the mark anywhere on or in connection with the goods or services; (iii) the date of the applicant's first use of the mark in commerce as a trademark or service mark; and (iv) one specimen for each class showing how the applicant actually uses the mark in commerce. If the specimen is not filed with the initial application, applicant must submit a statement that the specimen was in use in commerce at least as early as the application filing date. These items must be verified by the applicant, i.e. supported either by an affidavit or by a declaration under 37 CFR §§2.20 and 2.33. Trademark Act Section 1(a), 15 USC §1051(a); 37 CFR §§2.34(a)(1) and 2.59(a); TMEP §806.01(a).

US EFFECTIVE CONTROLLED FLEET = ФЛОТ, ДЕЙСТВУЮЩИЙ ПОД КОНТРОЛЕМ США – US Effective Controlled Fleet:- that fleet of merchant ships owned by United States citizens or corporations and registered under flags of 'convenience' or 'necessity' such

as Liberia or Panama. The term is used to emphasize that, while the fleet is not US-flag, it is effectively under US control by virtue of the ship's owners and can be called to serve US interests in time of emergency.

USEFUL LIFE = ПОЛЕЗНАЯ ЖИЗНЬ (или СРОК ПОЛЕЗНОГО ИСПОЛЬЗОВАНИЯ) – Useful Life is an estimate of how long one can expect to use an income-producing item in a trade or business setting. Useful life usually refers to the duration for which the item will be useful (to the business), and not how long the property will actually last. Many factors affect a property's useful life, including the frequency of use, the age when acquired and the repair policy and environmental conditions of the business. The useful life for identical types of property will differ from user to user depending on the above factors, as well as additional factors such as foreseeable technological improvements, economic changes and changes in laws. The US Internal Revenue Service (IRS) employs useful life for estimating the amount of time over which an asset can be depreciated. The estimate is based on certain facts which may change over time. The useful life can be adjusted to reflect these changes; however, the changes must be substantial and there must be clear reason for making the change. For example, a company purchases a machine January 01, 2007 and estimates it will have a useful life of eight years. In 2011, however, the company realized that improvements in technology will render the machine obsolete by the end of 2012. Now, rather than having a useful life of eight years, the machine has a useful life of six years. The depreciation that has already been reported for years 2007, 2008, 2009 and 2010 cannot be changed, and any amount not yet depreciated as of December 31, 2010 will have to be depreciated over the next two years until the machine is no longer in use. Useful Life is a period during which an asset or property is expected to be usable for the purpose it was acquired. It may or may not correspond with the item's actual physical life or economic life. Useful Life is the number of years in which an asset can reliably produce benefits. How It Works:- Let's assume you buy a car for USD20 000. You believe the car could last for 15 years. After that, the car is probably 'run into the ground', and its next stop is the junkyard. Thus, the useful life of the car is 15 years. In the business world, useful lives are very important because they help companies calculate depreciation. Let's assume Company XYZ purchases a piece of machinery for USD1 million, and that piece of machinery has a useful life of 10 years. After that, the machinery is estimated to be worth, say, USD10 000. Thus, Company XYZ would record a depreciation expense equal to USD990 000 over 10 years (there are a variety of ways to do that). Why It Matters:- Useful lives are important in business because they affect the size of a company's depreciation or amortization expense (and thus they affect net income). It is important to note, however, that useful lives (and scrap values) are merely estimates. After all, nobody knows what an asset will be worth 10 years in advance or whether it will actually last that long. Useful Life is an estimated amount of time during which an asset or facility will yield income or be useful. Useful Life is the estimated lifespan of a depreciable fixed asset, during which it can be expected to contribute to company operations. This is an important concept in accounting, since a fixed asset is depreciated over its useful life. Thus, altering the useful life has a direct impact on the amount of depreciation expense recognized by a business per period. For example, altering a useful life from two years to four years doubles the time over which depreciation is recognized, which cuts the amount of depreciation expense recognized per period in half. If changing circumstances impact a fixed asset, it is possible that the remaining useful life will also be changed; this impacts the remaining amount of depreciation that has not yet been recognized, but has no impact on depreciation that has already been recognized in prior periods. It is relatively common to assign a standard useful life to every asset recorded within an asset class (such as machinery or computer equipment). Doing so takes away the need to justify the useful life assigned to every individual asset. Instead, if an asset fits the definition of assets recorded within a particular asset class, then the assignment of a useful life is automatic. As an example of useful life, a fixed asset is purchased at a cost of USD10 000. The company controller estimates its useful life to be five years, which means that the business will recognize USD2 000 of depreciation expense per year in each of the next five years. If the controller had instead stated a useful life of six years, the annual depreciation would have been USD1 667. The useful life concept has no impact on cash flow, since depreciation is a non-cash expense. The useful life concept as employed within a business does not necessarily reflect the entire lifespan of an asset; it may be sold off to a third party, which then continues to use the asset for an extended period of time. Thus, the useful life figure used by a business may be a subset of an asset's actual usage period. Useful Life is the amount of time during which something is in good enough condition to be used; e.g., the useful life of a satellite. The Useful Life of an asset is an accounting estimate of the number of years it is likely to remain in service for the purpose of cost-effective revenue generation. The US Internal Revenue Service (IRS) employs useful life estimates to determine the amount of time during which an asset can be depreciated. There are a variety of factors that can affect useful life estimates, including usage patterns, the age of the asset at the time of purchase and technological advances. Useful life refers to estimated durations of utility placed on a variety of business assets, including buildings, machinery, equipment, vehicles, electronics and furniture. Useful life estimations terminate at the point when assets are expected to become obsolete, require major repairs, or cease to deliver economical results. The estimation of the useful life of each asset, which is measured in years, can serve as a reference for depreciation schedules used to write off expenses related to the purchase of capital goods. Useful Life And Straight Line Depreciation:- The depreciation of assets using the straight line model divides the cost of an asset by the number of years in its estimated life calculation to determine a yearly depreciation value. The value is depreciated in equal amounts over the course of the estimated useful life. For example, the depreciation of an asset purchased for USD1 million with an estimated useful life of 10 years is USD100 000 per year. Useful Life And Accelerated Depreciation:- Businesses may also elect to take higher depreciation levels at the beginning of the useful life period, with declining depreciation values over the duration of the time span using an accelerated model. The yearly write-offs in the reducing balance depreciation model decline by a set percentage rate to zero. Using the sum of the years method, depreciation declines by a set Dollar amount each year throughout the useful life period. Useful Life Adjustments:- The duration of utility in a useful life estimate can be changed under a variety of conditions, including early obsolescence of an asset due to technological advances in similar applications. To change a useful life estimate in this circumstance, the company must provide a clear explanation to the IRS, backed by documentation comparing the old and new technologies. For example, if a company's original useful life estimate is 10 years, but new technology is likely to render it obsolete after eight years, the company may be able to accelerate depreciation based on a shorter schedule. In this situation, a company that is depreciating assets based on a 10-year schedule may be able to increase yearly depreciation values based on a newly abbreviated eight-year useful life estimate. Useful Life is the expected period of time during which a depreciating asset will be productive. Useful Life is a period during which an asset or property is expected to be usable for the purpose it was acquired. It may or may not correspond with the item's actual physical life or economic life. / Срок Полезного Использования:- период, в котором ожидается использование амортизируемого актива; необходимая информация для расчёта износа и амортизации долгосрочных активов, определяется самим предприятием; в большинстве случаев измеряется периодами времени (годами) или количеством произведённых изделий, километрами пробега. Полезная Жизнь – срок полезного использования. Полезная Жизнь – период времени, в течение которого подлежащий амортизации (deprecation) актив можно целесообразно и эффективно использовать. Называется также Амортизируемая Жизнь или Срок Амортизации (Depreciable Life). Модифицированная система ускоренного возмещения издержек производства (modified accelerated cost recovery system (MACRS)) устанавливает полезную жизнь или полезный срок для различных групп активов. Смотрите также (Residial Value).

USEFUL THERMAL OUTPUT = ПОЛЕЗНАЯ ТЕРМАЛЬНАЯ ПРОИЗВОДИТЕЛЬНОСТЬ (или ПОЛЕЗНАЯ ТЕПЛОПРОИЗВОДИТЕЛЬНОСТЬ) – Useful Thermal Output is the thermal energy made available for use in any industrial or

commercial process, or used in any heating or cooling application, i.e. total thermal energy made available for processes and applications other than electrical generation.

USE IN COMMERCE = ИСПОЛЬЗОВАНИЕ В КОММЕРЦИИ – Use In Commerce:- in the US patent law, for the purpose of obtaining federal registration, 'Commerce' means all commerce that the US Congress may lawfully regulate; for example, interstate commerce or commerce between the United States and another country. 'Use In Commerce' must be a bona fide use of the mark in the ordinary course of trade, and not use simply made to reserve rights in the mark. Generally, acceptable use is as follows:- (i) for goods:- the mark must appear on the goods, the container for the goods, or displays associated with the goods, and the goods must be sold or transported in commerce; (ii) for services:- the mark must be used or displayed in the sale or advertising of the services, and the services must be rendered in commerce. If you have already started using the mark in commerce, you may file based on that use. A 'use' based application must include a sworn statement (usually in the form of a declaration) that the mark is in use in commerce, listing the date of first use of the mark anywhere and the date of first use of the mark in commerce. A properly worded declaration is included in the United States Patent and Trademark Office (USPTO) standard application form. The applicant or a person authorized to sign on behalf of the applicant must sign the statement. The application should include a specimen showing use of the mark in commerce. / заслуживающий доверия или действительный (bona fide).

USE OF CORRECT CONTAINERS = ИСПОЛЬЗОВАНИЕ ДОЛЖНЫХ КОНТЕЙНЕРОВ – Use Of Correct Containers:- the package itself must be suitable for the use to which it will be put, i.e. shipping, consumer display, etc. Finishing department defects, and namely – Packaging. / Порок или дефект заключительной обработки.

USEPA = UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

USER = ПОЛЬЗОВАТЕЛЬ – User is the system owner or the designated administrator. In a household, this is commonly the person operating the computer. / Пользователь это системный владелец (владелец системы) или назначенный администратор. В случае домашнего использования это относится обычно к лицу, оперирующему компьютером.

USER–ACCESSIBLE PROGRAMMABILITY = XX – User-Accessible Programmability (Cat 4, 5, and 6):- The facility allowing a user to insert, modify, or replace 'programs' by means other than:- (a) a physical change in wiring or interconnections; or (b) the setting of function controls including entry of parameters.

USER–COST–OF–CAPITAL THEORY = ТЕОРИЯ СТОИМОСТИ КАПИТАЛА ДЛЯ ЕГО ПОТРЕБИТЕЛЯ – User-Cost-Of-Capital Theory:- xxxxx. The User Cost Of Capital is the unit cost for the use of a capital asset for one period – that is, the price for employing or obtaining one unit of capital services. The user cost of capital is also referred to as the 'rental price' of a capital good, or the 'capital service price'. / Теория Стоимости Капитала Для Его Потребителя (User-Cost-Of-Capital Theory):- Теория, которая утверждает, что объём инвестиций (investment) определяется экономической стоимостью инвестиций, сопоставленной с потенциальными поступлениями от них. Стоимость инвестиций представлена ставкой процента, который надо выплачивать по займам, и ценой инвестиционных товаров. Поступления же представляют собой поток дохода от производства. Калькуляция стоимости и поступлений приводит к чистой текущей стоимости (net present value). Хотя эта теория более приемлема, чем такие модели, как теория акселератора (accelerator theory), её трудно проверить на практике или использовать в качестве основы прогнозирования уровня инвестиций в экономике. USER FEE = ВОЗНАГРАЖДЕНИЕ ПОЛЬЗОВАТЕЛЯ – (1) User Fee:- transaction fee set by the card issuer and paid by the cardholder to the issuing institution for card payments or ATM cash withdrawals; other user fees, sometimes called Foreign Fees, are paid by the cardholder to the issuing institution for the use of ATMs not owned by the issuing institution. A User Fee is a fee, tax, or impost payment paid to a facility owner or operator by a facility user as a necessary condition for using the facility. People pay user fees for the use of many public services and facilities. A User Fee is a sum of money paid as a necessary condition to gain access to a particular service or facility. Examples of user fees could include highway tolls or parking garages. People pay user fees for the use of many government-affiliated services and facilities as well. At the federal level, for example, there is a fee to go up to the top of the Statue of Liberty and to drive into the country's many national parks. Also, certain services offered by the Library of Congress in Washington, DC require the public to pay a fee. In levying or authorizing user fees from a government standpoint, the US Congress determines whether the revenue should go into the Treasury or should be available to the agency providing the goods or services. Government services and facilities that are supported by user fees instead of by taxes may closely resemble private businesses because it is not apparent whether a true demand exists for those services and facilities. In that sense, the line between user fees and taxes can blur in certain circumstances. Sometimes, a tax will be incorrectly labeled as a user fee for political reasons, i.e. user fees are often deemed more palatable and able to be passed on to voters, than taxes. For example, if a politician wants to keep a promise to not raise taxes but still take certain steps to try to increase government revenue streams, the politician may push for an increase in certain kinds of taxes that can be labeled as fees. In contrast to user fees, taxes must be paid and do not necessarily go toward a specific service or facility that an individual actually uses or benefits from. For example, the money governments spend to treat smoking-related illnesses, in this case via the sale of cigarettes, could be considered both a tax and a fee. Income taxes can be an alternative to funding facilities and services with user fees. Everyone pays income taxes, including those who may not necessarily use or benefit from a specific facility or service. User Fees And Economic Development:- Within international development circles, user fees refer to a system fee for fundamental health care, education and other essential services implemented by a developing country to make up for the costs of these services. For one, the International Monetary Fund often recommends that nations start charging fees for these services in order to reduce budget deficits. For poor nations, however, such user fees can have counteractive effect, adding a burdensome expense on the population. / Вознаграждение Пользователя:- операционное вознаграждение, устанавливаемое эмитентом карты и уплачиваемое держателем карты учреждению-эмитенту за осуществление платежей с использованием карты или операции по снятию наличных через банкоматы; прочие вознаграждения пользователя, иногда называемые Внешними Вознаграждениями, уплачиваются держателем карты учреждению-эмитенту за использование банкоматов, ему не принадлежащих.

(2) User Fee (in US Customs and Border Protection):- as used in connection with international trade, a fee assessed for the performance of some type of a service or the use of facilities. With respect to fees charged by Customs authorities or governmental entities in connection with the importation of goods, the General Agreement on Tariffs and Trade (GATT) requires that a user fee be based on the estimated or computed cost of actual service rendered. An example of an acceptable user fee under GATT is the US Customs and Border Protection Merchandise Processing Fee assessed on most types of Customs entries to offset the cost of custom processing the entry. / Вознаграждение Пользователя:- плата за услугу, которая согласно ГАТТ, должна основываться на оценке или расчётной стоимости услуги. Соединённые Штаты Америки (США) установили плату за услуги таможни (таможенные сборы), взимаемые с привозных (или импортных) товаров, для покрытия всех или части издержек, связанных с таможенными операциями.

USER–FRIENDLY = ДРУЖЕСТВЕННО К ПОЛЬЗОВАТЕЛЮ – User-Friendly:- easy to learn, use, understand, or deal with; e.g., user-friendly software. First Known Use of User-Friendly:- 1972, in the meaning defined above. User-Friendly describes a hardware device or software interface that is easy to use. It is 'friendly' to the user, meaning it is not difficult to learn or understand. While 'user-friendly' is a subjective term, the following are several common attributes found in user-friendly interfaces. (1) Simple:- a user-friendly interface is not overly complex, but instead is straightforward, providing quick access to common features or commands. (2) Clean:- a good user interface is well-organized, making it easy to locate different tools and options. (3) Intuitive:- in order to be user-friendly, an interface must be make sense to the average user and should require minimal explanation for how to use it. (4) Reliable:- an unreliable product is not user-friendly, since it will cause undue frustration for the user. A user-friendly product is reliable and does not malfunction or crash. The goal of a user-friendly product is to provide a good user experience (or 'UX'). This may look different depending on the end user for whom the product is designed. For example, a user-friendly kid's game will have a much different interface than a professional Computer-Aided Design (CAD) program. However, the rules above apply to both types of software. Even if a program has many advanced features, it is still possible to make it user-friendly by designing a simple, clean, and intuitive interface. User-friendly products are typically more successful than those with complex, convoluted interfaces that are difficult to use. Additionally, customers often avoid unreliable products, such as software programs that are full of bugs. In order to ensure a good user experience, companies often thoroughly test their products before releasing them to the public. / Дружественный По Отношению К Пользователю (User-Friendly):- название компьютерной системы, которая связана таким образом, чтобы облегчить пользование ею для людей, не являющихся специалистами по компьютерам. Этот термин возник для того, чтобы отличать такие системы от более старых систем, в которых предпочтение отдавалось эффективности использования машинных ресурсов и не уделялось значительного внимания удобствам пользователя в работе с ними. Как правило, дружественная по отношению к пользователю система легко запускается и выдаёт на экране подсказки, обычно в форме меню (menus). Если пользователь окончательно запутался, раздел меню 'Помощь' позволяет перечислить действия, необходимые для исправления наиболее распространённых ошибок. Некоторые устройства ввода, например, 'мышь' ('mouse'), считаются более простыми в обращении, нежели обычная клавиатура, поэтому в дружественных по отношению к пользователю машинах предусмотрено их использование.

USER INTERFACE = ПОЛЬЗОВАТЕЛЬСКИЙ ИНТЕРФЕЙС (или ИНТЕРФЕЙС ПОЛЬЗОВАТЕЛЯ) – User Interface:- the way a person interacts with a computer or electronic device. It comprises the screen menus and icons, keyboard shortcuts, command language and online help, as well as physical buttons, dials and levers. All input devices, such as a mouse, keyboard, touch screen, remote control, joy stick, game controller or data glove, are also included. In the future, natural language recognition and voice recognition will become standard components of the user interface. The man-machine interface between the user and the personal trusted device (PTD).

USER SYSTEM = СИСТЕМА ПОТРЕБИТЕЛЯ – In reference to electricity, User System refers to a system owned or operated by a user of the grid or distribution system. / По отношению к электричеству, термин Система Потребителя относится к системе, принадлежащей и управляемой потребителем энергосистемы или системы сбыта.

USES OF FUNDS = ИСПОЛЬЗОВАНИЯ ФОНДОВ – Uses Of Funds:- xxxxx. See also Sources And Applications (or Uses) Of Funds Statement.

USE TAX = НАЛОГ НА ПОЛЬЗОВАНИЕ (или НАЛОГ НА ИСПОЛЬЗОВАНИЕ) – Use Tax:- levy on the use or possession of a commodity. Under the principle that the taxpayer should pay according to the benefits received from public services, a use tax is often levied on the user of a service, so that costs of the service are not borne by the general taxpayer. Common examples are motor-vehicle and boat licenses and user fees for airports or harbour-docking privileges. The revenue from the tax is generally used by a government to cover the costs of the maintenance and regulation of the services – in these instances, highways, waterways, and airports. In the United States a use tax is often levied by state or local governments on purchases made outside the jurisdiction and therefore not subject to the jurisdiction's retail sales tax. In this case the use tax is generally equal to the retail sales tax. In the United States the first federal use tax was levied on telephone and telegraph messages during the Spanish-American War (1898). During World War I all freight and passenger transportation was subject to a use tax. A federal use tax was levied on all motor vehicles during World War II, but this tax was eventually shifted to the states. The use tax as a vehicle-licensing plan serves a dual purpose as revenue raiser and as a method for identifying all vehicles using the public streets and roads. However, it is a regressive tax, despite numerous attempts to make it more equitable.

US EXPORT ADMINISTRATION ACT (1979) = АКТ США ОБ АДМИНИСТРАЦИИ ВЫВОЗА (1979) (или АКТ США ОБ АДМИНИСТРАЦИИ ЭКСПОРТА (1979)) – US Export Administration Act (EAA) of 1979 provided legal authority to the President to control US exports for reasons of national security, foreign policy, and/or short supply. The act was in force from 29 September 1979 to 1994, with a lapse in 1984–85. During this lapse, and upon the law's expiration, the authority of export regulations was continued by executive authority. Presidents Reagan and Clinton each declared that the expiration created an emergency under the International Emergency Economic Powers Act and reauthorized all regulations on that basis. Subsequent Presidents extended the emergency each year by Presidential Notice, until the passing of the Export Controls Act of 2018 on 04 August 2018. Regulation Forbidding Anti-Israel Boycotts:- The US Department of Commerce's Bureau of Industry and Security is charged with enforcing and administering the anti-boycott laws under the Export Administration Act. 'Those laws discourage, and in some circumstances, prohibit US companies from furthering or supporting the boycott of Israel sponsored by the Arab League, and certain Muslim countries, including complying with certain requests for information designed to verify compliance with the boycott'. The Export Administration Act was enacted in 1979 as Public Law 96–72 and has been amended several times since then. The law shown here is as codified in Title 50-Appendix of the US Code. US Export Administration Act (EAA) of 1979 is only the most recent legislative enactment by which Congress has authorized the President to regulate US exports. (The Act of 1979 was considered and passed by the Senate on July 21 and September 27, 1979. S. REP. No. 169, 96th Cong., 1st Sess. I, reprinted in (1979) US CODE CONG. & AD. NEWS 1147. The House considered and passed the legislation on September 25 and 28, 1979. Id. For a good summary of the historical progression of US export control policy as embodied in the three major pieces of US export control legislation (the Act of 1949, Pub. L. No. 80-11, 63 Stat. 7 (1949) (repealed 1969), the Act of 1969, Pub. L. No. 91-184, 83 Stat. 841 (1962) (superseded 1979), and the Act of 1979, 50 USC app. § 2401 et seq. (1980)), see Whitman, supra note 6. In her article, Whitman states that:- (r)estrictions on US trade with the Soviet Union in the interests of national security have long been an integral part of US foreign policy – indeed, for most of the postwar period, such trade was essentially embargoed entirely. Over the past decade, however, economic relations between East and West have been expanding and, by the heyday of detente, US restrictions were largely confined to items having a direct military application. Most recently, the Administration has attempted a broader balancing of the trade-offs between the effects of a particular export decision on restraining Soviet expansionism, US-Soviet relations, and the United States' trade competitiveness and world leadership position.) The Executive has had the power since the enactment of the Trading with the Enemy Act of 1917 (50 USC app. § I et seq. (1980)), to prohibit all exports to countries at war with the United States and its allies. It was under the authority of that Act that the President, in

1950, placed a halt on all economic dealings with Communist China and North Korea following the incursion of Communist Chinese forces into Korea. (31 CFR §§ 500.101-.808 (1967)) In contrast to the wartime power given the President under the Trading with the Enemy Act of 1917 (50 USC app. § I et seq. (1980)), the Mutual Security Act of 1954 (Ch. II., § 114, 68 Stat. 848 (1954) (repealed 1976). The Mutual Security Act of 1954, id., was replaced by the Arms Export Control Act, 22 USC § 2778 (1980). For a discussion of legislation governing US military exports generally, see Note, US Military Exports and the Armed Export Control Act of 1976:- The F-16 Sale 10 Iran, 9 CASE W. RES. J. INT'L L. 407 (1977)) authorized the President to restrict the peacetime exportation of arms, munitions, implements of war and related technology to any nation. (Mutual Security Act of 1954, ch. II, § 114, 68 Stat. 848 (1954) (repealed 1976)) A third statute dealing with US export controls was the Mutual Defense Assistance Control Act of 1951 (Ch. 575, § 101, 65 Stat. 645 (1951) (superseded 1979). The Mutual Defense Assistance Control Act of 1951, id., was superseded by the Act of 1979, 50 USC app. § 2401 et seq. (1980)) which conditioned the extension of Marshall Plan Aid to US allies upon assurances that they would not export goods subject to US strategic export control to the Soviet Union. (Id. at ch. 575, § 103, 65 Stat. 645 (1951)) The leverage provided by Marshall Plan Aid assured the compliance of US allies in imposing multilateral trade controls against the eastern block countries. (See 125 CONG. REC. S9795 (daily ed. July 18, 1979)) However, since World War II, the economic growth of Western Europe, coupled with changing international political relationships, has resulted in a reduction of US export control leverage and a less than unified export control approach by the United States and its allies. The extent of multilateral export control cooperation between the United States and its allies, and the role that this factor has in the formulation of US export control policy, is a topic of current concern. The ramifications of multilateral export control cooperation will be explored in detail, below, within the context of the new provisions of the Act of 1979 which are intended to increase US participation in multilateral controls. The Act of 1979, the current authority for the regulation of US exports, has two predecessors:- the Export Control Act of 1949 (Act of 1949) and the Export Administration Act of 1969. The successive statutory changes in the degree of export control, evidenced in these three statutes, reflect the changing political relationship between the United States and the Communist world. The Act of 1949, passed in the midst of the Cold War, imposed an almost complete embargo on all trade with the Soviet bloc; exports which would contribute to either the military or economic strength of the Communist nations were prohibited. The Act of 1969 narrowed the broad controls mandated by the earlier Act of 1949; only goods of potential str.ategic value were banned for export to the Communist bloc. Essentially, there were three reasons for the shift in US policy from a broad economic embargo under the Act of 1949 to a more narrow, national security approach to export controls under the Act of 1969. First, trade with the Soviets, a part ofthe Nixon-Kissinger era détente would create a relationship of interdependence and interreliance between East and West, thereby making it difficult for the Soviets to take any harmful unilateral actions. Second, the USSR had become one of the world's major economic and military powers, despite the broad embargo of the Act of 1949. Third, the uniformity of allied multilateral export restrictions against the Eastern bloc had waned as the leverage provided by the Marshall Plan had declined, with the result that the allies were exporting goods to the Soviets that were subject to US trade restrictions. Indeed, the relaxation of export controls under the Act of 1969 resulted in the opening and the expansion of East West trade. During the first year of the existence of the Act of 1969, 1 550 commodities in 775 Commodity Control List (CCL) entries were removed from the CCL and were made available for export to the Soviet bloc countries. Similarly, the Act of 1979 indicates a still greater willingness on the part of Congress to expand East-West trade. The preface to the statute discloses that it is 'An Act to provide authority to regulate exports, to improve the efficiency of export regulation, and to minimize interference with the ability to engage in commerce'. In reality, the Act of 1979 is more of a legislative effort at improving the procedural and administrative efficiency of the existing export control system than a direct attempt to promote US export performance. However, by improving the technical and functional aspects of export licensing and by mandating a more careful consideration of the economic and balance of payments impacts of controls, the new legislation should serve to free many unjustifiably controlled commodities. / Президенты США Ранэлд Вилсэн Рэйген (Ronald Wilson Reagan; 1911–2004) и Бил Клынтчэн (Bill Clinton настоящее имя Вилъйэм Дьжефёсэн Клынтчэн (William Jefferson Clinton), урождённый Вилъйэм Дьжефёсэн Блайз III (William Jefferson Blythe III); 1946–). Помощь по Плану Маршэла (Marshall Plan Aid). Эра Никсэна-Кисиндьжё (Nixon-Kissinger era; в честь Президента США Ричода Милхауса Никсэна (Richard Milhous Nixon; 1913–1994) и Американского государственного деятеля, политического учёного, дипломата и геополитического консультанта Хэнри Алфрэда Кисиндьжё (Henry Alfred Kissinger; 1923–)). Акт США Об Администрации Вывоза от 1979 или Акт Об Администрации Экспорта США от 1979:- акт, разрешивший вывозной (или экспортный) контроль за товарами и услугами, вывозимыми из Соединённых Штатов Америки (США), уполномочил Президента вводить контроль в действие и следить за его соблюдением.

US FLAG VESSELS = СУДА ПОД ФЛАГОМ США – US Flag Vessels are registered in the United States and are subject to additional US laws and regulations to which foreign-flag vessels are not. They must be owned by US citizens, corporations, or governments and must be crewed mainly by US citizens.

US FUTURES EXCHANGE, LLC = Ю.ЭС. ФЬЮЧЕЗ ЭКСЧЭЙНДЬЖ, ЭЛ.ЭЛ.СИ. (или БИРЖА ФЬЮЧЕРСОВ США, КОО) – US Futures Exchange, LLC (USFE) offers specialized products to retail, hedge fund, and institutional customers in a regulated futures and options exchange. Its products include equity index futures, foreign exchange products, and binary derivatives. The company offers equity index derivatives, FX spot equivalent futures, and binary options for individual investors, as well as offers wind power contracts, credit derivatives, and fixed income contracts for institutions and hedge funds. The company was formerly known as Eurex US and changed its name to US Futures Exchange, LLC in October, 2006, as a result of its acquisition by Man Group PLC. US Futures Exchange, LLC was founded in 2004 and is based in Chicago, State of Illinois (IL) with an additional office in New York, State of New York (NY). As of October 01, 2006, US Futures Exchange, LLC operates as a subsidiary of Man Group PLC. US Futures Exchange (USFE) was a Chicago-based, electronic futures exchange that terminated all exchange operations on December 31, 2008. On December 17, 2008, MF Global had announced USFE was for sale or would be closed by December 31, 2008. USFE was originally Eurex US who bought BrokerTec, but applied and received its own futures exchange license from the US Commodity Futures Trading Commission. In October 2006, Man Group bought a majority share of Eurex US and rebranded the exchange US Futures Exchange. It has been working to release a set of new products under a strategy of bringing innovation to the more than century-old derivatives business. The Chief Executive Officer was John Spiegel. Products:- on September 03, 2008, USFE announced an exclusive licensing agreement with Deutsche Börse to launch a mini-sized US Dollar-denominated DAX(R) futures contract to be launched October 01, 2008. The new contract carried a USD10 multiplier, enabling US futures traders access to a leading German stock market index without currency exposure. On April 18, 2007, USFE launched its first contracts since its rebranding. The first was a Binary Event Future on whether the Chicago Mercantile Exchange (CME) would successfully purchase the Chicago Board of Trade (CBOT). The second was similar except on whether the Intercontinental Exchange would purchase the Chicago Board of Trade. A binary event future settles to 100 if the event occurs and 0 if the event does not occur. The CME-CBOT contract settled on July 13, 2007, to 100 when the Chicago Mercantile Exchange and the Chicago Board of Trade completed a merger and became the CME Group. On March 14, 2007, USFE announced plans to launch futures based on ISE (short for the International Securities Exchange Holdings, Inc., New York, USA) indexes, including the Homebuilders, Gold, SINdex, Revere Natural Gas, and Water Indexes. USFE also announced an exclusive deal with Morningstar to list futures based on their 16 capitalization and style-based indexes on May 23, 2007. On June 28,

2007, USFE announced it would launch a series of renewable energy futures starting with on NORDIX Financial Wind Index futures in seven distinct US regions. All of these futures were due to be released in Q4 of 2007. On September 21, 2007, USFE announced that it would begin trading Spot Equivalent foreign exchange futures on a 23-hour basis. Spot Equivalent Futures are futures which pay out basis nightly so that the futures contract will price the same as a spot contract in the foreign exchange market. However, at the same time, it would trade on a transparent, regulated exchange. The first contracts included Euro (EUR/USD), British Pound (GBP/USD), Japanese Yen (USD/JPY), Australian Dollar (AUD/USD), Swiss Franc (USD/CHF), and Canadian Dollar (USD/CAD). Trading Platform:- USFE was a fully electronic exchange. Its last platform release, USFE 1.0, was based on Eurex 8.0 developed by Deutsche Börse Systems with an additional market allocation algorithm to incentivize liquidity providers. USFE used the Eurex network backbone to provide connectivity worldwide. US Futures Exchange, LLC (Eurex US) is owned 80% by US Exchange Holdings, Inc., a Delaware corporation that is a separately capitalized wholly-owned subsidiary of Eurex Frankfurt, AG, and 20% by Exchange Place Holdings, LP, a Delaware limited partnership. US Futures Exchange was a US registered futures exchange that offered electronic trading of derivatives. It was formed in late 2006 when Man Group and its MF Global brokerage unit bought a majority stake in the US exchange formed by Eurex, which was then known as Eurex US. The exchange was rebranded as US Futures Exchange in April 2007 focusing on trading binary contracts, which offer an all-or-nothing pay-out on a range of specific outcomes. The exchange discontinued operations on December 31, 2008. Business Overview:- US Futures Exchange (USFE) concentrated on developing products to attract the retail market with mini-sized equity foreign equity index products and currency products. USFE tried to use a low-cost structure to provide a 'turnkey' platform for the listing of products developed in partnership with third parties. Clearing was provided by The Clearing Corporation, the platform was operated by Deutsche Boerse Systems, and it was regulated by the National Futures Association.The USFE had a page on MySpace, the social networking platform, though this has since been pulled. Shareholders:- the spin-off of MF Global made it the largest single shareholder in the USFE, with a 49.9 percent stake, with Man Group's holding reduced to 17 percent. Both companies committed to a proportionate reduction in their holdings to bring in other partners, but the rogue-trading scandal and other issues that dogged MF Global complicated those plans. Eurex had a 27 percent stake, with management and other investors holding 6.1 percent. Product Development:- the new USFE launched its first product on April 20, 2007, a binary future based on the outcome of the takeover battle for the Chicago Board of Trade between the Chicago Mercantile Exchange and the Intercontinental Exchange. USFE's push into the retail market saw its first foreign exchange contracts listed on September 21, 2007. The FX Spot Equivalent Futures traded on a 23-hour basis, with six initial currency pairs including the US Dollar against the Euro, Yen, Sterling, Swiss Franc, Canadian Dollar and the Australian Dollar. USFE announced on November 12, 2007, that it would exclusively license the Bombay Stock Exchange's (BSE) benchmark SENSEX Index. US Dollar-denominated futures trading began on April 04, 2008. USFE's SENSEX contract allows eligible US investors to participate in India's equity markets without requiring American Depository Receipt (ADR) authorization. The SENSEX Index is composed of 30 major Indian stocks and is regarded as the country's premier stock market index. The exchange launched a Dollar-denominated mini-Dax contract licensed from Deutsche Börse on October 01, 2008, tracking the benchmark Dax 30 and using a maker-taker pricing model. / БрокёТэк (BrokerTec). US GOVERNMENT SECURITIES BROKER–DEALER = БРОКЕР–ДЕЛЕЦ ПО ЦЕННЫМ БУМАГАМ ПРАВИТЕЛЬСТВА США – The US Government Securities Broker-Dealer is a broker-dealer registered with the Securities and Exchange Commission that functions in the operation of markets for US Treasuries. The functions may include, but are not limited to:- (i) Acting as a channel for the United States Department of the Treasury and investors in primary market for US Treasuries (for example, by participating in auctions); (ii) Acting as providers of liquidity in primary and secondary markets for US Treasuries; and (iii) Acting as providers of asset transformation and market making services in the market for US Treasuries.

US INTERAGENCY TRADE ORGANIZATION = МЕЖВЕДОМСТВЕННАЯ ОРГАНИЗАЦИЯ США ПО ТОРГОВЛЕ – US Interagency Trade Organization:- xxxxx. / Межведомственная Торговая Организация США:- была предусмотрена Актом О Торговле от 1988 (1988 Trade Act), возглавляется Торговым Представителем США на торговых переговорах; совещательный орган при Президенте и Представителе по вопросам, относящимся к выработке политики и международной торговле и её проведению в жизнь во всемирном масштабе.

US INTERNATIONAL TRADE ADMINISTRATION = АДМИНИСТРАЦИЯ США ПО МЕЖДУНАРОДНОЙ ТОРГОВЛЕ – The International Trade Administration (ITA) is an agency in the United States Department of Commerce that promotes United States (US) exports of nonagricultural US services and goods. ITA was formed on 02 January 1980 and headquartered in Washington, DC, the United States. ITA strengthens the competitiveness of US industry, promotes trade and investment, and ensures fair trade through the rigorous enforcement of our trade laws and agreements. ITA works to improve the global business environment and helps US organizations compete at home and abroad. ITA is organized into three distinct but complementary business units:- The Global Markets unit combines ITA's country and regional experts, overseas and domestic field staff, and specific trade promotion programs to provide US firms with the full suite of country-specific export promotion services and market access advocacy, while promoting the United States as an investment destination. The Industry and Analysis (I&A) unit brings together ITA's industry, trade, and economic experts to advance the competitiveness of US industries through the development and execution of international trade and investment policies and promotion strategies. I&A will leverage ITA's relationships with manufacturing and services industries to increase US exports. The Enforcement and Compliance unit enhances ITA's responsibilities to enforce US trade laws and ensure compliance with trade agreements negotiated on behalf of US industry. On October 01, 2013, ITA implemented a consolidation into these three business units. ITA Mission:- Create prosperity by strengthening the international competitiveness of US industry, promoting trade and investment, and ensuring fair trade and compliance with trade laws and agreements. ITA Vision:- Foster economic growth and prosperity through global trade. ITA Values:- (i) High standards of personal integrity and professional excellence; (ii) Mutual respect and teamwork; and (iii) Creativity and individual initiative. / Администрация США По Международной Торговле или Управление По

Международной Торговле США:- подразделение Департамента Торговли Соединённых Штатов Америки (США), образованное в 1980; возглавляется Заместителем Министра по Международной Торговле. Основные сферы компетенции включают международную экономическую политику, регулирование привоза (или импорта), развитие торговли, зарубежные коммерческие услуги.

US INTERNATIONAL TRADE COMMISSION = КОМИССИЯ США ПО МЕЖДУНАРОДНОЙ ТОРГОВЛЕ – The United States International Trade Commission (USITC) is an independent, quasi judicial Federal agency with broad investigative responsibilities on matters of trade. The Commission (1) administers US trade remedy laws within its mandate in a fair and objective manner; (2) provides the President, The US Trade Representative and Congress with independent analysis, information, and support on matters of tariffs, international trade, and US competitiveness; and (3) maintains the Harmonized Tariff Schedule of the United States (HTS). The USITC serves as a federal resource where trade data and other trade policy-related information are gathered and analyzed. The information and analysis are provided to the President, the Office of the United States Trade Representative, and the Congress to contribute to the development of sound and informed US trade policy. The USITC makes most of its information and analysis available to the public to promote understanding of international trade issues. US International Trade Commission (USITC) is an independent federal agency that provides trade expertise to both the legislative and executive branches of government, determines the impact of imports on US industries, directs actions against unfair trade practices, updates and publishes the Harmonized Tariff Schedule (HTS) of the US.The site features comprehensive information about its activities and provides access to its publications and the Tariff Database. Founded:- 08 September 1916; headquartered in Washington, DC, the United States; preceding agency:- US Tariff Commission. The United States International Trade Commission (USITC) is an independent, quasijudicial Federal agency with broad investigative responsibilities on matters of trade. The agency investigates the effects of dumped and subsidized imports on domestic industries and conducts global safeguard investigations. The Commission also adjudicates cases involving imports that allegedly infringe intellectual property rights. Through such proceedings, the agency facilitates a rules-based international trading system. The Commission also serves as a Federal resource where trade data and other trade policy-related information are gathered and analyzed. The information and analysis are provided to the President, the Office of the United States Trade Representative (USTR), and Congress to facilitate the development of sound and informed US trade policy. The Commission makes most of its information and analysis available to the public to promote understanding of international trade issues. The mission of the Commission is to (1) administer US trade remedy laws within its mandate in a fair and objective manner; (2) provide the President, USTR, and Congress with independent analysis, information, and support on matters of tariffs, international trade, and US competitiveness; and (3) maintain the Harmonized Tariff Schedule of the United States (HTS). The Commission has five major operations that serve its external customers:- (i) Import Injury Investigations; (ii) Intellectual Property-Based Import Investigations; (iii) Industry and Economic Analysis; (iv) Tariff and Trade Information Services; and (v) Trade Policy Support. The US International Trade Commission (USITC) is a federal agency that provides trade expertise to the legislative and executive branches of government, determines the impact of imports on United States industries. In addition it directs actions against unfair trade practices such as patent, trademark, and copyright infringement. The commission was formerly known as US Tariff Commission. It was founded in 1916 and is based in Washington, District of Columbia. The Tariff Commission, renamed the United States International Trade Commission by the Trade Act of 1974, again was required to investigate injury claims and to propose remedies for those claims found to be valid. Apparently tariffs will play a comparatively less important role in the control and shaping of international trade in the future. / Комиссия По Международной Торговле США:- образована в соответствии с Актом О Торговле от 1974 (The Trade Act of 1974) для регулирования и защиты торговли Соединённых Штатов Америки (США) согласно законам страны и международным договорам, подписанным США. Комиссия может вводить пошлины и сборы в ответ на нечестную торговую практику и причинённый ущерб. Основные функции Комиссии включают:- (1) консультации по вопросам торговых переговоров; (2) консультации по вопросам общей системы преференций; (3) расследования (по заявлениям) с целью регулирования привоза (или импорта) с учётом интересов отечественной промышленности; (4) слежение за торговлей между Востоком и Западом; (5) расследования в отношении привозимых (или импортируемых) промышленных и сельскохозяйственных товаров, если предполагается, что они субсидируются или являются предметом нечестной торговли или демпинга; (6) составление и публикация тарифных справочников США, статистических данных о международной торговле и тарифных сводок.

US–ISRAEL FREE TRADE AGREEMENT = СОГЛАШЕНИЕ США–ИЗРАИЛЬ О СВОБОДНОЙ ТОРГОВЛЕ – US-Israel Free Trade Agreement:- The United States and Israel have decided to eliminate the requirement for a certificate of origin (also known as the Green Form) under the Agreement on the Establishment of a Free Trade Area between the United States and Israel (FTA). The agreement needs to be confirmed by the Israeli Parliament. This could take months. Until then, US exporters are still required to submit the green form Certificate of Origin. The US-Israel Free Trade Agreement (FTA) was the first US FTA to enter into force and eliminated duties on manufactured goods as of January 01, 1995. Non-tariff barriers to trade remain in the areas of intellectual property rights, standards and technical regulations and a lack of transparency in government tendering process. Also, tariff and non-tariff barriers continues to affect a certain portion of US agricultural exports. As a result, in 1996 the United States and Israel signed an Agreement on Trade in Agricultural Products (ATAP), establishing gradual and steady market access liberalization for food and agricultural products effective through December 31, 2001. Negotiation and implementation of a successor ATAP was completed in 2004. It was effective through December 31, 2008 and was extended through December 31, 2010 and again through December 31, 2011. The FTA includes a non-binding statement of intent to eliminate barriers to trade in services such as tourism, communications, banking, insurance, management consulting, accounting, law, computer services and advertising. It also includes an agreement to eliminate all restrictions on government procurement and calls on Israel to relax its offset requirements for government agencies other than the Israeli Ministry of Defense. US-Israel Free Trade Area (FTA) Agreement is the agreement on the establishment of a Free Trade Area between the Government of Israel and the Government of the United States of America; signed on April 22, 1985; entered into force on September 01, 1985. The Free Trade Agreement (FTA) signed by the United States and Israel in 1985 affords American products the opportunity to compete on an equal basis with European goods, which all have free access to Israel's domestic markets. Israel was the first country to conclude a free trade area agreement with the United States and the FTA served as a model for later agreements signed between the United States and Canada, Jordan, and Mexico. The FTA eliminated all duties and virtually all other restrictions on trade in goods between the two countries. The FTA was signed April 22, 1985, by the United States Trade Representative (USTR) and the Israeli Minister of Industry and Trade and was officially entered into force in September of that year after it was approved by the US House of Representaives in a 422-0 vote and a voice vote in the US Senate. The final phase of the agreement was fully implemented on January 01, 1995 when the two countries completely eliminated all duties and tariffs on manufacted goods. The FTA also includes a Declaration on Trade in Services, a non-binding statement of intent to eliminate barriers to trade in services such as tourism, communications, banking, insurance, management consulting, accounting, law, computer services, and advertising. The US and Israel also signed an Agricultural Agreement, to reduce trade barriers on agricultural products and boost agricultural trade between the two countries. Finally, the FTA includes provisions to protect American industry. For example, certain non-tariff import restrictions on agricultural products are allowed. Both the United States and Israel have benefitted immensely from the FTA as can be evidenced in the exponential growth of

their bilateral trade over the past 25 years. Between 1986 and 1996, the first decade of the FTA's implementation, bilateral trade in goods more than tripled, from USD3.9 billion to USD12.4 billion, with US exports to Israel totaling USD6 billion. In the following fourteen years, from 1996 to 2010, the bilateral trade nearly tripled again, rising to an estimated total of USD32 billion. Over this time, US imports from Israel have jumped from less than USD2.2 billion in 1984 to more than USD22 billion in 2010, an increase of 954 percent. Meanwhile, Israeli imports from the US have risen from around USD1.8 billion to more than USD13 billion. Due to the success of the FTA, Israel is now among America's 12 largest export markets per capita. Despite having a population under 8 million, ranking just 96th highest in the world, Israel is still among the US's 25 largest export markets by value, ahead of much largers countries such as Russia, Spain and Argentina. The FTA gives American companies exporting to Israel an advantage over competitors by virtue of the elimination of all tariffs on American exports to Israel. In addition, as one of only three countries (Jordan and Mexico are the others) with free trade agreements with both the United States and the European Community, Israel can act as a bridge for international trade between America and Europe. The US-Israel Free Trade Area (FTA) Agreement was signed on 22 April 1985, ratified and signed into law (Public Law No. 99-47) by the United States on 11 June 1985 and ratified by the Israeli Cabinet on 20 August 1985, and came into force on 19 August 1985. In July 2004, the United States and Israel exchanged letters agreeing to certain aspects of trade in agricultural products. On 18 October 2010, a joint statement was released on the 25th anniversary of the signing of their FTA. During the week of August 21, 2011, the United States and Israel reached an agreement on a process to expand trade and investment between both countries. A meeting of the Joint Committee of the United-States-Israel Free Trade Agreement was held on 16 February 2012. Documents relating to the agreement:- (i) 22 May 1985:- Israel-US Free Trade Agreement; (ii) 11 June 1985:- Statement on Signing the United States-Israel Free Trade Area Implementation Act of 1985; (iii) 20 August 1985:- US-Israel Free Trade Zone Agreement ratified; (iv) 27 July 2004:- 2004 US-Israel Agricultural Agreement; (v) 18 October 2010:- Joint statement on the 25th Anniversary of the United States-Israel FTA; (vi) 26 August 2011:- US and Israel reaffirm commitment to expand bilateral trade and investment; and (vii) 16 February 2012:- Meeting of the Joint Committee of the United-States-Israel Free Trade Agreement. / Соглашение О Свободной Торговле Между США И Израилем:- договор от 1985, предусматривающий специальный режим (например, преференциальные таможенные пошлины или их отмену) для определённых товаров, привозимых (или импортируемых) из Израиля. Синоним (US-Israel Free Trade Area Implementation Act).

US–ISRAEL FREE TRADE AREA IMPLEMENTATION ACT = АКТ О ВЫПОЛНЕНИИ ЗОНЫ СВОБОДНОЙ ТОРГОВЛИ США–ИЗРАИЛЬ – Under the United States-Israel Free Trade Area Implementation Act (IFTA Act), articles of qualifying industrial zones encompassing portions of Israel and Jordan or Israel and Egypt are eligible to receive duty-free treatment. Effective upon publication of this notice, the United States Trade Representative, pursuant to authority delegated by the President, is designating the Beni Suief zone and the Al Minya zone as qualifying industrial zones under the IFTA Act. US-Israel Free Trade Area Implementation Act (of 1985) was signed on June 11, 1985. This act approves and provides the necessary authority to implement the Free Trade Area Agreement between the United States and Israel. The signing of this act is the culmination of an effort that began in November 1983 when former Israeli Prime Minister Shamir and I (the United States Trade Representative) agreed to begin discussions toward the establishment of a bilateral free trade area between our countries. On October 30, 1984, I signed into law the Trade and Tariff Act of 1984 that, among other things, authorized the negotiation of an agreement with Israel. On April 22, 1985, after completion of negotiations, the Agreement on the Establishment of a Free Trade Area between the Government of the United States of America and the Government of Israel was signed in Washington by Ambassador William E. Brock and Minister of Industry and Trade Ariel Sharon. Today this act provides congressional approval of that agreement and provides the necessary legal authority to implement all of its terms. The passage of this act and the approval of the agreement that underlies it is of great significance for three reasons:- First, the establishment of the US-Israel Free Trade Area will stand as a model of the close cooperation between the administration and the Congress that can bring about a result benefiting all Americans. This was a bipartisan accomplishment. I especially wish to recommend the leadership of Senate Majority Leader Dole, Chairman Packwood and Senator Danforth of the Senate Committee on Finance, and Chairman Rostenkowski and Representatives Sam Gibbons and Bill Frenzel of the House Committee on Ways and Means for their efforts in making the US-Israel free trade area a reality. Second, the new free trade area between the United States and Israel represents an important milestone in this administration's efforts to liberalize trade. We hope that it will also serve to encourage greater liberalization of the multilateral trading system and that it will help us move ahead in our continued attempts to expand world trade. Third, and finally, I believe this new economic relationship with our friends in Israel will further our historic friendship, strengthen both of our economies, and provide for new opportunities between our peoples for communication and commerce. Nothing better demonstrates the shared community of aspirations between our nations than our promotion of free and harmonious trade for our mutual benefit. See also US-Israel Free Trade Agreement. / зона Бэнай Суиф (Beni Suief zone) и зона Эль Минья (Al Minya zone). Израильский Премьер Министр Ицхак Щамир (Israeli Prime Minister Yitzhak Shamir; 1915–2012). Посол Вилъйэм Эмёсэн Брок (Ambassador William Emerson Brock III; 1930–) и Министр Промышленности и Торговли Арыэль Щарон (Minister of Industry and Trade Ariel Sharon; 1928–2014). USTER® TESTER = УШТЭР® ТЭСТЁР – Uster® Tester is an instrument that provides a continuous measurement of the variation in weight per unit length of sliver, roving, and yarn. For example, the USTER® TESTER 5 is acknowledged throughout textiles as the global standard in evenness testing. It means spinners can control yarn quality levels precisely. So it's a basis for optimizing profitability. There are two latest-technology models in the range:- the USTER® TESTER 5-S800 and USTER® TESTER 5-S400. Company Uster Technologies AG is headquartered in Uster, Switzerland. / Уштэр Тчэкнолодьжиз А.Ге. (Цельвига Уштэр) (Uster Technologies AG (Zellweger Uster)), Уштэр (или Устер), Швейцария.

USTIC = УСТИЧЕСКОЕ – The Ustic (Latin Ustus = Burnt; implying dryness) moisture regime is intermediate between the aridic regime and the udic regime. Its concept is one of moisture that is limited but is present at a time when conditions are suitable for plant growth. The concept of the ustic moisture regime is not applied to soils that have permafrost or a cryic soil temperature regime (defined below). If the mean annual soil temperature is 22 °C or higher or if the mean summer and winter soil temperatures differ by less than 6 °C at a depth of 50 cm below the soil surface, the soil moisture control section in areas of the ustic moisture regime is dry in some or all parts for 90 or more cumulative days in normal years. It is moist, however, in some part either for more than 180 cumulative days per year or for 90 or more consecutive days. If the mean annual soil temperature is lower than 22 °C and if the mean summer and winter soil temperatures differ by 6 °C or more at a depth of 50 cm from the soil surface, the soil moisture control section in areas of the ustic moisture regime is dry in some or all parts for 90 or more cumulative days in normal years, but it is not dry in all parts for more than half of the cumulative days when the soil temperature at a depth of 50 cm is higher than 5 °C. If in normal years the moisture control section is moist in all parts for 45 or more consecutive days in the 4 months following the winter solstice, the moisture control section is dry in all parts for less than 45 consecutive days in the 4 months following the summer solstice. In tropical and subtropical regions that have a monsoon climate with either one or two dry seasons, summer and winter seasons have little meaning. In those regions the moisture regime is ustic if there is at least one rainy season of 3 months or more. In temperate regions of subhumid or semiarid climates, the rainy seasons are usually spring and summer or spring and fall, but never winter. Native plants are mostly annuals or plants that have a dormant period while the soil is dry. Ustic:- pertaining to a soil moisture regime characterized by limited moisture during most of the year but with at least 1 rainy season of 3 months or more (e.g., in a monsoon climate) during which the soil is moist.

USTR = UNITED STATES TRADE REPRESENTATIVE

US TRADE REPRESENTATIVE = ТОРГОВЫЙ ПРЕДСТАВИТЕЛЬ США (или ПРЕДСТАВИТЕЛЬ США ПО ТОРГОВЛЕ) – US Trade Representative:- The Office of the United States Trade Representative was created as the Office of the Special Representative for Trade Negotiations by Executive Order 11075 of January 15, 1963. The Trade Act of 1974 (19 USC 2171) established the Office as an agency of the Executive Office of the President charged with administering the trade agreements program. The Office of the United States Trade Representative is responsible for setting and administering overall trade policy. The Office is headed by the United States Trade Representative, a Cabinet-level official with the rank of Ambassador, who is directly responsible to the President. There are three Deputy United States Trade Representatives, who also hold the rank of Ambassador – two located in Washington and one in Geneva. The Chief Agricultural Negotiator also holds the rank of Ambassador. The United States Trade Representative serves as an ex officio member of the Boards of Directors of the Export-Import Bank and the Overseas Private Investment Corporation, and serves on the National Advisory Council for International Monetary and Financial Policy. The Office of the US Trade Representative (USTR) is responsible for developing and coordinating US international trade, commodity, and direct investment policy, and overseeing negotiations with other countries. The head of USTR is the US Trade Representative, a Cabinet member who serves as the president's principal trade advisor, negotiator, and spokesperson on trade issues. USTR consults with US trading partners on a wide range of issues related to trade and investment – from market access issues to labor, the environment, protection and enforcement of intellectual property rights. Export Promotion:- Working with the International Trade Administration, USTR coordinates export promotion for US based small and medium enterprises (including affiliates of foreign-owned firms). The Office of the United States Trade Representative (USTR) is an agency of more than 200 committed professionals with decades of specialized experience in trade issues and regions of the world. We negotiate directly with foreign governments to create trade agreements, to resolve disputes, and to participate in global trade policy organizations. We also meet with governments, with business groups, with legislators and with public interest groups to gather input on trade issues and to discuss the President's trade policy positions. USTR was created in 1962 and

has offices in Washington, Geneva, and Brussels. History Of Washington Office:- The headquarters of the Office of the United States Trade Representative are located in the Winder Building at 600 17th St., NW in Washington, DC, a pre-Civil War building of historic significance that narrowly escaped demolition in an urban renewal city program in the 1970s. Named after its builder, William H. Winder, the Winder building was Washington's first 'skyscraper' when it opened for business in 1848. The government purchased the building in 1854. Originally designed as office space for the US Army and Navy, the building has housed a variety of government tenants over the years, including a military arms museum. Around the time of the Civil War ordinance of the Winder Building included the Quartermaster General and the Navy's Bureau of Ordinance and Hydrography and later, the headquarters for the Bureau of Military under Judge Advocate General Joseph Holt. In 1865, the Winder roof served as a signal station of the Washington detachment of the US Signal Corps for communication via flag signals to military fortifications and camps around Washington. In 1888, the building was transferred to the Department of Treasury. The Second Auditor of the Treasury and his staff occupied the building exclusively for many years. During World War I, the Army occupied part of the building. In 1949, the US General Services Administration, which is the building manager for many government facilities, took control of the Winder Building and has maintained it ever since. During the 1970s, the White House used the building, which was undergoing renovation. At the end of the Carter Administration, the Council on Wage Price Stability occupied the building for a short time. USTR took up residence in 1981. History of the United States Trade Representative:- Until the early 1960s, the Department of State was responsible for conducting US trade and investment diplomacy and administering the President's trade agreement program. In the Trade Expansion Act of 1962, Congress called for the President to appoint a Special Representative for Trade Negotiations to conduct US trade negotiations. The Act provided for the Special Trade Representative to serve as chair of a new interagency trade organization established to make recommendations to the President on his trade agreement program. The legislation reflected Congressional interest in achieving a better balance between competing domestic and international interests in formulating and implementing US trade policy. In 1963, President Kennedy created a new Office of the Special Trade Representative (STR) in the Executive Office of the President and designated two new Deputies – one in Washington, DC, and the other in Geneva, Switzerland. Through the mid-1960's, STR had the chief responsibility for US participation in the Kennedy Round of multilateral trade negotiations held under the auspices of the General Agreement on Tariffs and Trade (GATT). In the 1970s, the Congress substantially expanded STR's responsibilities. Section 141 of the Trade Act of 1974 provided a legislative charter for STR as part of the Executive Office of the President, making it responsible for the trade agreements programs under the Tariff Act of 1930, the Trade Expansion Act of 1962, and the 1974 act. The act also made STR directly accountable to both the President and the Congress for these and other trade responsibilities and elevated the Special Trade Representative to cabinet level. Reorganization Plan No. 3 of 1979 consolidated and further broadened STR's responsibilities. The 1979 reorganization and Executive Order 12188 of the next year renamed STR as the Office of the United States Trade Representative (USTR), centralized US government policy-making and negotiating functions for international trade, and greatly expanded the office. These changes:- (i) Assigned lead responsibility to USTR for developing and coordinating US trade policy and for conducting international trade and trade-related investment negotiations; (ii) Designated the Trade Representative as the principal advisor to the President on trade policy and on the impact of other US government policies on international trade; (iii) Authorized USTR to set US policy on key trade issues, such the General Agreement on Tariffs and Trade and 'the assertion and protection of the rights of the United States under all bilateral and multilateral international trade and commodity agreements'. USTR shares with the Department of Commerce responsibility for monitoring foreign government compliance with United States trade agreements. (iv) Made the Trade Representative the Vice Chairman of the Overseas Private Investment Corporation (OPIC), a non-voting member of the Export-Import Bank Board of Directors, and a member of the National Advisory Committee on International Monetary and Financial Policies; and (v) Made the USTR the chief US representative in bilateral negotiations over barriers to investment. The Trade and Tariff Act of 1984 gave USTR the further responsibility of developing and coordinating implementation of US policies concerning trade in services. USTR's authority was further enhanced under the Omnibus Trade and Competitiveness Act of 1988. Section 1601 of the 1988 legislation codified and expanded USTR's responsibilities. In so doing, the legislation reinforced the Congressional-Executive partnership for the conduct of US trade policy. Among USTR's additional responsibilities as enumerated in the 1988 act are:- (i) To coordinate trade policy with other agencies; (ii) To act as the principal international trade policy spokesperson of the President; (iii) To report and be responsible to the President and the Congress on the administration of the trade agreements program, and to advise them on non-tariff barriers, international commodity agreements, and other matters relating to the trade agreements program; and (iv) To chair the interagency committee that assists and advises the President in developing and implementing US trade policy. The 1988 legislation also included a 'Sense of the Congress' statement that the USTR should be the senior representative on any body the President establishes to advise him on overall economic policies in which international trade matters predominate and that the USTR should be included in all economic summits and other international meetings in which international trade is a major topic. Finally, this legislation further elevated the importance of USTR in trade matters by shifting to USTR the Presidential responsibility for implementing actions under Section 301 of the Trade Act of 1974 (enforcement of US rights under trade agreements), subject to specific direction, if any, from the President. The Uruguay Round Agreements Act, enacted in 1994, specifies that USTR has lead responsibility for all negotiations under the auspices of the WTO. The conclusion of such major comprehensive trade agreements as the North American Free Trade Agreement (NAFTA) and the WTO Agreement vastly expanded the scope and task of USTR's efforts to implement and enforce US trade agreements. The Trade and Development Act of 2000 created two new posts in USTR Chief Agricultural Negotiator and Assistant United States Trade Representative for African Affairs. The principal function of the Chief Agricultural Negotiator is to conduct trade negotiations and enforce trade agreements relating to United States agricultural interests and products. The AUSTR for African Affairs serves as the chief advisor to the US Trade Representative on issues of trade and investment with Africa and serves as coordinator and point of contact within the Administration on such issues. / Вилъйэм Хэнри Виндё (William Henry Winder; 1775–1824). Дьжозэф Холт (Joseph Holt; 1807–1894). Президент Дьжон Фитцдьжерэлд 'Дьжак' Кенэди (President John Fitzgerald 'Jack' Kennedy; 1917–1963). Представитель США По Торговле:- пост, учреждённый в 1963 с полномочиями, расширенными в результате принятия Акта О Торговле в 1988 (1988 Trade Act). Соответствует положению члена кабинета и имеет звание посла. Возглавляет соответствующее ведомство и отвечает перед Президентом за развитие и координацию политики и переговоров в сфере международной торговли Соединённых Штатов Америки (США). Смотрите также (Section 301), и (Super 301).

USTRANSCOM = UNITED STATES TRANSPORTATION COMMAND

USTTA = UNITED STATES TRAVEL AND TOURISM ADMINISTRATION

USUAL CONTROL LIMIT = ОБЫЧНЫЙ КОНТРОЛЬНЫЙ ЛИМИТ – In Cotton industry, 'Usual Control Limit' and 'UCL' mean the variation allowed in readings to account for the normal variation expected from different instruments, even if the same Cotton is used.

USUFRUCT = УЗУФРУКТ – Usufruct is a temporary legal right to derive profits from property owned by others, given that the property is not damaged. See also Beneficial Ownership. Usufruct is the legal right of using and enjoying the profits of something belonging to another party. Usufruct:- in Roman-based legal systems, the temporary right to the use and enjoyment of the property of another, without changing the character of the property. This legal concept developed in Roman law and found significant application in the

determination of the property interests between a slave held under a Usus Fructus (Latin:- 'Use And Enjoyment') bond and a temporary master. Any property acquired by a slave as a result of his labor legally belonged to that master. Modern civil-law systems recognize two types of usufructs. The perfect usufruct includes only those things that a usufructuary (one who holds property under right of usufruct) can use without changing their substance, such as land, buildings, or movable objects; the substance of the property, however, may be altered naturally over time and by the elements. The quasi-, or imperfect, usufruct includes property that is consumable or expendable, such as money, agricultural products, and the like, which would be of no advantage to the usufructuary if he could not consume them, expend them, or change their substance. The term usufruct never found its way into the English common law, although certain general similarities can be found in the common-law concept of estate. / Законное право использования и получения прибыли от чего-то, принадлежащего другому лицу. Под Узуфруктом, от Латинского слова Ususfructus, от Латинских слов Usus, означающее Пользование, и Fructus, означающее Доход или Плод или Прирост, в Древнем Риме понималось право пользования вещью, принадлежащей другому лицу, с получением от неё плодов или выгод, но с сохранением целостности вещи. Узуфрукт относился к числу так называемых личных сервитутов, которые устанавливались в пользу какого-либо конкретного лица пожизненно или на определённый срок без права отчуждения или передачи по наследству. Широкое распространение узуфрукт получил в средние века и особенно в буржуазном праве (например, во Франции), где рассматривался, как правило, в качестве самостоятельного вещного права. В праве Романских государств устанавливаемое законом или по договору право пользования имуществом, принадлежащим другому лицу, с присвоением плодов, но под условием сохранения существа вещи. Узуфрукт может быть установлен пожизненно, на определённый срок или под условием, наступление которого прекращает право Узуфруктария (пользователя). Узуфрукт, возникающий чаще всего в сфере наследования, действует в течение жизни пользователя. Собственник, допустивший установление узуфрукта, сохраняет на это время лишь право собственности (без возможности его реализации) и только юридически контролирует пользователя, К выгодам узуфруктария относится получение естественных плодов (урожая, приплода и тому подобного) и денежных доходов (процентов по займам, арендной платы и так далее). На нём лежит обязанность сохранения данного имущества и его эксплуатации по хозяйственному назначению, исключающему порчу или обесценение. Узуфрукт – право пожизненного пользования вещью и её плодами с обязанностью не изменять хозяйственного назначения вещи. Под Узуфруктом, от Латинского слова Usufructus от слов Usus, означающее Обычай, и Fructus, означающее Плод, понимается владение чужим имуществом с правом пользования доходами от него, но без права подвергать его каким-либо существенным изменениям.

USURY = РОСТОВЩИЧЕСТВО – Usury:- this term is generally used to denote an illegal predatory lending practice in which a lender charges an interest rate on a loan that is considered to be excessive or in violation with interest rate limits as established by some state governments. An excessively high interest rate that is overly burdensome for the borrower. A lender may set an interest rate unreasonably high if they believe that the borrower may not be able to repay the loan and interest. Limits on interest rates vary from state to state within the United States. See also Loan Shark, and Usury Laws. Moneylending at an excessive rate of interest, not in itself illegal. Usury:- in modern law, the practice of charging an illegal rate of interest for the loan of money. In Old English law, the taking of any compensation whatsoever was termed usury. With the expansion of trade in the XIII century, however, the demand for credit increased, necessitating a modification in the definition of the term. Usury then was applied to exorbitant or unconscionable interest rates. In 1545 England fixed a legal maximum interest; any amount in excess of the maximum was usury. The practice of setting a legal maximum on interest rates later was followed by most states of the United States and most other Western nations. In some Muslim countries the charging of interest is still forbidden, at least in theory. The Qurʾān, the Muslim holy book, prohibits the charging of interest, although various methods have been devised in order to circumvent the prohibition. For instance, a higher price may be charged for goods when payment is deferred than is charged if payment is made in advance or upon delivery. Usury is the illegal practice of charging interest in excess of the maximum allowed by law. / Под Ростовщичеством понимается предоставление денежных ссуд под высокий процент. Ростовщичество, в эксплуататорских обществах предоставление денежных ссуд из очень высокого процента. Как правило, эти ссуды используются не как капитал, а в качестве покупательного и платёжного средства (смотрите Ростовщический Капитал). Ростовщичество:- незаконная практика взимания процентов, превышающих максимальный размер процентов, предусмотренный законодательством. Ростовщичество:- процентная ставка, уплачиваемая за использование чужих денег или предоставленный кредит, которая превышает установленный законом предел для такого рода сделок в стране, где государство регулирует законность сделок. Ростовщичество (Usury):- чрезвычайно высокая ставка процента.

USURY LAWS = ЗАКОНЫ О РОСТОВЩИЧЕСТВЕ – Usury Laws are the laws limiting the amount of interest that can be charged on loans. / Законы о Ростовщичестве:- штатные законы, ограничивающие верхний предел процентных ставок по кредитам.

USW = UNITED STATES WHEAT ASSOCIATES

USWA = UNITED STATES WAREHOUSE ACT OF 1916

USWC = UNITED STATES WEST COST

UT = UNIVERSAL TIME

UTA = UNIT TRUST ASSOCIATION

UTAC = UPSTAIRS TRADERS ADVISORY COMMITTEE

UTC = TEMPS UNIVERSEL COORDONNÉ = COORDINATED UNIVERSAL TIME

UTCS = URBAN TRAFFIC CONTROL SYSTEM

UTILISATION RATE = СТАВКА ЗА УТИЛИЗАЦИЮ (или СТАВКА ЗА ИСПОЛЬЗОВАНИЕ) – Utilisation Rate:- the quotient of used capacity and available capacity. / Под Утилизацией, от Латинского слова Utilis, означающее Полезный, понимается употребление с пользой.

UTILISATION RATE = СТЕПЕНЬ УТИЛИЗАЦИИ (или СТЕПЕНЬ ИСПОЛЬЗОВАНИЯ) – In oil industry, refinery Utilisation Rate represents the utilization rate of the atmospheric crude oil distillation units. The rate is calculated by dividing the gross input to these units by the operating capacity of the units. / Под Утилизацией, от Латинского слова Utilis, означающее Полезный, понимается употребление с пользой.

UTILITIES SELECT SECTOR SPDR FUND = ФОНД ДРСП ПО ИЗБРАННОМУ СЕКТОРУ СНАБЖАЮЩИХ ПРЕДПРИЯТИЙ – The Utilities Select Sector SPDR Fund is the Exchange Traded Fund (ETF). (Note:- SPDR is short for the Standard & Poor's Depository Receipts.) It trades on the New York Stock Exchange (NYSE) under the ticker symbol XLU. In mid-2007, the XLU was about 3.5% of the S&P 500 Index. The fund holds investments in the Utilities Index which include the following industries:- (i) electric utilities; (ii) multi-utilities; (iii) independent power producers and energy traders; and (iv) gas utilities. Criteria:- (i) each of the component

securities in the Index is a constituent company of the S&P 500 Index; (ii) each stock in the S&P 500 Index is allocated to one and only one of the Select Sector Indexes; and (iii) the Index is calculated by the New York Stock Exchange's Index Services Group using a modified 'market capitalization' methodology. As of December 31, 2009, the Index was comprised of 34 stocks.

UTILITY = СНАБЖАЮЩЕЕ ПРЕДПРИЯТИЕ – Utilities (water, electricity and gas) are essential services that play a vital role in economic and social development. Quality utilities are a prerequisite for effective poverty eradication. Governments are ultimately responsible for ensuring reliable universal access of service under accountable regulatory frameworks. Increased competition in the utilities sectors in recent years has entailed changes in regulatory frameworks and ownership structures of enterprises, in addition to business diversification. These have impacted job security and working conditions in the sector. Adequate staffing levels and training in the use of new technologies are important for ensuring efficiency and safety in the workplace. Social dialogue plays a significant role in developing joint strategies by the social partners to improve utility services, with the common goal of extending access to services to all communities, enhancing efficiency of delivery and reviewing tariffs and other sources of income collection. One of the key issues in the Utilities sector is the need to respect international conventions protecting freedom of association and collective bargaining and to avoid breakdowns in the provision of utilities where possible. The average age of workers in the sector is increasing in a number of countries and there is a severe gender imbalance in some occupations, which presents challenges for human resource planning by employers. Making employment in the sector accessible and attractive to young men and women can be a means to address the recruiting challenges of replacing an ageing workforce. In addition, establishing national or sector specific training programmes, and investing in workers through apprenticeships and lifelong learning mechanisms can be instrumental in meeting the demands of changing skills needs of the industry. Utility is a regulated entity which exhibits the characteristics of a natural monopoly. For the purposes of electric industry restructuring, 'Utility' refers to the regulated, vertically-integrated electric company. 'Transmission Utility' refers to the regulated owner/operator of the transmission system only. 'Distribution Utility' refers to the regulated owner/operator of the distribution system which serves retail customers. The Utilities Sector refers to a category of companies that provide basic amenities, such as water, sewage services, electricity, dams, and natural gas. Although utilities earn profits, they are part of the public service landscape and are therefore heavily regulated. Investors typically treat utilities as long-term holdings and use them to inject steady income in their portfolios. Utilities typically offer investors stable and consistent dividends, coupled with less price volatility relative to the overall equity markets. Because of these facts, utilities tend to perform well during recessionary climates. Contrarily, utility stocks tend to fall out of favor with the market, during times of economic growth. The many types of utilities available include large companies that offer multiple services such as electricity and natural gas. Other utility interest might specialize in just one type of service, such as water. Some utilities rely on clean and renewable energy sources like wind turbines and solar panels, to produce electricity. Investors may also purchase regional utilities or invest in exchange-traded funds (ETFs) containing baskets of utility stocks located throughout the United States. Paradigm Shift:- While electric utility companies used to be regionally monopolistic, broadly speaking, the industry is breaking down into the following four supplier segments:- (i) Generators:- these operators create electrical power; (ii) Energy Network Operators:- grid operators, regional network operators and distribution network operators sell access to their networks to retail service providers; (iii) Energy Traders and Marketers:- by buying and selling energy futures and other derivatives and creating complex 'structured products', these companies usefully help utilities and power-hungry businesses secure a dependable supply of electricity at a stable, predictable price; and (iv) Energy Service Providers and Retailers:- in most US states, consumers can now choose their own retail service providers. Key Takeaways:- (i) The utility sector is a category of company stocks that provide basic services including electricity, natural gas, and water; (ii) Utilities earn a profit but are a public service and, as a result, have substantial regulation; (iii) Typically, investors buy utilities as long-term holdings for their dividend income and stability; (iv) The utility sector tends to do well as a defensive play against macroeconomic downturns; and (v) As the economy improves and interest rates rise, investors can find higher-yielding alternatives to utilities. Debt Levels of the Utilities Sector:- Utilities require a significant amount of expensive infrastructure and consequently carry large amounts of debt on their balance sheets. These debt loads make utilities hypersensitive to changes in the market interest rate. And because utilities are capital-intensive, they require a continuous inflow of funds to finance infrastructure upgrades and new asset purchases. The significant debt load also results in high utility debt-to-equity (D/E) ratios, which can impact companies' credit ratings, making it difficult to borrow funds, which ultimately increases their costs of operations. Consumer Impact on Utilities Sector:- Because many states let consumers move from one utility operator to another, consumers typically choose the least expensive local operator. Higher-cost producers are eventually eliminated from the market, unless they can cut their costs in time. Long-term power purchase agreements between companies and consumers also impact profits. When utility generation costs increase, companies must continue to honor the contract agreements and sell utilities at the current agreed-upon rate, which decreases their profits. How Investors Trade Utilities:- Because utility stocks pay reliable dividends, investors often favor them over lower-dividend paying equities. After the financial crisis of 2008, the Federal Reserve cut interest rates, in an effort to stimulate the economy. As a result, investors flocked to utilities, as safer investments. Simply put:- utility companies are a viable defensive choice for investors during macroeconomic downturns. However, as the economy improves and interest rates rise, investors can find higher-yielding alternatives than utilities. As rates rise, so do the yields of US Treasury bills. For example, if a utility pays a dividend yield of 3%, but increasing interest rates spike bond yields to 4%, the utility company would have to increase its dividend payout in order to match the rising yields of Treasuries. Therefore, utilities do well when interest rates decrease because their dividends are greater than Treasury yields. However, as the economy improves, utilities tend to sell off as interest rates rise back to normal levels and their dividends become once again lower than Treasuries. Pros and Cons of the Utilities Sector:- Utilities are stable investments that provide a regular dividend to shareholders, making them a popular long-term buy-and-hold option. Dividends yields are usually higher than those paid by other stocks. During times of economic downturns with low interest rates, such stocks become attractive. Primarily because they exhibit lower volatility and provide a desirable source of predictable investment returns from the dividends they pay on their shares. Investors may invest in utility company shares, industry sector ETFs (short for the exchange traded funds), and in utility bonds or other debt securities. Due to the utility sector's intense regulatory oversight, it's difficult for it to raise rates to increase revenue. Utilities require expensive infrastructure that needs routine updating and maintenance. To meet these infrastructure needs, utility companies often float debt products that, in turn, increase their debt loads. This debt also makes these services particularly sensitive to interest rate risk. Should rates rise, the company must offer higher yields to attract bond investors, driving up their costs. Pros:- (i) The utility sector offers stable, long-term investments with a regular and attractive dividend; (ii) Utilities act as a haven investment during times of economic downturns; and (iii) Utilities offer many options for investment including bonds, ETFs, and individual company stocks. Cons:- (i) Intense regulatory oversight causes difficulty in raising customer utility prices to increase revenue; (ii) Expensive utility infrastructure requires continual upgrades and maintance; and (iii) During times of high market interest rates, utilities become less attractive and must increase their bond yields. Real-World Example of Utilities:- Investors can buy into individual utility stocks or bonds, or they can invest in ETFs that comprise baskets of many utilities. For example, the Utilities Select Sector SPDR Fund (XLU) is one of the largest utility sector funds, with a whopping USD9 billion in assets under management. The ETF also is one of the most actively traded utility ETFs, with more than 10 million shares traded daily. The fund typically pays a dividend yield of around 3% with a low expense ratio of 0.13%. In comparison, the XLU's dividend yield beats out the yield for the S&P 500 equity ETF – SPDR S&P 500 Trust ETF (SPY) – that pays around 1.86%. Furthermore, if the benchmark 10-year Treasury yield trades below 3%, investors might consider buying the utility

sector through the XLU or individual stocks. It's important to check with your broker for current market pricing since Treasury yields, and dividend yields for both utilities and equities change with market conditions. Utility is a power company that owns or operates facilities used for the generation, transmission, or distribution of electric energy, which is regulated at state and federal levels. What is an Electric or Natural Gas Utility? Your local utility is your historic provider of natural gas and/or electricity. This means that they automatically deliver and supply your energy. We detail how utility service works in the United States, and how to switch to an alternate supplier. What is a Local Utility? Generally utilities exist in the following sectors of the market:- electricity, natural gas, water, sewage, and sometimes telephone service. In many markets, a public utility company still owns and maintains the infrastructure; in liberalized markets, energy may be purchased from private suppliers, even if it is still distributed through utility-owned transmission lines or pipes. Sometimes a private company might own electricity or gas infrastructure. In these cases, private utilities are regulated by a state's Public Utilities Commission, or PUC. In rural areas, it might be common to find a cooperative utility, which is owned by its customers. Can I Choose My Energy Utility? You cannot choose your utility, but you can choose your energy supplier in states with liberalized energy markets. Why do Utilities Exist? Generally utilities exist in the following sectors of the market:- electricity, natural gas, water, sewage, and sometimes telephone service. Why? Because infrastructure for these things is prohibitively expensive, and monopolistic by nature. Imagine five different sets of power lines running down your street – separate grids for each company that generates, distributes, and sells power. That wouldn't make much sense, would it? In fact, it would be incredibly expensive, and incredibly inefficient. The most expensive part of energy is delivery, and this is why utilities have maintained their control of delivery across the United States. Necessary investments have already been made. How do they Work? Public Versus Privately-Owned Utilities:- Even if utilities are privately-owned, states will normally have a hybrid system where the government still regulates prices and utility activity. For example, the California Public Utilities Commission regulates private utility activity with things like pollution limits and requirements, and energy rates. Utilities buy and sell electricity at the wholesale level through a network of Regional Transmission Organizations and Independent Service Operators (don't worry – even eperts would be hard pressed to come up with an actual difference between these two. It's mainly just semantic) within one of three grids (1) the Eastern grid, (2) Texas, which is a single ISO, and (3) the Western grid. You might encounter any of the following acronyms referring to utilities:- (i) IOU – investor-owned utility; (ii) MWA – municipal water authority; (iii) MWD – municipal water district; (iv) MUD – municipal utility district; (v) POU – publicly owned utility; and (vi) PUD – public utility district. Electric and Natural Gas Utility Service:- In states with liberalized markets, electric and gas utilties continue to exist alongside competition (for more information, see our page on deregulation). This means that there could very well be differences in price between what the utility will harge you for your electric and gas rates, and what a competitor would charge. Which is where we come in, because our specialty is finding lower rates for you, and helping you choose or switch energy providers. Power Plants:- Who Owns Them? In both regulated and deregulated markets, power plants can be owned by either public utilities or private enterprise. Electricity is purchased on wholesale markets, and then distributed to consumers through the grid. For more information, see our article on wholesale markets. How do I Sign Up for Service? Signing up for service differs by state. But don't worry, we are here to help! Check out our handy how-to guides, or give us a call at +1 (832) 460-0233! We're friendly, promise. Choosing Your Service Provider:- Choosing your energy provider is important! Companies not only offer different prices, but different types of plans and features, and of course, some are more reputable and have better customer service than others. Navigate all of that choice with our help by visiting our provider page and read our reviews. Utility is any private company, publicly-owned organization or other regulated entity that provides an essential service in a given area directly to end-use customers, and that has exclusive rights to provide that service or acts as a natural monopoly in the region it serves. Gas, water and electric companies all qualify as utilities. A Public Utility Company (usually just Utility) is an organization that maintains the infrastructure for a public service (often also providing a service using that infrastructure). Public utilities are subject to forms of public control and a regulation ranging from local community-based groups to statewide government monopolies. The term Utilities can also refer to the set of services provided by these organizations consumed by the public:- coal, electricity, natural gas, water, sewage, telephone, and transportation. Broadband internet services (both fixed-line and mobile) are increasingly being included within the definition. In the United States, public utilities are often natural monopolies because the infrastructure required to produce and deliver a product such as electricity or water is very expensive to build and maintain. As a result, they are often government monopolies, or if privately owned, the sectors are specially regulated by a public utilities commission. The first public utility in the United States was a grist mill erected on Mother Brook in Dedham, Massachusetts in 1640. Developments in technology have eroded some of the natural monopoly aspects of traditional public utilities. For instance, electricity generation, electricity retailing, telecommunication, some types of public transit and postal services have become competitive in some countries and the trend towards liberalization, deregulation and privatization of public utilities is growing. However, the infrastructure used to distribute most utility products and services has remained largely monopolistic. Public utilities can be privately owned or publicly owned. Publicly Owned Utilities include cooperative and municipal utilities. Municipal Utilities may actually include territories outside of city limits or may not even serve the entire city. Cooperative Utilities are owned by the customers they serve. They are usually found in rural areas. Publicly Owned Utilities are non-profit. Private Utilities, also called Investor-Owned Utilities, are owned by investors, and operate for profit, often referred to as a rate of return. Public utilities provide services at the consumer level, be it residential, commercial, or industrial consumer. In turn, utilities and very large consumers buy and sell electricity at the wholesale level through a network of regional transmission organizations (RTO) and independent system operators (ISO) within one of three grids, the Eastern Interconnection, the Texas Interconnection, which is a single ISO, and the Western Interconnection. In the United Kingdom and Ireland, the state, private firms, and charities ran the traditional public utilities. For instance, the Sanitary Districts were established in England and Wales in 1875 and in Ireland in 1878. The term can refer to the set of services provided by various organizations that are used in everyday life by the public, such as:- electricity generation, electricity retailing, electricity supplies, natural gas supplies, water supplies, Sewage works, sewage systems and broadband internet services. They are regulated by Ofgem, Ofwat and Ofcom. Disabled community transport services may occasionally be included within the definition. They were mostly privatised in the UK during the 1980s. Utilities means water, soil, steam, air, electricity, radio, television, telegraphic, telephone, telecommunications and other services and supplies of whatsoever nature. Utilities means any and all utility services and installations whatsoever including, but not limited to, gas, water, electricity, telephone, other telecommunications, steam, sewer and storm sewer, and all piping, wiring, conduit and/or other fixtures of every kind whatsoever related thereto or used in connection therewith. Utilities means public sanitary and storm sewers, natural gas, telephone, public water facilities, electrical facilities and all other utility facilities and services necessary for the operation and occupancy of the property as a hotel. / Снабжающее Предприятие – компания, производящая или предоставляющая услуги в области производства, передачи и распределения электроэнергии, газо- и водоснабжения. В США работа снабжающих предприятий регулируется на штатовском и федеральном уровне. Органы власти штатов регулируют перечень услуг (и величину тарифов), которые снабжающие предприятия должны предоставлять розничным потребителям. Федеральная Регуляторная Комиссия по Энергетике (ФРКЭ) (Federal Energy Regulatory Comission (FERC)) регулирует оптовые цены на электроэнергию, объёмы продаж и перепродаж, объёмы энергопоставок между штатами примерно для 200 акционерных компаний. Однако основная часть деятельности компаний и уровень их валового дохода регулируются на уровне штатов. На уровне штата также регулируются тарифы на поставку и передачу энергии для розничных потребителей, а также рассматриваются вопросы, связанные со строительством новых энергетических предприятий. Отрасль электроснабжения в

1920-х годах попала под регулирование на федеральном уровне из-за возможности возникновения монопольного (monopoly) производства энергии и передачи потребителям. Развившаяся отрасль стала включать акционерные компании и кооперативы. Проведённое в последние годы дерегулирование (deregulation) отрасли газоснабжения позволило создать в ней открытый конкурентный рынок, хотя транспортировка газа по газопроводам всё ещё находится под юрисдикцией ФРКЭ (FERC). Электроснабжение также стоит на пороге дерегулирования. Доходность акций снабжающих предприятий обычно выше среднего уровня, но роста капитала вследствие повышения стоимости акций не происходит. Акции снабжающих предприятий также очень чувствительны к изменению процентных ставок. Тенденция к росту процентных ставок негативно отражается на ценах этих акций, поскольку повышение ставок обеспечивает инвесторам более привлекательные направления вложений. Кроме того, снабжающие предприятия обычно являются крупными заёмщиками и рост процентных ставок увеличивает их затраты на обслуживание кредита. Наоборот, падение процентных ставок имеет тенденцию положительно влиять на стоимость их акций, поскольку повышенный уровень дивидендов делает эти акции более привлекательными, а затраты на обслуживание займов сокращаются. Коммунальные Услуги, услуги, предоставляемые предприятиями коммунального хозяйства населению городов, посёлков и сёл для удовлетворения их материально-бытовых нужд. Во многих городах и посёлках коммунальные предприятия общего пользования обслуживают также и промышленные предприятия, снабжая их водой, электроэнергией, газом и другим. Коммунальное Хозяйство, совокупность предприятий, служб и хозяйств по обслуживанию населения городов, посёлков и сёл; в городах входит в состав городского хозяйства. Во многих городах и поселках предприятия коммунального хозяйства обслуживают также и промышленные предприятия, снабжая их водой, электроэнергией, газом и прочим. Однако в зависимости от местных условий, промышленные предприятия имеют и собственные водопроводы, канализацию, и другие сооружения коммунального назначения. Степень развития и объём деятельности коммунального хозяйства непосредственно влияют на уровень благосостояния населения, бытовые условия его жизни, санитарно-гигиенические условия и чистоту водного и воздушного бассейнов, а также на уровень производительности труда. Коммунальное хозяйство включает:- (1) Санитарно-технические предприятия – водопроводы, канализации, предприятия по уборке территорий населённых мест и санитарной очистки домовладений, прачечные, бани, купально-плавательные сооружения; (2) Транспортные предприятия – городской общественный пассажирский транспорт (метрополитен, трамвай, троллейбус, фуникулёры, канатные дороги, автобусы, такси), водный транспорт местного назначения; (3) Энергетические предприятия – электрические, газовые и теплофикационные распределительные сети, отопительные котельные, ТЭЦ и электростанции, газовые заводы, обслуживающие населённые пункты. К сооружениям внешнего благоустройства населённых мест, которые входят в состав коммунального хозяйства относятся дороги и тротуары, мосты и путепроводы, подземные и наземные транспортные, пешеходные переходы и эстакады, сооружения и сети ливневой (водосточной) канализации, набережные, различные гидротехнические сооружения, предназначенные для предотвращения оползней и затопления территорий, их осушения, берегоукрепления, зелёные насаждения общего пользования, уличное освещение и другое. В коммунальное хозяйство входят также гостиницы, службы землепользования, инвентаризации строений, сооружений и сетей, ремонтно-строительные организации, обслуживающие жилищный фонд, кладбища и крематории и другие. В сферу деятельности коммунального хозяйства входит также и эксплуатация жилищного фонда, с которой органически связаны коммунальные предприятия и службы внешнего благоустройства населённых мест. Поэтому в бывшем Союзе Советских Социалистических Республик (СССР) в ведении коммунальных органов и местных Советов находилось жилищно-коммунальное хозяйство (смотрите Жилищное Хозяйство). В капиталистических странах коммунальное хозяйство носит явно выраженный классовый характер. Во многих городах наряду с хорошо благоустроенными районами встречаются трущобы, лишённые элементарных коммунальных удобств. Коммунальные предприятия, независимо от их принадлежности – частным лицам, компаниям, акционерным обществам или муниципалитетам, по своей природе есть капиталистические предприятия и служат, прежде всего, интересам буржуазии и крупных монополий. Конкретное проявление этого во многих капиталистических странах – непрерывное повышение тарифов оплаты коммунальных услуг, бесплановое строительство сооружений и сетей коммунального хозяйства, подчиняемое в первую очередь коммерческим целям. Остаются нерешёнными проблемы, связанные с загрязнением воздуха, почвы и воды. В дореволюционной России коммунальное хозяйство, как общегосударственная система взаимосвязанных предприятий и сооружений, отсутствовало, а населённые пункты страны (даже крупные города) отличались низким уровнем благоустройства и коммунального обслуживания населения. За годы Советской власти жилищно-коммунальное хозяйство бувшего СССР превратилось в крупнейшую, интенсивно развивающуюся на плановой основе отрасль, использующую современные научно-технические достижения. На 01 Января 1972 основные фонды жилищно-коммунального и бытового обслуживания населения оценивались в 27.7% стоимости (в ценах 1955) всех основных фондов народного хозяйства страны. Планы развития коммунального хозяйства – составная часть последовательно осуществляемой экономической и социальной политики Куммунистической Партии Советского Союза (КПСС) и Советского Правительства, направленной на непрерывный подъём уровня жизни народа. Темпы развития коммунального хозяйства определяются ростом промышленного производства и увеличением численности городского населения (смотрите Город и Градостроительство). Отсутствие частной собственности на землю, уничтожение капиталистического домовладения, сосредоточение всех коммунальных предприятий и служб в ведении местных Советов и государственных органов давало возможность осуществлять жилищное строительство крупными массивами на индустриальной основе, комплексно развивать сооружения и сети коммунального хозяйства, обеспечивать необходимые пропорции в развитии его отдельных предприятий и служб, кооперировать и координировать ресурсы и усилия всех заинтересованных организаций и предприятий в рамках единого градостроительного плана, в плановом порядке проводить по мере развития экономики страны реконструкцию городов (с выносом вредных производств или неудобно расположенных промышленных предприятий и тому подобного). За 1966–70 свыше 550 городов и рабочих посёлков страны получили новые водопроводные и канализационные системы, их сети возросли на 40 тысяч километров, было газифицировано более 13 миллионов квартир, на 19 тысяч единиц увеличился парк подвижного состава городского электротранспорта (смотрите Жилищно-Гражданское Строительство). Значительное развитие коммунального хозяйства осуществлялось во всех Союзных республиках страны. В Российской Советской Федеративной Социалистической Республике (РСФСР) за 1966–70 годовой отпуск воды потребителям коммунальными водопроводами увеличился на 34% (в том числе в сельской местности в 2.3 раза), пропуск сточных вод через канализацию – на 41%. Такое развитие хозяйства позволило к 1970 увеличить средний суточный отпуск питьевой воды для населения на 13%, а водоотведение довести до 75% против 68% в 1966. За эти годы в 105 городах республики были сданы в эксплуатацию крупные коммунальные водопроводы, в 95 городах – коммунальные канализации. Общая производительность коммунальных водопроводов в Белорусской Советской Социалистической Республике (БССР) выросла более чем на 60%, пропуск сточных вод через канализацию – на 75%. Почти в 2 раза увеличилась производительность водопроводов в городах и посёлках Киргизской ССР, Казахской ССР, Узбекской ССР. Таджикской ССР. К 1971 более 93 миллионов жителей страны пользовались газом для бытовых целей. Только в 1971 в стране было газифицировано 3.4 миллиона квартир. В 9-й пятилетке (1971–75) было намечено завершить в основном обеспечение городского населения централизованным водоснабжением, значительно расширить газификацию и использование

электроэнергии для бытовых нужд (смотрите Благоустройство Населённых Мест, и Коммунальное Строительство). С 1971 осуществлялись работы по проектированию и внедрению автоматизированных систем управления жилищно-коммунальным хозяйством крупных городов и его отдельных отраслей (водопроводное, газовое хозяйство, городской транспорт, гостиницы и другие). Сохранению чистоты воздушного бассейна способствовали теплофикация городов и посёлков, перевод теплоэлектроцентралей (ТЭЦ) с твёрдого топлива на газ, развитие электрического городского транспорта; принимались меры по предупреждению загрязнения рек и других водоёмов.

UTILITY = ПОЛЬЗА (или ВЫГОДА, или ПОЛЕЗНОСТЬ) – Utility is an economic concept referring to the precise degree of personal satisfaction, pleasure, or sense of want-fulfillment an individual derives from consuming some quantity of a good or service at a particular point in time. Obviously no two persons assign identical utilities to any given good because human tastes and preferences vary sharply. Nor is there any standard objective unit in which both 'utility for me' and 'utility for thee' can be measured and compared to each other. But presumably each of us can at least roughly compare the utilities of various possible goods (or combinations of goods) to ourselves and decide 'since I have to choose, I would much rather have this than that, all things considered'. The concept of precisely measurable utility was at the heart of the derivation of the classical theory of demand, in the form of the law of diminishing marginal utility. Nowadays, most theorists prefer the derivation of demand derived from the 'indifference curve' analysis popularized in the 1930s by Sir John Richard Hicks (a British economist), which reaches essentially the same conclusions as the older utility analysis, without the unnecessary assumption that individuals are capable of measuring their own utilities in so precise a fashion. / Британский экономист Сэр Дьжон Ричэд Хикс (Sir John Richard Hicks; 1904–1989). Полезность (Utility):- субъективная польза, извлекаемая индивидом из потребления товара или услуги. В Классической Школе (Classic School) политической экономии Полезностью называлась потребительская стоимость товара в противоположность его стоимости (value) (Смотрите Трудовая Теория Стоимости (Labour Theory Of Value)). Маржиналисты (marginalists) заложили фундамент Новой Классической Школы (Neoclassical School) экономики, заметив, что стоимость товара связана с субъективной полезностью его потребления с учётом редкости товара. Таким образом, вода полезна с точки зрения потребления, однако её стоимость крайне мала, так как она не относится к редким ресурсам. Анализы общего равновесия (general equilibrium) и частного равновесия (partial equilibrium) базируются на полезности и предпосылке стремления потребителей максимизировать полезность. Однако, в силу субъективности полезности её трудно измерить, поэтому обычно экономисты просто предполагают, что потребители отличаются рационализмом и, следовательно, стремятся максимизировать полезность. Смотрите также Потребительские Предпочтения (Consumer Preferences); и Теория Потребления (Consumer Theory).

UTILITY AND VALUE = ПОЛЬЗА И СТОИМОСТЬ (или ПОЛЕЗНОСТЬ И СТОИМОСТЬ) – Utility And Value:- in economics, the determination of the prices of goods and services. The modern industrial economy is characterized by a high degree of interdependence of its parts. The supplier of components or raw materials, for example, must deliver the desired quantities of his products at the right moment and in the desired specifications. In economies such as those of Western Europe, North America, and Japan, the coordination of these activities is done through the price system. The relative prices of the various inputs (e.g., labor, materials, machinery) tend to determine the proportions in which they will be used. Prices also affect the relative outputs of the various final products, and they determine who will consume them. Value theory, therefore, studies the structure of these decisions, analyzes the influence of prices, and examines the efficiency of the resulting allocation of resources. Value theory is also applied by business firms and government agencies in their decisions that relate to pricing and the allocation of resources. Theories Of Value:- Cost-Of-Production Analysis:- Modern value theory began with Adam Smith (1776), David Ricardo (1817), and a number of other writers, who are generally lumped together as the classical school. These writers sought to explain pricing primarily on the basis of cost of production. That is, if commodity A costs twice as much to produce as commodity B, the price of A will be pushed toward a level twice as high as that of B. If this were not the case – if, for example, A sold for three times the price of B – then the greater profitability of investment in A would cause its production to increase and drive down its price, while the production of B would decline, thus raising its price. Prices would finally be driven to the 2:1 ratio of the costs of production. The classical economists were well aware of the oversimplification in this explanation, but, as with most theoretical analysis, its strength lay in the amount it was able to explain with a very simple model. (It is highly misleading to interpret the classical analysis literally, as a picture of its authors' views of the complex world of reality.) It was soon recognized, however, that the cost-of-production analysis considered only part of the relevant problem. Since cost depends on the quantity produced (e.g., costs per unit may decline as production of an item increases), the analysis must take into account the demand for the product. The analysis of demand was made possible by the theory of utility, developed by Hermann Heinrich Gossen in Germany (1854), Carl Menger in Austria (1871), Marie-Esprit-Léon Walras in France (1874–77), and William Stanley Jevons in England (1871). The role of utility analysis in value theory will be discussed later. It need only be added at this point that modern value theory, following the lead of the English economist Alfred Marshall (Principles of Economics, 8th Ed., 1920), considers prices to be determined simultaneously by cost and demand considerations. The analysis also recognizes the complex interdependencies in the system, with demands and supplies of various commodities affecting one another. Resource Limitations And Allocation:- The fact that goods have value can be ascribed ultimately to the limitations in the world's material endowment. Man does not have all the arable land, petroleum, or platinum that he would like; their use must be rationed. That is why goods have prices; if they were available in unlimited supply they would be free. Price usually serves as the rationing device whereby their use is kept down to the available supply. Resources can be said to be scarce in both an absolute and in a relative sense:- the surface of the Earth is finite, imposing absolute scarcity; but the scarcity that concerns economists is the relative scarcity of resources in different uses. Materials used for one purpose cannot at the same time be used for other purposes; if the quantity of an input is limited, the increased use of it in one manufacturing process must cause it to become scarcer in other uses. The cost of a product in terms of money may not measure its true cost to society. The true cost of, say, the construction of a supersonic jet is the value of the schools and refrigerators that will never be built as a result. Every act of production uses up some of society's available resources; it means the foregoing of an opportunity to produce something else. In deciding how to use resources most effectively to satisfy the wants of the community, this opportunity cost must ultimately be taken into account. In a market economy the relationship between the price of a good and the quantity supplied depends on the cost of making it, and that cost, ultimately, is the cost of not making other goods. The market mechanism enforces this relationship. In the first instance, the cost of, say, a pair of shoes is the price of the leather, the labor, the fuel, and other elements used up in producing them. But the price of these inputs, in turn, depends on what they can produce elsewhere – if the handbags that can be produced with the leather are valued very highly by consumers, the price of leather will be bid up correspondingly. Theories Of Utility:- There are two sides to the analysis of price and value: the supply side and the demand side. If cost can be said to underlie the supply relationship that determines price, the demand side must be taken to reflect consumer tastes and preferences. 'Utility' is a concept that has been used to describe these tastes. As already indicated, the cost-of-production analysis of value given above is incomplete, because cost itself depends on the quantity produced. The cost analysis, moreover, applies only to commodities the production of which can be expanded and contracted. The price of a first-folio Shakespeare has no relation to cost of production; it must depend in some sense on its utility to purchasers as it affects their bids. Marginal Utility:- The classical economists suggested that this leads to a paradox. They argued that utility could not explain the relative price of fine jade and bread, because the

latter was for many consumers essential to life, and hence its utility must surely be greater than that of jade. Yet the price of bread is far lower than that of jade. The theory of marginal utility that flowered toward the end of the XIX century supplied the key to the paradox and provided the basis for today's analysis of demand. Marginal utility was defined as the value to the consumer of an additional unit of some commodity. If, for example, the consumer is offered a choice between 22 and 23 slices of bread for his family, marginal utility measures how much more valuable 23 slices are than 22. It is clear that the magnitude of the marginal utility varies with the magnitude of, say, the smaller of the alternatives. That is, for a family of four, the difference between seven and eight slices of bread per day can be substantial, if the family will still be hungry in either case. But the difference in value between 31 and 32 slices may be negligible. If 31 slices offer enough for everyone to fill his stomach, a 32nd slice may be worth very little. Moreover, the difference in value between 122 and 123 slices may be negative – a 123rd slice may just add to the family's disposal problem. These observations lead directly to the plausible notion that marginal utility in some sense diminishes with the base from which one starts the calculation. With only seven or eight slices the marginal utility (incremental value) of an eighth slice is high. With 31 or 32 slices it is lower, and so on. The less scarce a commodity, the lower is its marginal utility, because its possessor in any case will have enough to satisfy his most pressing uses for it, and an increment in his holdings will only permit him to satisfy, in addition, desires of lower priority. The consumer will be motivated to adjust his purchases so that the price of each and every good will be approximately equal to its marginal utility (that is, to the amount of money he is willing to pay for an additional unit). If the price of an item is P Dollars, for example, and the consumer is considering buying, say, 10 units, at which point the marginal utility of the good to him is M (which is greater than P), the consumer will be better off if he purchases 11 rather than 10 units, since the additional unit costs him P Dollars. He will keep revising his purchase plans upward until he reaches the point where the marginal utility of the item falls to P Dollars. In sum, the consumer's self-interest will lead him (without conscious calculation) to purchase an amount such that the marginal utility is as close as possible to market price. So long as the consumer selects a bundle of purchases that gives him the most benefit (pleasure, utility) for his money, he must end up with quantities such that the marginal utility of each commodity in the bundle is approximately equal to its price. It now becomes easy to explain the paradox underlying the relationship between the prices of jade and bread. Because a piece of fine jade is scarce, its marginal utility is high, and consumers are willing to pay comparatively high prices for it. The explanation is perfectly consistent with a utility analysis of demand, so long as one relates price to the marginal utility of the item rather than to its total utility. A family's bread may be very valuable to it, but, if it has enough, the marginal utility of the bread will be small, and this will be reflected in its low price. The relationship between price and marginal utility is important not because it explains issues like the jade-bread paradox but because it enables one to analyze the relationship between prices and quantities demanded. It also, as a practical matter, permits one to judge how well any portion of the price mechanism is working as a device to secure the efficient satisfaction of the wants of the public, within the limits set by available resources. The conclusion that at any price the consumer will purchase the quantity at which marginal utility is equal to price makes it possible to draw a demand curve showing – to a reasonable degree of approximation – how the amount demanded will vary with price. A curve based on the previous example of bread consumption is given in Figure 1. This shows that if the family gets 10 slices per day the marginal utility of bread will be nine cents (point A). One may reverse the question and ask how much the family would purchase at any particular price, say three cents. The graph indicates that at this price the quantity would be 30 slices, because only at that quantity is marginal utility equal to the three-cent price (point B). Thus the curve in Figure 1, to a reasonable degree of approximation, may be able to do double duty:- it may serve as a marginal-utility curve relating marginal utility to quantity and, at the same time, as a demand curve relating quantity demanded to price. Consumers' Surplus:- Figure 1 leads to an important conclusion about the consumer's gains from his purchases. The diagram shows that the difference between 10 and 11 slices of bread is worth nine cents to the consumer (marginal utility = nine cents). Similarly, a 12th slice of bread is worth eight cents (see the shaded bars). Thus, the two slices of bread together are worth 17 cents, the area of the two rectangles together. Suppose the price of bread is actually three cents, and the consumer, therefore, purchases 30 slices per day. The total value of his purchases to him is the sum of the areas of all such rectangles for each of the 30 slices; i.e. it is (approximately) equal to all of the area under the demand curve; that is, the area defined by the points 0CBE. The amount the consumer pays, however, is less than this area. His total expenditure is given by the area of rectangle 0CBD – 90 cents. The difference between these two areas, the quasi-triangular area DBE, represents how much more the consumer would be willing to spend on the bread over and above the 90 cents he actually pays for it, if he were forced to do so. It represents the absolute maximum that could be extracted from the consumer for the bread by an unscrupulous merchant who had cornered the market. Since, normally, the consumer only pays quantity 0CBD, the area DBE is a net gain derived by the consumer from the transaction. It is called Consumers' Surplus. Virtually every purchase yields such a surplus to the buyer. The concept of consumers' surplus is important for public policy, because it offers at least a crude measure of the public benefits of various types of economic activity. In deciding whether a government agency should build a dam, for example, one may estimate the consumers' surplus from the electricity the dam would generate and seek to compare it with the surplus that could be yielded by alternative uses of the resources needed to construct and operate the dam. Utility Measurement And Ordinal Utility:- As originally conceived, utility was taken to be a subjective measure of strength of feeling. An item that might be described as worth '40 utils' was to be interpreted to yield 'twice as much pleasure' as one valued at 20 utils. It was not long before the usefulness of this concept was questioned. It was criticized for its subjectivity and the difficulty (if not impossibility) of quantifying it. An alternative line of analysis developed that was able to accomplish most of the same purposes but without as many assumptions. First introduced by the economists Francis Ysidro Edgeworth in England (1881) and Vilfredo Federico Damaso Pareto in Italy (1896–97), it was brought to fruition by Eugen Slutsky in Russia (1915) and Sir John Richard. Hicks and Sir Roy George Douglas Allen in Great Britain (1934). The idea was that to analyze consumer choice between, say, two bundles of commodities, A and B, given their costs, one need know only that one is preferred to another. This may at first seem a trivial observation, but it is not as simple as it sounds. In the following discussion, it is assumed for simplicity that there are only two commodities in the world. Figure 2 is a graph in which the axes measure the quantities of two commodities, X and Y. Thus, point A represents a bundle composed of seven units of commodity X and five units of commodity Y. The assumption is made that the consumer prefers to own more of either or both commodities. That means he must prefer bundle C to bundle A, because C lies directly to the right of A and hence contains more of X and no less of Y. Similarly, B must be preferred to A. But one cannot say, in general, whether A is preferred to D or vice versa, since one offers more of X and the other more of Y. The consumer may in fact not care whether he receives A or D – that is, he may be indifferent (see Figure 3). Assuming that there is some continuity in his preferences, there will be a locus connecting A and D, any point on which (E or A or D) represents bundles of commodities of equal interest to this consumer. This locus (I–I' in Figure 3) is called an Indifference Curve. It represents the consumer's subjective trade off between the two commodities – how much more of one he will have to get to make up for the loss of a given amount of another. That is, one may treat the choice between bundle D and bundle E as involving the comparison of the gain of quantity FD of X with the loss of FE of Y. If the consumer is indifferent between D and E, the gain and loss just offset one another; hence, they indicate the proportion in which he is willing to exchange the two commodities. In mathematical terms, FE divided by FD represents the average slope of the indifference curve over arc ED; it is called the marginal rate of substitution between X and Y. Figure 3 also contains other indifference curves, some representing combinations preferred to A (curves lying above and to the right of A) and some representing combinations to which A is preferred. These are like contour lines on a map, each such line being a locus of combinations that the consumer considers equally desirable. Conceptually, through every point in the diagram there is an indifference

curve. Figure 3, with its family of indifference curves, is called an Indifference Map. This map obviously does no more than rank the available possibilities; it indicates whether one point is preferred to another but not by how much it is preferred. It is easy to show that at any point such as E the slope of the indifference curve, roughly FE divided by ED, equals the ratio of the marginal utility of X to the marginal utility of Y for the corresponding quantities. For in moving from E to D the consumer gives up FE of Y, a loss valued, by definition, at approximately FE multiplied by the marginal utility of Y, and he gains FD of X, a gain worth FD multiplied by the marginal utility of X. Relative marginal utilities can be measured in this way because their ratio does not measure subjective quantities – rather, it represents a rate of exchange of two commodities. The marginal utility of X measured in money terms tells one how much of the commodity used as money the consumer is willing to give for more of the commodity X but not what psychic pleasure the consumer gains. Prices And Incomes:- One other type of information is needed to complete the analysis of consumer choice: the prices of X and Y and the amount the consumer has available to spend. In what follows, it will be assumed that the consumer spends all his money on the available commodities (savings bonds being among the commodities). If PX and PY are the prices of commodities X and Y, respectively, and M represents the amount of money available for spending, the condition that all of the money is spent yields the equation:- PXX + PYY = M (1) or, solving for Y in terms of X:- Y = – (PX/PY)X + M/PY, (2). (2)This is obviously the equation of a straight line with slope:- –PX/PY. and with y-intercept M/PY. The line, called the budget line, or price line, represents all the combinations of X and Y that the consumer can afford to buy with income M at the given prices. Equilibrium of the Consumer:- Figure 4 combines this price line and the indifference curves, permitting direct analysis of the consumer purchase decision. Line PP' is the price line corresponding to equation (2) above. Any point R on that line represents a combination of X and Y that a given consumer can afford to purchase; however, R is not an optimal choice. This can be seen by comparing R with S on the same price line. Since S lies on a higher indifference curve than R, the former is the preferred position, and, since S costs no more than R (they are on the same price line, so each costs M Dollars), S gives the consumer more for his money. It is at T, however, the point of tangency between the price line and an indifference curve, that the consumer reaches his highest indifference curve; this is, therefore, the optimal point for him, given his pattern of tastes as shown by the shapes of his indifference curves. This is the solution of the choice problem – it explains, in principle, the consumer's purchase decision on the basis of his given preferences, with no assumptions as to degrees of measurable utility. The tangency at the solution point has a significant interpretation. It was noted above that the slope of the indifference curve is the ratio of the marginal utilities of the two commodities. It follows that, at the optimal point T, a Dollar of expenditure must offer the same utility whether spent on X or on Y. If this is not so – as at point R in Figure 4, where the consumer gets more for his money by spending a Dollar on Y rather than on X – it will pay him to reallocate his expenditures between the two commodities accordingly, moving toward S from R. Changes In Prices And Incomes:- The diagram becomes more illuminating when one investigates how the consumer's decision is affected by a change in his income or in the price of a commodity. Equation (2) indicates that a change in income, M, does not affect the slope of the price line, only its intercept. Thus, as the person's income increases, the price line undergoes a sequence of parallel shifts (Figure 5). For each such line there will be a point of tangency, T, with an indifference curve, showing the consumer's optimal bundle of purchases with the corresponding income. The locus of these points (T1, T2, T3 ...) may be called the income-consumption curve; it shows how the consumer's purchases vary with his income. Normally the curve will have a positive slope, as EE' does in Figure 5A, meaning that as a person grows wealthier he will buy more of each commodity. But the slope can be negative for some stretches (GG' in Figure 5B). In that case, X is said to be an inferior good of which the consumer buys less as his income rises. The diagram can also be used to show what happens as the price of X varies. From equation (2) it can be seen that the Y-intercept is not affected by an increase in the price of X but that the slope of the price line grows. Thus, as PX rises, the price line shifts from PP' to PR' in Figure 6. This means that, as PX rises, M Dollars will buy as much of good Y as before (the position of point P at which all M Dollars are spent on commodity Y does not change), but that M Dollars will now buy less of good X, so that the position of point P' must move toward the left. Once again, by following the points of tangency between indifference curves and the price lines for various values of PX, one contains a locus UU', τηε price-consumption curve, showing how the consumer's purchases vary with PX. Income And Substitution Effects:- It is useful to divide the effects of the price change conceptually into two parts. An increase in the price of X obviously affects the relative cost of X and Y. But it also decreases the consumer's overall purchasing power. The effect on purchases of this reduction of purchasing power is called the Income Effect of the price change. Its effect via the relative price change is called the Substitution Effect. The division can be carried out graphically as follows:- let the price of X increase so that the price line in Figure 7 moves from PP' to PR', and assume an imaginary intermediate price line, LL', with the slope of PR' but tangent to the indifference curve that was attained with the old price line PP'. The imaginary price line has the following properties:- (1) it involves the same real income as PP' (tangency points T and S are the same indifference curve), and (2) it involves the same relative prices as the new price line since their slopes are the same. The rise in price has, in the figure, caused the demand for X to fall from C to A (the quantities of X corresponding to tangency points T and U). It has been possible to divide the total effect, CA, into two parts, the income effect, BA, and the substitution effect, CB. This breakdown is important, because a number of interesting and important theorems can be proved about the substitution effect. Two of these theorems will illustrate the point. Under the normal assumptions of demand theory it can be proved that a rise in the price of X must, via the substitution effect, work to reduce the demand for X; the second theorem states the surprising result that, considering only substitution effects, a Dollar rise in the price of X must change the demand for Y by precisely the same amount as a Dollar rise in the price of Y changes the demand for X. Similar relationships have been shown to hold when there are more than two commodities involved. / Шотландский экономист и философ Эдэм Смис (Adam Smith; 1723–1790) (в 1776), Британский политический экономист Дэйвид Рикадо (David Ricardo; 1772–1823) (в 1817), . разработано Прусским экономистом Хэрманом Хайнрихем Госэном (Hermann Heinrich Gossen; 1810–1858) в Германии (в 1854), Австрийский экономист Карл Мэня (Carl Menger; 1840–1921) в Австрии (в 1871), Французский математический экономист Мари-Эспри-Леу Вальрас (Marie-Esprit-Léon Walras; 1834–1910) во Франции (в 1874–77), и Английский экономист и логик Вильэм Стэнли Дьжэвэнс (William Stanley Jevons; 1835–1882) в Англии (в 1871). Английский экономист Алфрид Машэл (Alfred Marshall; 1842–1924) (Principles of Economics, 8th Ed., 1920)). Англо-Ирландский философ и политический экономист Франсис Исидро Эдьжвос (Francis Ysidro Edgeworth; 1845–1926) в Англии (в 1881) и Итальянский инженер, социолог, экономист, политический учёный и философ Вильфрэдо Фэдэрико Дамасо Парето (Vilfredo Federico Damaso Pareto; 1848–1923) в Италии (в 1896–97), Российско-Советским статистом математиком, экономистом и политическим экономистом Евгением Евгеньевичем Слуцким (Eugen Slutsky; 1880–1948) в России (в 1915) и Британский экономист Сэр Дьжон Ричэд Хикс (Sir John Richard Hicks; 1904–1989) и Английский экономист, математик и статист Сэр Рой Дьжодьж Даглэс Алэн (Sir Roy George Douglas Allen; 1906–1983) в Великобритании (в 1934).

UTILITY–EARNED INCENTIVES = ЗАРАБОТАННЫЕ СНАБЖАЮЩИМ ПРЕДПРИЯТИЕМ ДОПЛАТЫ (или ПООЩРЕНИЯ, или СТИМУЛЫ) – Utility-Earned Incentives:- costs in the form of incentives paid to the utility for achievement in consumer participation in Demand-Side Management (DSM) programs. These financial incentives are intended to influence the utility's consideration of DSM as a resource option by addressing cost recovery, lost revenue, and profitability.

UTILITY EMPLOYEE = РАБОТНИК СНАБЖАЮЩЕГО ПРЕДПРИЯТИЯ (или СЛУЖАЩИЙ СНАБЖАЮЩЕГО ПРЕДПРИЯТИЯ) – Utility Employee:- a railroad employee assigned to and functioning as a temporary member of a train or yard crew whose primary

function is to assist the train or yard crew in the assembly, disassembly or classification of rail cars, or operation of trains (subject to the conditions set forth in the US 49CFR218.22).

UTILITY FUNCTION = ФУНКЦИЯ ПОЛЕЗНОСТИ (или ФУНКЦИЯ ВЫГОДЫ) – Utility Function is a mathematical expression that assigns a value to all possible choices. In portfolio theory, the utility function expresses the preferences of economic entities with respect to perceived risk and expected return. / Функция Полезности (Utility Function):- функция, которая описывает взаимосвязь между различными товарами и услугами, предлагаемыми экономикой, и предпочтениями индивидов (Смотрите Потребительское Предпочтение (Consumer Preference)). При определённых допущениях функция полезности может быть использована в анализе поведения потребителей (consumers) и рынков. Смотрите также Функция Прямой Полезности (Direct Utility Function); и Функция Косвенной Полезности (Indirect Utility Function).

UTILITY MODELS = ПОЛЕЗНЫЕ МОДЕЛИ – Utility Models:- while not as widespread as patents, utility models are also used to protect inventions. Utility models are found in the laws of more than 30 countries, as well as in the regional agreements of the African Regional Industrial Property Organization (ARIPO) and the Organisation Africaine de la Propriete Intellectuelle (OAPI). In addition, some countries, such as Australia and Malaysia, provide for titles of protection called innovation patents or utility innovations, which are similar to utility models. Other countries, like Hong Kong, Ireland and Slovenia, have a short-term patent that is equivalent to the utility model. The expression 'Utility Model' is simply a name given to a title of protection for certain inventions, such as inventions in the mechanical field. Utility models are usually sought for technically less complex inventions or for inventions that have a short commercial life. The procedure for obtaining protection for a utility model is usually shorter and simpler than for obtaining a patent. Substantive and procedural requirements under the applicable laws differ to a large extent among the countries and regions that have a utility model system, but utility models usually differ from patents for invention in the following main respects:- (i) The requirements for acquiring a utility model are less stringent than for patents. While the 'novelty' requirement must always be met, that of 'inventive step' or 'non-obviousness' may be much less or even absent altogether. In practice, protection for utility models is often sought for innovations of a rather incremental nature, which may not meet the patentability criteria. (ii) The maximum term of protection provided by law for a utility model is generally shorter than the maximum term of protection provided for a patent for invention (usually between 7 and 10 years). (iii) The fees required for obtaining and maintaining the right are generally lower than those for patents. / Полезные Модели – технические решения, относящиеся к устройству. Полезная модель признаётся соответствующей условиям патентоспособности, если она является новой и промышленно применимой. Полезная модель является новой, если совокупность её существенных признаков не известна из уровня техники. В качестве полезных моделей правовая охрана не предоставляется:- решениям, касающимся только внешнего вида изделий и направленным на удовлетворение эстетических потребностей; топологиям интегральных микросхем; решениям, противоречащим общественным интересам, принципам гуманности и морали. Полезная Модель – устройство обладающее новизной. Полезная модель – это техническое решение, относящееся исключительно к устройству, совокупность существенных признаков которого не известна из уровня техники, при этом устройство должно быть промышленно применимым. Патент на полезную модель имеет срок действия – 10 лет + продление на 3 года. Отличие полезной модели от изобретения:- полезные модели иногда называют малыми изобретениями. В отличие от изобретения к полезной модели не предъявляется требование изобретательского уровня. Это означает, что полезной моделью может быть признано любое устройство, даже вполне очевидное для специалиста, но, тем не менее, нигде не описанное и не применяющееся на практике, то есть обладающее мировой новизной. Государственная экспертиза полезной модели в Российской Федерации не проводится, ответственность за новизну заявляемого технического решения возлагается на заявителя. Не редки случаи одновременной подачи заявки на полезную модель и на изобретение, которые представляют одно техническое решение. Получить патент на полезную модель легче и дешевле, чем патент на изобретение. При этом следует иметь ввиду, что способы (технологии) и вещества патентами на полезные модели не защищаются. Полезная модель является достаточно удобным вариантом охраны разработок для малого и среднего бизнеса. Получить патент на полезную модель можно примерно через полгода после подачи заявки в патентное ведомство. Поскольку экспертиза заявок на полезные модели не проводится, чем объясняется короткий срок получения патента, то это фактически даёт возможность провести патентование таких технические решений, которые не обладают новизной. Такая регистрация является недобросовестной и уязвимой. Полученный недобросовестным путём патент на полезную модель может быть опротестован любым заинтересованным лицом. Требования к полезным моделям:- подать заявку на патентование полезной модели может как юридическое, так и физическое лицо, а также группа лиц. В заявке помимо заявителей указываются авторы технического решения, которые в соответствии с патентным законодательством имеют право на вознаграждение от патентообладателя. Заявителем и автором может являться одно и то же физическое лицо (лица). Основным требованием к полезной модели является мировая новизна. Техническое решение считается новым, если оно не известно из уровня техники. Под уровнем техники подразумеваются любые сведения, ставшие общедоступными в мире до даты подачи заявки. За подачу заявки, а также за выдачу патента (в случае положительного решения экспертизы) уплачивается государственная пошлина. Во избежание уязвимости патента, а также для выявления аналогов, перед подачей заявки необходимо провести проверку на мировую новизну и сформулировать объём притязаний заявителя. Что получает владелец патента? По завершении процедуры патентования, владелец патента получает исключительное право на полезную модель. Патент удостоверяет приоритет, авторство полезной модели, и содержит сведения о патентообладателе, сроке действия патента, а также формулу полезной модели. Патент, выданный Российским патентным ведомством, действует только на территории Российской Федерации. После публикации патента ни в одной стране мира иной заявитель не сможет получить законный патент на аналогичное техническое решение. При этом описанное в патенте техническое решение может быть свободно использовано любым лицом в своей продукции в других странах. Ввоз продукции из этих стран на территорию действия патента запрещён законом. Поэтому, при наличии заинтересованности в зарубежном рынке, рекомендуется провести патентование в других государствах. Любое физическое или юридическое лицо, незаконно использующее запатентованную полезную модель, считается нарушителем патента. Патентообладатель вправе требовать от нарушителя прекращения нарушения патента, возмещения причинённых убытков в соответствии с гражданским законодательством; публикации решения суда в целях защиты своей деловой репутации; осуществления иных способов защиты прав в порядке, предусмотренном законодательством Российской Федерации. Патенты можно продавать или предоставлять лицензии (разрешения) на их использование путём заключения соответствующих лицензионных договоров. Такого рода договоры подлежат обязательной государственной регистрации в Патентном ведомстве и публикации в официальных изданиях. Полезная Модель это предоставляемая государством юридическая форма защиты технических решений, не обладающих 'изобретательским уровнем' – критерием оценки патентоспособности, необходимым для выдачи патента на изобретение, но удовлетворяющее двум другим критериям оценки патентоспособности, один из которых требует, чтобы техническое решение обладало новизной, а другой требует, чтобы устройство было промышленно применимым. Эта форма принята не во всех странах и имеет место в Германии, Австрии, Аргентине, Италии, Бразилии, Испании, Китае, Тайване, Польше, Украине, Франции, Португалии, Мексике, Марокко, Чили, Узбекистане, России, Финляндии, Японии и Южной Корее. На какой срок

выдается патент на полезную модель? Патент на полезную модель выдаётся сроком на десять лет с даты подачи заявки в патентное ведомство, после чего он, в случае наличия соответствующего ходатайства патентообладателя, может быть продлён на три года. Что может быть запатентовано в качестве полезной модели? В качестве полезной модели охраняются техническое решение, относящееся исключительно к устройствам, не противоречащее нормам гуманности и морали и удовлетворяющее критериям новизны и промышленной применимости. Полезная модель считается удовлетворяющей критерию ‘новизна’, в том случае, если совокупность, описывающих её, существенных признаков не известна из уровня техники. Под ‘уровнем техники’ в патентной терминологии подразумевают любые ставшие общедоступными и/или опубликованные сведения о средствах того же назначения, что и заявленная полезная модель. Что не может быть запатентовано в качестве полезной модели? Правовая охрана в качестве полезной модели не предоставляется:- (i) способам, методам, техническим приёмам и правилам; (ii) решениям, касающимся только внешнего вида изделий и направленным на удовлетворение эстетических потребностей; (iii) топологиям интегральных микросхем; и (iv) решения, противоречащие общественным интересам, принципам гуманности и морали. В чём отличия патента на полезную модель от патента на изобретения? В отличие от изобретения к полезной модели не предъявляется требование изобретательского уровня. Это означает, что полезной моделью может быть признано любое устройство, даже вполне очевидное для специалиста, но формально нигде не описанное и широко не известное, вследствие чего удовлетворяющее критерию новизны. Все остальные требования, а также структура и наполнение заявки аналогичны патенту на изобретение. Какой объём прав по сравнению с патентом на изобретение получает владелец патента на полезную модель? Объём прав, делегируемый государством владельцу патента на полезную модель, идентичен объёму прав патента на изобретения, то есть владелец патента на полезную модель, также как в случае с изобретением обладает исключительными правами, на техническое решение, описанное в патенте. Возможно ли получить патент на полезную модель и патент на изобретение одновременно на одно и тоже устройство? Строго говоря нет, но в патентной практике уже типичной стала ситуация когда одновременно подаётся заявка на полезную модель и на изобретение, при этом формула полезной модели, по сравнению с формулой изобретения, немного сокращается и/или модифицируется и устройство, описанное такой формулой, юридически уже считается иным, и хотя по сути оно является тем же самым на сегодняшний день эксперты отраслевых отделов не видят препятствий в выдаче патента на изобретение на устройство, уже защищенного патентом на полезную модель. Конечно же такая ситуация является недоработкой законодательства и патентного ведомства, но это весьма выгодно заявителям, и пока существует такая возможность мы рекомендуем ей воспользоваться. В чём преимущества полезной модели над изобретением? Стоимость патентования полезной модели примерно в 1.5 раза ниже чем изобретения, процесс выдачи проще и быстрее. В данный момент патентную грамоту с момента сдачи материалов полезной модели в Федеральный Институт Промышленной Собственности (ФИПС) можно получить уже через 5–6 месяцев, а иногда и ранее, по сравнению с 1.5–2 годами для патента на изобретение. Кроме того, в патентном законодательстве и практике есть ещё одна, помимо описанной выше, недоработка, по сути, юридически делающая позиции патента на полезную модель более сильными, чем патента на изобретение. Хотя все должно было бы быть в точности наоборот, патент на полезную модель очень трудно, а некоторые невозможно, аннулировать через палату по патентным спорам, чего не скажешь о патентах на изобретения. Это связано с разницей критериев оценки патентоспособности. Так как к полезной модели предъявляются требование лишь новизны, то аннулирована она может быть в том случае если будет доказана её известность ссылкой на один информационный источник, то есть вся формула патента должна содержаться в этом источнике, причём в данный момент заседатели палаты требуют, чуть ли не дословного совпадения понятий формулы и противопоставляемого источника, при этом патент на изобретение может быть оспорен любым количеством ссылок на любые источники. Требования к полезным моделям:- Подать заявку на патентование полезной модели может как юридическое, так и физическое лицо, а также группа лиц. В заявке помимо заявителей указываются авторы технического решения, которые в соответствии с патентным законодательством имеют право на вознаграждение от патентообладателя. Заявителем и автором может являться одно и то же физическое лицо (лица). Основным требованием к полезной модели является мировая новизна. Техническое решение считается новым, если оно не известно из уровня техники. Под уровнем техники подразумеваются любые сведения, ставшие общедоступными в мире до даты подачи заявки. За подачу заявки, а также за выдачу патента (в случае положительного решения экспертизы) уплачивается государственная пошлина. Во избежание уязвимости патента, а также для выявления аналогов, перед подачей заявки необходимо провести проверку на мировую новизну и сформулировать объём притязаний заявителя. Что получает владелец патента? По завершении процедуры патентования, владелец патента получает исключительное право на полезную модель. Патент удостоверяет приоритет, авторство полезной модели, и содержит сведения о патентообладателе, сроке действия патента, а также формулу полезной модели. Патент, выданный Российским патентным ведомством, действует только на территории Российской Федерации. После публикации патента ни в одной стране мира иной заявитель не сможет получить законный патент на аналогичное техническое решение. При этом описанное в патенте техническое решение может быть свободно использовано любым лицом в своей продукции в других странах. Ввоз продукции из этих стран на территорию действия патента запрещён Законом. Поэтому, при наличии заинтересованности в зарубежном рынке, рекомендуется провести патентование в других государствах. Любое физическое или юридическое лицо, незаконно использующее запатентованную полезную модель, считается нарушителем патента. Патентообладатель вправе требовать от нарушителя прекращения нарушения патента, возмещения причинённых убытков в соответствии с гражданским законодательством; публикации решения суда в целях защиты своей деловой репутации; осуществления иных способов защиты прав в порядке, предусмотренном законодательством Российской Федерации. Патенты можно продавать или предоставлять лицензии (разрешения) на их использование путём заключения соответствующих лицензионных договоров. Такого рода договоры подлежат обязательной государственной регистрации в патентном ведомстве и публикации в официальных изданиях.

UTILITY PATENT = ПОЛЕЗНЫЙ ПАТЕНТ (или ПАТЕНТ НА ПОЛЕЗНУЮ МОДЕЛЬ) – Utility Patent may be granted to anyone who invents or discovers any new, useful, and nonobvious process, machine, article of manufacture, or composition of matter, or any new and useful improvement thereof.

UTILITY PATENT APPLICATION = ПРИМЕНЕНИЕ ПОЛЕЗНОГО ПАТЕНТА – Utility Patent Application:- protect useful processes, machines, articles of manufacture, and compositions of matter.

UTILITY REVENUE BOND = ОБЛИГАЦИЯ ПОД ДОХОДЫ СНАБЖАЮЩЕГО ПРЕДПРИЯТИЯ – Utility Revenue Bond is a municipal bond issued to finance the construction of public utility services. These bonds are repaid from the operating revenues the project produces after the utility is finished. / Utility Revenue Bond:- облигации, обеспеченные доходами от предприятий коммунального хозяйства. Муниципальные облигации (municipal bond), выпускаемые для финансирования строительства электростанций, газопроводов, водопроводов и канализационных систем, а также других общественных коммунальных служб. Эти облигации оплачиваются из прибылей от проектов после их завершения. По подобным облигациям обычно существует резервный фонд, в котором имеются суммы, равные годовым выплатам по обслуживанию задолженностей (debt service), эти

резервные фонды защищают акционеров в случае временной нехватки личных средств или если прибыли оказываются меньшими, чем ожидалось. Смотрите также Revenue Bond.

UTILITY STOCK = АКЦИЯ СНАБЖАЮЩЕГО ПРЕДПРИЯТИЯ (или АКЦИЯ КОММУНАЛЬЩИКА) – Those who are looking for ways to generate investment income often allocate a portion of their portfolios to Utility Stocks. Utilities have long been viewed as a conservative option that enables investors to capture higher dividends than are available in most areas of the stock market. Benefits of Utility Stocks:- utilities are companies that deliver essential services such as water, gas, and electricity. Since these services are always in demand no matter how fast or slowly the economy is growing, the sector tends to be one of the more stable areas of the market in terms of its day-to-day performance. Utility stocks also tend to hold up better in falling markets, since investors are usually in less of a rush to sell their lower-risk investments when the broader environment turns sour. While utility stocks are more risky than most asset classes within the bond market, they are generally seen as being lower risk compare to the overall stock market. The primary benefit of utilities is that they typically pay above-market dividends. In the past decade, exchange-traded fund Select Sector SPDR-Utilities (ticker:- XLU) – which invests across the entire US utilities sector with an emphasis on the largest companies – has typically offered a yield about 1.75 to 2.5 times that of the S&P 500 Index (a measure of broader US market performance). Notably, it has done so with a lower level of volatility than the market as a whole. High Dividends, But Limited Room for Capital Appreciation:- the flip side is that the potential for longer-term capital appreciation is limited with utilities. The growth opportunities for most companies in the sector is limited, and this is reflected in their stock price performance. One benefit of this, of course, is that with fewer opportunities to invest for future growth, the companies have more cash on hand to pay out dividends. Consider that the utilities ETF mentioned above debuted on December 22, 1998 at the price of USD30.25 per share. In mid-December, 2011, the ETF was trading at USD34.62 – indicating that while the ETF has made money on a share price basis in its 13-year history, the appreciation has been minimal. Keep in mind, however, that it paid out USD10.60 in dividends during this time. As a result, its cumulative total return was a solid 77%, well above that of the broader US stock market. This helps illustrate that yield makes up a much larger part of utilities' total return than price appreciation. The Risks of Utility Stocks:- like any segment of the stock market, utilities are subject to broader market forces. During both of the major market declines of the past decade – 2001–02 and 2008–09 – utilities stocks lost about half of their value on a price basis (i.e. not counting dividends). Income investors need to keep this in mind when deciding between an investment in bonds or dividend-paying stocks such as utilities. Two other factors can have a negative impact on the performance of utilities stocks. First, higher interest rates can cause the sector to underperform for two reasons:- (1) higher rates increase utilities' interest burden because companies in the sector tend to be capital-intensive and therefore more heavily indebted; and (2) higher rates cause income-oriented investors to gravitate toward bonds and away from riskier yield options in the stock market. In addition, the sector is heavily regulated and therefore vulnerable to shifts in government policy. How to Invest in Utility Stocks:- you can invest in utility stocks through any broker. It's possible to invest in either individual utility stocks, mutual funds that specialize in the sector, or ETFs such as Select Sector SPDR-Utilities. Be sure to contact a financial advisor or use all the vast online resources available to conduct comprehensive research before investing. Utility Stock:- share of a company providing utilities such as electricity, gas and water.

UTILITY SYSTEM DELIVERY = ПОСТАВКА СИСТЕМОЙ СНАБЖАЮЩИХ ПРЕДПРИЯТИЙ – Utility System Delivery:- in reference to electricity in the United States, this commercial practice allows a seller to initially determine the utility system transmission interface to be used for the sale of power to a buyer. The seller's designated interface refers to an interconnection with a neighboring utility system or to an internal generation or transmission node within the designated utility system. / Поставка Системой Электростанций:- по отношению к электричеству в Соединённых Штатах Америки, эта коммерческая практика позволяет продавцу первоначально определять границы раздела подачи системы электростанции, которые необходимо использовать для продажи электроэнергии покупателю. Выделенная продавцом граница раздела относится к взаимосвязи с соседней системой электростанций или к внутреннему генерирующему или передающему узлу, находящемуся в пределах выбранной системы электростанций.

UTILITY VALUE = ПОЛЕЗНАЯ СТОИМОСТЬ – Utility Value:- the welfare a given investor assigns to an investment with a particular expected return and risk.

UTILIZATION = XX (или ИСПОЛЬЗОВАНИЕ) – Utilization is an amount of time that an aircraft is used per unit of time.

UTILIZATION FACILITY = УСТАНОВКА XX – Utilization Facility is:- (1) as defined by 10 CFR 110.2 of the Nuclear Regulatory Commission Regulations, Utilization Facility means a nuclear reactor, other than one that is a production facility, any of the following major components of a nuclear reactor. Pressure vessels designed to contain the core of a nuclear reactor, other than one that is a production facility, and the following major components of a nuclear reactor:- (i) primary coolant pumps; (ii) fuel charging or discharging machines; and (iii) control rods. Utilization facility does not include the steam turbine generator portion of a nuclear power plant. (2) Utilization Facility does not include the steam turbine generator portion of a nuclear power plant.

UTILMD MESSAGE = UTILITIES MASTER DATA MESSAGE

UTILTS MESSAGE = UTILITIES TIME SERIES MESSAGE

UTMA = UNIFORM TRANSFERS TO MINORS ACT

UTMOST GOOD FAITH = НАИВЫСШАЯ ДОБРОСОВЕСТНОСТЬ (или НАИВЫСШАЯ СТЕПЕНЬ ДОВЕРИЯ) – Utmost Good Faith:- insurance contracts are one of a limited class that requires the parties (insurer and insured) to exercise the utmost good faith in their dealings with each other. Specifically the proposer of an insurance must disclose all material facts which would influence a prudent insurer in deciding whether to accept the insurance and if so on what terms. See also Uberrima Fides. Contracts of insurance and reinsurance are contracts of utmost good faith. In the event that either party fails to observe utmost good faith towards the other in regard to the negotiation of cover then the other party may avoid the contract. The duty of utmost good faith requires each party to inform the other all material facts during the negotiation of the placement, renewal or alteration of cover. An insured has a separate duty of good faith when making a claim under an insurance policy. A fundamental principle of insurance with which strict compliance is required during negotiations to conclude an insurance contract. Its intention is to ensure that. by proper disclosure and representation, both parties are aware of all circumstances material to the risk at the time the contract is concluded between them. Breach of good faith on the part of the assured or his broker entitles the insurer to avoid the contract from inception. Utmost Good Faith:- the insured should disclose all known material facts to the insurer at time of insurance enquiry. Utmost Good Faith (Uberrima Fides):- the fundamental principle of insurance practice, requiring that a person wishing to take out an insurance cover must provide all the information the insurer needs so as to calculate the correct premium for the risk involved. Nothing must be withheld from the insurers, even if they do not actually ask for the information on an application form. The principle is essential because an insurer usually has no knowledge of the facts involved in the risk they are being asked to cover; the only source of information is the person ... Utmost Good Faith is duty placed on both parties to an insurance contract. The insured has to disclose material facts while insurers have to act reasonably and communicate clearly. / Наивысшая Добросовестность (Utmost Good Faith или на Латинском Uberrima Fides):- фундаментальный

принцип страхового дела, предполагающий, что лицо, желающее оформить страховой полис, должно предоставить страховщику всю необходимую для правильного расчёта страховой премии за страхуемый риск информацию. От страховщиков ничего нельзя утаивать даже в тех случаях, когда они специально не требуют какой-либо информации. Принцип имеет очень большое значение, так как страховщик обычно не располагает всеми фактами, связанными со страхованием риска; единственным источником информации для него может служить сам страхователь. Если обнаружится, что страхователь утаил информацию или дал ложные сведения, страховщик имеет право рассматривать полис как недействительный, и суд подержит его отказ платить страховую сумму. Смотрите также Убэррима Фидэс (Uberrima Fides).

UTMS = URBAN TRANSPORTATION MODELING SYSTEM

UTOPIA = УТОПИЯ – Utopia:- an ideal commonwealth whose inhabitants exist under seemingly perfect conditions. Hence 'utopian' and 'utopianism' are words used to denote visionary reform that tends to be impossibly idealistic. The word first occurred in Sir Thomas More's Utopia, published in Latin as Libellus ... de optimo reipublicae statu, deque nova insula Utopia ('Concerning the highest state of the republic and the new island Utopia'; 1516); it was compounded by More from the Greek words for 'Not' (Ou) and 'Place' (Topos) and thus meant 'nowhere'. During his embassy to Flanders in 1515, More wrote Book II of Utopia, describing a pagan and communist city-state in which the institutions and policies were entirely governed by reason. The order and dignity of such a state was intended to provide a notable contrast with the unreasonable polity of Christian Europe, divided by self-interest and greed for power and riches, which More then described in Book I, written in England in 1516. The description of Utopia is put in the mouth of a mysterious traveller, Raphael Hythloday, in support of his argument that communism is the only cure against egoism in private and public life. More, in the dialogue, speaks in favor of mitigation of evil rather than cure, human nature being fallible. The reader is thus left guessing as to which parts of the brilliant jeu d'esprit are seriously intended and which are mere paradox. Written utopias may be practical or satirical, as well as speculative. Utopias are far older than their name. Plato's Republic was the model of many, from More to H.G. Wells. A utopian island occurs in the Sacred History of Euhemerus (flourished 300 BC), and Plutarch's life of Lycurgus describes a utopian Sparta. The legend of Atlantis inspired many utopian myths; but explorations in the XV century permitted more realistic settings, and Sir Thomas More associated Utopia with Amerigo Vespucci. Other utopias that were similar to More's in Humanist themes were the I Mondi (1552) of Antonio Francesco Doni and La città felice (1553) of Francesco Patrizi. An early practical utopia was the comprehensive La città del sole (written c. 1602) of Tommaso Campanella. Francis Bacon's New Atlantis (published 1627) was practical in its scientific program but speculative concerning philosophy and religion. Christian utopian commonwealths were described in Antangil (1616) by the anonymous 'I.D.M.', Christianopolis (1619) by Johann Valentin Andreae, and Novae Solymae libri sex (1648) by Samuel Gott. Puritanism produced many literary utopias, both religious and secular, notably, The Law of Freedom ... (1652), in which Gerrard Winstanley advocated the principles of the Diggers. The Common-Wealth of Oceana (1656) by James Harrington argued for the distribution of land as the condition of popular independence. In France such works as Gabriel de Foigny's Terre australe connue (1676) preached liberty. François Fénelon's Télémaque (1699) contained utopian episodes extolling the simple life. L'An 2440 by Louis-Sébastien Mercier (1770; Eng. trans., 1772) anticipated Revolutionary doctrines. G.A. Ellis' New Britain (1820) and Étienne Cabet's Voyage en Icarie (1840) were related to experimental communities in the United States that revealed the limitations of purely economic planning. Consequently, Bulwer-Lytton, in The Coming Race (1871), invented an essence that eliminated economics altogether, and William Morris demonstrated his contempt for economics in News from Nowhere (1890). Two influential utopias, however, had an economic basis:- Looking Backward, 2000–1887 (1888) by Edward Bellamy and Freiland (1890; A Visit to Freeland ..., 1894) by Theodor Herzka. H.G. Wells, in A Modern Utopia (1905), returned to speculation. Many utopias are satires that ridicule existent conditions rather than offering practical solutions for them. In this class are Swift's Gulliver's Travels (1726) and Samuel Butler's Erewhon (1872). In the XX century, when the possibility of a planned society became too imminent, a number of bitterly anti-utopian, or dystopian, novels appeared. Among these are The Iron Heel (1907) by Jack London, My (1924; We, 1925) by Yevgeny Zamyatin, Brave New World (1932) by Aldous Huxley, and Nineteen Eighty-four (1949) by George Orwell. The Story of Utopias (1922) by Lewis Mumford is an excellent survey. Concurrent with the literature, there have also been many attempts by religious groups and political reformers to establish utopian communities, especially in the Americas. In the two centuries between 1663 (when some Dutch Mennonites established the first such communitarian colony in what is now Lewes, Del.) and 1858, some 138 settlements were begun in North America. The first to outlast the lifetime of its founder was the Ephrata Community established in Pennsylvania in 1732 by some German Pietists. Other German Pietist settlements were founded by George Rapp (Harmony in Pennsylvania, Harmony (or Harmonie) in Indiana, and Economy in Pennsylvania), by the Amana group (in Iowa), and by the Shakers (18 villages in eight states). Some of them pursued celibacy. Other communal religious sects still flourish; among the largest are the Hutterites, chiefly in the United States and Canada but having colonies also in Paraguay and England. One of the first secular communities was New Harmony, founded in 1825 when the British manufacturer Robert Owen purchased Harmony, Ind., from the Rappites. It was a cooperative rather than communist society. Although it foundered, it sponsored the first kindergarten, the first trade school, the first free library, and the first community-supported public school in the United States. The ideas of the French social reformer Charles Fourier had a strong influence upon American reformers in the 1840s, particularly upon the leaders of Brook Farm in Massachusetts. Between 1841 and 1859, about 28 Fourierist colonies were established in the United States. The Icarians, followers of Cabet, established ill-fated communities in Illinois (Nauvoo, formerly settled by Mormons), Missouri, Iowa, and California. A unique venture was the Oneida Community founded in Putney, Vt., by John Humphrey Noyes in 1841 and moved to Oneida, N.Y., in 1848. The group practiced 'complex marriage', in which all husbands and wives were shared. Noyes said that Oneida was the continuation of Brook Farm without its mistakes. He was convinced that socialism was impossible without religion, and that the 'extended' family system would dissolve selfishness and demonstrate the practicality of this way of life. Children remained with their mothers until they could walk but were then placed in a common nursery. After the American Civil War the enthusiasm for secular utopian experiments waned. There were some new settlements in the 1890s, following the publication of such Utopian tracts as Laurence Gronlund's The Coöperative Commonwealth (1884) and Bellamy's Looking Backward, but the impulse had run its course and these latter movements were soon gathered into the fold of political socialism. The creation of utopian religious communities continued into the XX century, but they too were usually short-lived. The religious colonies, in almost all instances, were established and maintained by a single powerful personality who was believed by his disciples to have a singular gift of prophecy or wisdom. Most of these colonies flourished during the lifetime of the original leader and then declined slowly after his death. / Утопия (Utopia) Английского юриста и социального философа Сэра Томэса Мо (Sir Thomas More; 1478–1535). Португальский исследователь Нового Света (New World) Рафаэл Хислодэй (Raphael Hythloday). Республика (Republic) Греческого философа Платона (Plato; 428/427–348/347 до Нашей Эры) была моделью многих, от Мо до Английского писателя Хёбэта Дьжодьжа Вэлза (Herbert George Wells; 1866–1946). The Story of Utopias (1922) Американским историком, социологом, философом и литературным критиком Люисом Чарлзом Мэмфордом (Lewis Charles Mumford; 1895–1990).Основатель религиозной секты Сообщество Гармонии (Harmony Society) Немец Йохан Геог Рап (Johann Georg Rapp; 1757–1847). Британский текстильный мануфактурщик Робэтч Оэн (Robert Owen; 1771–1858). Французский философ и социальный реформатор Фросуа Мари Шарль Фурье (François Marie Charles Fourier; 1772–1837). Американский радикальный религиозный философ Дьжон Хамфри Нойиз (John Humphrey Noyes; 1811–1886) в 1841. The Coöperative Commonwealth (1884) родившегося в Дании Американского юриста, писателя и политического активиста Лёрэнса Конлюна (Laurence Gronlund; 1846–1899) и Looking Backward Американского журналиста и писателя Эдвода Бэлэми (Edward Bellamy; 1850–1898). Под Утопией, от Греческих слов U (Ou), означающее Нет, и Topos, означающее Место, то есть Место, Которого Нет; по другой версии, от Ей, означающее Благо, и Topos, означающее Место, то есть Благословенная Страна, понимается изображение идеального общественного строя, лишённое научного обоснования. Термин ‘Утопия’ ведёт происхождение от названия книги Английского юриста и социального философа Сэра Томэса Мо (Sir Thomas More; 1478–1535) в 1516. Понятие ‘Утопия’ стало нарицательным для обозначения различных описаний вымышленной страны, призванной служить образцом общественного строя, а также в расширительном смысле всех сочинений и трактатов, содержащих нереальные планы социальных преобразований. В истории человечества утопия как одна из своеобразных форм общественного сознания воплощала в себе такие черты, как осмысливание социального идеала, критику существующего строя, стремление бежать от мрачной действительности, а также попытки предвосхитить будущее общества. Первоначально утопия тесно переплетается с легендами о ‘золотом веке’, об ‘островах блаженных’. В античности и в эпоху Возрождения утопия приобрела преимущественно форму описания совершенных государств, якобы существующих где-то на земле либо существовавших в прошлом; в XVII–XVIII веках получили распространение различные утопические трактаты и проекты социальных и политических реформ. С середины XIX века утопия всё больше превращается в специфический жанр полемической литературы, посвящённой проблеме социального идеала и моральных ценностей. Утопии разнообразны по социальному содержанию и литературной форме – это различные течения утопического социализма, а также рабовладельческая утопия Греческого философа Платона (Plato; 428/427–348/347 до Нашей Эры) и Греческого философа и историка Ксенофонта (Xenophon; 445–354 до Нашей Эры); феодально-теократическая утопия Итальянского мыслителя Дьжоаккино да Фьёрэ (или Иоахима Флорского; Gioacchino da Fiore; 1135–1202), ‘Христианополис’ (1619) Немецкого теолога Йоханнэса Валентинуса Андрэа (Johannes Valentinus Andreä; 1586–1654) и других; буржуазная и мелкобуржуазная утопия – ‘Республика Океания’ (1656) Английского политического теоретика классического республиканизма Дьжеймза Хориньтчэна (James Harrington; 1611–1677), ‘Взгляд Назад’ (1888) Американского журналиста и писателя Эдвода Бэлэми (Edward Bellamy; 1850–1898), ‘Фрейландия’ (1890) Еврейско-Австро-Венгерского экономиста Теодора Хэрцка (Theodor Herzka; 1845–1924), а также многочисленные технократические, анархические и другие утопии. Многие утопические сочинения предлагали решение отдельных проблем:- трактаты о ‘вечном мире’ (Нидерландский Католический священник Хэрит Хэритшон (или Дездерий Эразм Роттердамский (Gerrit Gerritszoon; 1466–1536), Французский поэт и философ Эмерик Крюс (Émeric Crucé; 1590–1648), Французский аббат Шарль-Ирэнэ Кастэль, абе дё Са-Пьер (Charles-Irénée Castel, abbé de Saint-Pierre), Немецкий философ Иммануэль Кант (Immanuel Kant), Английский философ, юрист и социальный реформатор Дьжерэми Бенсэм (Jeremy Bentham; 1748–1832) и другие), педагогические утопии (Чешский педагог, теолог и философ Ян Амос Комэнский (Jan Amos Komenský (John Amos Comenius); 1592–1670), Французский философ и писатель Жо-Жакь Русу (Jean-Jacques Rousseau; 1712–1778) и другие), научно-технические (Английский философ и государственный деятель Фронсис Бэйкэн (Francis Bacon; 1561–1626)). Утопия ярко представлена также в истории общественной мысли древнего и средневекового Китая (утопические сочинения Мо-цзы (479–400 до Нашей Эры), Лао-цзы (Laozi; –533 BC), Шан Яна (390–338 до Нашей Эры) и других), народов Ближнего и Среднего Востока (аль-Фараби, Ибн Баджа, Ибн Туфайль, Низами и других), в литературе России XVIII–XX веков – ‘Путешествие В Землю Офирскую’ (1786) историка Князя Михаила Михайловича Щербатова (1733–1790), сочинения декабристов и революционных демократов, романы Российско-Советского научного фантаста, философа и врача Александра Александровича Богданова (1873–1928) и других. По мере развития общественных наук, особенно после возникновения Марксизма, утопия в значительной мере утрачивает свою познавательную и прогностическую роль. Своим возрождением в XX веке утопия во многом обязана Английскому писателю Хёбэту Дьжодьжу Вэлзу (или Герберту Джорджу Уэллсу; Herbert George Wells; 1866–1946), который не только написал множество утопических произведений, но и считал создание и критику социальных утопий одной из основных задач социологии. Французский социальный философ, теоретик анархо-синдикализма Жёржэ Сорэль (Georges Sorel; 1847–1922) противопоставлял утопию как рационализированное ложное сознание социальному мифу как стихийному выражению общественных потребностей. Исследование утопии занимает большое место в социологии знания Немецкого социолога Кала Манхайма (Karl Mannheim; или Карой Манхайм (Károly Manheim по месту рождения в Венгрии); 1893–1947), стремившегося обосновать отличие утопии, которая выполняет функции социальной критики, от идеологии, которая, по его мнению, выполняет апологетические функции. Согласно Американскому философу, историку и социологу Люису Чарлзу Мэмфорду (Lewis Charles Mumford; 1895–1990), основное назначение утопии состоит в том, чтобы

направить общественное развитие в русло ‘уготованного будущего’, заставляя массы примириться с ним как якобы с неизбежностью, продиктованной ‘технологическим императивом’. Буржуазные социологи, долгое время третировавшие утопии как химерические проекты преобразования общества, к числу которых они бездоказательно относили и Марксизм, резко меняют своё пренебрежительное отношение к ней после победы социалистической революции в России. Эта переоценка значения утопии в целом в общественном развитии была лаконично сформулирована Русским философом и публицистом Николаем Александровичем Бердяевым (1874–1948):- ‘Утопии выглядят гораздо более осуществимыми, чем в это верили прежде. И ныне перед нами стоит вопрос, терзающий нас совсем иначе:- как избежать их окончательного осуществления?’. (Английский писатель Олдэс Лэнэд Хаксли (Aldous Leonard Huxley; 1894–1963) приводит это высказывание в качестве эпиграфа к своей книге – смотрите Brave New World, L., 1958, p. 5.) Эта установка, воплотившая в себе волюнтаристскую идею ‘исторического произвола’, стала лейтмотивом в оценке утопии современными социологами-немарксистами; среди них явно возобладало отрицательное отношение к утопии:- её характеризуют как насилие над действительностью, над человеческой природой, как обоснование и идеализацию тоталитарного строя. Эта тенденция проявилась в широком распространении так называемой антиутопии, назначение которой состоит в том, чтобы изобразить социальные идеалы своего противника в заведомо пугающем или карикатурном виде, предположив их воплощение в жизнь. Хотя подобный приём, близкий к социальной сатире, встречался и прежде, например, в творчестве Англо-Ирландского сатирика Дьжонэсэна Свифта (Jonathan Swift; 1667–1745), Французского писателя, историка и философа Вольтэра (Voltaire; настоящее имя Фросуа-Мари Аруэ (François-Marie Arouet); 1694–1778), Английского автора Самьюэла Батлэ (Samuel Butler; 1835–1902), он стал ведущим в жанре утопии лишь в XX веке. Наиболее известными сочинениями такого рода являются романы ‘Мы’ Русского писателя Евгения Ивановича Замятина (1884–1937), ‘Отважный Новый Мир’ Английского писателя Олдэса Лэнэда Хаксли (Aldous Leonard Huxley; 1894–1963) и ‘1984 Год’ Английского писателя и публициста Дьжодьжа Овэла (George Orwell – псевдоним; настоящее имя Эрик Асо Блэа (Eric Arthur Blair; 1903–1950), в которых воплотились не только враждебность к социализму, но и смятение перед лицом грядущих социальных последствий научно-технического прогресса, стремление отстоять буржуазный индивидуализм от рационализированной технократической цивилизации. Одновременно в ряде антиутопий проявляются законная тревога за судьбу личности в ‘массовом обществе’ протест против манипуляции сознанием и поведением личности в условиях государственно-монополистического капитализма. В 1960–70-е, в связи с глубоким идейным кризисом буржуазного сознания, утопия привлекает к себе возрастающее внимание общественных деятелей, идеологов и социологов на капиталистическом Западе. С одной стороны, раздаются призывы создать привлекательную для широких масс либерально-демократическую утопию в качестве альтернативы Марксизму, научному коммунизму с прямой целью идеализировать государственно-монополистический капитализм или морально обосновать программу его обновления посредством ‘реформации сверху’, противопоставляемой социалистической революции (Австрийско-Британский экономист и философ Фридрихь Аугуст фон Хайэк (Friedrich August von Hayek; 1899–1992), Нидерландец Фрэдэрик Лёдэвэк Поляк (Frederik Lodewijk Polak; 1907–1985), Американский экономист и социолог Вилъйэм Мор (William Moore; 1914–)). С другой стороны, многие мелкобуржуазные радикалы, идеологи движения ‘новых левых’, не видя практических путей к достижению социальной справедливости, намеренно становятся на позиции воинствующего утопизма (Американский социолог и публицист Чарлз Райт Милз (Charles Wright Mills; 1916–1962), Немецко-Американский философ и социолог Хёбёт Макузэ (Herbert Marcuse; 1898–1979), Американский поэт, литературный критик и психотерапевт Пол Гудмэн (Paul Goodman; 1911–1972), Французский социолог Аля Турэн (Alain Touraine; 1925–), Немецкий поэт, писатель, переводчик, издатель и общественный деятель левого толка Ханс Магнус Энцэнсбэрга (Hans Magnus Enzensberger; 1929–) и другие). Для современной буржуазной утопии характерно переплетение утопических и антиутопических тенденций, которое выражается в том, что провозглашаемый в ней социальный идеал, как правило, оказывается отталкивающим для широких масс населения, ибо сопровождается отказом от традиционных гуманистических и демократических ценностей (‘Второй Волдэн’ (Walden Two) Американского психолога, лидера современного бихевиоризма Бораса Фрэдэрика Скинё (Burrhus Frederic Skinner; 1904–1990)). Марксистская социология рассматривает утопию как одну из форм неадекватного отражения социальной действительности; однако в прошлом утопия выполняла важные идеологические, воспитательные и познавательные функции в жизни общества и некоторые из них сохраняет. В соответствии с этим значение утопии определяется её классовым содержанием и социальным назначением. Утопия является выражением интересов определённых классов и социальных слоёв, как правило, не находящихся у власти (смотрите Владимир Ильич Ленин (1870–1924), Две Утопии, в кн.:- Полн. Собр. Соч., 5 Изд., Т. 22, С. 117–21). Утопия также имеет много общего с социальным мифом по идейному содержанию, с социальной сатирой – по литературной форме, с научной фантастикой – по познавательной функции. Вместе с тем утопия обладает целым рядом особенностей:- в первую очередь убеждением в возможности разрешения всех противоречий общества однократным применением какой-либо универсальной схемы, рассматриваемой как панацея от любого социального зла. Для утопии поэтому характерны антиисторизм, намеренный отрыв от реальности, обычно нигилистическое отношение к действительности, стремление конструировать вещи и отношения по принципу ‘всё должно быть наоборот’, склонность к формализму, пренебрежение к переходу от реального к идеальному, идеалистическое понимание истории, обнаруживающее себя в преувеличении роли воспитания и законодательства, а также упование на поддержку со стороны выдающихся личностей, обладателей власти, филантропов и тому подобного. Антиутопия, разделяя органические недостатки утопического сознания, вместе с тем является её своеобразным антиподом в том смысле, что представляет собой отречение от передового социального идеала и призывает к примирению с существующим строем во избежание худшего будущего. В истории общества и общественной мысли утопия нередко служила формой выражения революционной идеологии угнетённых масс, как это было во время восстания внебрачного сына Пергамского Царя Евмена II Аристоника (Aristynikos) в Пергаме (II век до Нашей Эры), ‘жёлтых повязок’ в Китае (конец II–начало III веков Нашей Эры), в ходе крестьянских войн в эпоху феодализма, в период буржуазно-демократических революций. Авторами многих утопических произведений были видные общественные и политические деятели; многие руководители Американских и Французских буржуазных революций испытали серьёзное влияние утопических идей:- первые – Английского политического теоретика классического республиканизма Дьжеймза Хориньтчэна (James Harrington; 1611–1677), а вторые – Французского философа и писателя Жо-Жакя Русу (Jean-Jacques Rousseau; 1712–1778) и других. Предпринимались даже попытки осуществить некоторые утопические проекты, например, колонии последователей Французского философа и утопического социалиста Этьена Кабэ (Étienne Cabet; 1788–1856) (Икария; утопическая коммунистическая страна) в Северной Америке и другие, хотя они и оказались недолговечными. Многие основные принципы освободительного движения трудящихся, нравственные и законодательные нормы, системы педагогики и образования были впервые сформулированы в утопии. Великие утописты, как отмечал Ленин, ‘... гениально предвосхитили бесчисленное множество таких истин, правильность которых мы доказываем теперь научно ...’ (там же, Т. 6, С. 26). Хотя возникновение научного социализма подорвало социальное значение утопии, лишило её многих прежних функций, утопия вообще, в отличие от утопического социализма, не утратила своей роли в качестве специфического жанра литературы. Положительное значение утопии в современную эпоху проявляется в двух направлениях:- она позволяет предвосхищать вероятное отдалённое будущее, которое на данном уровне познания не может быть научно предсказано в конкретных деталях; она может также

предостерегать от некоторых отрицательных социальных последствий человеческой деятельности и других нежелательных тенденций в обществе. Эти формы утопии стимулировали развитие в социологии метода нормативного прогнозирования и сценариев с целью анализа и оценки желательности и вероятности предполагаемого развития событий. UTPP = URBAN TRANSPORTATION PLANNING PACKAGE

UTPS = URBAN TRANSPORTATION PLANNING SYSTEM

UTRICLE = МЕШОЧЕК – Utricle is a small, bladdery, one-seed fruit or any small bladderlike structure.

UTRIS = UPPER TALAVERA IRRIGATION SYSTEM

UU = UNLESS USED

UUIWCTAUTC = UNLESS USED IN WHICH CASE TIME ACTUALLY USED TO COUNT

UV = ULTRAVIOLET

UV ABSORBERS = УФ АБСОРБЕРЫ – UV Absorbers are the polymer additives that absorb light in the UV region or that trap radicals produced in fiber during photooxidation. They provide stabilization against actinic degradation. Some critical applications include geotextiles, recreational surface polymers and fibers, tenting tarpaulins, etc. / УФ Абсорберы – химические соединения, преимущественно органической природы, которые препятствуют фотодеструкции лакокрасочного покрытия от ультрафиолетовой составляющей солнечного света. Принцип действия УФ абсорбера заключается в способности его молекул преобразовывать энергию падающего ультрафиолетового излучения в тепловую, которая уже никакого разрушающего действия не оказывает. Фотодеструкции подвержены и пигменты и полимеры, разрушение первых является причиной выцветания лакокрасочного покрытия, а деструкция связующего приводит к разрушению лакокрасочной плёнки.

UVA RADIATION = УФ ИЗЛУЧЕНИЕ ТИПА А (или УФ РАДИАЦИЯ ТИПА А) – UVA Radiation is the longest waveband in the UV (ultraviolet) region that includes radiation from 320–400 nm range and is less hazardous. The relatively long-wavelength UVA accounts for approximately 95 per cent of the UV radiation reaching the Earth's surface. It can penetrate into the deeper layers of the skin and is responsible for the immediate tanning effect. Furthermore, it also contributes to skin ageing and wrinkling. For a long time it was thought that UVA could not cause any lasting damage. Recent studies strongly suggest that it may also enhance the development of skin cancers. UVA Radiation:- invisible rays that are part of the energy that comes from the sun. UVA radiation also comes from sun lamps and tanning beds. UVA radiation may cause premature aging of the skin and skin cancer. It may also cause problems with the eyes and the immune system. Skin specialists recommend that people use sunscreens that protect the skin from ultraviolet radiation. In medicine, UVA radiation also comes from special lamps or a laser and is used to treat certain skin conditions such as psoriasis, vitiligo, and skin tumors of cutaneous T-cell lymphoma. Also called Ultraviolet A Radiation. UVA Radiation is the weakest type of UV radiation from the sun. These rays are able to penetrate deep into the skin causing premature aging, wrinkles and some skin cancers. / UVA – Ультрафиолет А = длинноволновой диапазон. Длина волны в нанометрах:- 400–315 нм. Энергия фотона:- 3.10–3.94 эВ. Примечание:- доходит до Земли.

UVAROVITE = УВАРОВИТ – Uvarovite ($Ca_3Cr_2(SiO_4)_3$):- calcium chromium garnet found as small, brilliant, green crystals. It is the rarest of all the garnets, and its crystals commonly are too small to be cut. Otherwise, it would rival emerald as a popular gemstone because of its beautiful color. Typical occurrences are in chromite, as in the Northern Urals, California, Canada, Finland, and Silesia in Poland. For details of chemistry and occurrence, see Garnet. / Под Уваровитом (от имени Русского государственного деятеля, Графа и академика Сергея Семёновича Уварова; 1786–1855), минерал из группы гранатов, $Ca_3Cr_2(SiO_4)_3$, с характерной изумрудно-зелёной окраской. Редкий. Встречается обычно в виде друз мелких кристалликов, приуроченных к трещинам в хромитовых рудах.

UV–B = ULTRAVIOLET–B

UVBBE = UVB BIOLOGICALLY EFFECTIVE

UVB BIOLOGICALLY EFFECTIVE = БИОЛОГИЧЕСКИ ЭФФЕКТИВНАЯ УФБ – Biologically Effective UVB radiation, which is the product of the action spectrum and the spectral irradiance at each wavelength in the UVB region.

UV–BIOMETER = УФ–БИОМЕТР – UV-Biometer is a broadband meter for UVB monitoring. It measures the biological effect of ultraviolet radiation.

UVB LAMPS = УФБ ЛАМПЫ – UVB Lamps are fluorescent lamps used for simulating the damage caused by sunlight especially in the UVB region.

UVB RADIATION = УФ ИЗЛУЧЕНИЕ ТИПА Б (или УФ РАДИАЦИЯ ТИПА В) – UVB Radiation is the middle UV (ultraviolet) region containing radiation between 280 and 320 nm and which affects plants and humans. Medium-wavelength UVB is very biologically active but cannot penetrate beyond the superficial skin layers. It is responsible for delayed tanning and burning; in addition to these short-term effects it enhances skin ageing and significantly promotes the development of skin cancer. Most solar UVB is filtered by the atmosphere. UVB Radiation:- invisible rays that are part of the energy that comes from the sun. UVB radiation causes sunburn, darkening and thickening of the outer layer of the skin, and melanoma and other types of skin cancer. It may also cause problems with the eyes and the immune system. Skin specialists recommend that people use sunscreens that protect the skin from ultraviolet radiation. In medicine, UVB radiation also comes from special lamps or a laser and is used to treat certain skin conditions such as psoriasis, vitiligo, and skin tumors of cutaneous T-cell lymphoma. Also called Ultraviolet B Radiation. UVB Radiation is the most harmful type of UV radiation. It mainly affects the outer layers of the skin, causing sunburns, premature aging, cataracts, depression of the immune system and skin cancer. / UVB – Ультрафиолет В = средний диапазон. Длина волны в нанометрах:- 315–280 нм. Энергия фотона:- 3.94–4.43 эВ. Примечание:- малая часть доходит до Земли.

UVC RADIATION = УФ ИЗЛУЧЕНИЕ ТИПА Ц (или УФ РАДИАЦИЯ ТИПА С) – UVC Radiation is the strongest form of UV radiation. This type of radiation does not reach earth's surface as it is absorbed by the atmosphere. UVC Radiation is the shortest waveband in the UV (ultraviolet) region, between 200 and 280 nm and is extremely hazardous. UVC Radiation:- invisible rays that are part of the energy that comes from the sun. Most UVC radiation from the sun is blocked from the Earth's surface by the ozone layer. In medicine, UVC radiation may also come from special lamps or a laser and is used to kill germs or to help heal wounds. It is also used to treat certain skin conditions such as psoriasis, vitiligo, and skin nodules of cutaneous T-cell lymphoma Also called Ultraviolet C Radiation. Short-wavelength UVC is the most damaging type of UV radiation. However, it is completely filtered by the atmosphere and does not reach the Earth's surface. UVC Radiation:- Sunlight has a profound effect on the skin causing premature skin aging, skin

cancer, and a host of skin changes. Exposure to ultraviolet light, UVA or UVB, from sunlight accounts for 90% of the symptoms of premature skin aging. Many skin changes that were commonly believed to be due to aging, such as easy bruising, are actually a result of prolonged exposure to UV radiation. What is UV? The sun gives off ultraviolet radiation that we divide into categories based on the wavelength. UVC:- 100 to 290 nm. UVB:- 290 to 320 nm. UVA:- 320 to 400 nm. UVC radiation is almost completely absorbed by the ozone layer and does not affect the skin. UVC radiation can be found in artificial sources such as mercury arc lamps and germicidal lamps. / UVC – Ультрафиолет С = коротковолновой = гермицидный диапазон. Длина волны в нанометрах:- 280–100 нм. Энергия фотона:- 4.43–12.4 эВ. Примечание:- задерживается атмосферой.

UV DEGRADATION = УФ ДЕГРАДАЦИЯ – UV Degradation is the breaking down of fibers or fabrics when exposed to ultraviolet rays.

UVX RADIOMETER = РАДИОМЕТР УФИ (или УФИ РАДИОМЕТР) – Maximum operating efficiencies of UV systems rely on proper knowledge of the lamp intensities. Gradual degradation of UV intensity is very difficult to detect and measurement of lamp irradiance is the most effective way to monitor the useful life of any UV light source. The UVX hand held radiometer is a state of the art measuring device ideal for obtaining accurate and repeatable UV irradiance measurements. The unit features three interchangeable probes sensitive in the 254 nm, 365 nm and 302 nm regions of the ultraviolet spectrum. All sensor calibration are traceable to National Bureau Standards to ensure precise readings. The UVX continuously monitors its own power and indicates low voltage conditions. The unit also includes automatic self-test circuitry, read/hold switch, measurement range from 0.1 to 19 999 microWatts/cm, 31/2 digit LCD readout, ±5% accuracy, ±1% linearity, and 120 hour battery life. Range changes are made with three position range switch. Also the sensors feature 3 foot (915 mm) electrically shielded cables and are designed to minimize errors due to temperature and humidity effects. Optional accessories include a tube guide for use with UV tube light sources, chart recorder output, and a 10:1 attenuator for measuring UV irradiance levels higher than 19.99 milliWatts/cm. Built to withstand day-to-day use in laboratory and production environments, the UVX Radiometer is a complete UV measuring system ready to use and easy to operate. UVX Radiometer is a broadband UV (ultraviolet) sensor used for the measurement of UV intensities. This digital UVX Radiometer is used with one of the three interchangeable sensors (ordered separately) for measuring 254 nm, 365 nm and 302 nm UV wavelengths. Measurement of lamp irradiance is the most effective way to monitor the useful life of any UV light source. / УФИ Радиометр предназначен для измерения энергетической освещённости, создаваемой различными источниками ультрафиолетового излучения в спектральном диапазоне 315–400 нм, создаваемой газоразрядными источниками в спектральном диапазоне 280–315 нм, а также создаваемой ртутными лампами высокого и низкого давления в спектральном диапазоне 200–280 нм. Число спектральных диапазонов может быть уменьшено по требованию потребителя. Диапазон измерений энергетической освещённости:- 1–200 000 мВт/м^2. Погрешность коррекции:- 10%. Основная относительная погрешность:- 17%.

UZBEK SUM = УЗБЕКСКИЙ СУМ – Uzbek Sum:- UZS is the three-letter currency ISO code representing the currency of Uzbekistan which is commonly known as the Sum.

UZS = UZBEK SUM

- V -

V = ВИ. – (1) V is fifth letter of a NASDAQ® stock symbol indicate that it is when-issued or when-distributed. / Ви. (V) – пятая буква фондового индекса НЭЗДЭК® (NASDAQ®), указывающая на то, что .

(2) V:- total volume (gals).

V = ПЯТЬ – V is the Roman numeral for 5. / V – Римское нумерологическое обозначение для числа 5.

V = VICTOR

V = VOLT

VA = VATICAN CITY STATE = HOLY SEE

VA = VETERANS ADMINISTRATION

VA = VOLT AMPERES

VAC = VOLTAGE IN AN ALTERNATING CURRENT CIRCUIT

VACANT POSSESSION = ВАКАНТНАЯ ПОСЭССИЯ (или ВАКАНТНАЯ ПОСЕССИЯ, или ВАКАНТНОЕ ВЛАДЕНИЕ, или ВАКАНТНОЕ ОБЛАДАНИЕ) – Vacant Possession:- the right of a purchaser to exclusive use of a property on completion of the sale, any previous occupant having moved out. Vacant Possession is a property law concept. Giving 'Vacant Possession' refers to a legal obligation to ensure that a property is in a state fit to be occupied at a given point in time. Vacant possession is most commonly known of on the sale and purchase of residential property and many find that, on the purchase of a new home, they do not obtain vacant possession as desired. The concept is also an essential element in the grant and termination of leases and other tenancy agreements. It is a topical issue for lawyers and surveyors along with estate agents and others connected to land and buildings. See also Possession. / Вакантная Посессия или Незанятое Собственником Имущество (Vacant Possession):- в сфере недвижимости это понятие относится к праву владения землёй или застроенным объектом, которые в настоящее время никто не занимает. Термин Незанятое Собственником Имущество используется в странах Содружества.

VACATION PAY = ОПЛАТА ОТПУСКА (или ОПЛАТА ОТПУСКНЫХ) – Vacation Pay is paid time off granted to an employee. This pay is usually accrued over time, where a certain proportion of vacation pay is earned for every hour of time worked. Under the accrual basis of accounting, the employer recognizes earned vacation pay as a liability as it is being earned (with a charge to the vacation

expense account). When an employee eventually uses the vacation time, the liability is eliminated. Unused vacation pay is typically paid to an employee in cash when he or she leaves the employment of an organization. The accrued amount of vacation pay for an employee automatically increases when he or she is given a raise, since the amount eventually paid out is now in the amount of the new and higher pay rate.

VACATION PAY EXPENSE = РАСХОД НА ОПЛАТУ ОТПУСКА (или РАСХОД НА ОТПУСКНЫЕ) – Vacation Pay Expense is a general ledger account in which is recorded the amount of vacation expense earned by employees. The amount in the account is updated at the end of each reporting period to reflect the additional expense generated as a result of employee time worked during the period.

VACATION PAY PAYABLE = ОПЛАТА ОТПУСКА К ОПЛАТЕ (или ОТПУСКНЫЕ К ОПЛАТЕ) – Vacation Pay Payable is a general ledger account that contains the liability that an employer has to pay employees for vacation time earned but not yet used. The balance in this account is updated at the end of each reporting period to reflect additions to accrued vacation expense, as well as employee usage of their vacation time. The account is usually classified as a Current Liability.

VACATION RESERVE = РЕЗЕРВ ОТПУСКНЫХ (или ВАКАЦИОННЫЙ РЕЗЕРВ) – Vacation Reserve:- xxxxx. / Резервы На Переоценку Активов:- резервы или ассигнования, выделенные дополнительно из общих расходов (фактически вычитаемые из прибылей) на случай изменений в оценке активов компании. Накопленные амортизационные отчисления (depreciation), ассигнования на списание задолженности (bad debts) и неамортизированные скидки по облигациям (unamortized bond discount) являются тремя хорошо знакомыми источниками резервов на переоценку активов. Называется также Счётом На Переоценку Активов (Valuation Account).

VACCINATION = ВАКЦИНАЦИЯ – Vaccination is an injection (usually subcutaneous) given to prevent diseases such as blackleg, tetanus, enterotoxaemia, black disease and malignant oedema (5 in 1) if prevention against two strains of Leptospirosis is included then it is called 7 in 1. / Вакцинация, применение вакцин с целью предупреждения инфекционных болезней – иммунизации.

VACCINE = ВАКЦИНА – Vaccine is any substance, bearing antigens on its surface, that causes activation of an animal's immune system without causing actual disease. The animals' immune system components (e.g., antibodies) are then prepared to quickly vanquish those particular pathogens when they later enter the body. Vaccine:- suspension of weakened, killed, or fragmented microorganisms or toxins or of antibodies or lymphocytes that is administered primarily to prevent disease. A vaccine can confer active immunity against a specific harmful agent by stimulating the immune system to attack the agent. Once stimulated by a vaccine, the antibody-producing cells, called B Lymphocytes, remain sensitized and ready to respond to the agent should it ever gain entry to the body. A vaccine may also confer passive immunity by providing antibodies or lymphocytes already made by an animal or human donor. Vaccines are usually administered by injection (parenteral administration), but some are given orally. Vaccines applied to mucosal surfaces, such as those lining the gut or nasal passages, seem to stimulate a greater antibody response and may be the most effective route of administration. The discovery of vaccination is attributed to the British physician Edward Jenner, who in 1796 used the cowpox virus (vaccinia) to confer protection against smallpox, a related virus, in humans. Prior to this use, however, the principle of vaccination was applied by Asian physicians who gave children dried crusts from the lesions of people suffering from smallpox to protect against the disease. While some developed immunity, others developed the disease. Jenner's contribution was to use a substance similar to, but safer than, smallpox to confer immunity. He thus exploited the relatively rare situation in which immunity to one virus confers protection against another viral disease. In 1881 the French microbiologist Louis Pasteur demonstrated immunization against anthrax by injecting sheep with a preparation containing attenuated forms of the bacillus that causes the disease. Four years later he developed a protective suspension against rabies. Since Pasteur's time, a widespread and intensive search for new vaccines has been conducted, and vaccines against both bacteria and viruses are produced, as well as vaccines against venoms and other toxins. Through vaccination, smallpox has been eradicated worldwide, and polio much reduced. Vaccines have also been developed for mumps, measles, typhoid, cholera, plague, tuberculosis, tularemia, pneumococcal infection, tetanus, influenza, yellow fever, hepatitis A and B, some types of encephalitis, and typhus – although some of these vaccines are less than 100 percent effective or are used only in selected population groups at high risk. Interest in bacterial vaccines slackened with the introduction of antibiotics in the mid-XX century, but vaccines remain a mainstay in the fight against many infectious diseases, especially viral infections, which do not generally respond to antibiotics. The challenge in vaccine development consists in devising a vaccine strong enough to ward off infection without making the individual seriously ill. To this end, investigators have devised different types of vaccines. Weakened, or attenuated, vaccines consist of microorganisms that have lost the ability to cause serious illness but retain the ability to stimulate immunity. They may produce a mild or subclinical form of the disease. Attenuated vaccines include those for measles, mumps, polio (the Sabin vaccine), rubella, and tuberculosis. Inactivated vaccines are those that contain organisms that have been killed or inactivated with heat or chemicals. These, too, elicit an immune response, but the response often is less complete. Because inactivated vaccines are not as effective at fighting infection as those made from attenuated microorganisms, greater quantities of inactivated vaccines are administered. Vaccines against rabies, polio (the Salk vaccine), some forms of influenza, and cholera are made from inactivated microorganisms. Another type is a subunit vaccine, which is made from proteins found on the surface of infectious agents. Vaccines for influenza and hepatitis B are of this type. When toxins, the metabolic by-products of infectious organisms, are inactivated to form toxoids, they can be used to stimulate immunity against tetanus, diphtheria, and whooping cough. In the late XX century, advances in laboratory techniques allowed approaches to vaccine development to be refined. Medical researchers could identify the genes of a pathogen (disease-causing microorganism) that encode the protein or proteins that stimulate the immune response to that organism. This has allowed the immunity-stimulating proteins (called Antigens) to be mass-produced and used in vaccines. It also has made it possible to alter pathogens genetically and produce weakened strains of viruses. In this way, harmful proteins from pathogens can be deleted or modified, thus providing a safer and more effective method by which to manufacture attenuated vaccines. Recombinant DNA technology has also proved useful in developing vaccines to viruses that cannot be grown successfully or that are inherently dangerous. Genetic material that codes for a desired antigen is inserted into the attenuated form of a large virus, such as the vaccinia virus, which carries the foreign genes 'piggyback'. The altered virus is injected into an individual to stimulate antibody production to the foreign proteins and thus confer immunity. This approach potentially enables the vaccinia virus to function as a live vaccine against several diseases, once it has received genes derived from the relevant disease-causing microorganisms. A similar procedure can be followed using a modified bacterium, such as Salmonella Typhimurium, as the carrier of a foreign gene. Another approach, called Naked DNA Therapy, involves injecting DNA that encodes a foreign protein into muscle cells. These cells produce the foreign antigen, which stimulates an immune response. See also Immunization. Vaccine is the dead or partial or modified antigen used to induce immunity to certain infectious diseases. / Британский физик Эдвод Дьженё (Edward Jenner), который в 1796 использовал . В 1881 Французский микробиолог Люи Пастёр (Louis Pasteur). Под Вакциной понимается препарат из живых (обезвреженных) или убитых микроорганизмов (а также из отдельных антигенных компонентов микробной клетки) и продуктов их жизнедеятельности. Применяется с лечебными и профилактическими целями. Под Вакциной, от Латинского слова Vaccinum, означающее Коровий, от Vacca, означающее Корова, понимается препарат, получаемый из микроорганизмов (Бактерий,

Риккетсий, Вирусов) или продуктов их жизнедеятельности и используемый для активной иммунизации людей и животных с профилактическими и лечебными целями. Впервые вакцина была применена в 1796 Английским врачом Эдводом Дьженёром (Edward Jenner; 1749–1823), который прививал людям для предохранения их от заболевания натуральной оспой коровью оспу (отсюда название Вакцина). Различают вакцины живые, убитые, химические и анатоксины. Живые вакцины приготовляют из специально ослабленных культур микроорганизмов, лишённых способности вызывать заболевание, но сохраняющих свойства размножаться в организме и вызывать иммунитет. Первым живые вакцины против Сибирской язвы (1881) и бешенства (1885) создал Французский микробиолог Люи Пастёр (Louis Pasteur; 1822–1895). Предложенная в 1926 Французским учёными Лео Шарлем Альбэром Кальмэтом (Léon Charles Albert Calmette; 1863–1933) и Жо-Мари Кямийэ Гера (Jean-Marie Camille Guérin; 1872–1961) живая туберкулёзная вакцина (БЦЖ (BCG = Bacille Calmette-Guérin)) получила всемирное признание; её применение значительно снизило заболеваемость туберкулёзом. Многие живые вакцины созданы Советскими учёными:- против сыпного тифа (Павел Феликсович Здродовский (1890–1976), в 1957–59), против гриппа (Анатолий Александрович Смородинцев (1901–1986), Валентин Дмитриевич Соловьёв (1907–1986), Виктор Михайлович Жданов (1914–1987), в 1960), против бруцеллёза (Пелагея Альбертовна Вершилова (1904–1992), в 1947–51), оспенная (Михаил Акимович Морозов (1879–1964), в 1941–60) и другие. При некоторых заболеваниях (бешенство, оспа, чума, туляремия) вакцины являются единственно эффективными прививочными препаратами; как правило, живые вакцины создают длительный иммунитет. Убитые вакцины изготовляют из микроорганизмов, убитых физическим (нагревание) или химическим (фенол, формалин, ацетон) методами. Убитые вакцины применяют для профилактики лишь тех заболеваний, в отношении которых не получены живые вакцины (брюшной тиф, паратиф В, коклюш, холера, клещевой энцефалит). Они обладают менее выраженными защитными свойствами, чем живые вакцины, поэтому развитие иммунитета наступает лишь после проведения курса иммунизации (вакцинации), состоящего из нескольких прививок. Химические вакцины представляют собой вещества, выделенные из бактериальных клеток при помощи различных химических методов и содержащие основные компоненты, вызывающие иммунитет. Впервые химические вакцины против кишечных инфекций начали вводить в 1941 в составе поливакцины НИИСИ, предложенной Советским учёными Николаем Ивановичем Александровым (1908–1972) и его женой – Ниной Ефимовной Гефен (1915–????). Химические вакцины применяют против паратифа В, брюшного тифа и риккетсиозов. Развитие иммунитета после введения анатоксинов связано с появлением в крови антител, нейтрализующих действие определённого токсина. Впервые анатоксины были получены в 1923–26 Французским учёным Гясто Рамо (Gaston Ramon; 1886–1963). Анатоксины применяют для профилактики дифтерии, столбняка, ботулизма, газовой гангрены и стафилококковых инфекций. Вакцины могут быть приготовлены из возбудителя одной инфекции – так называемой Моновакцины, или в виде комбинации двух и более возбудителей (Поливакцины). При применении поливакцины иммунитет вырабатывается к нескольким инфекционным заболеваниям. Способы введения вакцин различны:- для живых вакцин они в определённой степени связаны с естественными путями проникновения возбудителя в организм:- так, полиомиелитную вакцину вводят через рот, гриппозную – в полость носа, вакцину против оспы, Сибирской язвы и туляремии – накожно, против бруцеллёза – внутрикожно, сыпного тифа – подкожно; убитые вакцины и анатоксины вводят подкожно или внутримышечно. С лечебной целью применяют живую вакцину против бешенства (вакцинотерапия), что является единственным способом защиты человека от развития этого смертельного заболевания. При лечении некоторых хронических воспалительных заболеваний, вызванных стафилококками и стрептококками, используют аутовакцины. В бывшем Союзе Советских Социалистических Республик (СССР) вакцины изготовляют научно-производственные учреждения; контролирует качество выпускаемых препаратов Государственный Контрольный Институт Медицинских Биологических Препаратов имени Льва Александровича Тарасевича (Москва). Вакцины В Ветеринарии:- Принципы приготовления и классификация вакцин против болезней животных не отличаются от медицинских. Из живых вакцин в ветеринарной практике наиболее широко применяют:- сибиреязвенные – СТИ и ГНКИ; против рожи свиней – из штамма Конева и BP_2; бруцеллёзную – из штамма 19; против холеры, оспы, псевдочумы птиц. Убитые вакцины используют для профилактики и лечения более чем 20 инфекционных болезней животных. Вакцина – любое вещество, содержащее антиген на своей поверхности, способствующее стимуляции иммунной системы.

VACCINIA = ВАКЦИНИЯ (или ВАКЦИНАЛЬНАЯ БОЛЕЗНЬ) – Vaccinia:- a non-pathogenic virus that is believed to be a (modified) form of the virus that causes cowpox. Vaccinia readily accepts genes (inserted into its genome via genetic engineering) from pathogenic viruses so it can be used to make vaccines that do not possess the risk inherent in attenuated-virus vaccines (i.e. that the attenuated virus 'revives' and causes disease). Such genetically engineered vaccinia codes for (presents) the proteins of the pathogenic virus on its surface, which activates the immune system (e.g., of vaccinated animal) to produce antibodies against that pathogenic virus. / Вакцинальная Болезнь – реакция на введение противооспенной вакцины.

VACONNE VELVET = ВАКОНН ВЭЛЬВЭ (или ХХ БАРХАТ) – Vaconne Velvet is a patterned velvet made by burnt-out print process. The design is of velvet with background plain. / .

VACUITY = НЕЗАПОЛНЕННОСТЬ (или РАЗРЕЖЁННОСТЬ) – Vacuity:- from Middle English Vacuite, from Old French, from Latin Vacuitas, from Vacuus = Empty Space or Vacancy or Vacuity; the state of lacking any real meaning, importance, or intelligence. See also Ullage. Vacuity is the quality or state of being empty; emptiness. Vacuity is the state of being vacuous or without contents; vacancy; emptiness:- the vacuity of the open sea. / Пустота:- . Смотрите также Незаполненный Объём или Утечка или Недостача (Ullage).

VACUOLE = ВАКУОЛЬ – Vacuole:- in biology, a space within a cell that is empty of cytoplasm, lined with a membrane, and filled with fluid. Especially in protozoa, vacuoles are cytoplasmic organs (organelles), performing functions such as storage, ingestion, digestion, excretion, and expulsion of excess water. The large central vacuoles often found in plant cells enable them to attain a large size without accumulating the bulk that would make metabolism difficult. Vacuoles:- a membrane-bound sac within a cell, within which water, food, waste, or salt, etc are temporarily stored. Also pigments, in certain plant cells. / Под Вакуолями, от Французского слова Vacuole, от Латинского слова Vacuus, означающее Пустой, понимаются небольшие, большей частью шаровидные, полости в животных и растительных клетках или одноклеточных организмах. В клетках ряда многоклеточных беспозвоночных (губки, кишечнополостные, ресничные черви, некоторые моллюски), способных к внутриклеточному пищеварению, и в теле некоторых одноклеточных организмов (простейших) образуются пищеварительные вакуоли, содержащие пищеварительные ферменты. У высших животных пищеварительные вакуоли образуются в особых клетках – фагоцитах. В других клетках вакуоли содержат соли, ферменты и продукты обмена веществ (жиры и так далее). У многих одноклеточных организмов имеются также сократительные, или пульсирующие, вакуоли, периодически выбрасывающие своё содержимое во внешнюю среду. У простейших сократительные вакуоли – главным образом аппарат, регулирующий осмотическое давление, а также служащий для выведения из организма продуктов распада. Вакуоли растений наполнены бесцветным или окрашенным клеточным соком. Цитоплазма отделена от вакуолей липоидно-белковой полупроницаемой мембраной (смотрите Биологические Мембраны). Вещества, растворённые в клеточном соке вакуолей растений (сахара, полисахариды, алкалоиды, дубильные вещества, пигменты, некоторые соли и другие), вызывают в силу осмоса поступление в клетки питательных

веществ и воды и создают механическое напряжение клеток и тканей – тургор. В очень молодых клетках вакуолей нет или они почти незаметны; по мере роста и старения клетки вакуолей появляются в разных её участках, а затем, постепенно увеличиваясь, сливаются в одну большую вакуоль – так называемый Вакуом. Вакуоль – полость в цитоплазме клетки, ограниченная мембраной, заполненная жидкостью, включающей ферменты. У простейших имеются пищеварительные и сократительные вакуоли; у многоклеточных организмов – аутофагирующие (вторичные лизосомы) и пищеварительные вакуоли; вакуоли растительной клетки составляют сложную систему (вакуом) и сливаются у дифференцированной клетки в крупную центральную вакуоль, содержащую клеточный сок. Вакуоли – мембранные органоиды эукариотической клетки.

VACUS HOLD = УДЕРЖИВАНИЕ В ВАКУСЕ – Vacus Hold is when a container is taken and put through a larger X-ray machine to make sure that there is no unauthorized metal objects inside (something like the metal detector we walk through). VACUS is new X-ray equipment. The radiation monitors are complementary to what is known as Vacus Technology, which is X-ray technology we have at the ports designed to identify suspicious-looking shapes within the containers. They work in tandem.

VACUUM ASSIST POWER BRAKES = ТОРМОЗА С ГИДРОУСИЛИТЕЛЕМ НА ВАКУУМНОЙ ОСНОВЕ (или ХХ) – Vacuum Assist Power Brakes:- standard type hydraulic brakes with a pressure assist cylinder having a vacuum chamber which when atmospheric pressure is allowed to one side of the piston or diaphragm, drives a plunger in the hydraulic system thereby increasing the effect of pedal pressure.

VACUUM ATOMIZATION = ВАКУУМНОЕ РАСПЫЛЕНИЕ – Vacuum Atomization is a process to reduce a molten stream of metal to droplets of a diameter of 500 micrometer or less by the rapid evolution of a dissolved gas upon exposure to a vacuum. The problems inherent in metal atomization have spurred the development of Vacuum Atomization, a process showing much promise. In this process, the potential energy for atomization can be stored within the molten metal, which increases the efficiency. Also, the higher tap densities of vacuum-atomized powders, as compared with argon-atomized powders, is a distinct advantage. Alloy powders based on Ni, Co, Fe, Cu, Al, and misch metal have all been made successfully by this process. Powder metallurgy will play a significant role in this era of conservation and cost reduction, and vacuum atomization has shown that the unconventional approach may offer the most practical solutions to some of our current problems.

VACUUM DEHYDRATION = ВАКУУМНАЯ ДЕГИДРАТАЦИЯ (или ВАКУУМНОЕ ОБЕЗВОЖИВАНИЕ) – Vacuum Dehydration is a method which involves drying or freeing of moisture through a vacuum process. Vacuum Dehydration systems are designed to remove 100% of free and emulsified water and at least 90% of dissolved water from petroleum and synthetic-based fluids. And, vacuum dehydration systems remove 100% of free gases and least 90% of dissolved gases. By maintaining absolute fluid cleanliness, you can dramatically increase the life of critical electric transmission components, maintain dielectric strength and condition of insulation, minimize downtime and maximize profitability.

VACUUM DISTILLATION = ВАКУУМНАЯ ДИСТИЛЛЯЦИЯ – Vacuum Distillation is a distillation method which involved reducing the pressure above a liquid mixture to be distilled to less than its vapor pressure (usually less than atmospheric pressure). This causes evaporation of the most volatile liquid(s) – those with the lowest boiling points. This method works on the principle that boiling occurs when a liquid's vapor pressure exceeds the ambient pressure. It can be used with or without heating the solution. Vacuum Distillation is a distillation under reduced pressure (less the atmospheric), which lowers the boiling temperature of the liquid being distilled. This technique with its relatively low temperatures prevents cracking or decomposition of the charge stock. Vacuum Distillation is a distillation under reduced pressure (less than atmospheric) which lowers the boiling temperature of the liquid being distilled. This technique permits the production of distillates at lower temperature than would be necessary in atmospheric distillation, thus avoiding coke formation.

VACUUM DISTILLATION UNIT = УСТАНОВКА ВАКУУМНОЙ ДИСТИЛЛЯЦИИ – Vacuum Distillation Unit (VDU) is a distillation column that operates in a vacuum (where operating pressure is less than atmospheric pressure). Used in the production of oil sands. Distillation of crude oil is carried out in two units, first in an Atmospheric Distillation Unit (also known as Crude Distillation Unit, CDU), with further processing of the residue from atmospheric distillation in the Vacuum Distillation Unit (VDU). For sake of simplicity, Figure 4.2 does not include the network of heat exchangers and pump around loops to pre-heat the desalted crude before it is fed the fired furnace. In the furnace, the crude is heated to the desired temperatures (700–750 °F) such that all the distillate fraction and roughly 10–20% of the bottom product are evaporated, depending on the volatility of crude oil. The two-phase mixture is then introduced into the CDU flash zone for separation of vapor and liquid streams where vapor fraction rises toward the top of the column and the liquid fraction is subjected to stripping with steam to recover the low-boiling distillate components dissolved in heavier liquid before sending the bottom product (i.e. atmospheric distillation residue) to the vacuum distillation unit. A temperature gradient is established in the column by removing heat from the overhead vapor. The column condenses the naphtha fraction and sends a portion of the liquid naphtha, as reflux, to the column to achieve a good separation of the distillate products drawn from the side of the distillation column, such as kerosene, light gas oil (LGO), and heavy gas oil (HGO), as seen in the diagram. Steam strippers on the side of the column also provide reflux to the main column to help with clean separation of the distillate products. Additional reflux is provided to the main column by pump around loops associated with heat exchangers for preheating the crude. Counter-current flow of vapor and liquid streams through the contact stages (e.g., trays) in the main column, enabling good separation of the distillate fractions. The temperature at the bottom of CDU is limited to 700–750 °F to prevent cracking – breaking of the chemical bonds between carbon atoms in the aliphatic hydrocarbons constituting the crude oil. Cracking would cause coking (accumulation of carbonaceous solids) on the metal surfaces in the column and interferes with fractionation in distillation. Vacuum distillation is necessary to fractionate the heavy distillates because further increase in temperature would cause thermal cracking of the feed components. The atmospheric residue is reheated in a fired furnace to 730–850 °F before introduction into the vacuum distillation unit (VDU). Furnace outlet temperature is selected depending on the thermal reactivity (or coking propensity of crude oil, as will be discussed further) and the desired level of separation in the column. Steam ejectors, or, more recently, vacuum pumps, are used to create vacuum for evaporation of the light vacuum gas oil and heavy vacuum gas oil fractions. The temperature and pressure in VDU also depend on whether steam is introduced, or the separation is carried out without the steam addition in 'dry' towers, varying between 10 to 30 mmHg at the bottom of the tower. Lower pressures and higher temperatures are used in dry towers. To minimize the pressure difference between the bottom and top of the column, some special packing materials are used instead of trays for providing contact between liquid and vapor streams to improve fractionation. The heavy distillates (light vacuum gas oil and heavy vacuum gas oil) separated in VDU are further processed in downstream separation and conversion units to produce lubricating oil base stocks, or as feedstock for hydrocracking to produce light and middle distillates. The residue from vacuum distillation (VDR) can be upgraded into marketable products and fuels using processes such as visbreaking, deasphalting, and coking, as will be discussed in later sections.

VACUUM PUMP = ВАКУУМНЫЙ НАСОС – Vacuum Pump is a device that is used to extract gas or vapor from an enclosed space, leaving behind a partial vacuum in the container. Classification Of Vacuum Pumps:- vacuum pumps are categorized as gas transfer pumps and gas binding or capture pumps. While gas-displacement vacuum pumps can be used without limitation, gas-binding vacuum

pumps have a limited gas absorption capacity and must be regenerated at certain process-dependent intervals. Gas-displacement pumps, which are also referred to as gas transfer pumps, are classified either as positive displacement pumps or kinetic vacuum pumps. Positive displacement pumps displace gas from sealed areas to the atmosphere or to a downstream pump stage. Kinetic pumps displace gas by accelerating it in the pumping direction, either via a mechanical drive system or through a directed vapor stream that is condensed at the end of the pumping section. Gas-binding vacuum pumps either bind the gas to an especially active substrate through gettering or condense the gas at a suitable temperature. Chemisorption is performed technically by a pump type known as Getter Pumps which constantly generate pure getter surfaces through vaporization and/or sublimation or sputtering. If the gas particles to be bound are ionized in an ion getter pump before interacting with a getter surface, they can at the same time clean the getter surface by sputtering and be buried by sputtered material. Non evaporable getters (NEG) consist of highly reactive alloys, mainly of zirconium or titanium, and have a very large specific surface. Gases can penetrate into deeper layers of the getter material through micropores and be bound there into stable chemical compounds. See also Pump. Vacuum Pump:- vacuums are used in many vehicles for actuation, changing gear and pneumatic power assistance. In many cases, vacuum pumps are located directly on the cylinder head, and are driven by the camshaft. Due to these 'interfaces', the engine repairer should have an elementary knowledge of vacuum pumps. Vacuum pumps are used in motor vehicles in which the necessary vacuum cannot be generated in the intake manifold. These are direct injection engines, turbo engines and engines with variable valve timing, for example. The increasing number of pneumatic actuators can also render the use of a vacuum pump necessary. With pneumatic devices, high actuating forces can be achieved in a small installation space. Brake boosters, secondary air valves, EGR valves, switched intake manifolds, turbocharger control and comfort devices are just some examples. Since failure of the brake boosters can lead to dangerous situations, the vacuum pump is considered to be a safety component. Method Of Operation/Types:- the vacuum pumps used in motor vehicles generate a vacuum of approx. 0.7–0.9 bar. They suck the air out of the vacuum system and generally convey this to the cylinder head or the crankcase. In many cases, vacuum pumps are located directly on the cylinder head, are supplied with lubricating oil and driven by the camshaft. A vacuum pump's method of operation depends on its design and is not visible from the outside. Formerly, piston or diaphragm vacuum pumps were predominantly used, which were driven by the cam, tappet, chain, belt or cam disc. These days, vane pumps are used, which are mostly fi tted to the end of the camshaft. New developments tend to combine pumps supplying different media (tandem pumps):- (1) Combined fuel/vacuum pumps are situated on an axle shared with the camshaft. (2) Combined vacuum/oil pumps are installed in the oil pan. Continued Use Of A Used Vacuum Pump In A Reconditioned Engine:- vacuum pumps are connected to the engine and, depending on their design, are incorporated in the engine oil circuit. Following engine damage:- (i) Chips may get into the vacuum pump along with the engine oil; (ii) The vacuum pump may have been damaged by overheating; and (iii) The vacuum pump may have been damaged. For this reason, to prevent consequential damage following engine repair, we recommend also replacing the vacuum pump following engine damage. / Под Вакуумным Насосом понимается устройство для удаления (откачки) газов и паров из замкнутого объёма с целью получения в нём вакуума. Существуют различные типы вакуумных насосов, действие которых основано на разных физических явлениях:- механические (вращательные), струйные, сорбционные, конденсационные. Основные параметры вакуумного насоса:- предельное (наименьшее) давление (остаточное давление, предельный вакуум), которое может быть достигнуто насосом; быстрота откачки – объём газа, откачиваемый при данном давлении в единицу времени (кубических метров в секунду ($м^3$/сек), литров в секунду (л/сек)); допустимое (наибольшее) выпускное давление в выпускном сечении насоса, дальнейшее повышение которого нарушает нормальную работу вакуумного насоса. Механические насосы применяют для получения вакуума от 1 Ньютона на квадратный метр ($Н/м^2$) (10^{-2} миллиметров ртутного столба (мм рт.ст.)) до 10^{-8} $Н/м^2$ (10^{-10} мм рт.ст.). В рабочей камере простейшего механического насоса совершает возвратно-поступательное движение поршень, который вытесняет газ, создавая при обратном ходе разрежение со стороны откачиваемой системы. Поршневые Насосы были первыми механическими насосами. Их вытеснили Вращательные Насосы. В многопластинчатом вращательном насосе всасывание и выталкивание газа осуществляется при изменении объёмов ячеек, образованных эксцентрично расположенным ротором, в прорезях которого помещены подвижные пластины, прижимающиеся к внутренней поверхности камеры и скользящие по ней при его вращении. За счёт большой частоты вращения ротора эти насосы при сравнительно малых размерах обладают большой быстротой откачки (до 125 л/сек). Предельное давление достигает 2 000 $Н/м^2$ (15 мм рт.ст.) в одноступенчатых насосах и 10 $Н/м^2$ (10^{-1} мм рт.ст.) в двухступенчатых. Аналогично происходит процесс откачки газа Водокольцевыми Насосами. При вращении колеса с радиальными лопастями, эксцентрично расположенного в камере, вода, заполняющая камеру, увлекается лопастями и под действием центробежных сил отбрасывается к стенке корпуса, образуя водяное кольцо и серповидную камеру, в которую поступает откачиваемый газ. При вращении колеса ячейки поочерёдно соединяются с каналом, через который откачиваемый газ выходит в атмосферу. Эти насосы пригодны для откачки влажного и загрязнённого газа, кислорода и взрывоопасных газов. Предельный вакуум составляет 95% (в одноступенчатых насосах) и 99.5% (в двухступенчатых насосах) от теоретически возможного; например, при температуре воды 20 °C – до 7.1 $кН/м^2$ (53 мм рт.ст.) в одноступенчатых и 3.1 $кН/м^2$ (23 мм рт.ст.) в двухступенчатых насосах. Для получения среднего вакуума чаще применяют вращательные насосы с масляным уплотнением. Их рабочая камера заполнена маслом, либо они погружены в масляную ванну. Быстрота откачки этих насосов 0.1–750 л/сек, предельное давление 1 $Н/м^2$ (10^{-2} мм рт.ст.) в одноступенчатых и 10^{-1} $Н/м^2$ (10^{-3} мм рт.ст.) в двухступенчатых насосах. Масло хорошо уплотняет все зазоры, выполняет функцию дополнительной охлаждающей среды, однако при длительной работе сконденсированные пары загрязняют масло. Для предотвращения конденсации паров, возникающей при их сжатии, камеру заполняют определённым объёмом воздуха (балластным газом), который в момент выхлопа обеспечивает парциальное давление пара в паро-воздушной смеси, не превышающее давления насыщения. При этом пары из насоса выталкиваются без конденсации. Такие насосы называются Газобалластными Насосами и применяются как Форвакуумные Насосы (для создания предварительного разрежения). Двухроторные насосы имеют 2 фигурных ротора, которые при вращении входят один в другой, создавая направленное движение газа. Эти насосы обладают большой быстротой откачки и часто применяются как промежуточные (вспомогательные, или бустерные) между форвакуумными и высоковакуумными. Они обеспечивают вакуум 10^{-2}–10^{-3} $Н/м^2$ (10^{-4}–10^{-5} мм рт.ст.) при быстроте откачки до 15 $м^3$/сек. В молекулярных насосах при вращении ротора в газе молекулы получают дополнительную скорость в направлении их движения. Впервые такой насос был предложен в 1912 Немецким учёным физиком Вольфганом Максом Паулем Геде (Wolfgang Max Paul Gaede; 1878-Май-25–1945-Июнь-24), но долго не получал распространения из-за сложности конструкции. В 1957 Немецкий учёный Доктор Вилли Бека (Willi Becker) применил турбомолекулярный насос (turbomolecular pump), ротор которого состоит из системы дисков. Таким насосом получают вакуум до 10^{-8} $н/м^2$ (10^{-10} мм рт.ст.). В струйных насосах направленная струя рабочего вещества уносит молекулы газа, поступающие из откачиваемого объёма. В качестве рабочего вещества могут быть использованы жидкости или пары жидкостей. В зависимости от этого насосы называются Водоструйными, Пароводяными, Парортутными или Паромасляными. По принципу действия струйные насосы бывают Эжекторными и Диффузионными. В эжекторных насосах откачивающее действие струи основано на увеличении давления газового потока под действием струи более высокого напора. Такие насосы применяются для получения вакуума 10 $Н/м^2$ (10^{-1} мм рт.ст.). Простым эжекторным насосом является Водоструйный Насос, распространённый в лабораторной практике, в химической промышленности и другом. Предельное давление таких насосов не

намного превышает давление водяных паров. Например, при температуре воды в насосе, равной 20 °C, достигаемый вакуум равен 3 100 Н/м^2 (23 мм рт.ст.), а парциальное давление остаточных газов около 670 Н/м^2 (5 мм рт.ст.). К эжекторным насосам может быть отнесён Вихревой Насос (аппарат), откачивающее действие которого основано на использовании разрежения, развивающегося вдоль оси вихря. Значительно большей быстротой откачки и более низким предельным давлением обладают насосы, в которых рабочим веществом является водяной пар. В многоступенчатых пароводяных насосах быстрота откачки достигает 20 м^3/сек, создаваемый вакуум 0.7 Н/м^2 ($5 \cdot 10^{-3}$ мм рт.ст.). Откачивающее действие диффузионных насосов основано на диффузии молекул откачиваемого газа в области действия струи пара рабочего вещества за счёт перепада их парциальных давлений. В качестве рабочего вещества в 1915 Вольфган Геде применил пары ртути. Ртуть обеспечивает постоянное (для данной температуры) давление насыщенного пара, постоянную (для данного давления) температуру, остаётся химически неактивной, не боится перегрева, но пары ртути, даже в небольшом количестве, опасны для человеческого организма. Одним из заменителей ртути является масло (смотрите Вакуумное Масло). Такие вакуумные насосы называются Паромасляными Насосами. Применение в качестве рабочей жидкости масла привело к широкому распространению таких насосов с быстротой откачки до нескольких сотен м^3/сек при получении вакуума до 10^{-6} Н/м^2 (10^{-8} мм рт.ст.). В паромасляном вакуумном насосе последовательно соединены несколько откачивающих ступеней в одном корпусе. Диапазон рабочих давлений трёхступенчатого паромасляного насоса 10^{-3}–10^{-1} Н/м^2 (10^{-5}–10^{-3} мм рт.ст.). В сорбционных насосах используют способность некоторых веществ (например, Ti, Mo, Zr и других) поглощать газ. Откачиваемый газ оседает на поверхности внутри вакуумной системы. Один из активных поглотителей постоянно напыляется на поглощающую поверхность (Испарительный Насос). Поглотителем может быть также пористый адсорбент (смотрите Адсорбционный Насос). Действие Ионных Насосов основано на ионизации газа сильным электрическим разрядом и удалении ионизованных молекул электрическим полем. Этот способ мало распространён из-за сложности устройства и большой потребляемой мощности, затрачиваемой главным образом на создание магнитного поля. При комнатной температуре инертные газы и углеводороды практически не поглощаются напылёнными плёнками металлов. Для их удаления служат комбинированные Ионно-Сорбционные, или Ионно-Геттерные, насосы, в которых сорбционный способ поглощения химически активных газов сочетается с ионным способом откачки инертных газов и углеводородов. Поглощающая поверхность обновляется осаждением на стенках термически испаряемого титана, а также катодным распылением титана в электрическом разряде или в магнитном поле в электроразрядных или магниторазрядных ионно-сорбционных насосах. Ионно-сорбционные вакуумные насосы при предварительной откачке до 10^{-2} Н/м^2 (до 10^{-4} мм рт.ст.) создают вакуум до 10^{-5} Н/м^2 (10^{-7} мм рт.ст.). Быстрота откачки зависит от рода газа. Например, быстрота откачки водорода 5 000 л/сек, азота 2 000 л/сек, аргона 50 л/ сек. Достигаемое предельное давление в хорошо обезгаженных объёмах и без натекания газа ниже 10^{-8} Н/м^2 (10^{-10} мм рт.ст.). Действие Конденсационных, или Криогенных, Насосов основано на поглощении газа охлаждённой до низкой температуры поверхностью. Водородно-конденсационный насос, предложенный Советским физиком Борисом Георгиевичем Лазаревым (1906-Август-06–2001-Март-20) с сотрудниками (Физико-Технического Институт АН УССР), имеет постоянную быстроту откачки в широком диапазоне давлений. Охлаждающий жидкий водород вырабатывается ожижителем, находящимся в установке. Неконденсируемые газы (водород, гелий) откачиваются параллельно включённым насосом, например, диффузионным. Для включения такого насоса необходимо предварительное разрежение.

VACUUM SEPARATOR = ВАКУУМНЫЙ СЕПАРАТОР – Vacuum Separator is a separator that utilizes subatmospheric pressure to remove certain gases and liquids from another liquid because of their difference in vapor pressure.

VAD = VALUE–ADDED DATA

VAD = VALUE–ADDED DEALER

VAD = VALUE–ADDED DISTRIBUTOR

VAD = VALUE OF ANNUAL DEMAND

VAD = VITAMIN A DEFICIENCY

VADOSE ZONE = ВАДОЗНАЯ ЗОНА (или ЗОНА ВЕРХНИХ ГРУНТОВЫХ ВОД) – Vadose Zone:- region of aeration above the water table. This zone also includes the capillary fringe above the water table, the height of which will vary according to the grain size of the sediments. In coarse-grained mediums the fringe may be flat at the top and thin, whereas in finer grained material it will tend to be higher and may be very irregular along the upper surface. The vadose zone varies widely in thickness, from being absent to many hundreds of feet, depending upon several factors. These include the environment and the type of earth material present. Water within this interval, which is moving downward under the influence of gravity, is called Vadose Water, or Gravitational Water. / Вадозная Вода или Гравитационная Вода. Вадозные Воды, подразделяющиеся на:- (i) инфильтрационные воды – воды, просачивающиеся сквозь зернистые породы; (ii) инфлюационные воды – воды, втекающие с поверхности по трещинам и пустотам горных пород; (iii) конденсационные воды – воды, образующиеся из парообразной влаги воздуха, заключённого в подземных порах, трещинах и других пустотах. Вадозные воды – воды поверхностного (атмосферного) происхождения, представляют в процессе их подземного стока одно из звеньев общего круговорота воды.

VAGANS = ВАГАНС (или БЛУЖДАЮЩЕЕ) – Vagans:- wandering. / Ваганс, от Латинского слова Vagans (Vagaatis), от Vagare, означающее Странствовать:- блуждающее.

VAGILE = БРОДЯЧЕЕ (или ВАГИЛЬНОЕ) – Vagile:- wandering or roaming, e.g., a microorganism that is not attached to a solid support tends to 'wander' through its environment as it gets pushed about by currents of air or liquid. Vagile:- able or tending to move from place to place or disperse:- a vagile animal Species. / Бродячий или Вагильный – свободно передвигающийся или перемещающийся организм (о животных и растениях).

VAGILITY = ПОДВИЖНОСТЬ (или БЛУЖДАНИЕ) – Vagility is the ability of organisms to disseminate, e.g., spread throughout a given habitat. / Подвижность – способность организмов к расселению в пределах экосистемы.

VAGINATE = ВЛАГАЛИЩНОЕ – Vaginate:- sheathed or surrounded by a sheath. Vaginate (in botany; esp of plant parts):- having a sheath; sheathed:- a vaginate leaf. / Влагалищный Лист – лист, у которого нижняя часть расширена, трубкой обхватывает междоузлие.

VAGINOSIS = ВАГИНОЗИЗ – Vaginosis is the process whereby a cell internalizes an entity (such as a virus or a protein) that has bound to the cell's outer membrane. Once that 'bound entity' is inside the cell, the cell membrane fuses together again. / Вагинозиз – вагинальная инфекция, сопровождающаяся отеком.

VAGRANCY = БРОДЯЖНИЧЕСТВО (или ТУНЕЯДСТВО) – Vagrancy:- state or action of one who has no established home and drifts from place to place without visible or lawful means of support. Traditionally a vagrant was thought to be one who was able to work

for his maintenance but preferred instead to live idly, often as a beggar. The punishment for this ranged from branding and whipping to conscription into the military services and transportation to penal colonies. In English law, a man who deserted his wife and children was considered a vagrant, as was any man who gave a false account of himself. The vagueness of the common-law meanings of vagrancy has been reflected in subsequent statutory law. In the United States and northern Europe, vagrancy must generally be accompanied by the act of begging before it becomes punishable. Usually local authorities merely encourage the vagrant to move on, relieving themselves of the financial burden of maintaining the offender. In some countries the term describes a more serious offense than begging. Often it applies to a person who has a fixed habitation but pursues a calling condemned by the law as immoral, such as prostitution or gambling. Vagrancy is frequently used by police and prosecutors as a tool for proscribing a wide range of behaviour. Political demonstrations, the obstruction of streets or walks, riotous activities, and loitering have all been variously interpreted as violations of vagrancy laws. This fluid application of a vague statute or ordinance has been heavily criticized by legal scholars and civil libertarians. The United States Supreme Court declared a Florida state statute unconstitutional in February 1972 on the grounds that its terms were not sufficiently explicit to inform those subject to it what conduct would render them liable to its penalties. See also Disorderly Conduct. / Бродяжничество, в эксплуататорских государствах социальное явление, порождаемое необеспеченностью и неустойчивостью существования трудящихся. Выражается в постоянном перемещении человека с места на место, в бездомном образе жизни, в существовании за счёт подаяний и тому подобном. При эксплуататорском строе лица, вынужденные заниматься бродяжничеством, самим обществом лишены возможности участвовать в производительном труде. В царской России тяжёлое материальное положение трудящихся приводило к очень широкому распространению бродяжничества. На протяжении веков бродяжничали и нищенствовали обедневшие жители городов, беглые крепостные и ссыльные, не имевшие крова инвалиды и старики, странствующие монахи. Во 2-й половине XIX – начале XX веков в условиях общего экономического упадка деревни, а также в результате неурожаев, пожаров, падежей скота число бродяг увеличивалось и они массами направлялись в города, где основным источником их существования становилось нищенство. Причинами бродяжничества в современных буржуазных государствах являются эксплуатация, экономические кризисы, разорение деревни, хроническая безработица, войны и вызываемая ими необеспеченность беднейших слоёв населения. Накопление капитала, технический прогресс в буржуазном обществе неизбежно приводят к тому, что часть трудящихся становится избыточной, выталкивается из сферы общественного производства и тем самым обрекается на нищету и бездомный образ жизни. Число бродяг особенно велико в горных районах, населённых беднотой. Порождает бродяжничество и подневольный характер труда в капиталистическом обществе. Ряды хронических безработных, значительная часть которых становится бродягами, постоянно пополняются разорившимися мелкими производителями из города и деревни, опустившимися представителями интеллигенции и другими. Несмотря на объективную неизбежность бродяжничества в буржуазном обществе, законодательство многих капиталистических стран предусматривает наказание за бродяжничество. Например, в США Кодекс Штата Калифорния (§ 647) содержит пространное определение бродяжничества, наказуемого крупным штрафом или лишением свободы:- ‘каждое лицо, которое бродит по улицам в позднее время или в ночные часы без очевидных или законных оснований’, или ‘каждое лицо, которое ютится в каком-либо складе, сарае, железнодорожном вагоне ... без разрешения владельца’, или ‘каждое лицо, известное как пьяница’ и так далее. В Великобритании 3 категории лиц, несущих ответственность за бродяжничество:- (а) тунеядцы (‘мелкие разносчики товаров, странствующие и торгующие без надлежащего разрешения’, ‘попрошайки’ и другие); (б) бродяги (‘лица, занимающиеся выпрашиванием подаяния путём выставления напоказ ран или уродств’, ‘лица, проживающие в сараях ... и плохо себя зарекомендовавшие’ и другие); (в) неисправимые бродяги (лица, повторно совершившие действия, изложенные в пункте ‘б’). Уголовный Кодекс (УК) Италии (Статья 670) предусматривает наказание в виде лишения свободы (арест) за нищенство. Неопределённость и расплывчатость формулировок законов позволяют привлекать к ответственности за бродяжничество любого безработного или иного обездоленного человека, подвергнуть лишению свободы лиц, не представляющих опасности для общества. Нередко меры по борьбе с бродяжничеством используются полицией для репрессий против беднейших слоёв населения, выражающих протест против тяжёлых социальных условий. В социалистическом обществе, где нет эксплуатации человека человеком и отсутствует безработица, а материальные условия жизни трудящихся систематически улучшаются, бродяжничество как социальное явление изжито. Встречающиеся случаи бродяжничества и сопутствующего ему попрошайничества – форма уклонения антиобщественных элементов от общественно полезного труда, паразитическое стремление прожить на счёт общества, средство избежать уголовной ответственности за совершённые преступления, уклониться от уплаты алиментов, от заботы о детях (среди бродяг много разыскиваемых преступников и неплательщиков алиментов) и так далее. В бывшем Союзе Советских Социалистических Республик (СССР) действовавшее законодательство предусматривало при определённых условиях уголовную ответственность за бродяжничество и попрошайничество. Под Бродяжничеством понималась периодическая перемена места пребывания с целью уклонения от общественно полезного труда, а под попрошайничеством (которое нередко сочетается с бродяжничеством) – более или менее длительное существование за счёт выпрашивания у окружающих денег или других материальных ценностей в целях паразитического обогащения. К уголовной ответственности за бродяжничество и попрошайничество привлекались трудоспособные граждане, достигшие 18-летнего возраста. Подростков 16–18 лет, вовлечённых в бродяжничество и попрошайничество, трудоустраивали либо помещали в детские учреждения, иногда над ними устанавливали опеку и тому подобное. УК РСФСР (Статья 209) и УК некоторых других Союзных республик предусматривали за систематическое бродяжничество и попрошайничество наказание в виде исправительных работ до 1 года или лишения свободы на срок до 2 лет, если оно продолжалось после повторного предупреждения административными органами о необходимости трудоустройства и изменения образа жизни. Особый состав преступления образует вовлечение несовершеннолетних в занятие попрошайничеством или использование несовершеннолетних для целей паразитического существования (УК РСФСР, Статья 210). Учитывая опасность такого вовлечения, закон устанавливал за эти преступления строгое наказание – лишение свободы на срок до 5 лет. В некоторых Союзных республиках СССР ввиду полного отсутствия случаев бродяжничества и попрошайничества в УК отсутствовали эти составы преступления. Тунеядец – человек, который живёт на чужой счёт, чужим трудом.

VAH = VALUE AREA HIGH

VAL = VALUE AREA LOW

VALANCE = ПОДЗОР (или ОБОРКА, или СБОРКА) – Valance is a decorative fabric or board installed across the top of a window or a top for curtains or draperies. It is usually hung from a rod and made of fahric or fabric over a stiffening material, such as buckram. A valance differs from a ruffle in that it is absolutely flat. See also Buckram, Ruffle, and Trimming. / Подзор – спускающаяся кружевная оборка, кайма, например, покрывало с подзором. Оборка – полоска материи на одежде, изделии, пришитая складками или сборками, например, косая оборка, кружевная оборка или платье с оборками. Сборка – прошитая мелкая волнистая складка на материи, одежде, например, кофта со сборками или юбка в сборку.

VALENCE = ВАЛЕНТНОСТЬ – Valence:- also spelled Valency in chemistry, the property of an element that determines the number of other atoms with which an atom of the element can combine. Introduced in 1868, the term is used to express both the power of combination of an element in general and the numerical value of the power of combination. The explanation and the systematization of valence was a major challenge to XIX-century chemists. In the absence of any satisfactory theory of its cause, most of the effort centered on devising empirical rules for determining the valences of the elements. Characteristic valences for the elements were measured in terms of the number of atoms of hydrogen with which an atom of the element can combine or that it can replace in a compound. It became evident, however, that the valences of many elements vary in different compounds. The first great step in the development of a satisfactory explanation of valence and chemical combination was made by the American chemist Gilbert Newton Lewis (1875–1946; 1916) with the identification of the chemical bond of organic compounds with a pair of electrons held jointly by two atoms and serving to hold them together. In the same year, the nature of the chemical bond between electrically charged atoms (ions) was discussed by German physicist Walther Ludwig Julius Kossel (1888–1956). After the development of the detailed electronic theory of the periodic system of the elements, the theory of valence was reformulated in terms of electronic structures and interatomic forces. This situation led to the introduction of several new concepts – ionic valence, covalence, oxidation number, coordination number, metallic valence – corresponding to different modes of interaction of atoms. / Американский химик Гилбёт Ньютчэн Луис (Gilbert Newton Lewis (1875–1946; 1916)). Немецкий физик Вальта Людвихь Юлиус Косэль (Walther Ludwig Julius Kossel (1888–1956)). Под Валентностью, от Латинского слова Valentia, означающее Сила, понимается способность атома к образованию химических связей. Количественной мерой валентности обычно принято считать число других атомов в молекуле, с которыми данный атом образует связи. Валентность – одно из фундаментальных понятий теории химического строения (смотрите Теория Химического Строения). Оно формировалось вместе с понятием химической связи, параллельно с развитием синтетической химии и методов исследования строения и свойств веществ, и его содержание неоднократно расширялось и изменялось по мере того, как экспериментальная химия находила всё новые и новые классы соединений с неизвестными ранее типами взаимодействия атомов в молекуле, а в последние 30–40 лет (то есть до 1982) – с развитием квантовой химии. В настоящее время накопленный химией экспериментальный материал столь обширен и разнообразен, а картина химической связи в разных соединениях столь пестра, что задача нахождения последовательного, единого и всеобъемлющего определения валентности представляется крайне сложной. Эти трудности побуждают некоторых химиков вообще отказаться от поисков универсального понятия валентности и заменить его набором более узких, но зато более конкретных и более точных понятий (ковалентность, гетеровалентность, координационное число и так далее), область применимости каждого из которых ограничена соединениями с каким-либо одним преобладающим типом взаимодействия (ковалентным, ионным, координационным и так далее). Однако до настоящего времени и в специальной, и в учебной литературе валентность продолжает широко использоваться и как определение способности атома к образованию связей в самом общем смысле слова, и как количественная мера этой способности, и как синоним предлагаемых более узких понятий. Единое и последовательное определение валентности следует искать в рамках квантовохимической теории молекулярных орбиталей (смотрите Квантовая Химия, Метод Молекулярных Орбиталей, Химическая Связь, Молекула). Для отдельных классов соединений, где преобладает какой-либо один тип химического взаимодействия, полезную информацию о способности атомов к образованию связей могут дать перечисленные ниже частные понятия (частные определения валентности). Определение Понятия ‘Валентность’ И Связь Его С Другими Понятиями Химии:- Ковалентность – мера способности атома к образованию ковалентных химических связей, возникающих за счёт двух электронов (по одному от каждого атома) и имеющих малополярный характер (смотрите Ковалентная Связь). Ковалентность равна числу неспаренных электронов атома, участвующих в образовании связи, и часто может принимать все значения от 1 до максимальной, которая для большого числа элементов совпадает с номером их группы в Периодической Системе Менделеева (подробно смотрите разделы ниже). Гетеровалентность (употребляются также термины Электровалентность и Ионная Валентность) – мера способности атома к образованию ионных химических связей, возникающих за счёт электростатического взаимодействия ионов, которые образуются при полном (или почти полном) переходе электронов одного атома к другому (смотрите Ионная Связь). Гетеровалентность равна числу электронов, которые атом отдал или получил от другого атома, и совпадает с зарядом соответствующего иона (смотрите раздел ниже). Координационное Число (КЧ) равно числу атомов, ионов или молекул, находящихся в непосредственной близости с данным атомом в молекуле, комплексном соединении или кристалле. В отличие от ковалентности и гетеровалентности, это понятие имеет чисто геометрический смысл и не зависит от характера связи между центральным атомом и лигандом. Так, например, КЧ атомов Al, Si, P в комплексных ионах $(AlFe_6)^{3-}$, $(SiFe_6)^{2-}$, $(PFe_6)^{-}$ равно 6, а КЧ атомов B, Xe, Ni в $(BH_4)^{-}$, XeO_4, $Ni(CO)_4$ равно 4. В кристалле NaCl каждый атом Na окружён шестью атомами Cl, так что КЧ Na равно 6. Величина КЧ может определяться как относительными размерами атомов, так и другими, более сложными причинами (смотрите разделы ниже). Окислительное Число (ОЧ) (или Степень Окисления) – понятие, получившее в последнее время распространение в неорганической химии, – это электростатический заряд, условно приписываемый атому по следующим правилам. В ионных соединениях ОЧ совпадает с зарядом иона (например, в NaCl ОЧ Na равно +1, ОЧ Cl равно –1). В ковалентных соединениях ОЧ принято считать равным заряду, который получил бы атом, если бы все пары электронов, осуществляющие связь, были целиком перенесены к более электроотрицательным атомам (то есть если условно допустить, что связь имеет полностью ионный характер). Например, в HCl ОЧ H равно +1, ОЧ Cl равно –1. В элементарных соединениях ОЧ равно 0 (например, в O_2, Cl_2, P_4, S_8, в алмазе). При вычислении ОЧ в соединениях, где имеются два связанных атома одного элемента, их общую электронную пару принято делить пополам. Понятие ОЧ полезно при составлении уравнений окислительно-восстановительных реакций, для классификации неорганических и комплексных соединений и так далее. Однако по своему определению ОЧ, в отличие от ковалентности и ионной валентности, имеющих чёткий физический смысл, носит в общем случае условный характер и, за исключением весьма ограниченного класса соединений с чисто ионной связью, не совпадает ни с эффективными зарядами атомов в соединениях, ни с фактическим количеством связей, которые атом образует. Кроме того, в ряде случаев, в частности, когда электроотрицательности двух разных связанных атомов близки и связь между ними имеет почти чисто ковалентный характер, возникает неопределённость, к какому из них следует целиком относить электронную пару (смотрите Окислительное Число). Эволюция Понятия ‘Валентность’ И Его Роль В Истории Химии:- В начале XIX века Английским химиком, физиком и метеорологом Дьжоном Долтчэном (John Dalton; 1766–1844) был сформулирован закон кратных отношений, из которого следовало, что каждый атом одного элемента может соединяться с одним, двумя, тремя и так далее атомами другого элемента (как, например, в окислах азота – N_2O, NO, N_2O_3, NO_2 и N_2O_5). В середине XIX века, когда были определены точные относительные веса атомов (Шведский химик и минералог Барон Йонс Якоб Бэрсэлиос (Baron Jöns Jacob Berzelius; 1779–1848) и другие), стало ясно, что наибольшее число атомов, с которыми может соединяться данный атом, не превышает определённой величины, зависящей от его природы. Например, атом F может соединяться лишь с одним атомом H, O – с двумя, N – с тремя, C – с четырьмя, образуя соответственно HF, H_2O, NH_3 и CH_4. Два или четыре атома H в метане CH_4 могут быть замещены одним или двумя атомами O с образованием формальдегида CH_2O и двуокиси углерода CO_2 соответственно, три атома H в CH_4 могут замещаться одним атомом N с образованием цианистого водорода HCN, и так далее. Эта способность связывать или

замещать определённое число других атомов и была названа Валентностью (Английский химик-органик Сэр Эдвод Фрэнклэнд (Sir Edward Frankland; 1825–1899) в 1853). В таком определении валентность естественно, всегда выражается целыми числами. Поскольку в то время для водорода не были известны соединения, где он был бы связан более чем с одним атомом любого другого элемента, атом H был выбран в качестве стандарта, обладающего валентностью, равной 1. В ‘водородной’ шкале кислород и сера имеют валентность, равную 2, азот и фосфор 3, углерод и кремний 4. Однако ‘водородной’ шкалы оказалось недостаточно:- в других соединениях, например, в окислах, один и тот же элемент может реализовать валентности, которые не осуществляются в гидридах (существуют окислы P_2O_5, SO_3 и Cl_2O_7, но неизвестны гидриды PH_5, SH_6 и ClH_7). В качестве второго стандарта с валентностью, равной 2, был выбран кислород. В конце 1850-х Шотландский химик Ачэболд Скот Купё (Archibald Scott Couper; 1831–1892) и Немецкий химик-органик Фридрихь Огуст Кекуле (Friedrich August Kekulé; 1829–1896) постулировали принцип постоянной четырёхвалентности углерода в органических соединениях. Представления о валентности составили важную часть теории химического строения Русского химика Александра Михайловича Бутлерова (1828–1886) в 1861 (смотрите Теория Химического Строения). Образование химической связи рассматривалось как результат взаимного насыщения двух валентностей пары взаимодействующих атомов (по одной валентности от каждого), кратные связи соответствовали насыщению нескольких валентностей от каждого атома, и так далее. Каждая связь считалась локализованной между двумя атомами и изображалась одной чертой, соединяющей эти атомы. Молекулы стали изображать с помощью структурных формул, получивших особенно широкое распространение в органической химии. Положения Бутлерова в дальнейшем легли в основу структурной теории, рассматривающей и пространственное расположение атомов в молекуле. Было найдено, что простые молекулы типа MX_k с одинаковым центральным атомом M и разными заместителями X имеют схожее геометрическое строение. Независимость геометрического строения от типа связи в широких пределах привела к мысли, что пространственное расположение атомов в молекулах MX_k определяется валентностью центрального атома M и что эти валентности имеют направленный характер (смотрите соответствующий раздел). Периодический Закон Дмитрия Ивановича Менделеева (1834–1907) (в 1869) вскрыл зависимость валентности элемента от его положения в периодической системе (смотрите Периодическая Система Элементов Дмитрия Ивановича Менделеева). Элементы одинаковых групп системы обладают одинаковой высшей валентностью в большинстве случаев равной номеру той группы, в которой находится этот элемент; высшая валентность меняется на 1 при переходе от одной группы к соседним. Эта зависимость сыграла чрезвычайно важную роль в развитии химии:- зная лишь положение элемента (в том числе элементов, которые в то время ещё не были открыты) в периодической системе, можно было определить его валентные возможности, предсказать состав его соединений и впоследствии синтезировать их. С помощью представлений о формальной (стехиометрической) валентности (смотрите Стехиометрия) химикам удалось обобщить и систематизировать огромный экспериментальный материал по строению, стехиометрическому составу и свойствам многих десятков и сотен тысяч органических и неорганических соединений. Первые Электронные Теории Ковалентности И Гетеровалентности:- До электронных представлений о строении вещества валентность трактовалась формально. Лишь в XX веке было установлено, что химическая связь осуществляется за счёт электронов внешних (валентных) оболочек атомов. В 1916 Американский химик Гилбёт Ньютчэн Луис (Gilbert Newton Lewis (1875–1946; 1916)) постулировал, что химическая связь осуществляется парой электронов, принадлежащих одновременно обоим взаимодействующим атомам. В 1917 Немецкий физик Вальта Людвихь Юлиус Косэль (Walther Ludwig Julius Kossel (1888–1956)) выдвинул гипотезу, согласно которой электронная пара связи переходит целиком к одному из атомов с образованием ионной пары катион – анион, удерживающихся в молекуле электростатическими силами. Согласно обеим гипотезам наиболее устойчивыми оказываются соединения, в которых валентные электроны распределялись так, чтобы каждый атом был окружён оболочкой, имитирующей электронную оболочку ближайшего инертного газа (правило октета). Гипотеза Льюиса положила начало электронной теории ковалентной связи и ковалентности, гипотеза Косселя – теории ионной связи и гетеровалентности. Обе представляли крайние случаи общей картины полярной связи, когда электронная пара смещена к одному из атомов лишь частично и степень смещения может варьировать от 0 до 1 (смотрите Полярность Химических Связей). Валентность атома в соединении, согласно классической электронной теории, равна числу его неспаренных электронов, участвующих в связях, а максимальная валентность – обычно полному числу электронов в его валентной оболочке, то есть номеру группы периодической системы, в которой находится элемент. Элементы одинаковых групп имеют одинаковое число валентных электронов, а внутри одинаковых подгрупп – и одинаковые или очень близкие электронные конфигурации (смотрите соответствующий раздел). Сходство строения валентных оболочек атомов обусловливает сходство их соединений. Ковалентность и гетеровалентность отражают специфику соответствующего типа химической связи. Для ковалентности важна насыщаемость связей, обусловливающая существование молекул в виде дискретных частиц с определённым составом и структурой. Ковалентность эффективна для органических и большинства простых неорганических соединений. Напротив, в случае гетеровалентности максимальное число ионов противоположного знака, способное разместиться вокруг данного иона, в основном определяется соотношениями их размеров. Ионная валентность эффективна для сравнительно ограниченного класса соединений, в основном для различных солей щелочных, щелочноземельных и некоторых других металлов. Валентность В Комплексных Соединениях:- Ещё в конце XIX века было найдено (Швейцарский химик-неорганик Альфред Вэана (Alfred Werner; 1866–1919), в 1893), что многие соединения, как с максимальными (насыщенновалентные), так и с промежуточными валентностями типа BCl_3, $SiCl_4$, PCl_5, $CrCl_3$ и тому подобными, обладают склонностью к взаимодействию с другими насыщенновалентными соединениями – солями, окислами, молекулами типа H_2O, NH_3 и другими, с образованием довольно прочных комплексных соединений – K (BCl_4), $K_2(SiCl_6)$, $NH_4(PCl_6)$ и так далее. Исследования их строения Рентгеновскими методами показали, что в комплексных анионах MX_k^{m-} и катионах MX_k^{m+} атомы лигандов X обычно находятся в вершинах правильных многоугольников (октаэдра, тетраэдра и других), а все связи M–X одинаковы. Для представлений о валентности комплексные соединения необычны тем, что в них координационное число КЧ может быть больше общего числа валентных электронов атома M. Более того, в парамагнитных (смотрите Магнетохимия) комплексах переходных и редкоземельных металлов – $K_4(CrF_6)$, $K_3(CrF_6)$, $K_2(CrF_6)$ и других, некоторые электроны валентной оболочки остаются неспаренными и локализованными у центрального атома и практически не участвуют в связи. Классическая валентность и КЧ, как правило, не совпадают, а способность к образованию октаэдрических и тетраэдрических комплексов оказалась чрезвычайно распространённой и типичной для многих металлов и неметаллов, связанной сложной зависимостью с положением элемента в периодической системе и его валентности в исходном простом соединении. Поэтому было высказано предположение, что, наряду с ‘классической’ валентностью, которая реализуется в исходных простых соединениях типа BCl_3, $SiCl_4$ и других, атомы обладают также ‘координационной’ валентностью (смотрите Донорно-Акцепторная Связь), которая насыщается в комплексных соединениях (о природе координационной валентности смотрите соответствующий раздел). Предпринимались попытки описать связь в комплексных соединениях в рамках ионной теории, в которой считается, что анионы типа $(PF_6)^-$ и $(MnO_4)^-$ построены из ионов $P^{5+} + 6F^-$ и $Mn^{7+} + 4O^{2-}$ и что валентность центрального атома совпадает с зарядом его иона. Однако затраты энергии, необходимой для перевода 1 атома Mn и 4 атомов O в состояния Mn^{7+} и O^{2-}, далеко не компенсируются выигрышем в энергии при образовании связи. С появлением экспериментальных методов определения эффективных зарядов стало ясно, что

эффективные заряды вообще редко превышают значения +1 или +2 у положительно заряженных и –1 у отрицательно заряженных атомов и обычно выражаются дробными долями заряда электрона (в перманганатном анионе заряд на Mn составляет лишь +1.5–+2.0 электрона). Поэтому ионная теория для большинства неорганических соединений, простых и комплексных, не может считаться корректной. Успехи Химии XX Века И Проблемы Теории Валентности:- В XX веке экспериментальной химией было синтезировано и изучено строение множества новых соединений, которые также оказалось невозможно уместить в рамки классических представлений о валентности. Оказалось, что склонность к образованию координационных соединений и насыщению координационных валентностей вообще чрезвычайно распространена и характерна практически для всех элементов и что суждения о валентности на основании одного лишь стехиометрического состава очень часто оказываются несостоятельными без точных данных о структуре соединения и геометрическом расположении ближайшего окружения рассматриваемого атома. По мере развития структурных методов (смотрите Электронография Молекул, Рентгенография Молекул) стало известно, что многие соединения с простым брутто-составом ($AlCl_3$, $PdCl_2$, MoO_3 и другие), ранее считавшиеся простыми, в действительности даже в парах имеют димерное и полимерное строение – Al_2Cl_6, $(PdCl_2)_x$, $(MoO_3)_{2–5}$. В них ‘мостиковые’ лиганды, соединённые одинаковыми связями с двумя атомами металлов, обладают координационным числом КЧ = 2. У соединений в твёрдом состоянии, которые часто построены ещё сложнее, КЧ галогенов и кислорода, ранее выбранного в качестве стандартного двухвалентного элемента, могут быть 3 и даже 4. В бороводородах каждый ‘мостиковый’ атом водорода, считавшегося ранее стандартным одновалентным элементом, связан одинаковыми связями с двумя атомами бора. Алкильные группы также способны образовывать мостиковые связи в металлоорганических соединениях типа $Al_2(CH_3)_6$ и других. Для соединений переходных и ряда непереходных элементов оказалось характерным использование дополнительной валентности за счёт образования связей металл–металл (кластерные соединения), при этом расстояние между атомами металлов оказалось значительно меньшим, чем в индивидуальных металлах. Например, в дигалогенидах молибдена и вольфрама во многих химических реакциях сохраняется неизменной группа $Me_6Hal_8^{4+}$, в которой атомы металла (Me) образуют правильный октаэдр; каждый атом Me связан с четырьмя другими атомами Me и с четырьмя атомами галогена (Hal), а каждый атом Hal связан с тремя атомами Me. Связи Me–Me в кластерах могут быть кратными (как, например, в $Re_2Cl_8^{2–}$, где расстояние Re–Re на 0.5 Å меньше, чем в металлическом Re, и на их образование атомы могут тратить не одну, а несколько валентностей. Недостаточность классического понимания валентности видна также на примере так называемых ‘нуль-валентных’ соединений, где атом металла связан исключительно с нейтральными молекулами; таковы карбонилы металлов типа $Ti(CO)_7$, $Cr(CO)_6$, $Fe(CO)_5$, аммиакаты типа $Pt(NH_3)_4$ и так далее. В них вообще отсутствует классическое валентное взаимодействие (у атомов C и N в молекулах CO и NH_3 нет неспаренных электронов), а связь осуществляется только за счёт координационных валентностей атома металла и молекул лигандов. Нейтральные лиганды часто оказываются мостиковыми и образуют по две, например, в $Co_4(CO)_{12}$, и даже по три, например, в $Rh_6(CO)_{16}$, связи. Для теории валентности особый интерес представляют так называемые p-комплексы переходных металлов с ароматическими молекулами или молекулами с сопряжёнными связями в качестве лигандов (этиленом, циклопентадиенилом, бензолом и другими) типа ферроцена $Fe(C_5H_5)_2$, дибензолхрома $Cr(C_6H_6)_2$, тетрациклопентадиенила титана $Ti(C_5H_5)_4$ и других. В отличие от комплексов типа $(Cr(NH_3)_6)^{3+}$, $(Cr(H_2O)_6)^{2+}$ или $Cr(CO)_6$, где центральный атом осуществляет связь с лигандом через один атом от каждого лиганда (через N – в аммиакатах, через O – в гидратах, и так далее), в p-комплексах атомы Fe, Cr и Ti взаимодействуют совершенно одинаково со всеми атомами C каждого ароматического кольца. Непригодность классической валентности или КЧ здесь очевидна:- при этом пришлось бы считать все атомы углерода 5-валентными, а атомы Fe, Cr и Ti – соответственно 10-, 12- и 20-валентными. Единственный неспаренный электрон, который имеется у радикала $^{X}C_5H_5$ (так же как и у многих других ароматических радикалов типа тропила $^{X}C_7H_7$ и так далее), в равной степени принадлежит всем углеродным атомам кольца. Для этого класса соединений потребовались представления о делокализованной (‘групповой’) валентности, характеризующей всю совокупность атомов C в ароматическом кольце. Сейчас стало ясно, что КЧ в комплексах, так же как валентность в простых соединениях, не является жёстко специфической характеристикой элемента:- для большого числа металлов были найдены комплексы со всеми промежуточными значениями КЧ от 3 до 7, 8 и 9. При этом возникли трудности с самим определением КЧ:- в низкосимметричных высококоординационных комплексах расстояния M–X, даже для одинаковых лигандов X, часто оказываются неодинаковыми; при этом они могут быть больше тех достаточно коротких расстояний, при которых наличие сильного взаимодействия бесспорно, но всё же недостаточно велики, чтобы их можно было уверенно исключить из координационной сферы комплекса. Новые проблемы валентности возникли и в других разделах химии. Сильное развитие получила химия свободных радикалов (например, метил $^{X}CH_3$, трифенилметил $^{X}C(C_6H_5)_3$ и другие, смотрите Свободные Радикалы), в которых имеются атомы 3-валентного углерода. В последнем десятилетии были синтезированы соединения инертных газов типа XeF_2, XeF_4, XeF_6, XeO_3 и других, то есть соединения элементов, которые ранее считались вообще неспособными к химическому взаимодействию. Стало ясно и то, что валентность элементов может сильно меняться с изменением внешних условий, в частности температуры. Например, PCl_5, существующий при умеренных температурах в газовой фазе в виде мономерных молекул, при конденсации диспропорционирует (смотрите xxxxx).

VALENCE ELECTRON = ВАЛЕНТНЫЙ ЭЛЕКТРОН – Valence Electron:- any of the fundamental negatively charged particles in the outermost region of atoms that enters into the formation of chemical bonds. Whatever the type of chemical bond (ionic, covalent, metallic) between atoms, changes in the atomic structure are restricted to the outermost, or valence, electrons. They are more weakly attracted to the positive atomic nucleus than are the inner electrons and thus can be shared or transferred in the process of bonding with adjacent atoms. Valence electrons are also involved in the conduction of electric current in metals and semiconductors. / В химии Валентными Электронами называют электроны, находящиеся на внешней, или валентной, оболочке атома. Валентные электроны определяют поведение химического элемента в химических реакциях. Чем меньше валентных электронов имеет элемент, тем легче он отдаёт эти электроны (проявляет свойства восстановителя) в реакциях с другими элементами. И наоборот, чем больше валентных электронов содержится в атоме химического элемента, тем легче он приобретает электроны (проявляет свойства окислителя) в химических реакциях при прочих равных условиях. Полностью заполненные внешние электронные оболочки имеют инертные газы, которые проявляют минимальную химическую активность. Периодичность заполнения электронами внешней электронной оболочки определяет периодическое изменение химических свойств элементов в Таблице Дмитрия Ивановича Менделеева. Количество валентных электронов (максимальная валентность) равно номеру группы в Периодической Таблице Менделеева, в которой находится химический элемент (кроме побочных подгрупп).

VALENCIENNES LACE = ВАЛАНСЬЕНСКОЕ КРУЖЕВО – Valenciennes Lace is a flat babbin lace worked with one hand forming both the background and the design for the lace. Valenciennes:- a fine bobbin lace. / Валансьен (Valenciennes) – город на Севере Франции, в Департаменте Нор, на Реке Шельда, близ Бельгийской границы.

VALEUR MERCURIALE = ВАЛЁР МЭРКУРЬЯЛЕ (или ПРЕЙСКУРАНТНАЯ ЦЕННОСТЬ, или XX) – Valeur Mercuriale (in French):- xxxxx. / В переводе с Французского языка, Официальная Оценка:- применяется для определения пошлины на основе стоимости товаров (адвалорный налог; смотрите (Ad Valorem Tariff)), которую государственные чиновники устанавливают

применительно к некоторым классам привозных (или импортных) товаров. Используется главным образом в Западной Африке.

VALEURS = ВАЛЁР (или ЦЕННЫЕ БУМАГИ, или АКЦИИ, или СТОИМОСТЬ, или ЦЕННОСТЬ) – Valeurs (in French):- xxxxx. / Ценные Бумаги:- Французский термин Валёр (Valeurs), обозначающий Ценные Бумаги (Securities).

VALIDA = ПОЛНОЦЕННОЕ – Valida:- strong, healthy, well developed. / крепкое, здоровое, хорошо развитое.

VALIDATE = XX (или УТВЕРЖДАТЬ) – Validate is:- to (a) declare or make legally valid; (b) mark with an indication of official sanction; or (c) to establish the soundness of; corroborate.

VALIDATED EXPORT LICENSE = ПРИЗНАННАЯ ВЫВОЗНАЯ ЛИЦЕНЗИЯ (или ДЕЙСТВИТЕЛЬНАЯ ЛИЦЕНЗИЯ НА ВЫВОЗ, или ПРИЗНАННАЯ ЭКСПОРТНАЯ ЛИЦЕНЗИЯ, или УТВЕРЖДЁННАЯ ЭКСПОРТНАЯ ЛИЦЕНЗИЯ, или ДЕЙСТВИТЕЛЬНАЯ ЭКСПОРТНАЯ ЛИЦЕНЗИЯ) – Validated Export License is a document issued by the US government; authorizes the export of controlled commodities for which written export authorization is required by law. A license issued by the Bureau of Industry and Security of the US Department of Commerce allowing the holder to export specified goods (usually commodities) during the time the license is valid. Validated Export License is a document issued by the US Government (The Bureau of Export Administration (BXA)), authorizing the export of specific commoditites to a specified foreign country within a specified time period. / Признанная Вывозная Лицензия или Утверждённая Экспортная Лицензия:- документ, который выдаётся Правительством США, разрешая тем самым вывоз (или экспорт) некоторых товаров. Такая лицензия относится к конкретной сделке или определённому периоду времени, в течение которого производится вывоз (или экспорт). Сравните с Генеральной Лицензией На Вывоз или Общей Экспортной Лицензией (General Export License).

VALIDATION = ПРИЗНАНИЕ (или УТВЕРЖДЕНИЕ, или РАТИФИКАЦИЯ) – (1) Validation is an authentication of bill of lading (B/L) and when B/L becomes effective.

(2) Validation:- as a working definition for export certification purposes, validation is the verification of authenticity of a document. Specifically related to certifying the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) and the Endangered Species Act (ESA) plants for export, validation is an original stamp, signature, and date of inspection placed on documents by PPQ (short for the Plant Protection and Quarantine) Plant Health Safeguarding Specialists (PHSS).

(3) Validation:- the class of check performed by the SWIFT system upon data transmitted to ensure that such data conform to the standards laid down in the SWIFT User Handbook and elsewhere. / Класс сверки, выполненной системой Сообщества по Всемирной Межбанковской Финансовой Дальней Связи (СВМФДС; The Society for Worldwide Interbank Financial Telecommunication (SWIFT)) по переданным данным с тем, чтобы убедиться, что такие данные соответствуют стандартам, изложенным в Пособии Пользователя СВМФДС и в других публикациях. коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо).

(4) Validation is a continuous monitoring of the process of compilation and of the results of this process. Context:- in the Statistical Data and Metadata Exchange (SDMX), Validation describes methods and processes for routinely assessing source data – including censuses, sample surveys, and administrative records – and how the results of the assessments are monitored and made available to guide statistical processes. It also describes how intermediate results are validated against other information where applicable, how statistical discrepancies in intermediate data are assessed and investigated and how statistical discrepancies and other potential indicators or problems in statistical outputs are investigated. All the controls made in terms of quality of the data to be published or already published are included in the validation process. Validation also includes the results of studies and analysis of revisions and how they are used to inform the statistical processes. In this process, two dimensions can be distinguished:- (i) validation before publication of the figures; and (ii) validation after publication. See also Statistical Data and Metadata Exchange (SDMX).

(5) Validation (of target) is the process of verifying that a selected ‘target’ (e.g., receptor, ion channel, DNA segment, etc) of pharmaceuticals functions as expected in a given disease process.

VALIDATION EDIT = XX – A Validation Edit undertakes checks which are made between fields in a particular record. This includes the checking of every field of every record to ascertain whether it contains a valid entry and the checking that entries are consistent with each other.

VALID FOR ONE DAY = ДЕЙСТВИТЕЛЬНОЕ В ТЕЧЕНИЕ ОДНОГО ДНЯ – Valid For One Day:- securities buying or selling order which is valid only on the trading day specified in the order. If the order cannot be executed as specified, it lapses automatically. The opposite of Valid Until Canceled. / Действительное В Течение Одного Дня:- распоряжение на покупку или продажу ценных бумаг, которое является действительным только в данный торговый день, указанный в данном распоряжении. Если данное распоряжение не может быть исполнено в тех рамках, которые обозначены в нём, то оно автоматически перестаёт действовать. В противовес распоряжению Действительному Пока Не Отменено (Valid Until Canceled).

VALIDITY = ДЕЙСТВИТЕЛЬНОСТЬ (или ВЕСКОСТЬ, или ЗАКОННОСТЬ) – Validity is the time period for which a letter of credit is valid. After receiving notice of a letter of opened in his behalf, the seller/exporter/beneficiary must meet all the requirements of the letter of credit within the period of validity. See also Letter Of Credit.

VALIDITY ERROR = ОШИБКА ДЕЙСТВИТЕЛЬНОСТИ (или ВЕСКАЯ ОШИБКА) – A Validity Error is an occurrence of the value of a data item which is not an element of the set of permissible codes or values assigned to that data item.

VALINE = ВАЛИН – Valine is an amino acid obtained by hydrolysis of proteins and first isolated by the German chemist Hermann Emil Louis Fischer (1852–1919; 1901) from casein. It is one of several so-called Essential Amino Acids for fowl and mammals; i.e. they cannot synthesize it and require dietary sources. It is synthesized in plants and microorganisms from pyruvic acid (a product of the breakdown of carbohydrates). Valine (val) is an amino acid considered essential for normal growth of animals. It is biosynthesized (made) from pyruvic acid. / Валин, а-аминоизовалериановая кислота, $(CH_3)_2CHCH\ (NH_2)–COOH$, одна из незаменимых аминокислот. В состав белков валин входит в виде L-изомера. Содержание валина в белке обычно колеблется от 4.1% (миоглобин лошади) до 7–8% (сывороточный альбумин человека, казеин молока), в некоторых случаях – 13–14% (эластин соединительных тканей). Отсутствие валина в пище делает её неполноценной по белку и приводит к отрицательному азотистому балансу (смотрите Азотистое Равновесие). Валин – аминокислота, полученная гидролизом белков. Впервые выделил Немецкий химик Хэман Эмиль Люи Фиша (Hermann Emil Louis Fischer (1852–1919; 1901)) из казеина. Он является одной из нескольких так называемых .

VALLEY = METEOROLOGICAL MODEL TO CALCULATE CONCENTRATIONS ON ELEVATED TERRAIN

VALLEY = ДОЛИНА – Valley:- elongate depression of the Earth's surface. Valleys are most commonly drained by rivers and may occur in a relatively flat plain or between ranges of hills or mountains. Those valleys produced by tectonic action are called Rift Valleys. Very narrow, deep valleys of similar appearance are called Gorges. Both of these latter types are commonly cut in flat-lying strata but may occur in other geological situations. Wherever sufficient rainfall occurs, opportunity exists for the land surface to evolve to the familiar patterns of hills and valleys. There are, of course, hyperarid environments where fluvial activity is minimal. There also are geomorphological settings where the permeability of rocks or sediments induce so much infiltration that water is unable to concentrate on the land surface. Moreover, some landscapes may be so young that insufficient time has elapsed for modification by fluvial action. The role of fluvial action on landscape, including long-term evolutionary processes, is considered here in detail. For additional information on fluvial and hillslope processes relating to valley formation, see River. Probably the world's deepest subaerial valley is that of the Kāli Gandak River in Nepal. Lying between two 8 000-meter (26 000-foot) Himalayan peaks, Dhaulāgiri and Annapūrna, the valley has a total relief of six kilometers (four miles). Because the Himalayas are one of the Earth's most active areas of tectonic uplift, this valley well illustrates the principle that the most rapid downcutting occurs in areas of the most rapid uplift. The reason for this seeming paradox lies in the energetics of the processes of degradation that characterize valley formation. As will be discussed below, the steeper the gradient or slope of a stream, the greater its expenditure of power on the streambed. Thus, as uplift creates higher relief and steeper slopes, rivers achieve greater power for erosion. As a consequence, the most rapid processes of relief reduction can occur in areas of most rapid relief production. Perhaps the most famous example of a canyon is the Grand Canyon of the Colorado River in northern Arizona. The Grand Canyon is about 1.6 km (1 mile) deep and 180 meters (590 feet) to 30 km (19 miles) wide and occurs along a 443-km- (275-mile-) long reach where the Colorado River incised into a broad upwarp of sedimentary rocks. Geomorphic Characteristics:- the relief of valleys and canyons is produced by the incising action of rivers. Hillslope processes are indeed critical in the development of valley sides (see below), but it is rivers that lower the level of erosion through degradation. Rivers ultimately adjust to a baselevel, defined as the lowest point at which potential energy can be transformed to the kinetic energy of river flow. In most cases, the ultimate baselevel for rivers is sea level. Some rivers drain to enclosed basins below sea level, as, for example, the Jordan River, which flows to the Dead Sea in Israel and Jordan. Moreover, rivers may adjust to local baselevels, including zones of resistance to incision, lakes, and dams (both natural and artificial). Valley Longitudinal Profiles:- the longitudinal profile of a valley is the gradient throughout its length. Valleys formed by river action typically have a concave upward profile, steep in the headwaters and gentle in the lower reaches. The lower end of such a profile is adjusted to an effective lower limit of erosion defined by the baselevel. In an ideal case of river adjustment to uniformly resistant materials, the longitudinal profile of a stream assumes a characteristic form that minimizes variations in transporting power. Power in a river derives from the rate of transfer of potential energy, dE/dt, which depends on the rate of fall in elevation of water, dy/dt, according to:- $dE / dt = m g (dy / dt)$ (1), where E is energy, t is time, m is mass, g is the acceleration of gravity, and y is elevation. The rate of fall in elevation, in turn, can be expressed as follows:- $dy / dt = (dy / dx) (dx / dt) = S V$ (2), where S is the slope (fall in elevation, dy, with downstream horizontal distance, dx) and V is the flow velocity (change in horizontal distance, dx, with time, dt). Combining equations (1) and (2) and using the fluid density ρ (mass per unit volume of water), one obtains:- $dE / dt = pg (W \cdot D \cdot L) SV$, where W is channel width, D is channel depth, L is a unit length of stream, and the other parameters are as defined above. Because flow discharge Q is defined as:- $Q = W \cdot D \cdot V$; the power per unit length of flow, Ω, can be expressed as:- $\Omega = dE / dt / L = pgQS$ (5). It should be noted that in order to minimize variation in power, a river increasing its discharge in a downstream direction must decrease its slope. Thus, slope must be constantly decreasing downstream, explaining the concave upward character of the longitudinal profile. The idealized concave upward longitudinal profile defined purely by energy considerations, noted above, only occurs where channel bed resistances and adequate adjustment time permit. Resistant zones of bedrock require greater power for a stream to incise at a given discharge Q than do less resistant zones. Therefore, by equation (5) the stream gradient S must be locally steeper at resistant zones. Similarly, a rapid base-level change, such as a fall of sea level, may not allow adequate time for the entire longitudinal profile to adjust. One indication of such effects on a longitudinal profile is a nick point, or abrupt change in slope of the profile. Valley Cross Profiles:- the cross profiles of valleys involve a combination of fluvial and hillslope processes. Although slopes and rivers are often studied separately by process geomorphologists, hills and valleys are the features that dominate landscapes. In upland areas cross profiles of valleys are often narrow and deep. Canyon morphologies are most common. Further downstream, valley floors are wider and often dominated by floodplains and terraces. Types Of Valleys:- one of the few classifications of valleys is that used by the German climatic geomorphologists Herbert Louis and Julius Büdel. In areas of rapid uplift and intense fluvial action such as tropical mountains, Kerbtal (German for 'Notched Valley') forms occur. These are characterized by steep, knife-edge ridges and valley slopes meeting in a V-shape. Where slopes are steep but a broad valley floor occurs, Sohlenkerbtal (meaning precisely a valley with such characteristics) is the prevailing form. Valleys of this kind develop under the influence of groundwater flow in Hawaii (see below Processes). Gutter-shaped valleys with convex sides and broad floors are called Kehltal; and broad, flat valleys of planation surfaces are termed Fachmuldental. It is important to remember that the form of valleys reflects not only modern processes but also ancient ones. The entire valley or some landforms within it may be relict, with features inherited from past geologic periods during which occurred tectonic and climatic processes of intensities quite different from those prevailing today. Hillslopes:- hillslopes constitute the flanks of valleys and the margins of eroding uplands. They are the major zones where rock and soil are loosened by weathering processes and then transported down gradient, often to a river channel. Two major varieties of hillslopes occur in nature (see figure). On weathering-limited slopes, transport processes are so efficient that debris is removed more quickly than it can be generated by further weathering. Such hillslopes develop a faceted or angular morphology in which an upper free face, or cliff, contributes debris to a lower slope of accumulation. Slopes of this sort are especially common on bare rock where the profile of the slope is determined by the resistance of the rock, not by the erosional processes acting on it. One consequence of this is that many rock slopes retreat parallel to themselves in order to preserve the characteristic slope angle for a rock type of given strength. If the features of the rock change with depth into the slope, however, the characteristic angle of the slope will change. Rock slopes develop where weathering and soil erosion are slow (as in arid regions) and where rock resistance is high. The second major variety of slope is transport limited. Transport-limited slopes occur where weathering processes are efficient at producing debris but where transport processes are inefficient at removing it from the slope. Such slopes lack free faces and faceted appearances, and they are generally covered with a soil mantle. The profile of this type of slope generally has a sigmoid appearance, with convex, straight, and concave segments. The shape of the slope is an expression of the process acting upon it. Convex slope segments commonly occur in the upper parts of soil-mantled slopes, as near the drainage divide. The noted American geomorphologist Grove Karl Gilbert (1843–1918) elucidated the principles applying to convex slopes in his study of piles of mining-waste debris in California. The processes of soil creep and raindrop splash erode soil on the upper parts of slopes. Since soil eroded from the upper slope must pass each point below it, the volume of soil moved increases with distance from the divide. Since the transport rate for creep and rain splash is proportional to the slope angle, the slope angle must also increase from the divide, resulting in the slope convexity. Straight slope segments are dominated by mass movement processes. Talus slopes are a type in which debris piles up to a characteristic angle of repose. When new debris is added to the slope, thereby locally increasing the angle, the slope adjusts by movement of the debris to reestablish the angle. Again, the result is a dynamic equilibrium in which the landform adjusts to processes acting upon it. Concave slopes are especially common where overland-flow runoff transports sediment derived from upper slopes. Because the collection area for wash

increases downslope and discharge Q is proportional to collection area, stream power – equation (5) – can be maintained at lower slope angles. In addition, the size of particles being transported decreases downslope because of weathering and abrasion. Because the finer particles are easier to transport, slope angles can be reduced in the downslope direction. The result is a concave shape to the slope profile. Origin And Evolution:- river valleys figure prominently in the evolutionary sequence of landscape development conceived by William Morris Davis (1850–1934) (see Continental Landform:- Davis' erosion cycle theory and related concepts). Unfortunately Davis' marvelous deductive scheme of progressive landscape change with time was somewhat abused by those who employed it merely for description and classification. By the mid-XX century, the focus of geomorphological research shifted from evolutionary sequences to studies of processes. Today, new procedures for radiometric dating have rekindled interest in long-term landscape evolution. Valley development with time can be conceived of as a functional relationship, as follows:- v = f (c, r, l, p, t), where v is the valley morphology, c is the climate, r is relief factors including slope, l is lithology and rock structure, p is the type of process operating (surface runoff or spring sapping), and t is time. Valley morphology can be described in numerous ways. A useful measure is drainage density Dd, which relates the length of valleys (or streams) L to the area A in which they occur:- Dd = Σ L / A. In many applications, A is defined as the drainage area in which a network of valleys is developed. There is a close relationship of drainage density to hillslope angles and local relief. For a given relief, higher drainage density results in short, steep valley-side slopes. For the same relief, a lower drainage density results in long, gentle slopes. Processes:- Runoff Processes:- when rain falls on a land surface, part of it may infiltrate, depending on the rate of rainfall and the permeability of the substrate. The amount of rainfall that exceeds the infiltration capacity collects in pools and eventually flows over the land surface. This process of overland flow is quite inefficient because a large surface area greatly resists water movement. Depending on the substrate resistance and power of the flow, the tendency is to incise to form a channel. This transition from overland flow to channel flow is the first step toward a response to rainfall input. Eventually the dissection by channels leads to the differentiation of hills from valleys. Not all the rainfall is transformed to overland flow and infiltration to groundwater. A portion is lost to evaporation and to transpiration by plants. What eventually flows off the landscape from surface and subsurface sources is the runoff R given by:- R = P – ET ± S, where P is the precipitation and ET is the combination of evaporation and transpiration; S is a storage term for water held in plants, soils, and subsurface rocks. The overland flow component of runoff appears very quickly after storms, while the subsurface flow components appear much more slowly. In channels, all forms of runoff generate increased stream power because of increased discharge. This allows streams to incise, thereby deepening valleys, which may widen through hillslope processes. Sapping:- sapping is a process of hillslope or scarp recession by the undermining of an overlying resistant material in the form of weathering or water flow occurring in an underlying less-resistant material. A variation of this process, spring sapping, occurs where groundwater outflow undermines slopes and, where appropriately concentrated, contributes to the development of valleys. The action of groundwater in sapping may be concentrated at valley heads, leading to headward growth. Both enhanced weathering and direct erosion by the concentrated fluid flow lead to slope undermining and collapse at sites of groundwater outflow. A conceptual model of valley development by sapping can be envisioned with the initial condition of a water table having a regional slope toward a hydraulic sink provided by a depressed region. Water emerging along a spring line would then foster chemical weathering and thereby increase the porosity of the seepage zone, reducing the local rock tensile strength and rendering the weathering zone more susceptible to erosional undercutting of adjacent slopes. Local zones of heterogeneity in the rock will result in some zones achieving the critical conditions necessary for such undermining before other zones achieve them. Joints, faults, and folds serve this function. These critical zones then experience enhanced undermining. Once initiated, this process becomes self-enhancing because the lines of groundwater flow converge on the spring head. The increased flow accelerates chemical weathering, which leads to further piping at the same site. The farther a spring head retreats, the greater the flow convergence that it generates, thereby increasing the rate of headward erosion. Headward sapping proceeds faster than valley widening because the valley head is the site of greatest flow convergence. Headward growth, however, may intersect other zones that are highly susceptible to sapping. A particularly favorable zone will result in a tributary that also experiences headward growth and that may generate tributaries of its own. Thus, sapping that occurs in a zone of jointing or faulting will develop a pattern aligned with those structures. It will, however, be organized by the hydraulic controls on the groundwater flow. This process of sapping, headward retreat, and branching eventually forms a network of valleys. The developing network works to counteract the self-enhancing effect of flow concentration mentioned above. As spring heads migrate to the neighbourhood of one another, their demands for the available groundwater compete with each other. Eventually an equilibrium is achieved at some optimum drainage density. Excellent examples of valleys formed by sapping are found in the massive sandstone terrains of the Colorado Plateau. Groundwater seepage from the sandstone contributes to local disintegration of the bedrock at the bases of cliffs, thereby undermining slopes and leading to backwearing. Because of structural concentration of water flow along joints and faults, valleys grow headward along zones of structural weakness. Canyons formed by sapping have prominent structural control vertical to overhanging walls, flat floors, elongate shape, low drainage density (leaving undissected uplands), relatively short tributaries to main trunk valleys, irregular variation in valley width as a function of valley length, and theatre-like valley heads. Many of the sapping valleys of the Colorado Plateau are probably relict features, since lowered water tables and/or desiccating climatic conditions have in all likelihood resulted in reduced groundwater flow to the valley floors today. During wetter climatic episodes of the Quaternary (from about 2 000 000 years ago to the present), which probably coincided with periods of mountain glaciation, spring sapping activity would have been more pronounced. Under modern climatic conditions, the results of past spring-sapping processes are obscured by the modifying action of non-sapping morphogenetic processes. Valley Evolution In Hawaii:- the Hawaiian Islands comprise a chain of volcanic islands, with ages increasing progressively to the northwest from the island of Hawaii with its active volcanoes, Kilauea and Mauna Loa. In general, the dissection of the Hawaiian volcanoes also increases with age to the northwest, but the details of dissection are considerably influenced by climate, factors related to parent material, and changes in process. Nevertheless, a remarkable opportunity to study valley development with time is afforded by the phenomenon of the northwesterly movement of the Pacific Plate carrying a succession of volcanoes away from a stationary mantle plume (rising jet of partially molten rock material) located at the southern tip of Hawaii. Rainfall is heaviest on the northeastern slopes of the volcanoes because of the prevailing trade winds. Although this results in generally higher drainage densities on the windward rather than leeward slopes of islands such as Hawaii, there are important exceptions. Mauna Loa, for example, lacks dissection on its northeastern flanks in spite of having the same amount of rainfall as highly dissected parts of Mauna Kea. Such is the case because the basaltic lava flows of the volcanoes are so permeable that drainage will not develop until a less permeable ash mantle is emplaced or until weathering reduces infiltration. Examples of both phenomena occur in Hawaii. Kilauea Volcano, the youngest of the Hawaiian shields, displays essentially no dissection except where ash from the 1790 Keanakakoi eruption was emplaced. The older Mauna Loa and Mauna Kea shields display V-shaped ravines only where their flanks were mantled by Pahala ash. Dissection is more pronounced on Mauna Kea, which is older than Mauna Loa. Kohala Volcano is the oldest shield on the island of Hawaii, having formed about 700 000 years ago. Deep weathering of its basalt has reduced infiltration sufficiently to promote high-density drainage on its northeastern slopes. Valley initiation on the Hawaiian volcanoes thus depends on rainfall and infiltration capacity. When runoff valleys are initiated, their streams incise to form V-shaped ravines. The ravine systems eventually become deep enough that they expose deeper layers where groundwater activity and spring sapping become more important. The deepest incision produces U-shaped, theatre-headed valleys. Because the layered basalt flows are most permeable parallel to dip, there is efficient groundwater movement toward the sea. The regional water

table on the islands is near sea level, with a slight bulge in the central parts of the islands that have a gentle seaward slope in all directions. The U-shaped sapping valleys of the older Hawaiian volcanoes display enhanced weathering at the water table. This undermines the side slopes of the valleys, so that their steep-sided walls meet their floors at a sharp angle. The valleys widened laterally as they were developed by headward growth of springs at the valley heads. Perennial flow was maintained by large springs. Channels And Valleys On Mars:- at least one other planetary body in the solar system besides the Earth is dissected by valleys of fluvial origin – namely, Mars. The heavily cratered terrains of Mars are extensively dissected by interconnected, digitate networks of valleys. Many of the valleys are steep-walled and have theatre-like headward terminations, especially near the equatorial regions of the planet. Additional properties include common structural control of the networks, low drainage densities, and low junction angles with tributaries. This combination of features seems best explained by a sapping mechanism for much of the valley formation. The valleys of Mars are for the most part extremely ancient. Very large numbers of craters are superimposed on the valleys, indicating that they formed about the time of the phase of heavy bombardment early in the history of the solar system. Another variety of valley on Mars occurs at fairly high latitudes where temperatures are colder. These valleys have rounded, subdued wall topography, and their floors are covered with debris that appears to have been produced from the walls and flowed across the floors. Masses of similar debris surround isolated massifs. It is probable that subsurface ice facilitated the production and flowage of the debris in a manner similar to what is observed in the Earth's periglacial regions. Influence Of Structure:- the role of structure in drainage development may be passive, in which case the composition of rocks and various rock discontinuities (joints, faults, and bedding) dictate the details of erosion. In this way, structure provides the boundary conditions for landscape degradation. During tectonism, such as faulting and folding, structural controls change with time, and the erosional system must adjust to changing resistances. Different structural controls also are encountered as incision of streams exposes lower units in the Earth's crust. Over the years, Russian and eastern European investigators have emphasized structural control in geomorphic analysis. Innokentiy Petrovich Gerasimov (1918–1992) defined structural units of the landscape called Morphostructures as terrain types generated by a combination of tectonic activity and climate. Various morphostructures are produced by alternating periods of uplift (with resulting dissection) and stabilization (yielding planation surfaces). The history of a morphostructure and regional tectonism can be studied by analyses of river terraces, planation surfaces, and correlative sedimentary deposits. Drainage Patterns:- the pattern of fluvial dissection of a landscape is of considerable importance in understanding the structural influence on drainage evolution. Dendritic patterns (see Figure), so called because of their similarity to branching organic forms, are most common where rocks or sediments are flat-lying and preferential zones of structural weakness are minimal. The conveyance properties of a dendritic network are analogous to blood circulation systems and tree branching. Rectangular and angular patterns occur where faults, joints, and other linear structures introduce a grain to drainage. Where a broad tilt or regional slope occurs on a surface of otherwise uniform resistance, a parallel pattern occurs. Special drainage patterns characterize belts of parallel folds (trellis pattern), domes or volcanoes (radial pattern), and other landscape types. In a series of tilted sediments the differential erosion of softer units, such as clay and shale, results in valleys developed perpendicular to the dip or tilt of the units. These strike valleys are paralleled by ridges of the tilted sediments called Cuestas. Another term for a strike stream, which parallels the structural grain, is a longitudinal stream. In contrast, transverse streams cut across structural trends. Streams flowing down the tilted sediments of the cuesta are called Dip Streams because they parallel the structural dip of the strata. Streams draining the cuesta scarp into longitudinal valleys flowing opposite to the structural dip are called Antidip Streams. Cross-Axial Drainage:- one of the most interesting anomalies that occurs in drainage evolution is the development of stream courses across the axes of structural zones (e.g., upwarps and fold belts). Some examples of cross-axial, or discordant, drainage include rivers that appear to take the most difficult routes possible through folded regions such as the Appalachian Mountains of the United States and the Zagros Mountains of Iran. The classical studies of cross-axial drainage were made during the exploration of the Colorado River system in the XIX century by the American geologist John Wesley Powell (1834–1902). The Colorado River and its tributaries cross great structural upwarps. Rather than flowing around domes or plunging folds, the rivers carved canyons into what appears to be paths of greatest resistance. One theory posed by Powell for such relationships is that of antecedence. According to this view, the rivers were already in their present positions when the various anticlinal folds and upwarps began to grow. A relevant analogy is a saw into which a log is being pushed. The saw represents the river and its continuing degradation, and the log represents the growing upwarp. Another possible origin of cross-axial drainage is superimposition. According to this theory, a cover of sedimentary material must bury older structures. The river develops on this overlying sedimentary cover and subsequently imposes its pattern across the underlying structures as they are exposed by continuing degradation. A third explanation for cross-axial drainage is that of inheritance. In this hypothesis, an erosion surface is developed across the structure zone by long-continued planation. When the streams incise, abandoning the former planation surface, they become imposed across the structures. Alternatively, the stream may actually exploit zones of weakness or minimal resistance as it downcuts from former levels. Stream Capture (also called Stream Piracy) occurs as more aggressively eroding portions of the drainage cut through divides. In many cases, a complex combination of the above processes probably occurs to yield the final result. Stream capture is especially common where longitudinal streams flowing on the weaker rocks of a fold belt erode into the valleys of transverse streams that must cross the resistant strata. Sections of valley abandoned after such captures are known as wind gaps. These contrast with the water gaps that still contain transverse streams. The famous water gaps of the Appalachians are excellent examples of such patterns. Influence Of Climate:- the importance of climate in landscape evolution, particularly valley development, has been emphasized by many European geomorphologists. Jean Tricart and André Cailleux of France and Julius Büdel of Germany developed climatic geomorphology as a synthesis of relief-forming processes. Climatic geomorphologists define systematic morphoclimatic zones on the globe in which relief-forming mechanisms differ as a function of climate. Some of the important morphoclimatic zones are briefly outlined in the following sections. Periglacial Zone:- the term periglacial relates to cold-climate processes and landforms (see Glacial Landform:- Periglacial landforms). The most important periglacial influence on valleys is frost action, which produces abundant debris by freeze-thaw action on rock and soil. During the coldest periods of the Quaternary (the last 1 600 000 years), the periglacial zone was enlarged to approximately twice its present extent. Hillslopes became mantled with frost-shattered rubble that moved downslope during cycles of freezing and thawing. The relicts of this periglacial activity characterize much of the modern humid-temperate zone – e.g., in portions of Pennsylvania and Wisconsin in the United States and England and Poland. Arid Zone:- in arid regions moisture conditions are inadequate to support abundant vegetative cover of the land surface. As a result, the land is subjected to intense fluvial, eolian, and mass-wasting processes. The importance of fluvial action may seem ironic for an arid region. Although most arid regions receive little rainfall, the amount that falls is especially effective. Rare but intense arid-region rainstorms act upon a landscape that is unprotected by vegetation. Of course, some hyperarid regions receive such infrequent rainfall that fluvial processes are indeed ineffective. Nevertheless, even the most arid places on Earth show evidence of fluvial activity, either because of wetter conditions in the past or because of very rare rainstorms. Tropical Zone:- tropical regions are dominated by dense vegetative cover and deep weathering profiles. In continuously humid tropical zones, fluvial activity is facilitated by intense rainfall but inhibited by the protective effect of rainforests. The lateritic soils of these regions, however, do not promote deep root penetration, and the vegetative cover may be undermined by fluvial erosion or mass movement. Fluvial activity may be quite intense in the tropics, especially in tectonically active areas. In more stable cratons, however, the landscape is dominated by low-relief planation surfaces. Rivers flowing on the deeply weathered regolith of these surfaces have low stream power and transport mainly fine-grained weathering

products. Thus, immense contrasts in fluvial activity exist in the tropics. At higher tropical latitudes, the continuously humid zone of the Equator changes to a zone of seasonal rainfall. Such regions have savanna vegetation because of prolonged dry seasons. Erosion rates may be extremely high in savanna environments. Role Of Climatic Change:- because the Earth's climate has changed profoundly during the Quaternary and Tertiary (roughly the past 65 000 000 years), many landscapes are palimpsests – i.e., they are composed of relict elements produced under the influence of past climates and modern elements produced in the present climatic regime. The study of such landscape changes is sometimes called Climato-Genetic Geomorphology. Some researchers in the field, notably Büdel, have maintained that little of the extant relief in humid temperate regions of the Earth results from modern relief-forming processes. Rather, they believe, much of the familiar humid temperate landscape is inherited from past climatic conditions, including periglacial, arid, and tropical. Büdel focused attention on differences in the nature of valley formation as a function of climate through the history of a landscape. He argued that very rapid valley formation accompanied periods of periglacial activity in central Europe. Modern rivers in the region seem less effective at valley incision. Most of them flow on fills within great bedrock valleys, indicating that aggradation rather than downcutting is occurring today. Prior to the Quaternary phase of valley cutting, central Europe in the Tertiary seems to have experienced a prolonged period of planation, resulting in low-relief plains. Büdel proposed that the remnants of these Tertiary plains, now preserved as broad planar uplands, are inherited from a time of tropical planation. Remnants of a former tropical regolith on the uplands provide some evidence for this hypothesis. Paleovalleys:- the southwestern desert of Egypt is one of the most arid places on Earth. The region lacks surficial traces of active fluvial processes and is dominated by eolian activity. In this region, a research team headed by Dr. John ('Jack') F. McCauley (1932–2012) of the US Geological Survey discovered in 1982 that the local drift sand had buried an array of valleys and other relict fluvial features. The discovery was made possible by the imaging radar system of the US Space Shuttle, which penetrated several meters of the extremely dry sand to reveal the previously unknown valleys. The relict valleys were probably part of Late-Tertiary river systems that drained the eastern Sahara during relatively wet climatic conditions prior to the onset of hyperaridity in the Quaternary. A very important American paleovalley involves the complex history of the Ohio River. Prior to the glacial phases of the Quaternary, the preglacial predecessor of the Ohio drained northwestward from the Appalachians across the Midwest, but far north of its present course. Numerous water wells in Ohio, Indiana, and Illinois are located along this paleovalley, which is called the Teays River System. The advances of Quaternary ice over the course of the Teays River eventually caused the drainage to shift from the Teays route to one roughly paralleling the glacial boundary. The modern Ohio River is the product of this heritage. Misfit Streams:- another manifestation of the impact of climatic change is the misfit stream. Such streams are those for which some practical measure of size, most often the meander wavelength, indicates that the modern river is either too large or too small for the valley in which it flows. The former condition, known as an Overfit Stream, is relatively rare. An example, described below, occurs where cataclysmic glacial floods invaded valley systems formed by overland flow processes in a non-glacial climatic regime. The more common case is the underfit stream, in which valley morphology indicates a larger ancient stream (see Figure). The English-born geomorphologist George H. Dury (1919–1996) developed a theory for the widespread phenomenon of stream underfitness. He believed that, when the larger valley forms developed, climatic change was required to reduce the channel-forming discharges from past highs to the modern shrunken channel dimensions. Dury argued that the last phase of stream shrinkage occurred at the end of the last glaciation when the global climate changed from cool and moist to warm and dry. He quantified his theory, utilizing the relationship between the wavelength of modern meandering rivers (λ) and their bank-full discharge (q_b):- $\lambda = 54.3\ q_b^{0.5}$, where the units of λ and q_b are meters and cubic meters per second, respectively. Using equation (9), Dury found that since valley meanders were 5 to 10 times larger than modern river meanders, the ancient bank-full discharges must have been 25 to 100 times larger than the modern values. Such large modifications implied a phenomenal climatic change that was not accepted by the general scientific community. Numerous other factors besides climatic change play a role in the development of underfitness. These include changes in the type and amount of sediment transported by streams, the role of different rock types in shaping valley dimensions, and the role of large, rare floods (as opposed to bank-full discharge) in defining channel dimensions. The problem of underfitness remains a challenge awaiting complete geomorphological explanation. Probably the most remarkable example of a misfitness is the channeling of the basaltic plain of eastern Washington in the northwestern United States by cataclysmic glacial floods. The great floods emanated from glacial Lake Missoula, which was impounded between about 17 000 and 12 000 years ago by a lobe of the Cordilleran ice sheet that extended into Northern Idaho. Failure of this ice dam released a lake volume of about 2 500 cubic kilometers at discharges of up to $2 \cdot 10^7$ cubic meters per second. These immense flows completely overwhelmed the preglacial stream valleys of the Columbia Plain in eastern Washington. As the floods eroded loess and bedrock from former valley divides, a great plexus of scoured channel ways known collectively as the Channeled Scabland was formed. Because preglacial valleys were filled to overspilling, this process is really an example of stream overfitness. Numerous diagnostic landforms, including great cataracts, characterize the Channeled Scabland. The above relationships were first described in the 1920s by the American geologist J Harlen Bretz (1882–1981), who contended that the Channeled Scabland could only be explained by the action of cataclysmic flooding. He encountered vehement opposition to this hypothesis but was eventually able to convince most of his critics of its validity by carefully documenting the overwhelming evidence for flood-produced landforms. Of considerable importance was the discovery of giant current ripples composed predominantly of gravel. More than five meters (16 feet) high and spaced 100 meters (328 feet) apart, these current ripples occurred on large bars of gravel and boulders. The Channels Of Mars:- the landforms produced by large-scale fluid flow in the Channeled Scabland are remarkably similar to those in the channeled terrains of Mars. In contrast to the Martian valley networks (see above), the channels of the planet display evidence of large-scale fluid flows on their floors. Most Martian channels show that the erosive fluid emanated from zones of complex terrain. Apparently the fluid was derived from subsurface reservoirs, and the overlying materials collapsed as fluid was released. The channels, unlike the valley networks, probably formed over a considerable span of Martian history. The fluid for carving the channels was most likely water, perhaps with substantial amounts of entrained ice and sediment. Ground ice in Martian permafrost may have provided a source for the immense ancient floods. / Немецкие климатические геоморфологи Хэбэт Люис (Herbert Louis) и Юлиус Бюдэль (Julius Büdel). Кебталь (Kerbtal (по-Немецки для 'Notched Valley')). Золенкебталь (Sohlenkerbtal). Фахмульдэнталь (Fachmuldental). Американский геоморфолог Гроув Кал Гилбёрт (Grove Karl Gilbert; 1843–1918). Вилъйэмом Морисом Дэйвисом (William Morris Davis; 1850–1934)). Американский геолог Дьжон Вэсли Павэл (John Wesley Powell; 1834 – 1902). Доктор Дьжон ('Дьжак') Эф. МэКолы (Dr. John ('Jack') F. McCauley (1932–2012)). Родившийся в Англии геоморфолог Дьжодьж Эйч. Дурай (George H. Dury; 1919–1996)). Американский геолог Дьжей. Харлен Брэц (J Harlen Bretz; 1882–1981). Долины, отрицательные, линейно вытянутые формы рельефа, имеющие по тальвегу однообразное, хотя часто неравномерное падение; образуются в результате эрозионной (размывающей) деятельности текучей воды. Зачаточными формами речных долин являются балки, овраги, создаваемые непостоянными (периодическими) водотоками. Долины обычно образуют целые системы; одна долина открывается в другую, эта, в свою очередь, в третью и так далее, пока их сливающиеся водотоки одним общим руслом не впадут в какой-либо бассейн. У долин различают склоны (или борта) и дно. У молодых долин дно бывает неразвито, а склоны подходят к самой реке, являясь одновременно берегами текущей в ней реки. Склоны долин, сложенные коренными породами, могут быть высокими или низкими, крутыми или пологими, в профиле – вогнутыми, прямыми, выпуклыми или ступенчатыми (осложнёнными террасами). По крутизне и форме профиля оба склона долины бывают либо одинаковыми, либо различными (асимметричные долины). У асимметричных долин Северного Полушария более крутым бывает преимущественно правый, а в

Южном Полушарии – левый склон. В более развитых долинах в результате горизонтального блуждания реки (смотрите Излучины) вырабатывается плоское дно, выстланное речными отложениями (аллювием). В этом случае склон долины уже не является берегом реки. Поперечный профиль долины, в зависимости от стадии развития, геологического строения местности, сочетания экзогенных факторов и других, может иметь форму каньона, теснины, V⁻ образную, U⁻ образную, трапеце-, корытообразную и другие. Долинами называются тектоническими, если заложение их предопределено наличием отрицательных геологических структур, выраженных в рельефе (грабены, синклинальные прогибы и другие). Таковы:- Алайская Долина в Средней Азии, Калифорнийская Долина в Северной Америке. С этими долинами не следует смешивать эрозионные долины в областях нарушенного (складчатого или наклонного) залегания осадочных толщ, где размыв отпрепарировал ранее существовавший грабен, синклинальную складку и тому подобное. По отношению к простиранию структур и хребтов различают продольные долины, совпадающие с направлением простирания пластов, и поперечные долины, перпендикулярные к осям складок; реже встречаются диагональные долины. Продольные долины, в свою очередь, бывают синклинальные, моноклинальные и антиклинальные, в зависимости от того, заложились ли они вдоль оси синклинали, в крыле складки или вдоль антиклинального свода. Моноклинальные долины часто асимметричны в поперечном профиле:- крутой склон расположен в направлении падения пластов. Продольные долины шире и мало изменяются морфологически на значительных протяжениях. Поперечные долины, наоборот, часто изменяют свой характер на коротких расстояниях, представляя чередование узких ущелий и котловинообразных расширений (‘чётковидные долины’). Долины, прорезающие горную цепь вкрест простирания, называются сквозными долинами, или долинами прорыва. Они могут образоваться путём заложения в иных, ранее существовавших геоморфологических условиях, на поверхности, располагавшейся выше современных хребтов, которые они теперь пересекают, в породах иного состава и иной тектонической структуры (эпигенетические долины). Сквозные антецедентные долины образуются в результате пропиливания молодого хребта, начавшего подниматься поперёк долины уже существовавшей реки, а также в процессе перехвата верховьев других реки (смотрите Перехват Реки), текущей вдоль противоположного склона хребта. По морфологии резко различаются долины горные и равнинные. Первые характеризуются значительной глубиной при относительно небольшой ширине и неравномерным падением продольного профиля. Вторые, как правило, широки, имеют незначительную глубину и крутизну склонов, небольшие уклоны и тому подобное. В своём верховье долины чаще всего заканчивается водосборной воронкой или ледниковым цирком. Реже встречаются долины с открытыми верховьями, когда склон, замыкающий верховья, отсутствует. Устьевая часть долин часто сопровождается дельтой или конусом выноса либо представляет залив бассейна, куда впадает река, в виде губы или эстуария. Долины крупных рек представляют своеобразный ландшафт, резко отличающийся от междуречных пространств. Поймы равнинных рек служат хорошими сенокосными угодьями; в безопасных от эрозии местах распахиваются, террасы также используются под посев всевозможных сельскохозяйственных культур, часто служат местом расположения населённых пунктов (особенно в горных странах); склоны долин нередко бывают покрыты лесом. Геоморфологический анализ долин помогает выяснять новейшую геологическую историю развития района, выявлять россыпные месторождения полезных ископаемых, а также делать правильные выводы при проектировании гидротехнических сооружений ГЭС и оросительных каналов.

VALORIZATION = ВАЛОРИЗАЦИЯ (или РЕВАЛЬВАЦИЯ) – Valorization is:- (i) a stabilizing or fixing of prices, usually by government action; or (ii) a conferring of value upon something. Alternative spelling of Valorisation. The principle of valorization is generally conceded to be economically unsound, because it encourages overproduction. In Marxism, the Valorisation or Valorization of capital is the increase in the value of capital assets through the application of value-forming labor in production. The German original term is Verwertung (specifically Kapitalverwertung) but this is difficult to translate, and often wrongly rendered as ‘realisation of capital’, ‘creation of surplus-value’ or ‘self-expansion of capital’ or ‘increase in value’. In German, the general meaning of Verwertung is the productive use of a resource, and more specifically the use or application of something (an object, process or activity) so that it makes money, or generates value, with the connotation that the thing validates itself and proves its worth when it results in earnings, a yield. Thus, something is ‘valorised’ if it has yielded its value (which could be use-value or exchange-value). Similarly, Marx’s specific concept refers both to the process whereby a capital value is conferred or bestowed on something, and to the increase in the value of a capital asset, within the sphere of production. In modern translations of Marx’s economic writings, such as the Penguin edition of Capital and the English Marx-Engels Collected Works, the term Valorisation (as in French) is preferred because it is recognized that it denotes a highly specific economic concept, i.e. a term with a technical meaning. Marx first refers the concept of valorization in chapter 4 of Capital Vol. 1, when he discusses the capitalist activity of buying commodities in order to sell them, and realize more value than existed before. Marx writes:- This increment or excess over the original value I call ‘surplus-value’. The value originally advanced, therefore, not only remains intact while in circulation, but increases its magnitude, adds to itself a surplus-value, or is valorized. And this movement converts it into capital. The question then arises of how net new value can continuously and spontaneously emerge from trading activity. Marx’s answer is that net additional value can be realized in trading, because that additional value is already created previously in the production process. If a capitalist buys commodities for USD100 and sells them for USD120 then he has certainly made money, but he hasn’t truly created more value than existed before, since the quantity of commodities is still exactly what it was before. To create more value requires extra production. At that point, the concept of valorization is modified. The capitalist production process, Marx argues, is both a labor process creating use-values and a value-creation process through which additional new value is created. However, value creation as such is not what the capitalist aims at. The capitalist wants his capital to increase. This means that the worker must create more value for the capitalist than he receives as wage from the capitalist. The worker must create not only new value but surplus value. A value creation process which goes beyond the point at which the worker has just created the equivalent of the value of his own labor power, and begins to increase the value of capital, is a valorisation process, not just a value creation process. Valorisation thus specifically describes the increase in the value of capital assets through the application of living, value-forming labor in production. The ‘problem’ of valorisation is:- how can labor be applied in production so that capital value grows? How can assets be invested productively, so that they gain value rather than lose it? In Theories of Surplus Value, chapter 3 section 6, Marx emphasizes his view that ‘Capital is productive of value only as a relation, in so far as it is a coercive force on wage-labor, compelling it to perform surplus-labor, or spurring on the productive power of labor to produce relative surplus-value’. The Mysteries Of Capital’s Growth:- When a worker is put to work on a commercial basis, he initially produces a value equal to what it costs to hire him. But once this value has been created, and the work continues, he begins to valorise capital, i.e. increase its value. Thus, normally a worker works part of the day ‘for himself’ in the sense of producing the equivalent of his wage, and part of the day for the employer of his labor. On average, statistical information suggests the ratio is about 50/50, but it can be more or less. Valorisation And Management Theory:- By contrast, in management theory, analysts are extremely aware of value adding activities occurring when factors of production are withdrawn from the market in order to produce new outputs with them. That is because they aim to maximize productivity, i.e. get as much work and product out of the workers as efficiently as possible. Yet, because perceptions of value growth are based on the relationship between input costs and sales revenue, revealed by accounts, the central role of living labor in conserving, transferring and creating value is still obscured. The official story is that the factors of production all add value to the new output. In a sense this is true, since living labour conserves and transfers value from materials and equipment to the new product; and capitalist production could not

occur if capitalists did not supply capital in return for profit. But without the active human subject, no new value is created at all, and capital assets lose value. This becomes apparent when workers go on strike. Devalorisation:- The opposite process is devalorisation ('Entwertung') which refers to the process whereby production capital invested loses part or all of its value, because the labour maintaining the value of capital is withdrawn, or because output cannot be sold, or sold at the intended price, or because more modern production techniques devalue older equipment. Over time capitalist assertion of valorisation can be seen to always depreciate over extended periods of time. Marx describes the effect as 'tendency for the profit rate to fall'. Revitalised by the likes of Kliman (2010, cited in Giacché 2011) and Perri (2010, cited in Giacché 2011), whom in compliance with Marx's theory believe that although valorisation is the driving force of capitalisation, it also contributes to an impending downfall. However, due to excessive supply requirements and ever increasing demand from the global markets, industrial collapses tend to operate in favor for the emergence of new independent capitals. Typically what happens in a severe economic crisis is that the real cost structure of production is realigned with market prices. In Marx's terms, productivity growth has changed product-values in different sectors, but it is only after quite some time that prices adjust to changed underlying values. In that case, devalorisation may occur quite rapidly: capital assets are suddenly worth less, and as soon as capital assets are no longer utilised and maintained by living human labour (because of unemployment), the value of those capital assets begins to deteriorate. In the end, the total withdrawal of human labour leaves nothing but a ghost town. Devalorisation is not the same as devaluation of capital, because the term 'Devalorisation' applies specifically only to assets which function as production capital, whereas 'devaluation' of capital could refer to the loss in value of any capital asset in any particular form. Devalorization means specifically that means of production lose value because the living labour required to maintain them is withdrawn. Valorisation And The Realisation Of Capital:- Valorisation of capital is for Marx not at all the same as the 'realisation of capital'. Value may be added in the production process, but this additional value may not be realised as an additional sum of money, unless the outputs are sold at a favourable price. At an unfavourable price, output is sold without increasing capital assets. So, the new value added in production may be lost to the producer or owner, when the new product is traded. The capital is 'valorized' because a new output value has been created, but the value-increase is not (fully) realized by its owner. In reality, Marx argues, the valorisation of capital in one enterprise is dependent on the valorisation of many related enterprises, since they all influence each other with respect to costs, values and prices. When all is said, the preservation and increase of capital value is a purely social phenomenon. Rate Of Valorisation:- In Capital Vol. 3 (Penguin ed., p. 136) Marx defines the Rate Of Valorisation as S/C where 'S' is the surplus value produced and 'C' is the total capital invested to produce it. This is strictly a value ratio, a relationship between value proportions, not to be confused with the rate of profit on capital invested, since the amount of surplus value yielded by a capital investment, corresponding to a certain quantity of labour-time expended in production, typically diverges from that part of the surplus value which is realized as profit, since at any time products are likely to be traded above or below their value, rather than at prices which exactly reflect their value (Marx often assumes for the purpose of his analysis that the total mass of profit and the total surplus-value are the same magnitude, although in reality they can vary from each other, due to continual changes in labour productivity across time, imperfect pricing, and imperfect competition). The Conflict Between Physical Output Growth And Valorisation:- In Capital Vol. 3, chapter 15, section 2 (Penguin ed., p. 355f) Marx discusses how conflicts arise between expanding physical output and the valorization of capital. From the point of view of capital, increased productivity means both increase in the scale of production and a reduction of labor-costs as a fraction of the total capital invested. From the point of view of labour, increased productivity means both an increase in surplus labor and an increase in the amount of capital used per worker. Marx then explains that these four variables can come into conflict with each other, creating disturbances in the growth process of capital:- 'Simultaneously with impulses towards a genuine increase in the working population, which stem from the increase in the portion of the total social product that functions as capital, we have those agencies that create a relative surplus population. Simultaneously with the fall in the profit rate, the mass of capital grows, and this is associated with a devaluation of the existing capital, which puts a stop to this fall and gives an accelerating impulse to the accumulation of capital value. Simultaneously with the development of productivity, the composition of capital becomes higher, there is a relative decline in the variable portion as against the constant. These various influences sometimes tend to exhibit themselves side by side, spatially; at other times one after the other, temporally; and at certain points the conflict of contending agencies breaks through in crises. Crises are never more than momentary, violent solutions for the existing contradictions, violent eruptions that re-establish the disturbed balance for the time being. To express this contradiction in the most general terms, it consists in the fact that the capitalist mode of production tends towards an absolute development of the productive forces irrespective of value and the surplus value this contains, and even irrespective of the social relations within which capitalist production takes place; while on the other hand its purpose is to maintain the existing capital value and to valorize it to the utmost extent possible (i.e. an ever accelerated increase in this value). In its specific character it is directed towards using the existing capital value as a means for the greatest possible valorization of this value. The methods through which it attains this end involve a decline in the profit rate, the devaluation of the existing capital and the development of the productive forces of labor at the cost of the productive forces already produced'. (p. 357–358). / Ревальвация (Valorization):- повышение или стабилизация стоимости товара или валюты искусственным путём, как правило, при вмешательстве государства. Например, если государство намерено поднять цену вывозимого (или экспортируемого) товара, оно может попытаться сократить поставки этого товара, побуждая производителей снизить объёмы его производства, накапливая этот товар или – в экстремальных случаях – частично ликвидируя его производство. Валоризация (от Французского слова Valorisation) – повышение цены товаров, курса ценных бумаг, валюты, имеющее место в результате, вследствие мероприятий, проводимых государством, правительством. Под Ревальвацией, от Латинских слов – приставки Re..., указывающей на Противодействие или действие, Противоположное (Обратное) выраженному корнем слова, и Valeo, означающее Имею Значение или Стою, понимается официальное повышение золотого содержания денежной единицы страны или фактическое повышение её валютного курса. Одно из средств государственно-монополистического регулирования экономики капиталистических стран. По механизму воздействия на экономику ревальвация противоположна девальвации. До конца 1960-х ревальвация была сравнительно редким явлением в международной валютной практике. Это объясняется тем, что страна, осуществляющая ревальвацию своей валюты, ставит себя в менее выгодное положение в области внешней торговли, притока иностранных капиталов и международного туризма по сравнению с другими странами. Ревальвация, повышая курс валюты данной страны по отношению к валютам других стран, вызывает повышение цен вывозимых (или экспортируемых) товаров в иностранной валюте и тем самым снижает конкурентоспособность страны на мировом рынке, сдерживает вывоз (или экспорт) её товаров. Понижая выраженные в национальной валюте цены привозных (или импортных) товаров, ревальвация приводит к повышению спроса на них и увеличению привоза (или импорта), складывающиеся курсовые соотношения между ревальвированной валютой данной страны и валютами других стран делают для иностранных собственников невыгодным вложения капитала в этой стране, так как при обмене валют они получат меньшую сумму в местной валюте. И наоборот, для страны, ревальвировавшей свою валюту, становится более выгодным вывоз (или экспорт) капитала, так как возникает возможность более дешёвой покупки иностранной валюты. В области международного туризма ревальвация приводит к сокращению доходов от притока иностранных туристов, так как поездки в данную страну обходятся для них дороже, и, наоборот, стимулирует поездки за рубеж отечественных туристов, для которых иностранная валюта становится дешевле. Правительства капиталистических стран используют ревальвацию для борьбы с инфляцией. Именно как антиинфляционную

меру провели ревальвацию своих валют Федеральная Республика Германия (ФРГ) в 1969 и 1971, Нидерланды, Швейцария, Австрия и ряд других стран в 1971 и 1973. Ограничивая приток в страну иностранных и главным образом спекулятивных, блуждающих в поисках более прибыльного приложения капиталов, ревальвация позволяет в известной мере сдерживать увеличение денежной массы в обращении и на этой основе замедлять рост внутренних цен. Снижение в результате ревальвации затрат на привоз (или импорт) также ограничивает рост внутренних цен. Ревальвация осуществляется и с целью сдерживания роста активного сальдо торгового баланса. Такая ревальвация иногда проводится под нажимом других стран или международных валютно-финансовых организаций. Так, в Декабре 1971 правительство Японии под нажимом Соединённых Штатов Америки (США) ревальвировало Иену с целью выравнивания торгового баланса между двумя странами. В начале 1970-х с применением в ряде капиталистических стран ‘плавающих’, колеблющихся (отклоняющихся от установленного паритета под влиянием спроса и предложения) курсов валют некоторые капиталистические страны прибегали к фактической ревальвации своих валют в форме повышения их рыночного курса, не изменяя официально их золотого содержания. Так, введение в Феврале 1973 ‘плавающего’ курса Японской Иены означало фактическую ревальвацию Иены к Доллару США на 16.25%.

VALUABLE CARGO = ОЦЕНИВАЕМЫЙ ПО СТОИМОСТИ ГРУЗ (или ЦЕННЫЙ ГРУЗ) – Valuable Cargo is a consignment which contains one or more valuable articles (aircargo).

VALUABLES = ЦЕННОСТИ – Valuables:- goods of considerable value that are not used primarily for production or consumption but are held as stores of value over time. They consist of precious metals, precious stones, jewellery, works of art, etc. As a new category in the accounts the estimates for them are currently fairly rudimentary, though transactions are likely to have been recorded elsewhere in the accounts. Valuables are produced assets that are not used primarily for production or consumption, that are expected to appreciate or at least not to decline in real value, that do not deteriorate over time under normal conditions and that are acquired and held primarily as stores of value. Valuables are produced assets that are not used primarily for production or consumption, that are expected to appreciate or at least not to decline in real value, that do not deteriorate over time under normal conditions and that are acquired and held primarily as stores of value. These include non-monetary gold and paintings etc. Gold is valued at price not exceeding current market price. / Ценность – цена, стоимость, например, картина большой ценности. Ценность, термин, широко используемый в философской и социологической литературе для указания на человеческое, социальное и культурное значение определённых явлений действительности. По существу, всё многообразие предметов человеческой деятельности, общественных отношений и включённых в их круг природных явлений может выступать в качестве ‘предметных ценностей’ или объектов ценностного отношения, то есть оцениваться в плане добра или зла, истины или неистины, красоты или безобразия, допустимого или запретного, справедливого или несправедливого и так далее; подобные оценки иногда могут быть шкалированными (отмечающими различные уровни соответствующего качества). Способы и критерии, на основании которых производятся сами процедуры оценивания соответствующих явлений, закрепляются в общественном сознании и культуре как ‘субъектные ценности’ (установки и оценки, императивы и запреты, цели и проекты, выраженные в форме нормативных представлений), выступая ориентирами деятельности человека. ‘Предметные’ и ‘субъектные’ ценности являются, таким образом, как бы двумя полюсами ценностного отношения человека к миру. В структуре человеческой деятельности ценностные аспекты взаимосвязаны с познавательными и волевыми; в самих ценностных категориях выражены ‘предельные’ ориентации знаний, интересов и предпочтений различных общественных групп и личностей. Развитие рационального познания общества, в том числе исследование природы и генезиса ценностей, воздействует на всю сферу ценностных отношений, способствуя освобождению её от метафизической абсолютизации. Отвергая идеалистические представления о внеисторической и надсоциальной природе ценностей (смотрите Теория Ценностей), Марксизм подчёркивает общественно-практическую сущность, историчность и познаваемость ценностей, идеалов, норм человеческой жизни. Каждая исторически конкретная общественная форма может характеризоваться специфическим набором и иерархией ценностей, система которых выступает в качестве наиболее высокого уровня социальной регуляции. В ней зафиксированы те критерии социально признанного (данным обществом и социальной группой), на основе которых развёртываются более конкретные и специализированные системы нормативного контроля, соответствующие общественные институты и сами целенаправленные действия людей – как индивидуальные, так и коллективные. Усвоение этих критериев на уровне структуры личности (интернализация ценностей) составляет необходимую основу формирования личности и поддержания нормативного порядка в обществе. Интеграция, внутренняя противоречивость и динамизм общественных систем находят своё выражение в структуре соответствующих им ценностных систем и способах их воздействия на различные общественные группы. Важный элемент ценностных отношений в обществе – системы ценностных ориентаций личности, представляющих собой устойчивые, не полностью осознаваемые отношения человека к различным элементам общественной структуры и самим ценностям; субъективно окрашенные оценки не совпадают непосредственно с общественно значимыми характеристиками соответствующих ценностей. Эмпирическое изучение ценностных ориентаций занимает существенное место в социологических исследованиях воспитания, профессионального выбора, общественной и трудовой активности и других проблем. Ценностные системы формируются и трансформируются в историческом развитии общества; поскольку эти процессы связаны с изменениями в различных сферах человеческой жизни, их временные масштабы не совпадают с масштабами социально-экономических, политических и других изменений. Так, эстетические ценности античности сохранили своё значение и после гибели породившей их цивилизации, известна длительность воздействия гуманистических и демократических идеалов, Европейского Просвещения, истоки которых берут начало в античных и эллинистических культурах. Воззрения на историю общества как реализацию системы ‘вечных ценностей’ или как последовательную смену одного типа ценностей другим (например, трансцендентно ориентированных – светскими, а безусловных – конвенциональными) равно неприемлемы для материалистического понимания истории. В то же время конкретно-исторический анализ генезиса и развития ценностных систем составляет важную сторону всякого научного исследования истории общества и культуры.

VALUATION = ОЦЕНКА (или ОЦЕНКА СТОИМОСТИ, или СТОИМОСТНАЯ ОЦЕНКА, или ИСЧИСЛЕНИЕ) – Valuation is the process of determining how much an asset, company, or anything else is worth. Valuation is highly subjective, but it is easiest when one is considering the current value of tangible assets. For example, determining how much a willing buyer will pay a willing seller for a house right now is easier than determining the value of what a company’s brand recognition might be in 10 years. Valuation is important in fundamental analysis, the practitioners of which usually consider a company’s earnings to be indicative of its value. Valuation is the determination of the value of a company’s stock based on earnings and the market value of assets. Valuation is the process of estimating the value, or worth, of an asset or investment. Sometimes it means determining a fixed amount, such as establishing the value of your estate after your death. Othertimes, valuation means estimating future worth. For example, fundamental stock analysts estimate the outlook for a company’s stock by looking at data such as the stock’s price-to-earnings (P/E), price-to-sales, and price-to-book (net asset value) ratios. In general, a company with a high P/E is considered overvalued, and a company with a low P/E is considered undervalued. Valuation is a process for calculating the monetary value of an asset. Valuation is subjective and results in wide disparities for the values of most assets. Valuation is:- (1) In general:- appraising or estimating the worth of something

having economic or monetary value. (2) In insurance:- determination of the worth of the asset to be insured or that which has been damaged or lost. (3) In international trade:- determination of the dutiable value of imports by the customs authorities. The GATT (now WTO) Customs Valuation Code obligates the signatory governments to use the transaction value (actual price paid by the importer to the exporter) as the principal basis for imposing duties. Where transaction value cannot be used, the secondary basis of value, such as transaction value of identical or similar merchandise, computed value, or deductive value may be used. (4) In securities:- placing a value on a stock based on the market value of the issuer's assets and the outlook for its earnings. Valuation is the act of deciding how much money something might be sold for or the amount of money decided on:- You can receive a home loan of up to 95 percent of the official valuation of the property. Valuation is the process of determining the current worth of an asset or a company; there are many techniques used to determine value. An analyst placing a value on a company looks at the company's management, the composition of its capital structure, the prospect of future earnings and market value of assets. The market value of a security is determined by what a buyer is willing to pay a seller, assuming both parties enter the transaction willingly. When a security trades on an exchange, buyers and sellers determine the market value of a stock or bond. The concept of intrinsic value, however, refers to the perceived value of a security based on future earnings or some other company attribute unrelated to the market price of a security. How Earnings Impact Valuation:- the earnings per share (EPS) formula is stated as earnings available to common shareholders divided by number of common stock shares outstanding. EPS is an indicator of company profit because the more earnings a company can generate per share, the more valuable each share is to investors. Analysts also use the price-to-earnings (P/E) ratio for stock valuation, which is calculated as market price per share divided by EPS. The P/E ratio calculates how expensive a stock price is relative to the earnings produced per share. For example, if the P/E ratio of a stock is 20 times earnings, an analyst compares that P/E ratio to other companies in the same industry and to the ratio for the broader market. Factoring in Stock Options:- intrinsic value is also used to assess stock options. Assume an investor buys a USD50, or strike price, call option on XYZ common stock. The investor has the right to exercise the option and buy 100 shares of XYZ stock at USD50 per share before the option expiration date. Intrinsic value is the difference between the current market price of the stock and the option's strike price. If the current market value is USD65 per share, the intrinsic value is USD65 – USD50, or USD15 per share. Examples Of Discounted Cash Flows:- analysts also place a value on an asset or investment using the cash inflows and outflows generated by the asset. These cash flows are discounted into a current value using a discount rate, which is an assumption about interest rates or a minimum rate of return assumed by the investor. If a company is buying a piece of machinery, the firm analyzes the cash outflow for the purchase and the additional cash inflows generated by the new asset. All of the cash flows are discounted to a present value, and the business determines the net present value (NPV). If the NPV is a positive number, the company should make the investment and buy the asset. Valuation is an estimation of the value of an item, usually by appraisal. Valuation (in statistics):- under the Special Data Dissemination Standard (SDDS), valuation refers to such items as:- (1) the exchange rates or conversion factors used to convert foreign-currency-denominated assets and liabilities into the national currency equivalent; (2) whether transactions are recorded at market prices, face or nominal value vs. issue or discounted prices; (3) adjustments to convert CIF imports to an FOB basis; (4) adjustments to align data with balance of payments concepts as well as the frequency of any revaluation, e.g., daily, monthly, quarterly, yearly. See also Accounting Basis, Actuarial Valuation, and Special Data Dissemination Standard (SDDS). Valuation is a process of determining the worth of a company's assets. Valuation:- the worth placed on a business. It can be determined in a number of ways. Theoretically, it is what a business is worth in the marketplace to an arms-length buyer. Valuations can be determined from a discounted cash flow analysis, comparative market study, industry multiples or rules of thumb, market capitalizations, and liquidation value, to name a few approaches. See also Basic Prices, Factor Cost, and Purchaser's Prices. Valuation:- current market price of a security; the current flat price. Depending on the context, the current price can be the Bridge valuation, the offering price, or a user-entered price. / Оценка в метрологии, приближённое значение величины или параметра, найденное по экспериментальным данным. Смотрите также Обработка Наблюдений. Оценка:- процесс установления (расчёта) стоимости недвижимого имущества по состоянию на конкретную дату, проводимый оценщиком. Результатом проведения оценки является вывод оценщика о величине рыночной стоимости недвижимого имущества, оформленный в виде отчёта об оценке. Представление стоимости изделия, обычно методом оценки. Оценка:- (1) определение стоимости (ценности) чего-либо; (2) расчёт стоимости ввозных товаров таможенными властями, основанный на формуле Генерального Соглашения О Тарифах И Торговле (ГСТТ), для определения размера пошлины, подлежащей уплате импортёром ввозящей стране. Оценка (Valuation):- определение цены или стоимости актива. Аналитик по ценным бумагам определяет стоимость акций компании на основе обзора её доходов и рыночной стоимости её активов по балансу. Оценка акций обычно выражается в виде отношения цены акции к её доходу (P/E Ratio). О компании с высоким P/E говорят, что она имеет высокую оценку, а с низким P/E – что у неё низкая оценка. Другие активы, такие, как облигации и недвижимость, оцениваются путём анализа, который основан либо на стоимости их приобретения, либо на текущей цене их продажи. Имущество также должно оцениваться после смерти своего владельца. Оценка (Valuation):- процесс расчёта (estimation) стоимости. Valuation – по-Русски, чтобы не спутать с другими значениями термина Оценка, термин Valuation (а также Appraisal) переводят также Оценка Стоимости или Стоимостная Оценка. В профессиональном лексиконе применяется также и калька с Латинской основы – Русифицированный термин Вальвация (сравните с Девальвацией и Ревальвацией). Термин Вальвация, который подразумевает определение стоимости именно имущества, одновременно означает и процесс расчёта, и получаемую в его результате величину. Отличающийся от этого смысл имеет другой, происходящий от той же основы (во Французской версии, но применяемый в Англоязычных текстах), профессиональный термин Валоризация (Valorization), означающий:- 'установление и поддержание определённого уровня цен путём государственных мероприятий:- закупками по повышенным ценам, займами'. В современной Российской практике понятие Оценки приобрело ещё одну, сугубо Российскую терминологическую форму, а именно:- Оценочная Деятельность, которая возникла как симбиоз Оценки, как выполнения профессиональных оценочных процедур, и предпринимательской деятельности, каковой статус установлен для оценочной деятельности Федеральным Законом Об Оценочной Деятельности В Российской Федерации.

VALUATION ACCOUNT = СЧЁТ ОСТАТОЧНОЙ СТОИМОСТИ (или ПЕРЕОЦЕНОЧНЫЙ СЧЁТ) – Valuation Account is paired with an asset or liability account, and is used to offset the value of the assets or liabilities recorded in the account with which it is paired. The result of this account pairing is a net balance, which is the carrying amount of the underlying asset or liability. The Valuation Account term is a less-used phrase that has the same meaning as the contra account concept. Examples of valuation accounts are:- (i) allowance for doubtful accounts (paired with the trade accounts receivable account); (ii) allowance for obsolete inventory (paired with the inventory account); (iii) accumulated depreciation (paired with the various fixed asset accounts); (iv) discount on bonds payable (paired with the bonds payable account); and (v) premium on bonds payable (paired with the bonds payable account). The valuation account concept is useful for estimating any possible reductions in the values of assets or liabilities prior to a more definitive transaction that firmly establishes a reduction. Valuation accounts are only used in accrual basis accounting. They are not used in cash basis accounting. Also known as a Contra Account or Valuation Reserve. / Оценочный Счёт:- общее название для Контрсчёта (Contra Account) и Дополняющего Счёта (Adjunct Account), остатки по которым соответственно вычитаются или прибавляются к остатку основного, связанного с ними счёта.

VALUATION ALLOWANCE/RESERVE = ХХ/РЕЗЕРВ СТОИМОСТНОЙ ОЦЕНКИ – Valuation Allowance/Reserve is an allowance to provide for changes in the value of a company's assets, such as depreciation or if an asset is deemed impaired.

VALUATION APPROACH = ПОДХОД К СТОИМОСТНОЙ ОЦЕНКЕ – Valuation Approach:- is the methodology used to determine the fair market value of a business. The most common valuation approaches are:- (i) The Income Approach:- quantifies the net present value of future benefits associated with ownership of the equity interest or asset. The estimated future benefits that accrue to the owner are discounted or capitalized at a rate appropriate for the risks associated with those future benefits. Common methods within the income approach include the capitalization of earnings (or cash flow) methodology and the discounted cash flow methodology. (ii) The Market Approach:- determines fair market value by reviewing actual transactions of comparable companies and assets. Both M&A activity and stock market activity are considered in deriving various value measures to apply to the subject entity. (iii) The Asset-based Approach:- uses the current value of a company's tangible net assets as the key determinant of fair market value. This approach is typically used where a business is not a going concern, or where a business is a going concern but its value is tied directly to the liquidation value of its underlying tangible assets and investments. The asset-based approach also provides a useful reasonableness check when reviewing the value conclusions derived under the income or market approaches. Some valuation approaches are more appropriate than others, depending on the circumstances. The market approach is the most commonly used by business owners to determine the fair market value of their business. This approach may be misleading because the comparables used may be public companies or other private transactions that have altogether different characteristics and may not relate at all. As well, the market approach isn't applicable in circumstances where the company is experiencing rapid growth. In this instance, the discounted cash flow approach would be more appropriate. The valuation of a private company is a complicated process since it is 'part art, part science'. Our advice is for the seller to hire a business valuator with practical transactional experience or an M&A professional to provide either a full valuation or an indication of the company's value. / Подход К Оценке (Valuation Approach):- обычно – способ расчёта стоимости, при котором используется один или большее число методов оценки. В зависимости от характера и назначения имущества, могут применяться три подхода к оценке. Это сравнение продаж, затратный подход и подход капитализации дохода. Их применение даст оценщику возможность определять рыночную стоимость или стоимость, отличную от рыночной стоимости. Смотрите также Подход На Основе Активов, Метод Сопоставимых Продаж, Затратный Подход, Подход На Основе (Капитализации) Дохода, Рыночный Подход, Принцип Замещения, и Подход На Основе Сравнения Продаж.

VALUATION ASSIGNMENT = УСТУПКА ТРЕБОВАНИЯ ПО СТОИМОСТНОЙ ОЦЕНКЕ (или ОТЧУЖДЕНИЕ СТОИМОСТНОЙ ОЦЕНКИ, или ПРЕЕМСТВО СТОИМОСТНОЙ ОЦЕНКИ) – Valuation Assignment:- xxxxx. / Задание На Оценку (Valuation Assignment):- . Смотрите также Определение Задания На Оценку.

VALUATION BRIEF = ИНСТРУКТАЖ НА СТОИМОСТНУЮ ОЦЕНКУ – Valuation Brief:- xxxxx. / Инструктаж На Оценку (Valuation Brief):- . Смотрите также Определение Задания На Оценку.

VALUATION CHARGE = СБОР ЗА СТОИМОСТНУЮ ОЦЕНКУ – Valuation Charge:- transport charges for certain goods, based on the value declared for the carriage of such goods (aircargo). Valuation Charges are the transportation charges to shippers who declare a value of goods higher than the value of the carriers' limits of liability. / Сборы За Стоимостную Оценку – сборы при перевозках, взимаемые с отправителей, которые декларируют стоимость товаров, превышающую стоимость лимитов ответственности перевозчиков.

VALUATION CLAUSE = ОГОВОРКА О СТОИМОСТНОЙ ОЦЕНКЕ – Valuation Clause provides basis for determining insured value of a shipment under the Open Cargo Insurance Policy. Valuation Clause stipulates a fixed sum for insured property in the event of loss when included in a marine cargo insurance policy. Valuation Clause is a clause in a marine policy that fixes the insured value. / Оговорка Об Оценке обеспечивает базис для расчёта страховой суммы груза по Открытому Полису Страхования Груза.

VALUATION DATE = ДАТА СТОИМОСТНОЙ ОЦЕНКИ – The Valuation Date is the date on which the market value of a gift or inheritance is established. The market value is the best price you would get if you sold the item on the open market. The valuation date for a gift is the date you received it. The valuation date for an inheritance is the earliest of these dates:- (i) the date the executor or administrator can receive the inheritance to give it to you; (ii) the date the executor or administrator actually receives the inheritance to give it to you; and (iii) the date the executor or administrator gives the inheritance to you. The valuation date is the date of death if:- (i) someone gives you a gift in anticipation of their death; (ii) a power of revocation has not been used; and (iii) the property passes by survivorship or under a trust. If there is no will, the valuation date for an inheritance is normally the date of the Grant of Administration (for example, in Ireland). Example:- 'The valuation date of an inheritance received under a will. In his will, John left his house to his sister Ashley and EUR50 000 to his nephew James. He left the balance of his estate (shares and bank accounts) to his brother Ronald. The valuation date for each of these inheritances is the date on which the executor or administrator was appointed to deal with the estate'. Note:- The tax free group thresholds and rates of tax that apply when you receive:- (i) a gift are determined by the date of the gift (and not the valuation date); and (ii) an inheritance are determined by the date of death (and not the valuation date). Valuation Date is the day when the evaluation has been made or the date when the evaluation applies. Valuation Date refers to a point in time in which an asset is assigned a Dollar value. It is a term often used in reference to valuation of assets to be distributed upon occurrence of an event, or a periodic determination of worth for reporting purposes. For example, it may be the designated time of closing (monthly, quarterly, etc) for determination of account balances in a defined-contribution or defined benefit plan. The general rule will be that a court will most strongly consider the value at the date of distribution. By having within its discretionary power the ability to determine the valuation dates, the court has another tool in which to bring equity to asset distribution. For example, in a divorce matter, the court may be trying to determine how to distribute assets such as a family home or securities, commercial real estate or business goodwill. State law varies on when the valuation date is in a divorce case. Most often, states use either the trial date, the date of final separation, or date of divorce complaint asthe valuation date. However, the date may be discretionary in some states. Local laws should be consulted for specific requirements in your area. Relevant legal forms (in the United States) include:- (i) Chapter 13 Plan (Motion for 3012 Valuation Hearing); (ii) Valuation of Share of Partner; (iii) Discovery – Requests for Business Valuation Information; and (iv) Michigan Real Estate Tax Valuation Affidavit. Valuation Date is a day as of which a valuator's estimate of value applies. Also called Appraisal Date. Valuation Date is the date used to measure plan liabilities and plan assets based on current plan census data and actuarial assumptions. Valuation Date means a date as of which a trust company determines the value of the assets in a common trust fund that it administers. Valuation Date means the date on which the value of the assets of the Trust Fund is determined. The value of each Account which is maintained under this Plan shall be determined on the Valuation Date. In each Plan Year, the Valuation Date shall be the last day of the Plan Year. At the discretion of the Named Fiduciary, Plan Administrator or Insurer (whichever applies), assets of the Trust Fund may be valued more frequently. These dates also shall be Valuation Dates. / Дьжон (John) Эшли (Ashley) Дьжеймз (James). Ронэлд (Ronald). Дата Стоимостной Оценки:- дата, на которую применяется заключение оценщика о стоимости. Также называется Датой Действия и/или Действительно На Дату.

VALUATION HAIRCUT = СТРИЖКА СТОИМОСТНОЙ ОЦЕНКИ (или XX) – Valuation Haircut:- a risk control measure applied to underlying assets used in reverse transactions, in which the central bank calculates the value of underlying assets as their market value reduced by a certain percentage (haircut). The Eurosystem applies valuation haircuts reflecting features of the specific assets, such as their residual maturity.

VALUATION METHOD = МЕТОД СТОИМОСТНОЙ ОЦЕНКИ (или ОЦЕНОЧНЫЙ МЕТОД) – A term Valuation Method means employed by an adjuster to determine the occurrence of a loss and affixing a monetary value to it before processing a claim. The adjuster must establish that (1) the insured actually suffered a monetary loss, (2) the loss was covered in the insurance policy, (3) the monetary value of the loss or damage, and (4) estimated cost of repair or replacement. Valuation Method is a specific way to determine the value of a security, business, business ownership interest or intangible assets and hence estimate its worth. Valuation can be done on assets such as stocks, options, business enterprises or intangible assets such as patents or trademarks. Valuation method determines the current worth and therefore is used to quantify in terms of monetary terms considering its benefits. Valuation methods are generally of three types:- approaches that are based on the principle of substitution and consider sum of all business investments (cost approach), sum of all future benefits (income approach), or valuation by comparing it with the value of similar assets or businesses (market approach). Different approaches are followed to value different types of assets. For example, Valuation Methods used for determining value of different assets is briefly given below:- (i) Fixed Asset Valuation Methods:- Cost method, Market Value method, Base Cost method, Standard Cost method, Average Cost method etc; (ii) Inventory Valuation Methods:- First in First Out method, Last in First Out method, Weighted average method (as allowed by GAAP); (iii) Business Valuation Method:- Asset-bases approaches, Earning value approaches such as Discounted Cash Flow method and Market Value approaches (by comparing with similar businesses); and (iv) Intangible Assets Valuation Method:- Cost approach (based on economic principle of substitution), income approach Market approach, Income approach, Relief from Royalty approach (present value of royalties that company is relieved from paying as a result of owning assets), Technology factor approach (overall market value based on utilization of underlying technology). / Метод Оценки (Valuation Method):- в рамках подходов к оценке – конкретный способ расчёта стоимости.

VALUATION OF COMMODITIES IN EXTERNAL TRADE = СТОИМОСТНАЯ ОЦЕНКА СЫРЬЯ ВО ВНЕШНЕЙ ТОРГОВЛЕ – Valuation Of Commodities In External Trade:- xxxxx. / Стоимостная Оценка Сырья Во Внешней Торговле:- обуславливается коммерческими взаимоотношениями между отечественными резидентами и резидентами других стран. При внешнеторговых сделках учитываются не только цена сырья на собственном внутреннем рынке и рынке страны-импортёра, но и всевозможные начисления за страхование продукции, её хранение, перевалка и так далее. Статистика международной торговли в качестве первичного источника информации использует сведения о стоимости сырья, объявленной в соответствии с таможенными и связанными с ней административными процедурами.

VALUATION OF ECONOMIC LINKS WITH FOREIGN COUNTRIES = СТОИМОСТНАЯ ОЦЕНКА ЭКОНОМИЧЕСКИХ СВЯЗЕЙ С ЗАРУБЕЖНЫМИ СТРАНАМИ – Valuation Of Economic Links With Foreign Countries:- xxxxx. / Стоимостная Оценка Экономических Связей С Зарубежными Странами:- экономические результаты внешнеэкономических связей в Балансе Национальной Экономики (Balance of National Economy) характеризуются с помощью системы стоимостных показателей, предназначенной, во-первых, для выявления вклада внешней торговли в создание совокупного общественного продукта и национального дохода; во-вторых, для определения объёма вывоза (или экспорта) и привоза (или импорта) нематериальных услуг; в-третьих, для финансовой оценки внешнеэкономической деятельности страны, оказывающей влияние на пополнение валютных резервов и изменение задолженности по кредитам товаров, увеличивающих или уменьшающих материальные ресурсы страны. Вывоз (или экспорт) и привоз (или импорт) оцениваются в национальных денежных единицах как с помощью официальных валютных курсов, так и с учётом действующей внутри страны системы ценообразования. Коммерческие сделки, связанные с вывозом-привозом (или экспортом-импортом) услуг нематериального характера, и платежи типа трансфертов пересчитываются во внутренние цены по официальным валютным курсам.

VALUATION OF EXPORTS OF GOODS = СТОИМОСТНАЯ ОЦЕНКА ВЫВОЗА ТОВАРОВ (или СТОИМОСТНАЯ ОЦЕНКА ЭКСПОРТА ТОВАРОВ) – Valuation Of Exports Of Goods:- xxxxx. Determination of export value by comparison:- (1) The value of the export goods shall be based on the transaction value of goods of like kind and quality exported at or about the same time to other buyers in the same destination country of importation or in its absence another destination country of importation adjusted in accordance with the provisions of sub-rule (2). (2) In determining the value of export goods inder sub-rule (1), the proper officer shall make such adjustments as appear to him reasonable, taking into consideration the relevant factors, including:- (i) difference in the dates of exportation; (ii) difference in commercial levels and quantity levels; (iii) difference in composition, quality and design between the goods to be assessed and the goods with which they are being compared; and (iv) difference in domestic freight and insurance charges depending on the place of exportation. / Стоимостная Оценка Вывоза Товаров или Стоимостная Оценка Экспорта Товаров:- в международных методологических руководствах по ведению статистики международной торговли (international trade statistics) стоимостную оценку вывоза (или экспорта) товаров рекомендуется проводить по стоимости на условиях ФОБ (FOB value = Free On Board value), то есть по рыночным ценам товаров на границе страны-экспортёра. Рыночная цена товаров на границе страны-экспортёра – это цена производителя, увеличенная на размер, во-первых, торговой наценки; во-вторых, расходов по транспортировке товаров до границы; в-третьих, издержек, оплаченных импортёром в связи с погрузкой вывозимого (или экспортируемого) товара на судно или другое средство международного транспорта; в-четвёртых, налогов на вывоз (или экспорт). При формировании рыночных цен товаров на границе не учитываются расходы по уплате налогов с объёма производства товаров, на которые предоставляются льготы при их вывозе (или экспорте). Стоимостный объём товаров в виде безвозмездной помощи определяется по ценам ФОБ аналогичных товаров, вывозимых из страны в результате внешнеторговых коммерческих сделок.

VALUATION OF IMPORTS OF GOODS = СТОИМОСТНАЯ ОЦЕНКА ПРИВОЗА ТОВАРОВ (или СТОИМОСТНАЯ ОЦЕНКА ИМПОРТА ТОВАРОВ) – Valuation Of Imports Of Goods:- xxxxx. Valuation of Exports and Imports:- Statistics Canada describes the valuation of exports and imports as follows:- For Customs purposes, imports are recorded at values established according to the provisions of the Customs Act, which, since January 01, 1985, reflects valuation methods based on the General Agreement on Tariffs and Trade (GATT) Valuation Code System. It generally requires the value for duty of imported goods be equivalent to the transaction value or the price actually paid. To determine the transaction value of imported goods, all transportation and associated costs arising in respect of the goods being appraised prior to and at the place of direct shipment to Canada, are to be added to the price of the goods. Therefore, Canadian imports are valued FOB (Free on Board), place of direct shipment to Canada. It excludes freight and insurance costs in bringing the goods to Canada from the point of direct shipment. To countries other than the United States (US), exports are, in principal, valued or recorded at the values declared on export documents which usually reflect the transaction value, i.e. actual selling price, or in the case of a non-arm's length transaction, the transfer price used for company accounting purposes. Canadian exports to overseas countries are valued at FOB port of exit, including domestic freight charges to that point but net of discounts and allowances. As of January, 1990, Canadian exports to the US are valued FOB point of exit from Canada. Prior to 1990, they were valued FOB

place of lading net of freight charges, discounts and allowances. Note that Canada and the United States have a data sharing agreement in which import data from the United States are used to determine Canadian exports to the United States, and similarly, Canadian import data are used to determine American exports to Canada. The reason for this practice is that, generally, import data are of better quality than export data, since imports are more closely scrutinized. / Стоимостная Оценка Привоза Товаров или Стоимостная Оценка Импорта Товаров:- стоимостный объём привоза (или импорта) товаров в соответствии с мировой практикой определяется на условиях СИФ (CIF Value = Cost, Insurance and Freight Value). При таком способе денедной оценки внешнеторговых сделок учитываются стоимость товара, его фрахт и страхование. Стоимость товара определяется по рыночным ценам на границе страны-экспортёра. Стоимость фрахта – это издержки по транспортировке товаров между границей страны-экспортёра и границей страны-импортёра. Издержки на страхование – это стоимость услуг страхования от несчастных случаев с товарами во время их перемещения от границы страны экспортёра до границы страны-импортёра. Оценка импорта на условиях СИФ обусловливается необходимостью учёта чистых страховых премий. Для национальной экономики в целом условно предлагается, что общая величина чистых премий, выплаченных, чтобы застраховать весь привоз (или импорт), равна общей стоимости потерь, понесённых при транспортировке товаров между границами страны-экспортёра и импортёра. Поэтому для национальной экономики в целом общая стоимость товаров, фактически привозных (или импортированных) данной страной, должна включать в дополнение к стоимости поступивших из-за границы товаров, оцененных на условиях ФОБ (FOB Value = Free On Board Value), только величину затрат на оплату транспортных услуг и услуг страхования.

VALUATION OF INTERNATIONAL TRANSACTION = СТОИМОСТНАЯ ОЦЕНКА МЕЖДУНАРОДНОЙ ТРАНЗАКЦИИ – Valuation Of International Transaction:- xxxxx. / Стоимостная Оценка Международной Транзакции:- стоимостный объём международных экономических операций в платёжном балансе (balance of payments) определяется только на основе рыночных цен. Единый принцип стоимостного выражения международных экономических сделок обусловлен тем, что платёжный баланс не может быть сведён, если дебетовые и кредитные проводки по каждой операции не осуществлены на основе единой системы цен. Определение стоимости операции как с реальными ресурсами, так и с финансовыми требованиями при составлении платёжного баланса в соответствии с методологическими рекомендациями Международного Валютного Фонда (МВФ) осуществляется на основе мировых цен, которые представляют собой сумму денег, уплачиваемую добровольным покупателем добровольному продавцу в целях приобретения у последнего какого-либо товара при условии, что такой обмен совершается между независимыми сторонами исключительно на коммерческой основе. Однако рыночная цена характеризует только конкретную обменную операцию, совершённую при определённых условиях. Прочие обменные операции, совершаемые при практически равных условиях, могут лишь условно характеризоваться рыночными ценами, так как, во-первых, стоимостные показатели, в которых первоначально учтена та или иная операция, зачастую необходимо корректировать, чтобы привести их к рыночным ценам, а во-вторых, при оценке операций, фактически, не являющихся рыночными, возникает необходимость нахождения подходящих эквивалентов рыночных цен. Стоимостную оценку каждой операции МВФ рекомендует производить по характерной для неё рыночной цене.

VALUATION OF NATURAL ASSETS = СТОИМОСТНАЯ ОЦЕНКА ПРИРОДНЫХ АКТИВОВ – Valuation Of Natural Assets are methods of applying a monetary value to natural assets in environmental accounting that include:- (a) market valuation; (b) direct non-market valuation such as the assessment of the willingness to pay for environmental services (contingent valuation), and (c) indirect non-market valuation, for example, costing of environmental damage or of compliance with environmental standards. See also Contingent Valuation, Maintenance (Cost) Valuation (Environmental Accounting), and Market Valuation.

VALUATION OF STOCKS = СТОИМОСТНАЯ ОЦЕНКА ЗАПАСОВ – Valuation Of Stocks:- the fifth edition of the IMF (International Monetary Fund) Balance of Payments Manual (BPM5) and the OECD (Organisation for Economic Co-operation and Development) Benchmark Definition of Foreign Direct Investment recommend using market price as the basis for stock valuation. However, it is recognised that, in practice, book values from the balance sheets of direct investment enterprises (or investors) are often used to determine the value of the stock of direct investment. See also Book Value.

VALUATION OF THE DEGRADATION OF LAND AND SOIL = СТОИМОСТНАЯ ОЦЕНКА ДЕГРАДАЦИИ ЗЕМЛИ И ПОЧВЫ – Valuation Of The Degradation Of Land And Soil is the present value of the future rent on land that is foregone due to the degradation attributed to the period.

VALUATION OPPORTUNITY COST = ВМЕНЁННАЯ ИЗДЕРЖКА СТОИМОСТНОЙ ОЦЕНКИ (или ХХ) – Valuation Opportunity Cost:- the potential increase in firm value associated with investments that are for gone due to capital rationing.

VALUATION PRINCIPLES = ПРИНЦИПЫ СТОИМОСТНОЙ ОЦЕНКИ – Valuation Principles:- tax law principles regarding valuation of business and non-business assets, and inventory. Valuation Principles:- the theory and practice of estimating the value of various securities is the heart of investing and leads to the construction of a portfolio consistent with your risk and return objectives. The understanding of these Valuation Principles are essential to successful investing. / Принципы Оценки (Valuation Principles):- группа экономических принципов, применяемых при оценке. Сюда относятся:- принцип предвидения, принцип замещения, принцип изменения, принцип конкуренции, принцип сбалансированности, принцип повышающейся и понижающейся отдачи, принцип вклада, принцип избыточной продуктивности, принцип соответствия, принцип предложения и спроса, принцип наиболее эффективного использования.

VALUATION PROCEDURE = ПРОЦЕДУРА СТОИМОСТНОЙ ОЦЕНКИ – Valuation Procedure:- sequence of steps prescribed in a valuation Approach to arrive at an estimate of value. Also called Appraisal Procedure. / Процедура Оценки (Valuation Procedure):- акты, характер и техника выполнения шагов одного из методов оценки.

VALUATION RATIO = СООТНОШЕНИЕ СО СТОИМОСТНОЙ ОЦЕНКОЙ – Valuation Ratio is a measure of how cheap or expensive a security (or business) is, compared to some measure of profit or value. A valuation ratio is calculated by dividing a measure of price by a measure of value, or vice-versa. The point of a valuation ratio is to compare the cost of a security (or a company, or a business) to the benefits of owning it. The most widely used valuation ratio is the price earnings (PE) ratio which compares the cost of a share to the profits made for shareholders per share. The PE ratio has many variants. It may use adjusted or diluted earnings, it may be historical or forward looking, it may be an absolute or relative number, and it may be calculated over a single year or the long term. EV/EBITDA (short for the Enterprise Value/Earnings Before Interest, Taxes, Depreciation And Amortization) also compares price to profits, but in a somewhat more complex manner. It compares the cost of buying the businesses of a company free of debt, to profits. Because someone buying a company free of debt would no longer have to pay interest, the profit measure used changes to profit before interest. It is also adjusted for non-cash items. Price/book value compares a share price to the value of a company's assets. This ratio is generally only important for certain sectors, such as property holding companies and investment trusts. This is because investors buy shares for the cash flows they will generate, and because asset values shown in the accounts usually reflect the accrual principle rather than real economic value. The most theoretically correct way in which to value securities is to use a

discounted cash flow. So why do investors rely so much on valuation ratios? One advantage of valuation ratios is that they are a lot simpler. The uncertainties around the numbers used for a discounted cash flow means that it may not be any better in practice. It is also possible to regard valuation ratios as a quick equivalent to a discounted cash flow. Suppose one is comparing companies in the same sector, and they are broadly similar businesses with very similar risks and the same expected rates of cash flow growth. In that case a price/FCF (short for the Free Cash Flow) will show the same same companies as being relatively cheap and expensive as a free cash flow DCF (short for the Discounted Cash Flow) valuation will. Tobin's Q is usually used rather differently. By comparing market cap to the value of assets it provides a useful indicator of value, but is generally more useful for assessing whether the market is over-valued or under-valued, than for valuing individual securities. The PE ratio is also used in a similar manner (to look at the valuation of the market). This implicitly assumes mean reversion. The cyclically adjusted PE is often used this way. Xxxxx. Valuation Ratio is any one of several calculations that determines whether a particular security is cheap or expensive when compared to a certain measure, such as profits or enterprise value. In other words, valuation ratio helps an investor to determine the cost of an investment with respect to the value or benefits of owning that investment. Valuation ratios are commonly used because they are simple to calculate. Also, it gives a clear idea of the relationship between cost of an investment and the benefit of owning it. There are many valuation ratios used to determine the worth of investments, with the price earnings (PE) ratio being one of the most popular for public companies. The PE ratio compares the cost of a share to the profits earned by shareholders per share. The comparison between cost and return is direct, so it gives the investor an idea of the worth of his/her investment. There are many variations to the PE ratio where the adjusted earnings, or the diluted earnings, of a company is used to calculate whether the cost and return are commensurate. It can be calculated for a single year or for a period of several years. Another commonly used valuation ratio is EBITDA, which compares the price of the share with respect to its profits. This EBITDA is adjusted for non-cash items such as interest, tax, depreciation and amortization to arrive at the actual profits earned by the company. The third type of valuation ratio is the price/book value. This ratio compares the share price to the assets of the company. However, this ratio is applicable only to certain sectors, such as investment trusts, because the assets are calculated based on the accrual principle rather than its real economic worth. The idea behind this price/book ratio is to give investors a sense of the cash flow that their investment is likely to generate. Despite the popularity of valuation ratios, many experts prefer to use the discounted cash flow model for the purpose of evaluating an investment. / Тобинз Кью. (Tobin's Q). Коэффициент Оценки (Valuation Ratio):- отношение, в котором стоимость или цена служит в качестве числителя, а финансовые, операционные или физические показатели – в качестве знаменателя. Смотрите также Фактор Капитализации, и Мультипликатор Дохода.

VALUATION REPORT = ОТЧЁТ О СТОИМОСТНОЙ ОЦЕНКЕ – Valuation Report:- an actuarial valuation of a retirement plan is an estimate of a plan's financial position at a specific point in time. During a valuation, an actuary takes a 'snapshot' of the membership as of a given date to determine the plan's liabilities and funded status. An actuarial valuation projects the expected cash flow of plan members' benefits. Actuarial projections are derived from a combination of judgement and science, based on assumptions about the likely occurrence of future events that affect the outcome and duration of pension benefits. The completion of annual or biennial valuations of all 104 contributory retirement systems requires the assistance and cooperation of the private actuarial community. PERAC (short for the US Public Employee Retirement Administration Commission) encourages retirement systems to conduct RFP's (Request for Proposals) to select private actuaries with whom they can establish ongoing relationships. There are a number of firms that provide actuarial services for pension plans. Recently completed valuation studies (including those completed by PERAC in-house and those provided by private actuaries) are posted on the PERAC web page. Retirement boards are encouraged to view these reports and to contrast and compare the various presentations. PERAC will accept a private valuation as meeting the biennial requirement stipulated in Chapter 32, provided the Commission staff has the opportunity to work with the private actuarial firm throughout the valuation process and to review their draft report before the valuation is finalized. / Отчёт Об Оценке (Valuation Report):- документ, в котором отражаются инструкции по оценке, база оценки и цель оценки, а также результаты анализа, которые привели к данному мнению о стоимости. Отчёт об оценке может также разъяснять аналитические процессы, предпринимаемые для проведения оценки, представляющий содержательную информацию, используемую в анализе и описывающий результаты анализа, приводящего к заключению о стоимости. Отчёты об оценке могут иметь устную или письменную форму. Тип, содержание и объём отчёта меняются в соответствии с предполагаемым пользователем, регулятивными требованиями, постановлениями судов, типом имущества и характером и сложностью задания. Термины Сертификат Оценки и Отчёт Оценки иногда используются как равнозначные. Согласно использованию в некоторых государствах (Великобритания), термин Сертификат Оценки обозначает документ, в котором оценщик подтверждает сумму оценки имущества. Сертификат оценки обычно представляет собой краткое письмо, хотя он может также иметь форму подробного отчёта. Он включает:- дату оценки; назначение задания; дату сертификата; допущения, на которых основывается оценка; имя, адрес и квалификация оценщика. Сертификация оценки, используется в других странах (США) как заявление, в котором оценщик подтверждает, что представленные факты верны, анализ ограничен только указанными допущениями, гонорар оценщика не зависит от какого-либо аспекта отчёта, и оценщик провёл оценку в соответствии с этическими и профессиональными нормами. Смотрите также Минимальное Содержание Отчёта Об Оценке.

VALUATION RESERVE = РЕЗЕРВ СТОИМОСТНОЙ ОЦЕНКИ (или XX) – Valuation Reserve:- the funds set aside by life insurers as required by state law to compensate for declines in the value of investment instruments that are held by the insurance company as assets. Valuation reserves are required because life insurance contracts can be in effect for long periods of time, and the securities valuation reserve is intended to protect the company's loss reserves in the event that the insurer's investments are under-performing. Prior to 1992, the mandatory securities valuation reserve (MSVR) required a liability reserve to be maintained by the National Association of Insurance Commissioners (NAIC) to protect against value changes in an insurance company's securities investments. Following 1992, the requirements set forth by the MSVR were transferred into the asset valuation reserve. Valuation Reserve is an allowance to provide for changes in the value of a company's assets, such as depreciation. A Valuation Reserve is an amount of money that life insurance companies set aside as a hedge against the possibility that their investments go down in value. Required by law, they serve the purpose of supplementing loss reserves and making sure insurance companies are still able to settle claims in the event of a failed investment with money earned from premiums. A valuation reserve is also known as a Mandatory Securities Valuation Reserve. The reserve requirement exists because of the fact that life insurance policies can span long periods of time, and inevitable fluctuations in the insurer's investments may deplete too much of the loss reserves. Originally, the National Association of Insurance Commissioners (NAIC) maintaineda mandatory securities valuation reserve (MSVR); however, following 1992, it became required of the asset valuation reserves (ASV) of insurers. Valuation Reserve is a reserve fund created by a charge against profits in order to provide for changes in the value of a company's assets. Valuation Reserve is an amount set aside against an unforeseen event that the valuation of assets or investments might be higher than what can be actually realized or that a liability may turn out to be greater than the valuation placed on it. Value reserves are created to help a business make use of the company's assets if the value of the holdings of a corporation changes. It is an allowance, created by a charge against earnings, to provide for changes in the value of a company's assets. Accumulated depreciation and allowance for bad debts can be taken as examples for valuation reserve. Valuation

Reserve is a provision, charged against earnings, that reflects changes in the value of a company's assets. Valuation Reserve:- allowance, created by a charge against earnings, to provide for changes in the value of a company's assets. Examples include accumulated depreciation and allowance for bad debts.

VALUATION REVIEW = ПЕРЕСМОТР СТОИМОСТНОЙ ОЦЕНКИ (или ОЦЕНОЧНЫЙ ОБЗОР) – Valuation Review:- xxxxx. / Экспертиза Оценки (Valuation Review):- задание на оценку, которое охватывает круг типов и целей. Принципиальной характеристикой, общей для всех экспертиз оценок, является то, что Оценщик выражает беспристрастное суждение при рассмотрении работы другого Оценщика. При экспертизе оценки может быть поддержано то же заключение о стоимости в рассматриваемой оценке, либо её результатом может быть несогласие с заключением о стоимости. Экспертизы оценки могут обеспечивать проверку надёжности по оценке, равно как и проверку прочности работы Оценщика, который разрабатывал её, в том, что касается знаний опыта и независимости Оценщика. В некоторых государствах экспертиза оценки может быть также уточнением, проводимым Оценщиком той же оценочной фирмы, которая проводила первоначальную оценку. Проводящие оценки организации по всему миру проводят различие между разными типами экспертиз, например, – административными экспертизами (экспертизами соблюдения), техническими экспертизами, кабинетными экспертизами, полевыми экспертизами, экспертизами для того, чтобы убедиться, что оценка проведена в соответствии с профессиональными стандартами (где принимаются базы оценки, используемые в рассматриваемой оценке), экспертизы, в которых собирается общая рыночная информация для подкрепления или опровержения заключения о стоимости, и экспертизы, в которых исследуются специфические данные в рассматриваемой оценке с сопоставимыми данными из выборочной группы.

VALUATION STANDARDS = СТАНДАРТЫ СТОИМОСТНОЙ ОЦЕНКИ – Valuation Standards:- xxxxx. The International Valuation Standards (IVS) are standards for undertaking valuation assignments using generally recognised concepts and principles that promote transparency and consistency in valuation practice. Business Valuation Standards (BVS) are codes of practice that are used in business valuation. The major business appraisal standards are these:- Uniform Standards of Professional Appraisal Practice (USPAP). Standards 9 and 10 cover business valuation and reporting standards. Published by the Appraisal Foundation. / Стандарты Оценки (Valuation Standards):- если нет других указаний, то имеются в виду Международные Стандарты Оценки (МСО).

VALUE = ВЕЛИЧИНА (или ВАЛЁР, или ЗНАЧЕНИЕ) – Value:- the relative lightness or darkness of a color. It is an important tool for the designer/artist, in the way that it defines form and creates spatial illusions. Contrast of value separates objects in space, while gradation of value suggests mass and contour of a contiguous surface. In the drawing on the right, value contrast separates the artichoke from the background, and the separate leaves from one another, while gradation suggests the curves of leave surfaces and of the whole form. Hue also has value. When contrasting hues are made similar in value, the spatial effects are flattened out. The pair of images on the left demonstrate this. In the color image of the fashion model the coat draws our attention through contrast of hue although the skin tones blend with the background(remember the object of the image is to sell the coat, not the model). However, it also seems to be softly blending with a background that seems quite close, and is very similar to the coat in value. The face tends to blend with the background which is similar in both hue and value. In the black and white version, however, the coat virtually disappears, since only value, not hue, are available to distinguish it, and the values are quite similar. However, the strong value contrast of the eyes and hat draw our attention to the face, even though the contours of the face seem to melt into the background. Therefore the black and white version emphasizes the model more than the garment. To summarize:- If values are close, shapes will seem to flatten out, and seem closely connected in space; none will stand out from the others. If values contrast, shapes will appear to separate in space and some will stand out from the others. This works whether the colors are just black, white and gray, or whether hues are involved. / относительная светлость или темнота цвета. Под Валёром, от Французского слова Valeur, в живописи и графике понимается оттенок тона, выражающий (в соотношении с другими оттенками) какое-либо количество света и тени. Применительно к колориту в живописи термин Валёр служит для обозначения каждого из оттенков тона, находящихся в закономерной взаимосвязи и дающих последовательную градацию света и тени в пределах какого-либо цвета. Систематическое применение валёрных градаций (отличающее творчество многих крупнейших живописцев-колористов – Испанца Диэго Родригэ дэ Сильва и Вэляскэса (Diego Rodriguez de Silva y Velazquez; 1599–1660), Нидерландца Яна Фэрмиэ фон Дельфта (Jan Vermeer van Delft; 1632–1675), Французов Жо-Батиста Симеу Шарда (Jean-Baptiste Siméon Chardin; 1699–1779) и Жо-Батиста Кямийэ Коро (Jean-Baptiste Camille Corot; 1796–1875), Россиян Василия Ивановича Сурикова (1848–1916) и Исаака Ильича Левитана (1860–1900) и других) является одним из средств, позволяющих передавать предметы в их взаимоотношении со световоздушной средой, достигать особой глубины и богатства колорита, тонкости цветовых отношений и переходов.

VALUE = СТОИМОСТЬ (или ЦЕННОСТЬ) – (1) Value:- the monetary, material or assessed worth of an asset, good or service. In accounting, value describes what something is worth in terms of something else. For example, the value of a loaf of bread might be USD3; the USD3 for the loaf of bread would represent the generally accepted worth of the bread. In economics, value describes the merit of the benefits of ownership. The benefits of ownership include utility, the pleasure or satisfaction gained by consumption of a particular good or service; and power, the ability of a good or service to be exchanged for other goods, services or money. Value is used to quantify the worth of something, and different types of value can be applied to explain various situations. For example, the value of a company can be described in terms of its intrinsic value, book value, actual cash value or market value. Value can be perceived, as in the way consumers perceive the ability of a good or service to meet their needs and their willingness to pay for the good or service. The value of an asset, good or service can change over time. For example, the price of a security fluctuates. Value can also relate to how people feel about something, describing how something is regarded and its importance to the individual. For example, a memento may have very little monetary value but have significant sentimental value. See also Valuables. Value is a term that defines the worth of a thing. The term is usually preceded by the word, or words such as 'Fair' or 'Fair Market', and it is usually defined in the document where it is found. Not all value for an item is the same, i.e. value is usually perceived. Value at the level of a single, homogeneous good or service is equal to the price per unit of quantity multiplied by the number of quantity units of that good or service; in contrast to price, value is independent of the choice of quantity unit. Context:- values are expressed in terms of a common unit of currency and are commensurate and additive across different products. Quantities, on the other hand, are not commensurate and additive across different products even when measured in the same kind of physical units. Value is a fair return or equivalent in goods, services, or money for something exchanged. Value is:- (1) In accounting:- the monetary worth of an asset, business entity, good sold, service rendered, or liability or obligation acquired. (2) In economics:- the worth of all the benefits and rights arising from ownership. Two types of economic value are (i) the utility of a good or service, and (ii) power of a good or service to command other goods, services, or money, in voluntary exchange. (3) In marketing:- the extent to which a good or service is perceived by its customer to meet his or her needs or wants, measured by customer's willingness to pay for it. It commonly depends more on the customer's perception of the worth of the product than on its intrinsic value. (4) In mathematics:- a magnitude or quantity represented by numbers. Value is a currency code and amount. Value is:- (i) the amount of money that something is worth; (ii) the price or cost of something; (iii) something that can be bought for a low or fair price; or (iv) usefulness or importance. / Стоимость, воплощённый в товаре и овеществлённый в нём общественный труд товаропроизводителей. Стоимость – общественное свойство вещи, которое она

приобретает в определённых исторических условиях – при наличии товарного производства. Стоимость создаётся в производстве, проявляется в обмене, когда произведённый товаропроизводителем товар приравнивается к другим товарам. Товаропроизводители связаны между собой системой общественного разделения труда и потому работают друг на друга, в силу чего их труд приобретает общественный характер. Отличаясь друг от друга как потребительные стоимости, обмениваемые товары имеют одно общее свойство, а именно – они продукты труда, на их производство затрачен труд, образующий их стоимость. Определённая пропорция, в которой одни товары обмениваются на другие, называется Меновой Стоимостью. Таким образом, стоимость внешне проявляется в акте обмена, то есть в меновой стоимости, потребительная стоимость товара (полезность вещи) становится носителем меновой стоимости. Величина стоимости товара определяется количеством труда, общественно необходимого для его производства, и измеряется рабочим временем. Так как разные товаропроизводители затрачивают на производство одного и того же товара неодинаковое количество труда (времени), товары имеют различную индивидуальную стоимость. Но поскольку стоимость воплощает общественный труд, величина общественной (рыночной) стоимости не может определяться индивидуальными затратами труда. Общественная стоимость определяется общественно необходимым рабочим временем, то есть временем, затрачиваемым на изготовление товара при данных общественно нормальных условиях производства и среднем в данном обществе уровне умелости и интенсивности труда, или временем, затрачиваемым на производство основной массы товаров данного вида. В условиях частной собственности пропорции в обмене товаров стихийно регулируются общественно необходимыми затратами труда (рабочего времени) в процессе конкурентной борьбы (смотрите Конкуренция). На величину стоимости оказывает влияние и степень сложности труда. Величина стоимости измеряется затратами простого труда, к выполнению которого способен любой работник, не получивший специальной подготовки. В процессе обмена разнообразных товаров происходит редукция (сведение) всех видов сложного труда к простому (смотрите Редукция Труда). В результате сложный труд выступает как умноженный простой труд, и каждый час сложного труда в обмене приравнивается к большему количеству простого труда. Начало теории трудовой стоимости было положено Английским экономистом Сэром Вильэмом Пэти (Sir William Petty; 1623–1687), Шотландским экономистом и философом Эдэмом Смисом (или Адамом Смитом (Adam Smith); 1723–1790) и Английским экономистом Дэйвидом Рикадо (David Ricardo; 1772–1823). Но эта теория была научно обоснована, наиболее последовательно и всесторонне, со всеми вытекающими социальными и классовыми выводами разработана Немецким философом и экономистом Калом Максом (или Карлом Марксом (Karl Marx); 1818–1883). Буржуазная вульгарная политическая экономия пыталась и пытается опровергнуть теорию трудовой стоимости. В буржуазной экономической науке, например, широко распространена трактовка меновой стоимости как выражения потребительной стоимости. Согласно этой концепции, меновые пропорции товаров определяются не затраченным общественным трудом, а якобы потребительной стоимостью товара (смотрите Теория Предельной Полезности). Другая, не менее распространённая теория стоимости – это теория, согласно которой стоимость является результатом действия трёх факторов производства – труда, капитала и земли (смотрите Производительности Теории). В действительности количество общественно необходимого труда, затраченного на производство товара, определяет его стоимость и те пропорции, в которых один товар обменивается на другой. '... Чем больше производительная сила труда, тем меньше рабочее время, необходимое для изготовления известного изделия, тем меньше кристаллизованная в нём масса труда, тем меньше его стоимость' (Карл Маркс, смотрите Карл Маркс и Фридрих Энгельс, Соч., 2 Изд., Т. 23, С. 49). Теория трудовой стоимости, разработанная Марксом, послужила основой его теории прибавочной стоимости. Ранней стадии обмена, когда он носил случайный характер, соответствовала простая, единичная, или случайная, форма стоимости; товар, выражавший свою стоимость в другом товаре, выступал в относительной форме стоимости, товар, который выражал стоимость другого товара, находился в эквивалентной форме стоимости, то есть являлся эквивалентом первого товара. Относительная форма стоимости отражает прежде всего однородность обмениваемых товаров как продуктов человеческого абстрактного труда. На стадии случайного обмена роль эквивалента выполняет один, случайный товар. С первым крупным общественным разделением труда – отделением скотоводства от земледелия – обмен стал более регулярным, скот систематически обменивался на другие товары, которые выступали не как случайные, а как особенные эквиваленты, к которым он приравнивался. Этой стадии обмена соответствовала полная, или развёрнутая, форма стоимости, при которой один товар выражал свою стоимость в целом ряде других товаров. По мере того, как обмен становился регулярным, развёрнутая форма стоимости превращалась постепенно во всеобщую, когда из товарного мира стихийно выделился один товар, ставший эквивалентом всех других товаров, то есть всеобщим эквивалентом. Роль всеобщего эквивалента играл только один товар, в котором все товары выражали свою стоимость единообразно. Всеобщий эквивалент обладает свойством всеобщей обмениваемости. Функцию всеобщего эквивалента в зависимости от конкретных условий производства выполняли различные товары:- скот, шкуры диких зверей, рыба и так далее. Когда обмен вышел за рамки местного рынка, возникла необходимость в закреплении функции всеобщего эквивалента лишь за одним товаром, который стал деньгами. Этой стадии обмена соответствовала денежная форма стоимости. Роль денег первоначально выполняли различные товары, но окончательно она закрепилась за одним товаром – золотом, которое в силу своих свойств наиболее подходит к выполнению роли денег. С возникновением денег стоимость всех товаров выражается в деньгах, тем самым товары приобрели цену. На рынке под влиянием спроса и предложения цена колеблется вокруг стоимости (смотрите Закон Стоимости). Стоимость товара выражает стоимость, созданную прошлым трудом и перенесённую конкретным трудом на данный товар с потреблённых средств производства, и новую (вновь созданную) стоимость, присоединённую живым трудом к товару в данном производственном процессе. С ростом технической оснащённости производства при общем снижении стоимости единицы продукции доля в ней прошлого труда относительно возрастает, а доля вновь созданной стоимости уменьшается. В каждой общественно-экономической формации, где существует товарное производство, соотношение прошлой и вновь созданной стоимости выражает специфические для данной формации производственные отношения. В условиях капитализма стоимость состоит из:- постоянного капитала (с), потреблённого в процессе производства данного товара; переменного капитала (v) – часть вновь созданной стоимости, которая эквивалентна стоимости рабочей силы, потреблённой в процессе производства; прибавочной стоимости (т) – часть вновь созданной стоимости, безвозмездно присваиваемой капиталистами. Общественная стоимость товара совпадает с действительными общественными издержками производства, но отличается от капиталистических издержек производства на величину прибавочной стоимости. В условиях развитого капитализма в результате стихийного перераспределения прибавочной стоимости и выравнивания прибыли в среднюю прибыль стоимость товаров превращается в цену производства. При социализме стоимость выражает социалистические производственные отношения; формирование и использование её происходят в условиях господства общественной собственности на средства производства, планомерной организации общественного производства. В социалистическом обществе потребительская стоимость становится непосредственно общественной, то есть предназначена для планомерного удовлетворения растущих потребностей общества. Органическое единство стоимости и потребительской стоимости проявляется в планировании производства и реализации продукции как в натуральном, так и в денежном выражении, в использовании стоимостных форм для учёта и оценки затрат общественного труда, контроля за производством, распределением и обменом материальных благ, организации материального стимулирования, повышения эффективности

производства. Стоимость выражает стоимость потреблённых средств производства (затраты прошлого, овеществленного труда), стоимость необходимого продукта и стоимость прибавочного продукта (затраты живого труда). В условиях социалистической экономики различают стоимость и себестоимость продукции. Разница между ними – чистый доход предприятия, или прибыль. Стоимость через плановую цену выступает как ориентир для отдельных предприятий, показывающий средний уровень общественной производительности труда. Снижение общественной стоимости единицы продукта достигается путём снижения индивидуальной стоимости на отдельных предприятиях в результате роста производительности общественного труда. Те предприятия, которые производят продукты с затратами ниже общественно необходимых, получают большую прибыль, за счёт части которой по установленным государством нормативам они образуют фонды экономического стимулирования. Социалистическое общество заинтересовано в уменьшении стоимости единицы продукции, так как это обеспечивает необходимые средства для развития производства и повышения жизненного уровня народа. Образование стоимости в условиях социализма – объективный процесс, планомерно организуемый в масштабах всего общества. Социалистическое государство, установив потребность в том или ином продукте, его общественная значимость, определяет, на каких предприятиях этот продукт должен быть изготовлен и в каком количестве; оно планирует затраты труда и средств производства на каждом предприятии, организует выполнение этого плана и тем самым воздействует на величину общественно необходимого рабочего времени, добиваясь его снижения. Изменения величины стоимости в условиях социализма являются результатом сознательной деятельности людей, планируемой и направляемой социалистическим государством. Стоимость – историческая категория, существование которой связано с товарно-денежными отношениями, преодолеваемыми при полном коммунизме. Ценность – цена, стоимость, например, картина большой ценности. Стоимость:- стоимость (не индексированная) объекта недвижимости согласно последнему отчёту об оценке. Если кредит состоит из нескольких траншей, стоимость объекта недвижимости должна быть указана пропорционально размеру каждого транша, за исключением Немецкого и Швейцарского рынков. В результате текущий коэффициент Кредит/Залог по всем траншам кредита один и тот же. На рынках Германии и Нидерландов данный показатель отражает залоговую стоимость объекта недвижимости при его реализации. Стоимость или Ценность:- ценность, которую кто-либо придаёт чему-либо. Определение стоимости является одной из основных проблем экономической науки. Существуют два принципиальных подхода к решению проблемы. в классической политической экономии или Классической Школе (Classical School) и в Марксистской Экономической Науке (Marxist Economics) (Марксистская политическая экономия) стоимость рассматривается как объективная реальность, которую можно измерить количеством труда (labor), содержащегося в товарах и услугах. Неоклассическая Школа (Neoclassical School) считает стоимость субъективным качеством, зависящим от редкости того, что в данное время требуется. Большинство экономистов в настоящее время склоняются к неоклассическому представлению о стоимости. Стоимость (Value):- цена, на которую, скорее всего, соглашаются продавцы и покупатели товара или услуги, которые доступны для приобретения. Стоимость устанавливает гипотетическую или умозрительную цену, на которую покупатели и продавцы наиболее вероятно согласятся для товара или услуги. Стоимость – не факт, а расчётная величина вероятной цены, которая будет заплачена за товар или услугу в данное время – в соответствии с конкретным определением стоимости.

(2) Value (of shipments) is the value received for the complete systems at the company's net billing price, freight-on-board factory, including charges for cooperative advertising and warranties. This does not include excise taxes, freight or transportation charges, or installation charges.

VALUE ADDED = ДОБАВЛЕННАЯ СТОИМОСТЬ – (1) Value Added:- in national accounting, for a producer, difference between the purchase price of raw materials or parts and the sale price of the product. If depreciation and indirect business taxes are deducted from this difference, the value added for all output is national income. / В национальном бюджетном процессе, . выработка (output).

(2) Value Added:- difference between the increase in the value of goods produced and the increase in the value of the factors of production used by the producer, based on constant prices over a given period of time. Value Added is the balance on the production account:- output less intermediate consumption. Value added may be measured net or gross. Value Added is the difference, at each stage of production or the provisioning of a service, between the price of a product or service and all materials or activities paid for to produce the product or provide the service. Value Added is a term for the increment added by each partry involved in the manufacture of a particular item, becoming part of its price. Value Added describes the enhancement a company gives its product or service before offering the product to customers. Value-added applies to instances where a firm takes a product that may be considered a homogeneous product, with few differences (if any) from that of a competitor, and provides potential customers with a feature or add-on that gives it a greater perception of value. A value addition can either increase the product's price or value. For example, offering one year of free support on a new computer would be a value-added feature. Additionally, individuals can add value to services that they perform, such as bringing advanced financial modeling skills to a position in which the hiring manager may not have foreseen the need for such skills. In the digital age, when consumers can have access to any product they want and have it delivered in record time, companies are struggling to find a competitive advantage. Companies are constantly challenged to find a way to add value to justify their pricing to a more discerning market. Companies are learning that consumers are less focused on the product, and more focused on what the product will do for them. Finding out what the customer truly values is critical to how the company produces, packages, markets, and delivers its products. For example, Bose Corporation has successfully changed its focus from a company that produces speakers to a company that delivers an uncommon sound experience. When a BMW rolls off the assembly line, it sells for a high premium over the cost of production because of its reputation for high performance and sturdy mechanics. The value added has been created through the brand and years of refinement. Value added is the difference between the price of product or service and the cost of producing it. The price is determined by what customers are willing to pay based on their perceived value. Value is added or created in different ways. Value Added In Marketing:- Companies that build strong brands add value just by adding their logo to a product. Nike Inc. can sell shoes at a much higher price than some competitors, even though their production costs are similar. The Nike brand, which shows up on athletic apparel and uniforms of the top college and professional sports teams, represents a quality enjoyed by elite athletes. Buyers of luxury cars from BMW and Mercedes-Benz are willing to pay a premium price for their vehicles because of the ongoing maintenance programs that the companies offer. Amazon has been at the forefront of e-customer service with its policies of issuing automatic refunds for poor service, free shipping, and price guarantees on pre-ordered items. Consumers have become so accustomed to their services that they are willing to pay annual fees for Amazon Prime memberships because they value the two-day turnaround on orders. Value Added In GDP:- The contribution of a private industry or government sector to overall Gross Domestic Product (GDP) is the value added of an industry, also referred to as GDP-by-industry. If all stages of production occurred within a country's borders, the total value added at all stages is what is counted in GDP. The total value added is the market price of the final product or service, and only counts production within a specified time period. This is the basis on which value-added tax (VAT) is computed. Value added of an industry is the difference between the total revenue of an industry and the total cost of inputs purchased from other businesses within a reporting period. The total revenue or output of an industry consists of sales and other operating income, commodity taxes, and inventory change. Inputs that could be purchased form other firms to produce a final product include raw

materials, semi-finished goods, energy, and services. / Боуз Корпорэйшэн (Bose Corporation). Найки (Nike). Бе.Эм.Ве. (BMW) и Мяцидэс-Бэнц (Mercedes-Benz). Эмэзон Прайм (Amazon Prime). Добавленная Стоимость:- . выработка (output). Прибавочная Стоимость – стоимость, создаваемая неоплаченным трудом наёмного рабочего сверх стоимости его рабочей силы и безвозмездно присваиваемая капиталистом. Выражает специфически капиталистическую форму эксплуатации, при которой Прибавочный Продукт принимает форму прибавочной стоимости. Производство и присвоение прибавочной стоимости составляет сущность основного экономического закона капитализма. 'Производство прибавочной стоимости или нажива – таков абсолютный закон ...' капиталистического способа производства (Немецкий философ и экономист Кал Макс (или Карл Маркс (Karl Marx); 1818–1883)). Он отражает экономические отношения не только между капиталистами и наёмными рабочими, но и между различными группами буржуазии:- промышленниками, торговцами, банкирами, а также между ними и землевладельцами. Погоня за прибавочной стоимостью играет главную роль в развитии производительных сил при капитализме, определяет и направляет развитие производственных отношений капиталистического общества. Учение о прибавочной стоимости, которое Российский революционер, политик и теоретик Владимир Ильич Ленин (1870–1924) назвал '... краеугольным камнем экономической теории Маркса', было впервые разработано Марксом в 1857–58, в рукописи Критика Политической Экономии (первоначальный вариант Капитала), хотя отдельные положения имелись уже в таких работах 1840-х, как 'Экономическо-Философские Рукописи 1844 Года', 'Нищета Философии', 'Наёмный Труд И Капитал'. Предпосылкой производства прибавочной стоимости является превращение рабочей силы в товар. Только на определённой ступени развития общества владелец денег находит на рынке свободного от средств производства рабочего, вынужденного продавать свою рабочую силу. Потребление её равнозначно созданию новой стоимости. Центральной проблемой теории прибавочной стоимости является объяснение механизма капиталистической эксплуатации на основе господствующих в буржуазном обществе товарно-денежных отношений. Противоречивое действие этого механизма заключается в том, что неэквивалентный по существу обмен деятельностью между рабочим и капиталистом, между трудом и капиталом, осуществляется в действительности на основе закона стоимости, то есть на основе обмена эквивалентов – товаров, имеющих одинаковую стоимость (смотрите Закон Стоимости). Исследование процесса производства прибавочной стоимости Карл Маркс начинает с анализа всеобщей формулы капитала (Д–Т–Д; где Д' больше Д или Д' = Д + д), которая выражает покупку товара (Д–Т) для его продажи (Т–Д') с целью увеличения капитала. Прирост или избыток стоимости (д) над первоначально авансированной суммой денег (Д), пущенных в оборот, Rfhk Маркс называет Прибавочной Стоимостью. Возрастание первоначальной суммы денег за счёт присоединения прибавочной стоимости делает их Капиталом. Анализ всеобщей формулы капитала показывает, что прибавочная стоимость не может возникнуть из товарного обращения, совершающегося на основе закона стоимости; с другой стороны, если бы владелец денег не пускал их в обращение, то никакого прироста не могло бы быть. Следовательно, прибавочная стоимость не может возникнуть и вне обращения. Карл Маркс показал, что капиталист, покупая и продавая товары по их стоимости, всё-таки извлекает из этого процесса большую стоимость, чем та, которую вложил в него. Продажа рабочей силы капиталисту происходит по её стоимости, определяемой тем количеством общественно необходимого рабочего времени, в течение которого она воспроизводится. Капиталист приобретает потребительную стоимость товара рабочая сила, обладающую '... оригинальным свойством быть источником стоимости ...' (Карл Маркс). Реализуется она на втором этапе обмена между трудом и капиталом – в процессе производства, когда и создаётся новая стоимость, содержащая прибавочную стоимость. Последняя определяется Карлом Марксом как разность между той стоимостью, которую живой труд создаёт в процессе производства, и той, которую капиталист оплачивает рабочему в форме Заработной Платы. 'Прибавочная стоимость есть не что иное, как избыток того количества труда, которое дает рабочий, над тем количеством овеществленного труда, которое он получил в своей собственной заработной плате, в качестве стоимости своей рабочей силы' (Карл Маркс). Способность рабочего к труду, а следовательно, и продукт его труда принадлежат капиталисту. Закон стоимости, как закон обмена эквивалентов, не противоречит тому, что стоимость, созданная в результате затраты живого труда, превышает стоимость рабочей силы. Реально прибавочная стоимость выступает в виде прибыли, которая в процессе реализации и распределения принимает ряд форм:- (i) предпринимательского дохода, присваиваемого промышленными и торговыми предпринимателями; (ii) процента, присваиваемого банкирами; и (iii) земельной ренты, получаемой собственниками земли. Все эти конкретные виды доходов имеют свои особенности. Общее между ними состоит в том, что у них один источник – неоплаченный труд рабочих. В безграничном стремлении к увеличению производства прибавочной стоимости капиталисты различными способами усиливают эксплуатацию наёмных рабочих. Этим способам соответствуют две формы прибавочной стоимости – Абсолютная и Относительная. Абсолютная Прибавочная Стоимость является результатом удлинения рабочего дня сверх необходимого рабочего времени, в течение которого рабочий воспроизводит стоимость своей рабочей силы. Фактическая величина его зависит от соотношения классовых сил. Побуждаемые алчным стремлением к увеличению прибавочной стоимости, капиталисты всячески стараются удлинить пределы рабочего дня. Однако с ростом организованности рабочему классу в результате упорной борьбы удалось добиться законодательного ограничения рабочего дня. Абсолютная прибавочная стоимость возрастает также и в результате повышения интенсивности труда – при неизменной или даже при уменьшающейся величине рабочего дня. Другим способом увеличения производства прибавочной стоимости является сокращение необходимого и соответствующее увеличение прибавочного рабочего времени при неизменной продолжительности рабочего дня. Этому способу соответствует Относительная Прибавочная Стоимость. Сокращение необходимого рабочего времени связано прежде всего с повышением производительности труда в отраслях, производящих средства существования рабочего, так как в конечном счёте это ведёт к снижению стоимости рабочей силы. А это, в свою очередь, приводит к сокращению необходимого и соответственно увеличению прибавочного рабочего времени во всех отраслях капиталистического производства. Разновидностью относительной является Избыточная Прибавочная Стоимость, присваиваемая отдельными капиталистами на своих предприятиях в результате снижения индивидуальной стоимости товара по сравнению с его общественной стоимостью. Избыточная прибавочная стоимость не связана со снижением стоимости рабочей силы. Источником её является более высокая производительность труда рабочих технически более совершенных предприятий по сравнению со средним для данной отрасли уровнем производительности. Избыточная прибавочная стоимость носит временный характер, так как по мере распространения новой техники и технологии на другие предприятия соответствующей отрасли снижается общественная стоимость товаров и исчезает разница между индивидуальной и общественной стоимостью товара. Однако мимолётный характер избыточной прибавочной стоимости не означает, что она исчезает совсем. Она просто переходит от одних капиталистов к другим. Борьба за её получение составляет главный стимул Внутриотраслевой Конкуренции. Развитие капитализма характеризуется устойчивым возрастанием нормы прибавочной стоимости, представляющей собой отношение всей массы прибавочной стоимости к переменному капиталу или прибавочного рабочего времени к необходимому, выраженное в процентах:- m' = m / v, где m' – норма прибавочной стоимости, m – масса прибавочной стоимости, v – переменный капитал. Между нормой и массой прибавочной стоимости существует функциональная связь. Если норма прибавочной стоимости отражает степень эксплуатации рабочего класса, то масса – абсолютную величину прибавочной стоимости (m) и равна стоимости авансированного переменного капитала (v), умноженной на норму прибавочной стоимости (m'). Карл Маркс отмечал, что '... норма прибавочной стоимости есть точное выражение

степени эксплуатации рабочей силы капиталом, или рабочего капиталистом'. По его расчётам, в середине XIX века она составляла приблизительно 100%. Норма прибавочной стоимости в фабрично-заводской промышленности России в 1908 превышала 100%. По расчётам исследователей-марксистов, норма прибавочной стоимости в обрабатывающей промышленности США составляла в %:- 115 (1966, В. Перло, США), 118–120 (1955, В.М. Кудров и С.М. Никитин, СССР), 192 (1958, Е.С. Варга, СССР), 312 (1969, С.Л. Выгодский, СССР), 397 (1957, А.И. Кац, СССР), 1 187 (1965–69, Ю. Кучинский, ГДР). Колебания в величине нормы прибавочной стоимости объясняются различиями в применяемой методике подсчёта. Но все эти расчёты свидетельствуют о росте нормы прибавочной стоимости с развитием капитализма. При этом следует иметь в виду влияние таких противодействующих факторов, как борьба рабочего класса, рост стоимости рабочей силы, борьба двух систем и тому подобное. Карл Маркс отмечал, что возможное улучшение '... жизненного положения рабочего, ничего не меняет в природе и законе относительной прибавочной стоимости, ничего не меняет в том, что в результате повышения производительности труда всё более значительная часть рабочего дня присваивается капиталом. Отсюда видна вся вздорность попыток опровергнуть этот закон путём подбора статистических выкладок в доказательство того, будто материальное положение рабочего ... улучшилось ... вследствие развития производительной силы труда' (Карл Маркс). Теория прибавочной стоимости Маркса дала возможность вскрыть несостоятельность буржуазных апологетических теорий прибыли. Многие из 'концепций', противопоставляемых современными буржуазными экономистами теории прибавочной стоимости Маркса, представляют собой по существу модернизированные варианты теории доходов, сформулированной Французским экономистом и деловым человеком Жо Батисте Сэем (Jean-Baptiste Say; 1767–1832), воспринятой затем Англичанами историком, экономистом, политическим теоретиком и философом Дьжеймзом Милом (James Mill; 1773–1836), экономистом Дьжоном Рэмзи МэКалоком (John Ramsey McCulloch; 1789–1864) и экономистом Наco Вильэмом Синьором (Nassau William Senior; 1790–1864). Представители вульгарной политической экономии ставили задачу опровергнуть главное в экономической теории марксизма – учение о прибавочной стоимости, так как именно оно раскрывает сущность и механизм капиталистической эксплуатации, вооружает рабочий класс научным пониманием его исторической миссии. Американский экономист Дьжоном Бэйтсом Клаком (John Bates Clark; 1847–1938) пытался 'углубить' теорию трёх факторов Сэя. Считая, что распределение общественного продукта осуществляется в соответствии с вкладом каждого из факторов производства (труда, капитала, земли) в национальный доход, он создал теорию предельной производительности. Учение о прибавочной стоимости позволило Карлу Марксу сформулировать основной экономический закон движения капиталистического общества, раскрыть объективные тенденции его развития, дало ключ к пониманию капиталистического способа производства. Поскольку присвоение классом капиталистов прибавочной стоимости, созданной рабочим классом, происходит в соответствии с внутренними законами капиталистического способа производства, и прежде всего с законом стоимости, то капиталистическая эксплуатация вытекает из самого существа капиталистических производственных отношений. Следовательно, освобождение рабочего класса от 'наёмного рабства' невозможно в рамках буржуазного строя; для этого необходима социалистическая революция. Вместе с тем гигантское развитие производительных сил, которым сопровождается усиление эксплуатации труда капиталом, означает также создание и накопление материальных предпосылок, обусловливающих возможность социалистической революции. Таким образом, из теории прибавочной стоимости непосредственно следует вывод о непримиримости классовых противоречий между капиталом и наёмным трудом. Добавленная Стоимость:- стоимость, добавленная товару при его прохождении по цепочке от места его первоначального приобретения, производства и так далее до розничной продажи. Например, если производитель приобретает полуфабрикат, добавленная стоимость будет представлять собой комбинацию стоимости труда и прибыли, которые увеличат стоимость полуфабриката, прежде чем он будет продан. Смотрите также Налог На Добавленную Стоимость (Value-Added Tax).

(3) Value Added:- the value is added to the distribution process when there is a contribution made to the functionality, value, or usefulness of a product. / Добавленная Стоимость:- .

(4) Value Added is the risk adjusted return generated by an investment strategy:- the return of the investment strategy minus the return of the benchmark.

(5) Value Added (for railway enterprises):- gross output of the railway enterprise less the value of its intermediate consumption. Value added of domestic production of all railway enterprises in a country is equal to their contribution to the gross domestic product (GDP) of that country. Context:- it is understood that Value Added, in this context, is expressed in market prices.

(6) Value Added (of inland waterways transport (IWT) enterprises):- gross output of the IWT enterprise less the value of its intermediate consumption. Value added of domestic production of all of a country's IWT enterprises is equal to their contribution to the gross domestic product (GDP) of that country. Context:- it is understood that Value Added, in this context, is expressed in market prices.

(7) Value Added (of oil pipeline enterprises):- gross output of the oil pipeline transport enterprise less the value of its intermediate consumption. Value added of domestic production of all oil pipeline transport enterprises in a country is equal to their contribution to the gross domestic product (GDP) of that country. Context:- it is understood that Value Added, in this context, is expressed in market prices.

(8) Value Added (of road transport enterprises):- gross output of the road transport enterprise less the value of its intermediate consumption. Value added of domestic production of all road transport enterprises in a country is equal to their contribution to the gross domestic product (GDP) of that country. Context:- it is understood that Value Added, in this context, is expressed in market prices.

(9) Value-Added (agricultural) (product(s)):- (1) Increasing the value of a good by further processing. Examples of value-added products include soybean meal and oil, frozen vegetables for retail consumption, and processed meats. (2) Under the Value-Added Agricultural Product Marketing Development Grants Program, any agricultural commodity or product that (a) has undergone a change in physical state, (b) was produced in a manner that enhances the value of the agricultural commodity or product (as demonstrated through a business plan that shows the enhanced value), or (c) is physically segregated in a manner that results in the enhancement of the value of the agricultural commodity or product, and as a result, the customer base for the agricultural commodity or product has been expanded and a greater portion of the revenue derived from the marketing, processing, or physical segregation of the agricultural commodity or product is available to the producer of the commodity or product. Xxxxx. In general, adding value is the process of changing or transforming a product from its original state to a more valuable state. Many raw commodities have intrinsic value in their original state. For example, field corn grown, harvested and stored on a farm and then fed to livestock on that farm has value. In fact, value usually is added by feeding it to an animal, which transforms the corn into animal protein or meat. The value of a changed product is added value, such as processing wheat into flour. It is important to identify the value-added activities that will support the necessary investment in research, processing and marketing. The application of biotechnology, the engineering of food from raw products to the consumers and the restructuring of the distribution system to and from the producer all provide opportunities for adding value. A broad definition of value added is to economically add value to a product by changing its current place, time and from one set of characteristics to other characteristics that are more preferred in the marketplace. As a specific example, a more narrow definition

would be to economically add value to an agricultural product (such as wheat) by processing it into a product (such as flour) desired by customers (such as bread bakers). Producers involved in adding value should think of themselves as members of a food company that processes and markets products to consumers. Often, this involves building processing plants in the producers' geographical regions to process locally produced crops or animals. However, another model has occurred, which involves building the processing plant wherever it is most feasible and profitable, such as closer to where the final products will be marketed. An example of adding value to wheat through a distant processing plant is illustrated by the following case study.

VALUE–ADDED AGRICULTURAL PRODUCT MARKETING DEVELOPMENT = РАЗВИТИЕ XX – Value-Added Agricultural Product Marketing Development (Grant Program):- authorized in the Agricultural Risk Protection Act of 2000 (Title II, Sec. 231) and amended by the Farm Security and Rural Investment Act of 2002 (Sec. 6401). The program encourages independent producers of agricultural commodities and products of agricultural commodities to further refine such products to increase their value to the end user of the product.

VALUE–ADDED AGRICULTURE = СЕЛЬСКОЕ ХОЗЯЙСТВО С ДОБАВЛЕННОЙ СТОИМОСТЬЮ – Value-Added Agriculture:- a process of increasing the economic value and consumer appeal of an agricultural commodity. It is a production and marketing strategy that requires a better understanding of the rapidly changing food industry and food safety issues, alternative crops, and diversified skills, producer-owned cooperatives, and marketing savvy. Value-Added Agriculture entails changing a raw agricultural product into something new through packaging, processing, cooling, drying, extracting or any other type of process that differentiates the product from the original raw commodity. Examples of value added agricultural products include garlic braids, bagged salad mix, artisan bread, lavender soaps and sausages. Adding value to agricultural products is a worthwhile endeavor because of the higher returns that come with the investment, the opportunity to open new markets and extend the producer's marketing season as well as the ability to create new recognition for the farm. Increasingly, value-added products are hitting the local market as producers take advantage of high-demand product niches. This is the key to success in value added agriculture – niche markets are where smaller producers can be most successful in creating value and establishing a profitable business. A study of fourteen farmers in the Southern US conducted by ATTRA (ATTRA is a program developed and managed by the National Center for Appropriate Technology (NCAT)) and the Southern Sustainable Agriculture Working Group identified ten keys to success when pursuing a value-added business. These include:- starting small and growing naturally; making decisions based on good records; creating a high-quality product; following demand-driven production; getting the whole family or partners involved; keeping informed; planning for the future; continuing evaluation; persevering and having adequate capitalization. Take these recommendations into mind when you are designing your product and business plan. Value added agriculture is not without its challenges to farmers. One of the largest hurdles to overcome is that of food business and safety regulations. For example, if you are interested in taking your organic blueberries and turning them into a high quality jam that you can sell at the local farmers' market, you must be a licensed commercial kitchen in order to produce that product and sell to local consumers. You will also need to carry liability insurance if you are selling at the farmers' market to cover any sort of illness or other food safety issues that may arise. The Oregon Department of Agriculture's Food Safety department handles the licensing of food businesses in the State of Oregon. These regulation challenges make it difficult to get started in the valueadded business, but with a solid business plan in place, producers can be successful in overcoming obstacles to their food business dream. Another example of a significant challenge for starting a value-added business is putting together your recipes or formulations for the product you are developing. For instance, making soap from your lavender flowers requires time and effort in finding the right recipe for high-quality soap. You will also want to research the market potential for your product in order to define your customer profile, so that you are not wasting your time in formulating a product that will not sell. The Food Innovation Center is an excellent resource for small business owners interested in starting a value-added business. They can assist with formulation, education etc. Starting a value-added agricultural business is an exciting opportunity for the small farmer interested in diversifying and exploring new markets, but starting small and finding your niche is key to your long-term success. Evaluate the risks associated with the business and have a solid plan in place to keep you on the right track.

VALUE ADDED AT FACTOR COST = ДОБАВЛЕННАЯ СТОМОСТЬ В ФАКТОРНОМ РАСХОДЕ (или XX) – Value Added At Factor Cost is the gross income from operating activities after adjusting for operating subsidies and indirect taxes. It can be calculated from turnover, plus capitalised production, plus other operating income, plus or minus the changes in stocks, minus the purchases of goods and services, minus other taxes on products which are linked to turnover but not deductible, minus the duties and taxes linked to production.

VALUE ADDED – BASIC PRICES = ДОБАВЛЕННАЯ СТОИМОСТЬ – ОСНОВНЫЕ (или БАЗОВЫЕ) ЦЕНЫ – Value Added – Basic Prices (NACE (short for the Nomenclature generale des activites economiques dans les Communautes Europeennes, Revision 1, Eurostat, Luxembourg, 1996)):- value added at basic prices is calculated from the production value plus subsidies on products less the purchases of goods and services (other than those purchased for resale in the same condition) plus or minus the change in stocks of raw materials and consumables less other taxes on products which are linked to turnover but not deductible. It represents the value added by the various factor inputs in the operating activities of the unit concerned. Income and expenditure classified as financial or extra-ordinary in company accounts is excluded from value added. Value added at basic prices is calculated 'gross' because value adjustments (such as depreciation) are not subtracted. Context:- operating subsidies can be separated into two groups:- (i) Subsidies on products are subsidies payable per unit of a good or service. The subsidy may be a specific amount of money per unit of a good or service or it may be calculated ad valorem as a specified percentage of the price per unit. A subsidy on a product usually becomes payable when the good or service is produced, sold or imported, but it may also be payable in other circumstances such as when a good is transferred, leased, delivered or used for own consumption or own capital formation. (ii) Subsidies linked to production are subsidies received by a unit which are not linked to the quantity or the value of goods produced or sold. Notably these subsidies include subsidies on the payroll and workforce, subsidies for environmental protection and grants for interest relief. Investment subsidies are excluded. Specific calculation methods are needed for NACE Rev. 1 classes 66.01 and 66.03. Note:- Indirect taxes can be separated into three groups:- (i) The first comprises VAT and other deductible taxes directly linked to turnover which are excluded from turnover. These taxes are collected in stages by the enterprise and fully borne by the final purchaser. (ii) The second group concerns all other taxes and duties linked to products which are either (1) linked to turnover and not deductible or (2) taxes on products not linked to turnover. Included here are taxes and duties on imports and taxes on the production, export, sale, transfer, leasing or delivery of goods and services or as a result of their use for own consumption or own capital formation. (iii) The third group concerns taxes and duties linked to production. These are compulsory, unrequited payments, in cash or in kind which are levied by general government, or by the Institutions of the European Union, in respect of the production and importation of goods and services, the employment of labour, the ownership or use of land, buildings or other assets used in production irrespective of the quantity or the value of goods and services produced or sold. Value Added – Basic Prices – System of National Accounts (SNA) refers to output valued at basic prices less intermediate consumption valued at purchasers' prices. / привоз (importation).

VALUE ADDED BY MANUFACTURE = ДОБАВЛЕННАЯ СТОИМОСТЬ ПОСРЕДСТВОМ ИЗГОТОВЛЕНИЯ – Value Added By Manufacture is a measure of manufacturing activity that is derived by subtracting the cost of materials (which covers materials, supplies, containers, fuel, purchased electricity, and contract work) from the value of shipments. This difference is then adjusted by the net change in finished goods and work-in-progress between the beginning- and end-of-year inventories.

VALUE ADDED COST = ЗАТРАТА НА ДОБАВЛЕННУЮ СТОИМОСТЬ – Value Added Cost is incurred when an asset is consumed in order to increase the value of goods or services to the consumer. Examples of value added costs are the direct materials, direct labor, and installation costs associated with a sale. These costs are typically a minority of the total costs incurred by a business, which leaves a significant opportunity to strip out non-value-added costs, thereby increasing profits or allowing for the reduction of product prices.

VALUE ADDED COUNSELING = КОНСУЛЬТИРОВАНИЕ ПО ВОПРОСАМ ДОБАВЛЕННОЙ СТОИМОСТИ – Valued Added Counseling is defined as assessing a company's current international business operations and assisting a client in one or more of the following:- (a) identifying and selecting the most viable markets; (b) developing an export market strategy; (c) implementing the export market strategy; and (d) increasing market presence.

VALUE ADDED FUNCTION = ФУНКЦИЯ ДОБАВЛЕННОЙ СТОИМОСТИ – The Value Added Function indicates the maximum amount of current-price value-added that an establishment or industry can generate, given a set of prices for its output and for its intermediate inputs, and given a certain quantity of primary inputs.

VALUE–ADDED GRAINS = ЗЁРНА ДОБАВЛЕННОЙ СТОИМОСТИ – Value-Added Grains:- xxxxx. See also Value-Enhanced Grains.

VALUE–ADDED INTERMEDIATE = ПОЛУФАБРИКАТ С ДОБАВЛЕННОЙ СТОИМОСТЬЮ – Value-Added Intermediate (Agricultural Products):- for the BICO Report, commodities such as Wheat flour, vegetable oils, and hides and skins that receive some processing, but are generally not ready for final consumption. Wheat flour is further processed into noodles and bakery products, while vegetable oils are an ingredient in many processed foods. Slaughter animals are value-added intermediate products because they are range fed then finished with mixed feeds, Corn, and oilseed meal before they are processed further into meat cuts. See also BICO Report.

VALUE ADDED MONTHLY INDEX = ПОМЕСЯЧНЫЙ ИНДЕКС ДОБАВЛЕННОЙ СТОИМОСТИ – Value Added Monthly Index (VAMI) is a way of reporting fund performance whereby each reporting period is indexed at 100 or 1000. Hence, for a fund with a total return of 39% over the year, the VAMI indexed at 100 is 139. Value Added Monthly Index (VAMI) is an index that tracks the monthly performance of a hypothetical USD1 000 investment. The calculation for the current month's VAMI is:- VAMI = Previous VAMI x (1 + Current Rate of Return). The value-added monthly index charts the total return gained by an investor from reinvestment of any dividends and additional interest gained through compounding. The VAMI index is sometimes used to evaluate the performance of a fund manager.

VALUE ADDED PRODUCER PRICE INDEX = ДОБАВЛЕННАЯ СТОИМОСТЬ ИНДЕКСА ПО ЦЕНАМ ПРОИЗВОДИТЕЛЕЙ – Value Added Producer Price Index is the weighted average of an output producer price index (PPI) and input PPI.

VALUE ADDED RATIO = СООТНОШЕНИЕ С ДОБАВЛЕННОЙ СТОИМОСТЬЮ – Value Added Ratio (VAR) is the time spent adding value to a product or service, divided by the total time from the receipt of an order to its delivery. A less expansive variation only includes in the denominator the period from the beginning of production or service through delivery. In either case, the VAR is designed to showcase the very large proportion of time and money that a company wastes during its servicing of customers. As such, it is a cost-reduction tool that complements constraint analysis. Example of the Value Added Ratio:- The International Plastic Case Company (IPC) manufactures cases for a high-end MP3 player that is assembled and marketed by a Swedish consumer goods company. The value-added steps of the case production process are a few seconds of molding time during a long injection molding batch run, as well as hand trimming and spraying three layers of urethane gloss on the case. Including drying time for the urethane gloss, these steps require six hours per case. Non value-added steps include moving plastic resin pellets to the injection molding machine, wait time at the machine, batch setup time, multiple movements between the molding, trimming, and painting workstations, and the storage interval before a full truckload is available for shipment. Thus, non value-added time is one week, which results in a VAR of 6 hours divided by 168 hours, or 3.6%. The VAR percentage in the example is typical, and would be considered quite respectable in some industries. A world-class manufacturing company, such as Toyota, rarely exceeds a VAR of 20%. Clearly, a detailed analysis of the processes underlying a VAR calculation can be used to pinpoint a considerable amount of wasted time in the production process, which can then lead to much greater inventory turnover and higher order fulfillment speeds. Other Uses of the Value Added Ratio:- we can apply the VAR to the effectiveness of the accounting function by dividing the time spent on business risk management and decision support by the total time worked by all accounting staff. This is an excellent way to determine the effectiveness of the department in supporting strategic company activities (rather than the usual transaction processing functions). Alternatively, we can include incremental changes in VAR in a capital expenditure request form. By doing so, applicants can show how an investment will change the value added amount of a process. However, since capital expenditures are not usually needed to improve the VAR, it can be used to deny capital expenditures. If the VAR is used as a principal management metric, then watch out for a shift to outsourced administrative and production processes. Managers will simply avoid the metric by shifting work away from the company, where it can only be measured with the active cooperation of suppliers. In short, the value added ratio is a useful analysis tool that focuses on the effectiveness of time spent. / Интёнэшэнэл Пластик Кэйс Кампэни (Ай.Пи.Си.; International Plastic Case Company (IPC)).

VALUE ADDED SERVICES = УСЛУГИ С ДОБАВЛЕННОЙ СТОИМОСТЬЮ – Value Added Services are the extra services that a distribution center will perform in order to meet the needs of their customers. Typically refer to special assembly, packaging, or picking services.

VALUE ADDED STATEMENT = ОТЧЁТ О ДОБАВЛЕННОЙ СТОИМОСТИ – A Value Added Statement (VAS) is a statement showing the net added value of a business firm during a certain period on its total transaction. The main purpose of value added statement (VAS) is to ascertain how much of the total net value was added and how it was distributed to the contributors of the value. Therefore, a value added statement (VAS) is regarded as a part of social responsibility accounting. A value added statement shows the wealth or value created and attributed to all stakeholders rather than just the shareholders. While the income statement reports on the income of shareholders, the value added statement (VAS) reports on the income earned by a large group of stakeholders, all the providers of capital plus employees and the government. Value Added Statement is the financial statement which shows how much value (wealth) has been created by an enterprise through utilization of its capacity, capital, manpower, and other resources, and how it is allocated among different stakeholders (employees, lenders, shareholders, government, etc) in an accounting period. Value-Added Statement (VAS) or reporting is a modified version of the profit and loss account. Like profit and loss account, the VAS reveals the operating performance of a company at a given point in time, using both accrual and matching procedures. However,

the VAS does not aim to provide a profit (or loss) figure as in the case of profit and loss account but a figure or return to a larger group of capital and labor providers (i.e. owners, employees), other claimants or interested parties. The term 'Value-Added' means the market price of the output of an enterprise less cost of bought-in goods and services. The resulting balance money is known as the Value-Added by an enterprise and this money can be divided among the various parties who have contributed in the production of goods and services of the enterprise in the form of factor inputs. Thus, the owners (or shareholders), creditors and governments (through taxation) are recipients of the enterprise income. Thus, the value-added income would include wages, rent, interest, taxes, dividends paid to shareholders and retained income of the company. The value-added statements can be derived from the profit and loss account. Generally, the profit and loss account is expressed as follows:- (1) RE = S – B – DP – W – I – DD – T (1); where RE = Retained Earnings, S = Sales Revenue, B = Bought in materials and services, DP = Depreciation, W = Wages, I = Interest, DD = Dividends, T = Taxes. Equation (1) expresses the profit as a return to shareholders. The value-added statement can be obtained by rearranging Equation (1), as follows:- (2) S – B = W + I + DD + T + DP + RE or (3) S – B – DP = W + I + DD + T + RE. Equation (2) indicates the gross value-added and Equation (3) indicates the net value added. In both the cases (equation) the left part of the equation indicates the value-added (net or gross) and the right part of the equation divides the value-added among the groups involved. Tables 4 shows, the preparation of a value-added statement and also indicates as to how a VAS can be derived from the profit and loss account. The value-added statement reflects a broader view of an enterprise's role and objectives than profit does. Profit is considered by some to convey narrow, sectional interpretation. Value-added reflects the performance of a team, i.e. employees, managers, shareholders, creditors. VAS helps the employees to perceive them as responsible participators in a team effort with management and thus may motivate them to work harder. Based on the value-added and maximized productivity incentives can be given to employees. VAS provides a better measure of the size and importance of companies. Value-added based ratios are interpreted as more indicative and predictive of the strength of the company than conventional ratios. The value-added concept is useful in the context of large companies that influence a large sections of society and have a general economic and social importance besides the limited interests of shareholders. Value-Added Statement is a simplified financial statement that shows how much wealth has been created by a company. A value-added statement calculates total output by adding sales, changes in stock, and other incomes, then subtracting depreciation, interest, taxation, dividends, and the amounts paid to suppliers and employees. Value Added Statement is a financial statement that depicts wealth created by an organization and how is that wealth distributed among various stakeholders. The various stakeholders comprise of the employees, shareholders, government, creditors and the wealth that is retained in the business. As per the concept of Enterprise Theory, profit is calculated for various stakeholders by an organization. Value Added is this profit generated by the collective efforts of management, employees, capital and the utilization of its capacity that is distributed amongst its various stakeholders. Consider a manufacturing firm. A typical firm would buy raw materials from the market. Process the raw materials and assemble them to produce the finished goods. The finished goods are then sold in the market. The additional work that the firm does to the raw materials in order for it to be sold in the market is the value added by that firm. Value added can also be defined as the difference between the value that the customers are willing to pay for the finished goods and the cost of materials. Advantages of a Value Added Statement:- (i) it is easy to calculate; (ii) helps a company to apportion the value to various stakeholders. The company can use this to analyze what proportion of value added is allocated to which stakeholder. (iii) Useful for doing a direct comparison with your competitors. (iv) Useful for internal comparison purposes and to devise employee incentive schemes. Difference between Value Added and Profit:- profit subtracts all the cost incurred in the process of generating revenues. The value added, on the other hand only subtracts the cost of bought-in goods and services. Profits are meant for shareholders whereas value added is meant for stakeholders who include shareholders also. Therefore, value added is a wider term. / Отчёт О Добавленной Стоимости.

VALUE ADDED TAX = НАЛОГ НА ДОБАВЛЕННУЮ СТОИМОСТЬ – Value Added Tax (VAT):- a value added type tax (VAT) is a tax on goods and services collected in stages by enterprises and which is ultimately charged in full to the final purchasers. This heading value added type taxes comprises the value added tax which is collected by the general government and which is applied to national and imported products, as well as, where appropriate, other deductible taxes applied under similar rules to those governing VAT, for simplicity henceforth called 'VAT'. Producers are obliged to pay only the difference between the VAT on their sales and the VAT on their purchases for their own intermediate consumption or gross fixed capital formation. Value Added Tax (VAT) is a tax assessed on the increased value of goods as they pass from the raw material stage through the production process to final consumption. The tax on processors or merchants is levied on the amount by which they increase the value of items they purchase. The European Union charges a tax equivalent to the value added to imports and rebates value-added taxes on exports. A Value Added Tax (VAT):- a tax on products collected in stages by enterprises; it is a wide-ranging tax usually designed to cover most or all goods and services but producers are obliged to pay to government only the difference between the VAT on their sales and the VAT on their purchases for intermediate consumption or capital formation, while VAT is not usually charged on sales to non-residents, i.e. exports. See also Deductible Value Added Tax, and Non-Deductible Value Added Tax. Value Added Tax (VAT) is a form of indirect sales tax paid on products and services at each stage of production or distribution, based on the value added at that stage and included in the cost to the ultimate customer. Value-Added Tax (VAT):- taxes collected at each designated stage of production or marketing. Raw material costs used from earlier stages are subtracted from each subsequent selling price, and the tax is applied only to the value added. For example, the cost of wheat from a producer is subtracted from the miller's selling price in calculating the miller's value added. The European Union (EU) levies a tax on the amount by which processors or merchants increase the value of items they purchase. The EU charges a tax equivalent to the value added to imports and rebates value-added taxes on exports. Value Added Tax (VAT) is the sales tax paid on products and services at each stage of production or distribution, based on the value added at each individual stage and included in the cost to the end customer. In Switzerland, the Value Added Tax is payable on each phase of production, distribution and import of goods, domestic services and the procurement of services from abroad. The method of pre-tax deduction avoids tax accumulations such that the tax burden will only be borne by the end consumer. Turnovers generated by export deliveries and (transport) services for the benefit of persons abroad are generally exempted. The standard tax rate currently is 7.6 per cent. The system basically complies with the relevant European Union Directive. In the United Kingdom (UK), VAT for most things is 17.5%, although some goods and services are exempt and some zero-rated. Value Added Tax (VAT) is a tax paid by enterprises. In broad terms an enterprise is liable for VAT on the total of its taxable sales but may deduct tax already paid by suppliers on its inputs (intermediate consumption). Thus the tax is effectively on the value added by the enterprise. Where the enterprise cannot deduct tax on its inputs the tax is referred to as Nondeductible. VAT is the main UK tax on products. Value Added Tax (VAT) is a consumption tax where taxes are levied at each step of a manufacturing process where value is added to that product at that point in the manufacturing cycle; as well as at the point where the consumer purchases the end product. Value Added Tax (VAT) is a tax which must be charged by VAT registered businesses on goods and services which they supply. In the UK, VAT is administered by HM Customs and Excise, not the Inland Revenue. Registered businesses must pay to HM Customs and Excise any VAT that they charge on their sales (outputs), but can normally deduct VAT they have paid on goods purchased for the business (inputs). Tax on consumption based on the value added by the operations of a business. Value Added Tax (VAT) is a form of consumption tax. As a buyer, it is a tax on the purchase price. As a seller, it is a tax on the 'value added' to a product, material or service at his/her stage of its manufacture or distribution. For example, if a television is built by a company in a country that charges VAT, the manufacturer is charged VAT on all of

the parts they purchase to produce the television. Once the television is sold, the consumer pays VAT on the entire product. The VAT is ultimately passed on to the end user. In international trade, Value Added Tax (VAT) is generally payable on all imports at the same rate that would apply to the product or service if supplied in the United Kingdom. Most exports are zero-rated for VAT. Value-Added Tax (VAT) is a government levy on the amount that a business firm adds to the price of a commodity during production and distribution of a good. Three major types of value-added tax have been identified, depending on the deductions allowed, but only one – called the 'Consumption' type – is widely used today. Calculation of the value-added tax of the consumption type can be made in any of three different ways, but virtually every country imposing the tax uses the 'Invoice', or 'Credit', method of computation. Using this method, each seller (the party responsible for collecting the tax and paying it to the government) first calculates the sum of all the taxes that he has collected on goods sold; he then totals the sum of all the taxes that he has paid on goods purchased. His net tax liability is the difference between the tax collected and the tax paid. It is generally assumed that the burden of the value-added tax, like that of other sales taxes, falls upon the final consumer. Although the tax is collected at each stage of the production-distribution chain, the fact that sellers receive a credit for their tax payments causes the tax, in effect, to be passed on to the final consumer, who receives no credit. The tax can be regressive (i.e. the percentage of income paid in tax rises as income falls), but most countries have at least partly avoided this effect by applying a lower rate to necessities than to luxury items. In 1954 France was the first country to adopt the value-added tax on a large scale. It served as an improvement on the earlier turnover tax, by which a product was taxed repeatedly at every stage of production and distribution, without relief for taxes paid at previous stages. Although easier to administer, such a tax discriminated heavily against industries and sectors in which products were bought and sold several times, encouraging an undesirable concentration of economic power. In 1968 West Germany adopted the value-added tax, and since then most other western European nations have followed suit, largely as the result of a desire to harmonize tax systems. All members of the European Union are required to implement value-added taxes that conform to a model prescribed by the union. Many countries in South America, Asia, and Africa have also adopted the tax. The US state of Michigan used a value-added tax from 1953 through 1967 and again from 1975. Value-Added Tax:- method of indirect taxation that levies a tax is at each stage of production on the value added at that specific stage. Value-Added Tax (VAT) is a sales or consumption tax which the end user pays. Typically, this is a 'hidden' tax, added to the list price of the goods in question. / Смотрите также Налог На Добавленную Стоимость (Value Added Tax – ESA), Не Подлежащий Вычету Налог На Добавленную Стоимость (Non-Deductible Value Added Tax), и Подлежащий Вычету Налог На Добавленную Стоимость (Deductible Value Added Tax). Налог На Добавленную Стоимость (НДС):- хотя теоретически НДС является налогом на добавленную стоимость (value added), на практике он похож на налог с оборота, когда каждый торговец добавляет в выписываемые им счета-фактуры этот налог и ведёт учёт собранного налога для последующего предоставления информации в Департамент Налогов и Сборов. Однако продавец имеет право вычитать сумму налога, который он, согласно выписанным ему счетам-фактурам, уплатил за товары и услуги (но не в виде заработной платы или жалованья). Таким образом, этот налог является косвенным налогом (indirect tax), а его бремя ложится в итоге не на торговцев, а на конечных потребителей товаров и услуг. Данная система налогообложения создана для того, чтобы избежать уплаты налога на налог в связи с тем, что товары и услуги проходят длинный путь к потребителю; при системе НДС все товары и услуги несут в себе только налог, который взимается при окончательной продаже товара потребителю. НДС был введён в Великобритании в 1973 и одновременно в странах – её партнёрах по ЕЭС. В Великобритании НДС взимается со всех товаров и услуг, кроме освобождённых от него или облагаемых НДС по нулевой ставке (zero-rated). Налог На Добавленную Стоимость (НДС; Value-Added Tax (VAT)):- налог с оборота или потребления, уплачиваемый на товары и услуги коммерческих организаций. НДС используют во всех странах ЕС, хотя ставки по странам весьма различны, причём выше всего она во Франции. Он взимается с фирм, функционирующих в пределах Общего Рынка, и служит основой для определения соответствующего элемента системы 'собственных средств' для финансирования бюджета Сообщества. В первой Директиве (от 1967) были сформулированы принципы гармонизации законодательства, относящегося к налогам с оборота. Вторая Директива (от 1967) определила структуры и процедуры применения. Ещё одна Директива (от 1979) относилась к возврату НДС фирмам, функционирующим в каком-либо государстве ЕС, за исключением случаев, когда фирмы включили НДС в свои счета за товары и услуги. Обязательной предпосылкой отмены пограничного контроля во внутренней торговле Сообщества служит упразднение нынешней системы, согласно которой вывозные (или экспортные) товары освобождаются от НДС, а привозные (или импортные) товары облагаются им. Предполагается создать Расчётную Палату по НДС. Кроме того, единообразный налог, как ожидается, сделает излишней беспошлинную (duty-free) торговлю для тех, кто путешествует между 12 странами ЕС, а она означает потерю оборота в сумме 2 миллиарда Долларов в год. 29 Июля 1992 министры финансов стран-участниц ЕС договорились о временной унификации НДС, предусматривающей единую ставку налога во всём Сообществе. Она установлена в размере 15% сроком на четыре года, начиная с Января 1993. В течение этого срока налоги со сделок, подлежащих обложению, между лицами в различных странах будут взиматься в привозящей (или импортирующей) стране. В условиях постоянной системы, которая начнёт действовать в 1997, налог будет взиматься в стране происхождения. Смотрите также Европа Без Границ (Europe Without Frontiers); Акцизный Налог (Excise Tax); и Пограничные Барьеры (Frontier Barriers). Налог на Добавленную Стоимость (НДС; Value-Added Tax (VAT)):- потребительский налог, установленный на каждой стадии производственного цикла продукции, а также в момент приобретения товара конечным потребителем. Налог на добавленную стоимость давно введён в Европейских странах и является основным источником дохода стран Европейского общего рынка. Сторонники введения налога на добавленную стоимость в США утверждают, что это наиболее эффективный метод взыскания доходов и что размер поступлений от этого дохода позволит сократить ставку подоходного налога. Противники этой идеи утверждают, что налог на добавленную стоимость эквивалентен общенациональному налогу на продажи и, следовательно, является несправедливым и регрессивным. Это наиболее тяжёлое бремя для тех, кто меньше других может себе позволить платить 'лишнее'. Например, за каждую деталь, поступающую на сборку автомобиля, производитель должен уплачивать поставщику налог на добавленную стоимость, вероятно, составляющий распределённый процент от цены продажи, как в случае налога на продажу. Когда автомобиль продаётся, покупатель платит налог на добавленную стоимость готовой продукции за вычетом налогов на материалы и детали, которые облагались налогом на более ранних стадиях. Это позволяет избежать двойного налогообложения и, таким образом, отличается от единого налога на продажу, основанного на совокупной стоимости покупки. Налог на Добавленную Стоимость (НДС) является косвенным налогом, форма изъятия в бюджет части добавленной стоимости, которая появляется во всех стадия производства и продажи товаров или услуг. Сумма налога, подлежащая уплате в бюджет, в Российском законодательстве определяется как разница между суммой налога, исчисленной по установленной ставке с налоговой базы, определяемой в соответствии с положениями законодательства, и суммой налоговых вычетов (то есть суммы налога, уплаченного при приобретении товаров, работ, услуг, используемых в деятельности компании, облагаемой НДС). Расчёт налога осуществляется отдельно по каждой из применяемых ставок. НДС, уплаченный при приобретении товаров, работ, услуг, не подлежащих налогообложению, к вычету не принимается. В России НДС начал свое действие с 1992. Отдельные виды операций и категории налогоплательщиков не подлежат уплате НДС. Максимальная ставка НДС составляла 28%. С 01 Января 2004 ставка НДС составляет 18%. Что не облагается НДС? Что освобождается от НДС? Что облагается меньшим НДС? Некторые продовольственные товары и товары для детей попадают под пониженную ставку

НДС 10%. Для товаров на вывоз (или экспорт) ставка равна 0%. Существует ряд товаров, работ, услуг, операций, которые не подлежат налогообложению. Организации, которые перешли на упрощённую систему налогообложения (так называемая ‘упрощёнка’), не уплачивают НДС. В последнее время много обсуждают вопрос о снижении ставки НДС или полной отмене, но это сомнительно, так как НДС формирует около четверти федерального бюджета России. Формула расчёта НДС:- пусть известна сумма S. Надо вычислить сумму НДС, составляющую 18 процентов от S. НДС = S * 18 / 100. Пример. Сумма 10 000 Рублей, НДС составит:- НДС = 10 000 * 18 / 100 = 1 800. Налог на Добавленную Стоимость (НДС) – это косвенный налог на прибавочную (добавленную) стоимость, возникающую в процессе создания товаров, работ, услуг. Налог уплачивается по мере реализации произведённой продукции (выполнения работ, оказания услуг) или получения предварительной оплаты от покупателя. Исчисление и уплата налога регламентированы Главой 21 Налогового Кодекса РФ. Плательщики НДС, Ставка налога:- Плательщиками НДС являются организации, индивидуальные предприниматели, а также лица, признаваемые налогоплательщиками в связи с перемещением товаров через таможенную границу Таможенного Союза. В настоящее время основная ставка НДС в Российской Федерации составляет 18%. Однако для некоторых продовольственных товаров, товаров для детей действует пониженная ставка 10%, а для вывозимых (или экспортируемых) товаров налог фактически отсутствует – ставка 0% (при этом не следует смешивать понятия ‘освобождение от налога’ и ‘обложение по ставке 0%’ – это разные случаи). Особенности исчисления НДС:- налог на добавленную стоимость – один из самых трудных для расчёта и сложных для государственного администрирования налогов. Связано это с тем, что НДС – косвенный налог. Это значит, что его уплачивает организация за счёт средств, которые получает от покупателя (НДС включается в цену товара). Более того, чтобы исключить двойное обложение добавленной стоимости, покупатели сырья, материалов, услуг, предъявляют уплаченный в составе покупной цены налог к вычету. А уже после создания и реализации своего продукта вновь исчисляют НДС и удерживают его с покупателя. В итоге, конечным плательщиком всей суммы НДС становится конечный покупатель – обычно это граждане РФ. А в случае с вывозом (или экспортом) товаров за пределы России (Таможенного Союза), НДС не платит никто, уже уплаченный налог возвращается организациям-продавцам после специальной процедуры документального подтверждения факта вывоза (или экспорта). Процесс исчисления налога усложняется льготами и различными ставками. Несмотря на огромную экономическую важность налога, сложность его исчисления и уплаты/возмещения делает НДС одним из самых ‘криминальных’ и проблемных для бухгалтера налогов – его незаконно возмещают из бюджета фирмы-однодневки, а бухгалтерам добропорядочных предприятий приходится доказывать право на получение вычета. НДС не является изобретением Российской налоговой системы. Налог на добавленную стоимость существует в большинстве развитых стран мира, различаются только ставки налога (в РФ – одна из самых низких). Налог На Добавленную Стоимость (НДС) – косвенный налог на товары и услуги, применяемый в странах – членах ЕЭС, а также в некоторых других промышленно развитых странах. Налоговая база – стоимость, добавленная на каждой стадии производства и реализации товара. Добавленная стоимость (прирост стоимости) включает заработную плату с начислениями, амортизацию, процент за кредит, прибыль, расходы на электроэнергию, рекламу, транспорт и другое. В цену входят общая сумма НДС, внесённая предпринимателем на всех стадиях продвижения товара или услуги к потребителю.

VALUE ADDED TAX AND DUTIES TRIBUNAL = ТРИБУНАЛ ПО НАЛОГУ НА ДОБАВЛЕННУЮ СТОИМОСТЬ И ПОШЛИНЫ – Value Added Tax And Duties Tribunal (in the United Kingdom) is an independent body that provides a method of dealing with disputes concerning VAT, and both Customs and excise duties.

VALUE ADDED TIME = СРОК НА ДОБАВЛЕННУЮ СТОИМОСТЬ (или ХХ) – Value Added Time is the time spent that improves the outcome of a process. This is typically just the processing time associated with production. All of the other intervals associated with a process, such as wait time and queue time, contribute nothing to the outcome and so are considered non-value added time. This concept is used to identify non-value added activities and eliminate them from a process, so that the total time required to complete a process is reduced. When the duration of the production process has been shrunken in this manner, it can be a competitive advantage, since a business can respond more quickly to customer demands. It may be possible to compress the amount of value added time in a process. However, it is usually easier to first eliminate or reduce non-value added time, since it comprises such a large part of the total processing time.

VALUE ADDED VERTICAL INTEGRATION = ВЕРТИКАЛЬНАЯ ИНТЕГРАЦИЯ ДОБАВЛЕННОЙ СТОИМОСТИ (или ХХ) – Value Added Vertical Integration is controlling as much of the build stream, both upstream and downstream, in producing a product or service as possible while ensuring that every part of the stream provides added value. See also Value Added; and Vertical Integration.

VALUE ADDITIVITY PRINCIPAL = ПРИНЦИПАЛ АДДИТИВНОСТИ СТОИМОСТИ (или ХХ) – Value Additivity Principal (VAP) is:- (1) a situation in which the market value of a portfolio or other group of assets exactly equals the market value of the individual assets or securities represented therein. (2) A situation in which the net present value of a portfolio or other group of assets exactly equals the net present value of the individual assets or securities represented therein. Value Additivity Principal:- when the value of a whole group of assets exactly equals the sum of the values of the individual assets that make up the group of assets. Or, the principle that the net present value of a set of independent projects is just the sum of the net present values of the individual projects. Value Additivity Principal (VAP):- a scenario where a group of asset’s value is exactly equal to the resultant figure derived by adding the value of individual assets comprising the asset group. It is the principle which states that net present value of group of separate projects is equal to the sum of net present values of each of the projects. Value Additivity Principal:- finance concept that the present value of a set of expected cash flows is equal to the sum of their individual present value.

VALUE ADJUSTMENT = ПЕРЕОЦЕНКА СТОИМОСТИ (или ПЕРЕОЦЕНКА ЦЕННОСТИ) – Value Adjustment is an adjustment of the value of an asset on the balance sheet to its true value. / Переоценка Ценности актива в балансовом отчёте исходя из его истинной ценности.

VALUE ANALYSIS = СТОИМОСТНОЙ АНАЛИЗ (или АНАЛИЗ СТОИМОСТИ) – Value Analysis:- the systematic application of recognized techniques which identify the function of a product or service, establish a monetary value for the function, and provide the necessary function reliably at the lowest overall cost. The term Value Analysis is sometimes considered as a synonym for Value Engineering. Value Analysis is:- (1) In manufacturing:- systematic analysis that identifies and selects the best value alternatives for designs, materials, processes, and systems. It proceeds by repeatedly asking ‘can the cost of this item or step be reduced or eliminated, without diminishing the effectiveness, required quality, or customer satisfaction’? Also called Value Engineering, its objectives are (i) to distinguish between the incurred costs (actual use of resources) and the costs inherent (locked in) in a particular design (and which determine the incurring costs), and (ii) to minimize the locked-in costs. (2) In purchasing:- examination of each procurement item to ascertain its total cost of acquisition, maintenance, and usage over its useful life and, wherever feasible, to replace it with a more cost effective substitute. Also called Value-In-Use Analysis. Value Analysis is the systematic and critical assessment by an organization of every feature of a product to ensure that its cost is no greater than is necessary to carry out its functions. Value Analysis is one of the major techniques of cost reduction and control. It is a disciplined approach which ensures the necessary

functions for the minimum cost without diminishing quality, reliability, performance and appearance. It is a creative approach to eliminate the unnecessary costs which add neither to quality nor to the appearance of the product. It is a systematic application of techniques to identify the functions of a product or a component and to provide the desired function at the lowest total cost. These are the days of providing the customer with really best quality products at least cost which is possible through value analysis which proves wrong rightly 'Best and Cheap' or 'Best is never cheap' or 'Cheap is Costly'. What is Value Analysis? Before understanding the meaning of phrase 'Value Analysis' or 'Value Engineering', let us know about value. 'Value' is one of those terms having good many connotations and even contradictory definitions. 'Value' is a word that is very often used by individuals without being clearly understood. Forget about common people. Even different departments of the same organization have different opinions of the 'value' of the product that the company manufactures. The designer equates value with reliability; purchase people with price paid for them; production personnel with that of cost from the angle of manufacture; sales people with what customer is willing to pay. In the field of value investigation, value refers to economic value, which itself can be sub-divided into four types as cost value, exchange value, use value and esteem value. 'Cost Value' is the measure of sum of all costs incurred in producing the product. The 'Cost Value', therefore is the sum of raw-material cost, labour cost, tool cost and overheads expended to produce the product. 'Exchange Value' is the measure of all the properties, qualities and features of the product which make the product possible of being traded for another product or for money. In a conventional sense, 'exchange value' refers to the price that a purchaser will offer for the product, the price being dependent upon the satisfaction value which derives from the product. Value derived from the product consists of two components namely (a) value due to reliability of performance of the product and the value which the possession bestows upon the buyer. These are often referred to as Value In Value and Esteem In Value. 'Use Value' is the measure of properties, qualities and features which make the product accomplish a use, work or service. Use value, therefore, is the price paid by the buyer or the cost incurred by the manufacturer in order to ensure that the product performs its intended function efficiently. Use value in the fundamental form of economic value. An item without use value can have neither exchange value nor esteem value. 'Esteem Value' is the measure of properties, features, attractiveness graphic packaging and the like which increases sales appeal or which attracts customers and create in them a strong desire to own the product. 'Esteem Value', therefore, is the price paid by the buyer or the cost incurred by the manufacturer beyond the use value. It is the perception value. Value Analysis Proper:- Value Analysis is an organised approach to identify unnecessary costs associated with any product, material, part, component, system or service by analysis of function and efficiently eliminating them without impairing the quality functional reliability or its capacity to give service. According to Society of American Value Engineers (SAVE) 'Value Analysis is the systematic application of recognised techniques which identify the function of a product or services establish a monetary value for the function and provide the necessary function reliability at that lowest overall cost'. Mr. Lorry D. Miles production engineer working at General Electric of USA defined it as 'Value Analysis is the study of the relationship of design, function and cost of any material or service with an object of reducing its cost through modification of design or material specifications, manufacture by more efficient process, changes in sources of supply, elimination or incorporation into another item'. Thus, value analysis is a systematic application of established techniques to identify the functions of a product or component and to provide the desired functions at the lowest total cost. It is a creative approach to eliminate unnecessary costs which add neither to quality no to the appearance of the product. It is a rational and structured process consisting of:- (a) Functional analysis to define the reason for the existence of a product or its components; (b) Creatively analysis for generating new and better alternatives; and (c) Measurement for evaluating the value of present and future concepts. The phrase value analysis can be defined as a technique which examines the facts of a function and cost of a product in order to determine whether the cost can be reduced or altogether eliminated, while retaining all the features of performance and quality of a product or both. Therefore, logically, VA is an organised approach of exposing and eliminating unnecessary costs. The method has logical foundation in its fundamental approach to cost reduction and profit improvement and in this objective approach, the VA techniques has to analyse the functional cost of an item and recommend a change. Put alternatively, VA is a team approach to think functionally about a component as to 'what it does' rather than 'what it is'. This approach is the real test of understanding problems under study. Value Analysis And Value Engineering:- 'VA' and 'VE' are closely related terms so much so that many people use them interchangeably. Though the philosophy understanding the two is the same the identification of unnecessary costs yet they are different. The difference lies in the time and stage at which the technique is applied. 'Value Analysis' is the application of a set of techniques to an existing product with a view to improve its value. Thus, it is remedial process. 'Value Engineering' is the application of exactly the same set of techniques to a new product at the design stage project concept or preliminary design when no hardware exists to ensure that bad features not added. Thus, it is a 'preventive' measure. In that sense, 'VE' is fundamental and VA is collateral because 'prevention is better than cure'. Value Analysis Versus Other Conventional Approaches:- speaking in terms of 'cost reduction' value analysis is an effective tool of cost reduction which differs from established conventional approaches such as industrial engineering, production engineering, methods engineering and the like. The 'traditional' or 'conventional' approaches differ from this non-conventional or modern technique of VA as under:- First:- traditional approaches concern 'post-production' stage but VA can be the 'pre-production' as well as 'post production stage' technique. Second:- traditional approaches are 'methods concerned'. They accept the drawing of the part 'as is' and, therefore, set to improve the part through analysis of manufacturing methods, machines, materials, tools, jigs and fixtures and the like. On the other hand, 'VA' does not accept the designed product and its components 'as is' but advocates cost reduction through identification of the function and subsequent redesign of the product so as to make it perform its functions at the lowest possible cost. 'VA', therefore, challenges the very design specifications, design requirements and the design itself. Third:- traditional methods are mere 'cost centered' while VA, in addition to cost improvement, usually seeks to improve quality, reliability, maintainability, safety, performance and alluring features. Fourth:- VA is more potent than traditional cost reduction techniques. Instances can be brought to surface to demonstrate that VA can remove ten to twenty percent of cost after the traditional methods of cost reduction have applied. Award of warning is essential at this stage, Inspite of VA's better potential and greater effectiveness, it is not a substitute nor is it intended to replace effective cost reduction techniques which have been in use for many years and have proved effective and valuable in their areas of application. What can be said is that VA can augment or strengthen the process of cost reduction and quality improvement. Phases Of Value Analysis:- as an exercise, the phases of value analysis are:- (1) Phase Of Origination:- in the first phase, a value analysis study team is constituted. The project is selected and clearly defined. The team examines in detail the product and its components to understand thoroughly their nature. (2) Phase Of Information:- after familiarisation, a functional analysis is carried out to determine the functions and uses of the product and its components. The cost and importance of each function are identified. A value index is calculated on the basis of cost benefit ratio for each function. A list is being prepared in which the items of functions are arranged in decreasing order of value. (3) Phase Of Innovation:- this is the creative phase concerned with the generation of new alternatives to replace or removing the existing ones. (4) Phase Of Evaluation:- each and every alternative is analysed and the most promising alternatives are selected. These alternatives are further examined for economic and technical feasibility. The alternatives finally selected must be capable of performances the desired functions satisfactorily. These must meet the standards of accuracy, reliability, safety, maintenance and repairs, environmental effects and so on. (5) Phase Of Choice:- in this phase, report is prepared. This report contains a summary of the study, conclusions and specific proposals. The decision makers choose the alternative. The programs and action places are then developed to implement the chosen alternative. (6) Phase Of Implementation:- the chosen alternative is put to the actual use with the help of the programs and

action plans so developed in advance. (7) Phase Of Review:- the progress of analysis changes in continuously monitored and followed up in order to provide assistance, to clarify any misconceptions and to ensure that the desired results are achieved. Merits Of Value Analysis:- Value Analysis is really a very valuable technique of cost reduction and quality improvement. The specific merits of its are:- (1) Improvement In Product Design:- it leads to improvements in the product design so that more useful products are given shape. Now in case of ball points, we do not have clogging, there is easy and even flow of ink and rubber pad is surrounding that reduces figures fatigue. (2) High Quality Is Maintained:- high quality implies higher value. Thus, dry cells were leaking; now they are leak proof; they are pen size with same power. Latest is that they are rechargeable. (3) Elimination Of Wastage:- Value Analysis improves the overall efficiency by eliminating the wastages of various types. It was a problem to correct the mistakes. It was done by pasting a paper. Now, pens are there and liquid paper is developed which dries fast and can write back. (4) Savings In Costs:- the main aim of value analysis is to cut the unwanted costs by retaining all the features of performance or even bettering the performance. Good deal of research and development has taken place. Now milk, oils, purees pulp can be packed in tetra packing presuming the qualities and the tetra pack is degradable unlike plastic packs. (5) Generation Of New Ideas And Products:- in case of took brushes, those in 1930's were flat and hard, over 60 to 70 years brushes have come making brushing teeth easy, cosy and dosy as it glides and massages gums. (6) Encourages Team-Spirit And Morale:- Value Analysis is a tool which is not handled by one, but groups or teams and an organisation itself is a team of personnel having specification. A product is the product of all team efforts. Therefore, it fosters team spirit and manures employee morale as they are pulling together for greater success. (7) Neglected Areas Are Brought Under Focus:- the organisational areas which need attention and improvement are brought under the spot-light and even the weakest gets a chance of getting stronger and more useful finally join's the main strain. (8) Qualification of Intangibles:- the whole process of value analysis is an exercise of converting the intangibles to tangible for decision making purpose. It is really difficult to make decisions on the issues where the things are (variables) not quantifiable. However, value analysis does it. The decision makers are provided with qualified data and on the basis of decisions are made. Such decisions are bound to be sound. (9) Wide Spectrum Of Application:- the principles and techniques of value analysis can be applied to all areas-man be purchasing, hardware, products, systems, procedures and so on. (10) Building And Improving Company Image:- the company's status or image or personality is built up or improved to a great extent. Improvement in quality and reduction in cost means competitive product and good name in product market; it is a good pay master as sales and profits higher and labour market it enjoys reputation; it capital market, nobody hesitates to invest as it is a quality company. Limitations:- like any other cost reduction technique, value analysis has its own limitations. The most common limitations are that the man made excuses are the blocks in implementing these plans of value analysis. The most common excuses given are:- (a) Lack of motivation; (b) Resistive to change; (c) Inertia; (d) Lack of knowledge and patience; (e) Attitude of 'It will not work in India; (f) We are very small or very big; (g) This has been tried earlier and failed; (h) The change is too big; (i) 'Let competitors try before we try'; and (j) Difficulty of teams meeting or team meeting for getting consensus. These limitations are man-made and can be over-come one the company divides to implement. However, they should be educated of the plus and minus points and the main beneficiaries are those that are to be told and they are to be taken into confidence. / Г-н Лори Ди. Майлз (Mr. Lorry D. Miles) в Дьженерэл Элэктрик (General Electric). Стоимостной Анализ:- проверка каждой характеристики товара с целью убедиться, что его стоимость не будет выше той, которая необходима для выполнения им своих функций. Стоимостной анализ может проводиться на этапе разработки нового товара либо применяться к уже существующим товарам.

VALUE AREA = СТОИМОСТНАЯ ОБЛАСТЬ (или ОБЛАСТЬ СТОИМОСТИ) – The Value Area is a Market Profile concept. This is an area demarcated by 2 prices which bound the 'most traded in' part of a time period. Technically the value area is 1 standard deviation away from the most traded at price which is the price which has the highest number of the Time Price Opportunities (TPO's). This price is also known as the Point of Control (POC). Each time that the market trades at a price during a half hour bracket a letter is added to that price (one per half hour) and a vertically aligned bell curve is created. The middle chunk of that chart is the Value Area. Typically, the upper and lower prices of the Value Area, know as Value Area High (VAH) and Value Area Low (VAL) are seen as support and resistance lines – in their simplest terms. Sample:- 1287.50 G, 1287.25 G, 1287.00 EFG, 1286.75 EFGH, 1286.50 EFGH, 1286.25 EFGH, 1286.00 EFGH, 1285.75 EFGH, 1285.50 EFGHL, 1285.25 EFGHL, 1285.00 EFGHL, 1284.75 EFGHIL, 1284.50 EFGHIL, 1284.25 EFHIL, 1284.00 DEFHIKL, 1283.75 DEHIJKL, 1283.50 DEHIJKLMQ, 1283.25 DEIJKLMQR, 1283.00 DEIJKLMQR, 1282.75 DEIJKLMQR, 1282.50 DEIJKMPQR, 1282.25 DEIJMPQR, 1282.00 DEIJMPQR, 1281.75 DIJMNPQR, 1281.50 DIMNPQR, 1281.25 DIMNPQ, 1281.00 DIMNPQ, 1280.75 DNPQ, 1280.50 DNPQ, 1280.25 DNP, 1280.00 NP, 1279.75 NP, 1279.50 N. Generally, the top of the value area provides intraday resistance while the bottom of the value area intraday support. This is more likely to happen when the market opens inside the value area.

VALUE AREA HIGH = СТОИМОСТНАЯ ОБЛАСТЬ ВЫСОКАЯ – Value Area High (VAH) is a Market Profile concept. The VAH is the highest price in the Value Area and is often used and seen as an area of support or resistance by traders. Traders will frequently use this area (with other methods and indicators) to enter and exit trades due to the support/resistance nature of this area. Together with the Value Area Low (VAL), the VAH bounds 68% of market activity around the Point of Control (POC). The Value Area High is also sometimes know as the Upper Value Area. This value can be calculated using the Market Profile Calculator. Values for popular futures contracts are calculated daily and posted in the Market Profile Forum.

VALUE AREA LOW = СТОИМОСТНАЯ ОБЛАСТЬ НИЗКАЯ – Value Area Low (VAL) is a Market Profile concept. The VAL is the lowest price in the Value Area and is often used and seen as an area of support or resistance by traders. Traders will frequently use this area (with other methods and indicators) to enter and exit trades due to the support/resistance nature of this area. Together with the Value Area High (VAH), the VAL bounds 68% of market activity around the Point of Control (POC). The Value Area Low is also sometimes know as the Lower Value Area. This value can be calculated using the Market Profile Calculator. Values for popular futures contracts are calculated daily and posted in the Market Profile Forum.

VALUE ASSET = СТОИМОСТНОЙ АКТИВ (или ЦЕННЫЙ АКТИВ) – Value Asset:- xxxxx. Low-Value Assets (LVA) are generally assets that have acquisition and production costs within specific value limits. These value limits are set by law, international accounting standards, or internal company regulations. The regulations define how LVA can and must be treated in accounting. In Australia, Low-Value Asset is a depreciating asset that is not a low-cost asset but which has an opening net book value less than AUD1 000 (as of July 01 in the year that it is allocated to the pool), and for which the organization has previously worked out any deduction using the reducing balance depreciation method. / Ценные Активы или Стоимостные Активы:- показатель, который рассчитывается двумя способами. Первый способ (на одну обыкновенную акцию (per common share)):- чистые активы компании (после вычета всех обязательств, ликвидационной стоимости привилегированных акций и накопленных дивидендов, если таковые есть), делятся на количество находящихся в обращении обыкновенных акций. Второй способ (на одну привилегированную акцию (per preffered share)):- чистые активы компании (после вычета всех обязательств, ликвидационной стоимости любой имеющей приоритет привилегированной акции и накопленных дивидендов, если таковые есть), делятся на количество находящихся в обращении привилегированных акций.

VALUE AT RISK = ЦЕННОСТЬ ПРИ РИСКЕ (или СТОИМОСТЬ, ПОДВЕРЖЕННАЯ РИСКУ) – Value At Risk (VaR):- generally speaks to the riskiness of a portfolio. A Value at Risk (VaR) is a financial measure of risk that seeks to capture the potential loss one might expect to see in a portfolio or position, if the market or other risk factors were to move in an unfavorable direction. VaR numbers calculated on a daily basis reflect changes in the value of the portfolio or position from one day to the next, not from the original position. Put another way, Given a fair value of a portfolio of USDXXX million, VaR would represent the variability of actually realizing that value given a certain comfort level, i.e. confidence interval. VaR is traditionally calculated using a set confidence interval and a set holding period. At a 95% confidence interval with a one-day holding period, Williams Power is suggesting that a 5% chance exists that Williams could lose USDXXX million in one day given certain historical market movements. The estimate of the maximum amount that the value of covered positions could decline during a fixed holding period within a stated confidence level. Value At Risk (VaR) is a statistical technique used to measure and quantify the level of financial risk within a firm or investment portfolio over a specific time frame. This metric is most commonly used by investment and commercial banks to determine the extent and occurrence ratio of potential losses in their institutional portfolios. VaR calculations can be applied to specific positions or portfolios as a whole or to measure firm-wide risk exposure. VaR modeling determines the potential for loss in the entity being assessed, as well as the probability of occurrence for the defined loss. VaR is measured by assessing the amount of potential loss, the probability of occurrence for the amount of loss and the time frame. For example, a financial firm may determine an asset has a 3% one-month VaR of 2%, representing a 3% chance of the asset declining in value by 2% during the one-month time frame. The conversion of the 3% chance of occurrence to a daily ratio places the odds of a 2% loss at one day per month. Applying VaR:- investment banks commonly apply VaR modeling to firm-wide risk due to the potential for independent trading desks to expose the firm to highly correlated assets unintentionally. Employing a firm-wide VaR assessment allows for the determination of the cumulative risks from aggregated positions held by different trading desks and departments within the institution. Using the data provided by VaR modeling, financial institutions can determine whether they have sufficient capital reserves in place to cover losses or whether higher-than-acceptable risks require concentrated holdings to be reduced. Problems With VaR Calculations:- there is no standard protocol for the statistics used to determine asset, portfolio or firm-wide risk. For example, statistics pulled arbitrarily from a period of low volatility may understate the potential for risk events to occur, as well as the potential magnitude. Risk may be further understated using normal distribution probabilities, which generally do not account for extreme or black swan events. The assessment of potential loss represents the lowest amount of risk in a range of outcomes. For example, a VaR determination of 95% with 20% asset risk represents an expectation of losing at least 20% one of every 20 days on average. In this calculation, a loss of 50% still validates the risk assessment. These problems were exposed in the financial crisis of 2008, as relatively benign VaR calculations understated the potential occurrence of risk events posed by portfolios of subprime mortgages. Risk magnitude was also underestimated, which resulted in extreme leverage ratios within subprime portfolios. As a result, the underestimations of occurrence and risk magnitude left institutions unable to cover billions of Dollars in losses as subprime mortgage values collapsed. Value-At-Risk concept is a procedure for calculating the loss potential resulting from price changes of the trading position. This loss potential is calculated on the basis of market-orientated price changes and is quoted subject to a certain probability (99% for instance). Value-At-Risk (VaR) is:- (1) the worst loss expected to be suffered over a given period of time with a given probability. The time period is known as the holding period and the probability is known as the Confidence Interval. (2) Value-at-risk is not an estimate of the worst possible loss, but the largest likely loss. For example, a firm might estimate its VAR over ten days to be USD100 million with a confidence interval of 95%. This would mean there is a one-in-twenty (5%) chance of a loss larger than USD100 million in the next 10 days. In order to calculate VAR, a firm must model both the way the relevant market factors will change over the holding period and the way (if any) in which these changes are correlated between market factors. It must then evaluate the potential effects of these changes on its portfolio at the desired level of consolidation (by asset class, group or business line, for example). Value At Risk (VaR) an estimate of the upper bound on losses an institution would expect to incur during a given period (e.g., one day) for a given confidence level (e.g., 95%). Value-At-Tisk (VaR):- the VaR of a portfolio is the worst loss expected to be suffered over a given period of time with a given probability. The time period is known as the holding period, and the probability is known as the confidence interval. VaR is not an estimate of the worst possible loss, but the largest likely loss. For example, a firm might estimate its VaR over 10 days to be USD100 million, with a confidence interval of 95%. This would mean there is a one-in-20 (5%) chance of a loss larger than USD100 million in the next 10 days. In order to calculate VaR, a firm must model both the way the relevant market factors will change over the holding period and the way, if any, these changes are correlated between market factors. It must then evaluate the potential effects of these changes on its portfolio at the desired level of consolidation (by asset class, group or business line, for example). See also Credit Value-At-Risk. Value At Risk is a measure of the potential financial loss in the investment portfolio or on the whole balance sheet. Value at risk provides an estimate of the worst expected loss over a certain period of time at a given confidence level. For example, a 12 month value at risk with a 95% confidence level of USD1 million means that an insurer would only expect to lose more than USD1 million 5% of the time or once in 20 years. / Вилъйэмз Павё (Williams Power). Стоимость Под Риском:- оценка верхнего предела убытков, которые учреждение могло бы понести в течение данного периода (например, одного дня) для заданного уровня доверия (например, 95%). Стоимость, Подверженная Риску:- метод оценки уровня убытков с определённой вероятностью за фиксированный промежуток времени. Метод основан на статистическом анализе исторических цен и волатильности.

VALUE–AT–RISK MODEL = МОДЕЛЬ СТОИМОСТИ ПРИ РИСКЕ – Value-At-Risk (VaR) Model is a risk management model that calculates the largest possible loss that an institution or other investor could incur on a portfolio. Value at risk describes the probability of losing more than a given amount of assets, based on a current portfolio. It was developed (not originated) at JPMorgan in response to a demand from then chairman Dennis Weatherstone to be told at 04:15 pm every day what the overall risk position of the bank was. He was concerned the various trading desks and business units might be taking correlated bets without knowing about it. Without having time to check each trader's position individually, he wanted a way to understand the overall position. This has a couple of important implications:- one, that it is a snapshot, a picture of what the risk level is now, based on what you hold now. The longer the time period you apply it to, the fuzzier it is likely to become. Two, it is a lower bound for loss, not an upper bound – if your model says that at a 95 per cent VaR, the value at risk is half of your assets, you can expect to lose half or more of your assets one day in 20. It should be used to make sure you can withstand these losses, not necessarily to prevent them. VaR is a mathematical model that purports to estimate the maximum future losses expected from a trading portfolio, with a degree of statistical confidence. VaR's calculation can be extremely technical, or it can be as simple as looking at a subjective past period and then projecting future risks from there. A big problem with VaR is that it can very easily produce very low numbers, gravely misrepresenting true exposures. Relying on the past can be treacherous:- a quiet past period need not imply future quietness, historical volatility and correlation may betray you. Also, Var models can use the 'normal probability distribution', which very unrealistically assumes no chance of extreme events. VaR played a key negative role in the 2008 credit crisis, by severely underestimating the danger from toxic mortgage products and by allowing banks to enjoy excessive levels of leverage on their trading positions. Given that toxic leverage is what sank the banks, we could argue that VaR, in the end, caused the crisis. Recognising all this, the Basel Committee for Banking Supervision, which had enthusiastically adopted VaR since 1995, has been busy at work disowning the model and tweaking the bank capital formula. Just a few weeks ago, Basel announced that it no longer wants to keep using VaR. Value At Tisk (VaR) Models are the systems which use

statistical approaches to determine the value at risk of all or part of an insurer's operations. Value-At-Risk (VaR) Model:- procedure for estimating the probability of portfolio losses exceeding some specified proportion based on a statistical analysis of historical market price trends, correlations, and volatilities. / Дьжей.Пи.Моргэн (JPMorgan) Дэнис Вэзёрстоун (Dennis Weatherstone).

VALUE AVERAGING INVESTING = ИНВЕСТИРОВАНИЕ ЧЕРЕЗ УСРЕДНЕНИЕ СТОИМОСТИ – Value Averaging Investing:- Value Averaging is an investing strategy that works like Dollar cost averaging (DCA) in terms of steady monthly contributions, but differs in its approach to the amount of each monthly contribution. In value averaging, the investor sets a target growth rate or amount on his or her asset base or portfolio each month, and then adjusts the next month's contribution according to the relative gain or shortfall made on the original asset base. For example, suppose that an account has a value of USD2 000 and the goal is for the portfolio to increase by USD200 every month. If, in a month's time, the assets have grown to USD2 024, the investor will fund the account with USD176 (USD200 – USD24) worth of assets. In the following month, the goal would be to have account holdings of USD2 400. This pattern continues to be repeated in the following month. The main goal of value averaging is to acquire more shares when prices are falling and fewer shares when prices are rising. This happens in Dollar cost averaging as well, but the effect is less pronounced. Several independent studies have shown that over multiyear periods, value averaging can produce slightly superior returns to dollar-cost averaging, although both will closely resemble market returns over the same period. The biggest potential pitfall with value averaging is that as an investor's asset base grows, the ability to fund shortfalls can become too large to keep up with. This is especially noteworthy in retirement plans, where an investor might not even have the potential to fund a shortfall given limits on annual contributions. One way around this problem is to allocate a portion of assets to a fixed-income fund or funds, then rotate money in and out of equity holdings as dictated by the monthly targeted return. This way, instead of allocating cash in the form of new funding, cash can be raised in the fixed income portion and allocated in higher amounts to equity holdings as needed. / Инвестирование Через Усреднение Стоимости:- инвестиционная стратегия, направленная на постоянное увеличение стоимости фонда на определённую сумму за определённый период времени.

VALUE BASED PRICING = ЦЕНООБРАЗОВАНИЕ, ОСНОВАННОЕ НА СТОИМОСТИ – Value Based Pricing is the practice of setting the price of a product or service at its perceived value to the customer. This approach tends to result in very high prices and correspondingly high profits for those companies that can persuade their customers to agree to it. It does not take into account the cost of the product or service, nor existing market prices. Value based pricing is usually applied to very specialized services. For example, an attorney experienced in defense against criminal charges can charge a very high price to his or her clients, since the value to them of not being incarcerated is presumably quite high. Similarly, an attorney skilled in initial public offerings can use value pricing, since clients might not otherwise raise millions of Dollars without their services. Other areas where value based pricing may be an option include:- (i) product design; (ii) bankruptcy work outs; (iii) cost reduction analysis; (iv) lawsuit defense; and (v) pharmaceuticals engineering. Value based pricing is also more applicable to situations where customer approval is made at the executive level, rather than by the procurement department. The purchasing staff is more skilled in evaluating supplier prices, and so would be less likely to allow such pricing. The Value Based Pricing Calculation:- ABC Legal has built up an investment banking service that assists its clients with preferred stock placements. The internal cost for ABC to provide this service is usually about 1 000 hours of staff time at a cost of USD100 per hour, or USD100 000 in total. The typical stock placement is for USD10 million, for which ABC charges 5%; this works out to an average fee of USD500 000. There is no relationship between the fee charged and the cost incurred by ABC. Thus, ABC earns USD400 000 on US100 000 of internal costs. The company's clients do not complain, because they have obtained an average of USD10 million each. Advantages of Value Based Pricing:- the following are advantages to using the value based pricing method:- (i) Increases Profits:- this method results in the highest possible price that you can charge, and so maximizes profits; (ii) Customer Loyalty:- despite the high prices charged, you can achieve extremely high customer loyalty for repeat business and referrals, but only if the service or product provided justifies the high price. This advantage tends to also derive from the nature of the sales relationship, which needs to be both close and trusting before value based pricing can even be contemplated. Disadvantages of Value Based Pricing:- the following are disadvantages of using the value based pricing method:- (i) Niche Market:- the very high prices to be expected under this method will only be acceptable to a small number of customers. It may even alienate some prospective customers; (ii) Not Scalable:- this method tends to work best for smaller organizations that are highly specialized. It is difficult to apply it in larger businesses where employee skill levels may not be so high; (iii) Competition:- any company that persistently engages in value based pricing is leaving a great deal of room for competitors to offer lower prices and take away their market share; (iv) Labor Costs:- assuming that a service is being provided, you are likely offering such a high-end skill set that the employees needed to provide the service will be quite expensive. There is also a risk that they may leave to start competing firms. Evaluation of Value Based Pricing:- this method is exceptionally profitable in those niche areas where a company can offer premium services that are highly valued by their customers. Many attorneys and investment bankers have engaged in value based pricing for decades, so it is clearly a viable method. However, it is not applicable in most businesses, where normal competitive pressures make it impossible to use value based pricing. See also Pricing Grid.

VALUE BILLING = ВЫСТАВЛЕНИЕ СТОИМОСТИ – Value Billing is a charge to a customer based on the value received, rather than the cost of the services provided. This type of billing is most common in situations where the value provided is unique and essential to the customer. For example, an investment banker or criminal defense attorney can issue value billings because the value provided is so great. In areas where there is a competitive market for services, it is not possible for a supplier to enforce value billing, since similar services can be provided by competitors that are cost-based, and therefore much lower.

VALUE BROKER = СТОИМОСТНОЙ БРОКЕР – Value Broker is a broker that bases his or her rates off the Dollar value associated with each transactions. These brokers can be beneficial to investors seeking to minimize commission costs especially if an investor is interested in trading a small amount of shares or low priced shares. Both of these options typically would not have a high Dollar value, thus lowering the rate that the broker is able to charge the investor. Value Broker is a discount broker whose rates are a percentage of the Dollar value of each transaction. / Стоимостной Брокер, взимающий комиссионные в виде процента от стоимости акций. Дисконтный брокер (discount broker) взимает комиссионные по ставкам на основе процента от стоимости каждой сделки. Торговые операции через брокеров, взимающих комиссионные в виде процента от стоимости акций, обычно выгодны для тех, кто совершает операции с недорогими акциями или небольшим числом акций, поскольку комиссионные в этом случае будут относительно меньшими чем, если бы акционер воспользовался услугами брокера, взимающего комиссионные в зависимости от числа акций (share broker) или дисконтного брокера иного типа, который взимает комиссионные в зависимости от числа и цены акций, участвующих в сделке. Стоимостной Брокер – брокер с пониженной комиссей, имеющий ставки комиссионных, основанные на доле в процентах от стоимости, выраженной в Долларах по каждой сделке. По сделкам с акциямис низкими ценами или небольшим количеством акций размещение распоряжения у подобного брокера приведёт к более низким комиссионным.

VALUE CERTIFICATE = ОЦЕНОЧНЫЙ СЕРТИФИКАТ (или СВИДЕТЕЛЬСТВО О СТОИМОСТНОЙ ОЦЕНКЕ) – Value Certificate certifies that the value declared and accounts charged on the shipper's invoice are accurate. / Оценочный Сертификат:- этот

сертификат свидетельствует о том, что задекларированная стоимость и оплаченные по счёту-фактуре грузоотправителя счета являются точными.

VALUE CHAIN = ЦЕННОСТНАЯ ЦЕПОЧКА – Value Chain is the sequential set of primary and support activities that an enterprise performs to turn inputs into value-added outputs for its external customers. As developed by Michael E. Porter, it is a connected series of organizations, resources, and knowledge streams involved in the creation and delivery of value to end customers. Value systems integrate supply chain activities, from determination of customer needs through product/service development, production/operations and distribution, including (as appropriate) first-, second-, and third-tier suppliers. The objective of value systems is to position organizations in the supply chain to achieve the highest levels of customer satisfaction and value while effectively exploiting the competencies of all organizations in the supply chain. / Майкэл И. Потчё (Michael E. Porter).

VALUE CHAIN ANALYSIS = АНАЛИЗ ЦЕННОСТНОЙ ЦЕПОЧКИ – Value Chain Analysis reviews the processing steps that a business follows to deliver goods and services. The intent is to locate those processing steps at which value is added to the final product. In addition, the chain of activities is reviewed to see where costs are being incurred. The ultimate goal of the analysis is to achieve the highest possible value increase for customers while incurring the lowest possible cost. The basic processing steps involved in value chain analysis are:- (i) Inbound Logistics, which involves sourcing the correct raw materials and merchandise, and bringing them to the business in the most cost-effective manner; (ii) Operations, which transform the raw materials into finished goods; or, if the company is a retailer, operations can refer to the positioning of acquired merchandise within its stores; (iii) Outbound Logistics, which involves the transport of sold goods to customers in the most cost-effective manner. Though positioned outside of this process flow, the marketing function can be used to increase the level of value perceived by customers when they acquire goods or services from the company. Also, the field servicing function can be employed in a similar manner. Thus, both functions can be considered part of the value chain. All other parts of a business, such as accounting, administration, human resources, and information technology, are usually considered to be cost centers, where the focus is solely on cost reduction. However, it is possible to add value in some of these areas. For example, hiring specific personality types can improve the customer experience in a retail operation. Also, information technology can be used to develop unique applications that give a business a competitive advantage. Once management understands where value and costs are being generated in the organization, it can focus its attention on these areas. A common outcome of value chain analysis is that some operations are outsourced, on the grounds that they provide little additional value to customers, and yet involve a significant cost to the business.

VALUE CHANGE = ИЗМЕНЕНИЕ СТОИМОСТИ – Value Change is an adjustment made to a stock's price to reflect the number of outstanding stock shares, or shares of stock that have been issued and are currently held by investors. A value change allows the group of stocks to be equally weighted and, therefore, more easily evaluated. Since the number of shares held by investors changes daily, this number can be updated daily to reflect the changes. A value change adjustment is intended to equally weight the stocks that are included in a group. Value change can be used in a variety of settings and describes a type of calculation used to compare and evaluate investment instruments by taking the number of shares held by investors into consideration. Value Change is an adjustment to a stock's price based on the shares of a corporation's stock that have been issued and are in the hands of the public. The purpose of this adjustment is to properly and equally weigh the stocks included in this group. / Изменение Стоимости:- изменение цены акции, скорректированной с учётом числа этих акций, находящихся на руках акционеров. Цена пакета скорректированных таким образом акций взвешивается по числу акций, например, данного типа. Единица изменения котировок в этой группе называется Индексом (Index), который отражает усреднённую таким образом цену. Стоимостное Изменение – изменение цены ценной бумаги, скорректированное на количество находящихся на руках держателей долей выпуска данной ценной бумаги таким образом, чтобы группа ценных бумаг, скорректированных этим способом, была одинаково взвешена.

VALUE COMPENSATED = КОМПЕНСИРОВАННАЯ СТОИМОСТЬ – Value Compensated:- a purchase or sale of foreign exchange to be executed by cable. The purchaser reimburses the seller for the earlier value on the date of actual payment abroad of the foreign currency, theoretically resulting in no loss of interest to either party. / Компенсированная Стоимость:- покупка или продажа иностранной валюты по телеграфу. Покупатель возмещает продавцу прежнюю стоимость на день фактического перевода за границу иностранной валюты, что теоретически приводит к отсутствию потерь в процентах для каждой из сторон. Скомпенсированная Стоимость:- описание покупки или продажи иностранной валюты, совершаемой по телеграфу. Покупатель компенсирует продавцу прежнюю стоимость на дату реального платежа за границей в иностранной валюте, что теоретически приводит к отсутствию потери процентов у любой стороны.

VALUE–CONTENT RULE = ПРАВИЛО О СТОИМОСТНОМ СОДЕРЖИМОМ – Value-Content Rule (rules of origin):- two explicit and strict rules of origin mechanisms are established under the North American Free Trade Agreement (NAFTA):- (i) tariff-shift rule and (ii) value-content rule. Tariff-shift rules require that all non-NAFTA inputs must be transformed into a product with a different HS (short for the Harmonized System) Chapter Heading or Tariff Item Number from that under which they were admitted. Under NAFTA calue-content rules, a set percentage of the value of the product must be of North American origin. This rule is often used in conjunction with a tariff-shift requirements, although some goods with non-NAFTA inputs are subject to the value-content rule as an alternative to the tariff-shift test. In addition a de minimis rule allows NAFTA origin treatment for items containing as much as 7 percent non-NAFTA content. NAFTA Rules Of Origin:- Regional Value Content (RVC) Rules do not require any sort of tariff shift in order to qualify. It is a pure calculation of content using the above equations in the same manner. RVC Only rules are very rare within Annex 401, but are possible. Format of RVC Only rules:- 'No change required, provided there is a regional value content of not less than:- (a) 60% where the transaction value method is used, or (b) 50% where the net cost method is used'. / Правило О Стоимостном Содержании:- в соответствии с Северо-Американским Соглашением О Свободной Торговле (САССТ; North American Free Trade Agreement (NAFTA)), правила о происхождении построены с учётом согласованной классификации продукта. Имеются два вида правил; оба они предусматривают значительную долю переработки в странах Северной Америки, но измеряют её по-разному. Согласно Правилу О Стоимостном Содержании определённая доля стоимости товаров должна быть Северо-Американской (обычно это сочетается с требованием изменения тарифа). Некоторые товары подпадают под это правило лишь тогда, когда они не выдерживают проверки на изменение тарифа, так как в них велика доля затрат, произведённых вне стран САССТ. Сравните с Правилом Изменения Тарифа (Tariff-Shift Rule). Смотрите также Правила Происхождения (Rules Of Origin).

VALUE CREATION = СОЗДАНИЕ СТОИМОСТИ – Value Creation is performing activities that increase the value of goods or services to consumers. Value Creation is the primary aim of any business entity. Creating value for customers helps sell products and services, while creating value for shareholders, in the form of increases in stock price, insures the future availability of investment capital to fund operations. From a financial perspective, value is said to be created when a business earns revenue (or a return on capital) that exceeds expenses (or the cost of capital). But some analysts insist on a broader definition of 'Value Creation' that can be considered separate from traditional financial measures. 'Traditional methods of assessing organizational performance are no longer adequate in today's economy', according to ValueBasedManagement.net. 'Stock price is less and less determined by earnings or asset

base. Value creation in today's companies is increasingly represented in the intangible drivers like innovation, people, ideas, and brand'. When broadly defined, value creation is increasingly being recognized as a better management goal than strict financial measures of performance, many of which tend to place cost-cutting that produces short-term results ahead of investments that enhance long-term competitiveness and growth. As a result, some experts recommend making value creation the first priority for all employees and all company decisions. 'If you put value creation first in the right way, your managers will know where and how to grow; they will deploy capital better than your competitors; and they will develop more talent than your competition', Ken Favaro explained in Marakon Commentary. 'This will give you an enormous advantage in building your company's ability to achieve profitable and long-lasting growth'. The first step in achieving an organization-wide focus on value creation is understanding the sources and drivers of value creation within the industry, company, and marketplace. Understanding what creates value will help managers focus capital and talent on the most profitable opportunities for growth. 'If customers value consistent quality and timely delivery, then the skills, systems, and processes that produce and deliver quality products and services are highly valuable to the organization', Robert S. Kaplan and David P. Norton wrote in their book Strategy Maps:- Converting Intangible Assets into Tangible Outcomes. 'If customers value innovation and high performance, then the skills, systems, and processes that create new products and services with superior functionality take on high value. Consistent alignment of actions and capabilities with the customer value proposition is the core of strategy execution'. Although the intangible factors that drive value creation differ by industry, some of the major categories of intangible assets include technology, innovation, intellectual property, alliances, management capabilities, employee relations, customer relations, community relations, and brand value. According to Kaplan and Norton, the link between these intangible assets and value creation is corporate strategy. It is important to note that investments made to enhance intangible assets (research and development, employee training, and brand building, for example) usually provide indirect rather than direct benefits. In this way, focusing on value creation forces an organization to adopt a long-term perspective and align all of its resources toward future goals. / Кэн Фаваро (Ken Favaro). Робёт Эс. Каплэн (Robert S. Kaplan) и Дэйвид Пи. Нотэн (David P. Norton).

VALUE DATE = ДАТА ЗАЧИСЛЕНИЯ – Value Date shall mean a reference time used by a payment service provider for the calculation of interest on the funds debited from or credited to a payment account; where no calculation of interest is agreed for a payment account, the value date shall be the date on which the payment service provider shall be obliged to debit or credit the payment account. It is a field name in a SWIFT message:- the identification of a date in the transaction. The date on which funds are at the disposal of the receiver. Value Date is the date on which a sum of money transferred to a beneficiary is received by his bank, credited to his account and made available for withdrawal; interest is accrued with effect from the value date. Also date on which an amount is debited. Value Date is the date on which it is agreed to place a payment or transfer at the disposal of the receiving user. The value date is also used as a point of reference for the calculation of interest on the funds held on an account. Value Date:- when a bank receives a deposit of checks from a payee, it will credit the payee's account with the funds represented by the checks. However, the bank has not really received the cash yet, since it must still collect the funds from the bank of the paying party. Until the bank collects the funds, it is at risk of having a negative cash flow situation if the payee uses the cash it has just received. To avoid this risk, the bank posts the amount of the deposit with a value date that is one or more days later than the book date. This value date is the presumed date of receipt of the cash by the bank. Once the value date is reached, the payee has use of the funds. The value date may be categorized by the bank as 1-day float, 2+-day float, or some similar term. A larger bank customer may be able to negotiate the time period before the value date is reached. Value Date is a date of value. Value Date:- In the market for Eurodollar deposits and foreign exchange, the delivery date of funds traded. For spot transactions, it is normally on spot transactions two days after a transaction is agreed upon. In the case of a forward foreign exchange trade, it is the future date. Value Date is the account date for foreign exchange transactions. / Дата Зачисления:- идентификация даты операции в сообщении Сообщества по Всемирной Межбанковской Финансовой Дальней Связи (СВМФДС; The Society for Worldwide Interbank Financial Telecommunication (SWIFT)). Она определяет дату, на которую фонды поступают в распоряжение получателя. коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Дата Зачисления:- (1) дата, с которой банковский депозит начинает приносить проценты. (2) На рынке Евровалюты и иностранных валют:- дата поставки валюты для исполнения сделки. (3) На рынке Еврооблигаций эта дата приходится на седьмой календарный день после заключения сделки, независимо от праздников. Дата Зачисления:- на валютном рынке по сделкам на срок дата наступления срока по контракту с добавлением одного рабочего дня для Северо-Американских валют и двух дней для прочих валют. По наличным сделкам, включающим Северо-Американские валюты, – дата наступления срока по контракту с добавлением одного рабочего дня, а для остальных валют – двух дней. Дата Зачисления – дата, начиная с которой владелец счёта вправе распоряжаться зачисленными на этот счёт средствами. Дата Зачисления (Value Date):- дата сделки, дата оплаты, дата, с которой актив начинает приносить проценты. В банковских операциях:- официальная дата (entry date), на которую происходит перевод денег, то есть средства поступают в распоряжение вкладчика. Дата оплаты отличается от даты внесения средств, когда средства платежа вносятся на счёт в сберегательный банк, они затем передаются в банк, производящий оплату, или должны быть иным образом востребованы. Этот термин используется главным образом по отношению к иностранным счетам либо ведущимся в банках внутри страны, либо 'внутренним' банком в банке за рубежом. Смотрите также Float. Евродоллары и сделки с иностранной валютой – синонимичны – расчётная дата (settlement date) или дата поставки (delivery date), которая при наличных сделках, в которой участвуют Североамериканские валюты (Доллар США, Канадский Доллар и Мексиканский Песо) составляет один рабочий день, а при наличных сделках с другими валютами – два рабочих дня. При форвардных валютных сделках дата оплаты определяется как дата погашения контракта плюс один рабочий день – для Североамериканских валют и два рабочих дня – для остальных валют. Смотрите также Forward Exchange Transaction, и Spot Market. Дата Валютирования (value date):- дата исполнения условий сделки, то есть физического перемещения денежных средств. Датами валютирования могут быть только рабочие дни, исключая выходные и праздничные дни для данной валюты.

(2) Value Date is the date on which interest is earned. / Дата Зачисления:- дата, на которую заработан процент.

(3) For exchange contracts Value Date is the day on which the two contracting parties exchange the currencies which are being bought or sold. For a spot transaction it is two business banking days forward in the country of the bank providing quotations which determine the spot value date. The only exception to this general rule is the spot day in the quoting center coinciding with a banking holiday in the country(ies) of the foreign currency(ies). The value date then moves forward a day. The enquirer is the party who must make sure that his spot day coincides with the one applied by the respondent. The forward months maturity must fall on the corresponding date in the relevant calendar month. If the one month date falls on a non-banking day in one of the centers then the operative date would be the next business day that is common. The adjustment of the maturity for a particular month does not effect the other maturities that will continue to fall on the original corresponding date if they meet the open day requirement. If the last spot date falls on the last business day of a month, the forward dates will match this date by also falling due on the last business day. Also referred to as Maturity Date. Value Date is a date on which a foreign exchange contract is executed, i.e. seller delivers foreign currency. Value Date is a settlement date on which interest payments are credited or debited to the customer's bank account; interest payments are made from this date

onwards. Value Date is the maturity date of a foreign exchange contract, at which time two currencies are exchange. A spot deal is usually done for value two business days from the trading date.

(4) Value Date is the date agreed between parties for the settlement of a transaction.

VALUE DATING = ОПРЕДЕЛЕНИЕ ДАТЫ ЗАЧИСЛЕНИЯ – Value Dating:- when a customer's account is electronically credited with funds that will be made available at some specified future date. Value Dating:- when value or credit is given for funds transferred between banks. Value Dating is the practice of dating a customer transaction at some date other than the date at which the bank itself lost or gained value. Used by banks in some countries as an indirect method of earning fees, and in such cases can make assessing bank charges very difficult. It can be applied to all methods of payment both forwards and backwards in time.

VALUE DECLARATION = ДЕКЛАРАЦИЯ О СТОИМОСТИ – Value Declaration is a document in which a declarant (importer) states the invoice or other price (e.g., selling price, price of identical goods), and specifies costs for freight, insurance and packing, etc, terms of delivery and payment, any relationship with the trading partner etc, for the purpose of determining the Customs value of goods imported. The Customs Value Declaration is a document which must be presented to the customs authorities when the value of the imported goods exceeds EUR10 000. The main reason for this requirement is to estimate the value of the transaction in order to calculate the applicable tariff duty for the good. Value Declaration:- in order to declare valuables which are inside checked baggage, Neos gives passengers the opportunity to make a statement declaring them. In order to make a statement:- (i) showing up at the check-in 2 hours before the departure of short and medium haul flights (duration of the flight by 7 hours) and 3 hours before the departure of long haul flights (duration of the flight by 7 hours); (ii) during the check-in producing a valid identity document (or passport), together with the confirmation of the booking, is mandatory; (iii) delivering to the check-in attendant the form from Neos completly filled in and reporting the inventory of the contents of your baggage; (iv) opening the baggage in front of check-in attendant who will verify all valuable items declared are in the same quantity and condition reported on the filled in form; and (v) close the baggage with a key or combination padlock. In order to avoid damage during the transportation, it is mandatory that the contents are carefully packed in the baggage in order to avoid damage during the transportation. The compensation will depend on the value declared and according to the conditions reported on the form itself if damaged. / Итальянская авиалиния Нэос (Neos). Декларация О Стоимости – документ, в котором декларант (или заявитель (импортёр)) указывает фактурную или иную цену (например, цену продажи, цену на идентичный товар) и специфицирует расходы на фрахт, страхование, упаковку и так далее, порядки поставки и оплаты, какие-либо отношения с торговым партнёром и так далее, в целях определения таможенной стоимости привозимых (или импортируемых) товаров.

VALUE DOMAIN = ОБЛАСТЬ ЗНАЧЕНИЙ (или XX) – A Value Domain is a set of permissible values. Context:- in the context of ISO 11179, a domain is the set of possible data values of an attribute. A 'Data Value' is an element of a value domain. 'Enumerated Value Domain' is a value domain that is specified by a list of all its permissible values. The value domain provides representation, but has no implication as to what data element concept the values may be associated with or what the values mean. The permissible values may either be enumerated or expressed via a description. Non-enumerated value domain is a value domain that is specified by a description rather than a list of all Permissible values. Non-enumerated value domain description is a description or specification of a rule, reference, or range for a set of all permissible values for the value domain. Value domain representation class is the class of representation of a value domain. Attributes of value domain:- (i) value domain administration record is the administration record for a value domain; (ii) value domain datatype is the datatype used in a value domain; (iii) value domain format is a template for the structure of the presentation of the Value(s), e.g., YYYY-MM-DD for a date; (iv) value domain maximum character quantity is the maximum number of characters to represent the Data Element value and is applicable only to character datatypes; (v) value domain relationship is a relationship among two or more value domains; and (vi) value domain unit of measure is the unit of measure used in a value domain. See also Attribute, Permissible Value, Permitted Value, and Value Item.

VALUED POLICY = ОЦЕНЕННЫЙ ПОЛИС (или ПОЛИС С ОЦЕНЕННОЙ СТОИМОСТЬЮ) – Valued Policy is a policy which specifies the insured value of the ship or goods insured, as the case may be. The value so expressed is conclusive of the insurable value of the ship or goods, as applicable, in the absence of fraud; but is not to be used to establish a constructive total loss, except where the policy so provides (as in hull policies). A policy that does not specify the insured value as such is an 'Unvalued' Policy. See also Agreed Value Policy. / Оцененный Полис:- страховой полис, в котором указана согласованная стоимость объекта страхования. В результате размер подлежащей выплате страховой суммы в случае полной фактической утраты объекта страхования уже определён и не нуждается в дополнительном обсуждении.

VALUE–ENHANCED GRAINS = ЗЁРНА ПОВЫШЕННОЙ ЦЕННОСТИ (или XX) – Value-Enhanced Grains are those grains that possess novel traits that are economically valuable (e.g., higher-than-normal protein content, better quality protein, higher-than-normal oil content, etc). For example, high-oil Corn (Maize) possesses a kernel oil content of 5.8% of greater, versus oil content of 3.5% or less for traditional No. 2 Yellow Corn.

VALUE FOR CUSTOMS PURPOSES ONLY = СТОИМОСТЬ ТОЛЬКО ДЛЯ ТАМОЖЕННЫХ ЦЕЛЕЙ – The US Customs Service defines 'Value For Customs Purposes Only' (VCPO) as the value submitted on the entry documentation by the importer which may or may not reflect information from the manufacturer but in no way reflects Customs appraisement of the merchandise.

VALUE FOR MONEY = СТОИМОСТЬ ДЕНЕГ (или XX) – Value For Money is in the perception of the buyer or receiver of goods and/or services. Proof of good value for money is in believing or concluding that the goods/services received was worth the price paid. Examples of the types of factors that may be considered are suitability, quality, skills, price, whole of life costs and other criteria. The mix of these and other factors and the relevant importance of each will vary on a case by case basis.

VALUE FOR MONEY AUDIT = АУДИТ СТОИМОСТИ ДЕНЕГ (или XX) – Value For Money Audit is an independent audit of a not-for-profit organization (government agency or unit, charity, trust, etc) to assess the effectiveness and efficiency of its utilization of funds. It is employed where the standard commercial performance (profit oriented) measures cannot be used. Also called Value For Money Analysis. Value For Money Audit is an independent audit of a non-profit organization to determine it is using its money efficiently and effectively. / Ревизия Стоимости Денег:- проверка государственного департамента, благотворительной организации или другой бесприбыльной организации с целью оценить, насколько эффективно функционирует организация и какова стоимость истраченных её денег.

VALUE FUND = СТОИМОСТНОЙ ФОНД (или ФОНД СТОИМОСТИ) – Value Fund is a mutual fund that invests in companies which it determines to be underpriced by fundamental measures. Assuming that a company's share price will not remain undervalued indefinitely, the fund looks to make money by buying before the expected upturn. Value funds tend to focus on safety rather than growth, and often choose investments providing dividends as well as capital appreciation. They invest in companies that have low P/E ratios (short for the Price-to-Earnings Ratios), and stocks that have fallen out of favor with mainstream investors, either due to changing investor preferences, a poor quarterly earnings report, or hard times in a particular industry. A Value Fund is a stock mutual fund that

primarily holds stocks that are deemed to be undervalued in price and that are likely to pay dividends. Value funds are one of three main mutual fund types; the other two are growth and blend (a mix of value and growth stocks) funds. Every large mutual fund family has a value fund component in which funds are often broken down by size. For example, a fund family may include small-, mid- and large-cap value funds for investors to choose from. The premise of value investing is that the market has inherent inefficiencies that enable companies to trade at levels below what they are actually worth. In theory, once the market corrects these inefficiencies, the value investor will see the share price rise. A common misconception is that value investors simply seek out stocks with low price/earnings ratios. Although this can be a characteristic of an undervalued company, this is not the sole feature that astute value investors seek. / Стоимостной Фонд или Ценный Фонд:- взаимный фонд, который осуществляет инвестиции преимущественно в ценные бумаги с низкими показателями отношения рыночной цены к чистой прибыли компании. Фонды Стоимости (Value Funds):- фонды, инвестирующие в акции, которые считаются недооценёнными с точки зрения коэффициентов 'цена/прибыль' или 'цена/балансовая стоимость', либо на базе показателя внутренней стоимости компании (intrinsic value). Управляющие фондов стоимости стремятся раньше других открыть акции перспективных с этой точки зрения компаний, рассчитывая, что впоследствии эти акции будут по достоинству оценены остальными участниками рынка, и их цена существенно вырастет. Целью таких фондов являются акции, стоимость которых низка в сравнении с потенциалом роста прибыли их эмитентов. Причиной низкой стоимости могут быть краткосрочные проблемы, испытываемые компанией, или её небольшой размер и небольшая известность на рынке. В любом случае управляющий фонда стоимости делает ставку на будущее признание компании рынком, которое повлечёт за собой рост курса её акций. Соответственно, основной риск состоит в том, что 'неоткрытые сокровища' так и останутся неоткрытыми, и фонд не получит прибыли. В то же время лихорадочность подобных фондов довольно низка, и при выборе надёжного фонда вероятность того, что капиталовложения в него не принесут доходов, является минимальной. Кроме того, фонды стоимости характеризуются низкими коэффициентами расходов и оборачиваемости активов, поскольку они склонны держать приобретённые акции в течение длительных периодов времени. Поэтому данные фонды являются наиболее подходящим выбором для консервативных инвесторов, стремящихся избежать уплаты высоких налогов.

VALUE INDEX = ИНДЕКС ПО СТОИМОСТИ – Value Index is an index number formed from the ratio of aggregate values in the given period to the aggregate values in the base period. Strictly speaking this is not an index number as ordinarily understood but a value relative.

VALUE IN EXCHANGE = СТОИМОСТЬ В ОБМЕНЕ – Value In Exchange:- the ability to trade an item or asset, especially money, for other goods and services that can then be used to satisfy wants and needs. Value in exchange means that value (that is, satisfaction) is obtained indirectly through the acquisition of something else. For an item to have value in exchange it need not have value in use, value obtained directly from the consumption of a good or service. The notion of value in exchange is most important for money. In particular, almost all modern money is fiat money, which has value in exchange, but little or no value in use. In contrast, commodity money has value in exchange and value in use. Value in exchange goes hand-in-hand with the medium of exchange function of money. When an item is generally accepted in payment for goods and services and thus serves the medium of exchange function, then it has value in exchange. People are willing to accept money in exchange for the goods they have because they know that this money can then be exchanged for other goods that they want. The value in exchange of commodity money is largely based on the commodity's value in use. In fact, the earliest forms of money were commodities that provided value in use to virtually everyone in an economy, such as grains for food and animal skins for clothing. For example, in the early eons of civiliaation, people were willing to accept bushels of grain in trade for another good because they were hungry, because the grain had value in use, not necessarily because they planned to use the grain to buy another good, not because the grain had value in exchange. However, knowing that everyone was willing to trade for grain gave it value in exchange. Because people couldd trade the grain to others, they were willing to accept grain in payment even when they were not hungry, even when the grain. did not provide them with value in use. The value in exchange of fiat money is based exclusively on an item's widespread acceptance as money. In the modern world, people accept fiat money in payment because everyone accepts fiat money in payment. Continued acceptance of fiat money rests largely with the authority responsible for issuing the money, usually government. If the issuing government remains healthy, trustworthy, and responsible, then the money that it issues continues to be accepted as payment. A primary way that government maintains the 'official' status of money is to accept it in payment for taxes. Usually, not always, but usually, whatever item the government is willing to accept as payment is good enough for the rest of the economy. Such acceptance gives the item value in exchange. Some folks overlook the point that money only requires value in exchange to function effectively as the medium of exchange. Money does not require value in use. Value in use definitely played a key role in the historical progression from barter to fiat money. Commodities with economy-wide value in use that evolved into commodity money revealed the benefits of money over barter. But those who study money now know that the benefits associated with value in exchange are distinct from value in use. Money is only valuable not for what it is, but for what it can buy. Amount of other goods and services for which a unit of a specific good can be exchanged in a market. The money price often is one measure of value in an exchange. Worth of property based on exchanging it for goods and services. Contrast with Investment Value, Value in Use. Example:- Value in exchange is generally thought to be the same as Market Value. / В соответствии с Международными Стандартами Оценки (МСО 2003) Стоимость в Обмене – это стоимость, признанная рынком, на котором предположительно имеет место обмен актива. Иными словами – это та цена, по которой объект оценки может быть продан на открытом рынке на дату оценки. Именно определение рыночной стоимости в обмене необходимо при оценке для целей залога активов. Банк, принимая оцениваемое имущество в залог, исходит из предположения о том, что в будущем возможно возникнет необходимость реализации объекта залога (в случае дифолта по выданному кредиту). В этом случае заложенное имущество должно быть в достаточно короткий срок реализовано на открытом рынке. Стоимость В Обмене (Value In Exchange):- (1) стоимость, признанная рынком, на котором умозрительно имеет место обмен собственности актив. Определение Рыночной стоимости МКСО для походящей финансовой отчётности основывается на принципе стоимости в обмене. (2) Стоимость в денежном выражении имущества, которое обменивается на другой актив или активы. Деньги являются мерилом, с помощью которого можно оценить сравнительную стоимость каждого.

VALUE INSURED = ЗАСТРАХОВАННАЯ СТОИМОСТЬ – Value Insured is the amount the insurer is contractually obliged to pay in the case of a claim. The main attributes of the value insured are as follows:- type of value insured (such as debris removal costs); valuation data (currency, exchange rate, valuation date); value insured data (sunset period, rank, index type, start of index period, start of value insured period); values (you can enter several values and corresponding values types in a table); and external reference (ID of the value type in operational or partner systems). Use:- creating a Value Insured:- you first call the coverage for which you want to create a value insured. On the FS-RI (short for the Financial Services for Reinsurance): RM (Non-Life) – Change Policy screen, switch to the Coverage tab page. Double-click the coverage for which you want to create a value insured. Choose Value Insured. The Create Value Insured dialog box appears. Here you enter the key identifying attributes of the value insured. Attributes:- value insured (user-defined name); type of value insured (such as debris removal costs), value insured valid from/to; valuation date (required for currency translation); underwriting date; status; reason for change; and currency. Choose Continue. The screen for the Value Insured tab page

appears. You can then make your entries in the sections Value Insured Data, Statistics/Values, and References. Value Insured Data:- you can enter the following information in the value insured data:- sunset period; start of value insured after; relevant for liability; rank; index type; start of index period; extension service; and exclusion of values insured. Statistics/Values:- you can enter several values in the Statistics/Values section. However, a value type may be used only once. You first enter the desired value type and choose Continue. You can then enter the following:- (i) amount (% or absolute amount, depending on the value type); (ii) currency and exchange rate type; (iii) indicate whether the value type is relevant for liability aggregation; (iv) underwriting date; and (v) validity period. In the References section you can enter the ID used in operational or partner systems. Changing A Value Insured:- on the FS-RI: RM (Non-Life) – Change Policy screen, switch to the Coverage tab page. Double-click the coverage for which you want to create a value insured. On the next screen, switch to the Value Insured Journals tab page. Select the value insured you want to change. Deleting A Value Insured:- to delete a value insured, navigate to the value insured as described under 'Changing a Value Insured'. In the overview of values insured, select the row for the value insured you want to delete and choose the Delete pushbutton. Structure:- the value types and values are key entries for the values insured. The statistical value types are transferred from the corresponding operational value types and propagated upwards to the higher levels. The sequence of the levels from bottom to top is:- value insured – coverage – policy section – policy – accumulation. In Customizing you can define the levels at which operational value types can be entered based on your own requirements. The Gross Liability is the statistical value type upon which further functions are based. It is always taken from the operational value type defined as the liability calculation base. You define the liability calculation base for each class of business in Customizing. Unlike the values for other operational value types, you can only enter the value for the liability calculation base at value insured and policy section levels. If you enter the value at both levels, and the Relevant for Aggregation checkbox is also set at both levels, the system uses the values entered at value insured level. Insured Value is an amount for which an insurance cover is bought on a building, and the basis on which insurance premium is computed. According to the coinsurance clause, it must not be lower than a certain percentage (usually 80 percent) of the insurable value of the building to be able to claim a partial loss in full. / Застрахованная Стоимость:- .

VALUE IN USE = СТОИМОСТЬ В ИСПОЛЬЗОВАНИИ – Value In Use is the net present value (NPV) of a cash flow or other benefits that an asset generates for a specific owner under a specific use. In the United States, Value-in-Use is generally estimated at a use which is less than highest-and-best use, and therefore value-in-use is generally lower than market value. When a particular user enjoys special benefits, such as extraordinary financing, agglomeration benefits, or grandfathered zoning, then the value may be higher than market value, and the value is considered to be an investment value. The current edition of International Valuation Standards (IVS 2007) re-states the International Financial Reporting Standards (IFRS) definition of Value-in-Use, which would allow for either a higher value than market value or a lower value than market value:- Value in Use is the present value of the future cash flows expected to be derived from an asset or a cash-generating unit. The present value of estimated future cash flows expected to arise from the continuing use of an asset and from its disposal at the end of its useful life. Value In Use is the present value of the future cash flows expected to be derived from an asset or cash-generating unit. Value in use:- the calculation of value in use should reflect the following elements:- (i) an estimate of the future cash flows the entity expects to derive from the asset; (ii) expectations about possible variations in the amount or timing of those future cash flows; (iii) the time value of money, represented by the current market risk-free rate of interest; (iv) the price for bearing the uncertainty inherent in the asset; and (v) other factors, such as illiquidity, that market participants would reflect in pricing the future cash flows the entity expects to derive from the asset. Cash flow projections should be based on reasonable and supportable assumptions, the most recent budgets and forecasts, and extrapolation for periods beyond budgeted projections. IAS 36 presumes that budgets and forecasts should not go beyond five years; for periods after five years, extrapolate from the earlier budgets. Management should assess the reasonableness of its assumptions by examining the causes of differences between past cash flow projections and actual cash flows. Cash flow projections should relate to the asset in its current condition – future restructurings to which the entity is not committed and expenditures to improve or enhance the asset's performance should not be anticipated. Estimates of future cash flows should not include cash inflows or outflows from financing activities, or income tax receipts or payments. Value In Use is the value of an asset in the opinion of the owner. Value-In-Use is the net present value of the cash flows generated by an asset as it is currently being used by the owner. This amount may be less than the net present value of cash flows from the highest and best use to which an asset can be put. For example, the value-in-use of farmland in an urban area could be much lower than its highest and best use, since the farmer could earn more by constructing commercial or residential buildings on the property. Value In Use is the worth of a property in a certain use, typically as it is currently being used. This amount may be greater or less than its market value. Contrast highest and best use. Example:- a tract of land in the path of growth of a major metropolitan area is being used as a cotton farm. The value in use of that land is USD2 000.00 per acre, whereas its market value as land for a subdivision would be USD40 000.00 per acre. / Рыночная Стоимость в Использовании – стоимость, которую конкретное имущество имеет для конкретного использования конкретным пользователем. Величина рыночной стоимости в использовании может быть отождествлена с затратами, которые понёс собственник на приобретение или создание объекта, или величиной денежного потока, который данный актив приносит в составе действующего имущественного комплекса. Ценность От Использования:- . Возмещаемая Сумма (Value In Use):- большее из двух значений:- чистой продажной цены актива и его эксплуатационной ценности. Стоимость В Использовании (Value In Use):- (1) приведённая стоимость расчётных будущих денежных потоков, которые, как ожидается, возникнут в результате постоянного использования актива и в результате его реализации в конце срока службы. Следует заметить, что приведённое выше определение, которое применяется к финансовой отчётности, рассматривает стоимость актива в конце срока его службы. Это значение отличается от того, как этот термин обычно определяется в практике оценки (смотрите ниже Пункт 2). (2) Стоимость, которую конкретное имущество имеет для конкретного использования конкретным пользователем и поэтому она не связана с рынком. Это тип ставит во главу угла стоимость, вносимую конкретным имуществом в предприятие, частью которого оно является, безотносительно к его наиболее эффективному использованию и денежной сумме, которую можно было бы получить при его продаже.

VALUE IN USE CONCEPT = КОНЦЕПЦИЯ СТОИМОСТИ В ИСПОЛЬЗОВАНИИ – Value In Use Concept:- in stark contrast to market value, Use Value (often referred to as Value In Use) is the value a specific property has for a specific use. In estimating use value, an appraiser focuses on the value the real estate contributes to the enterprise of which it is a part or the use to which it is devoted, without regard to the highest and best use of the property or the monetary amount that might be realized from its sale. Value means the utility of a commodity. However, in economics, the term 'Value' has a quite different meaning. According to Adam Smith, the word value can be used in two senses, i.e. value-in-use and value-in-exchange. These are explained below:- (1) Value-In-Use:- it is the want satisfying power of a commodity. The satisfaction which one obtains from the use of a commodity is known as the value-in-use. For example water has immense use value, because it quenches thirst and without it daily life is just impossible. The quality of water is the value-in-use of water. (2) Value-In-Exchange:- it is the amount of goods and services which we may obtain in the market in exchange of a particular thing. In other words, it is the price of a particular good which can be sold and bought in the market. For instance, if one kg of Rice can be obtained in exchange of one dozen of Banana, then we may say that value of one kg of Rice is equal to one dozen of Banana. Thus, value-in-exchange depends on two things:- (i) Time:- value-in-exchange depends on time element. That

is, with the change in time value-in-exchange for a commodity in respect to other commodity will vary. (ii) Place:- value-in-exchange also depends from place to place. Value-in-exchange for a particular commodity varies from one market to other markets. Hence, it varies according to time and place. Again, one commodity may have immense use value but no exchange value or vice versa. For example, water has immense use value but not exchange value. On the contrary, diamond has huge exchange value but no use value. / Эдэм Смис (Adam Smith).

VALUE INVESTING = ОЦЕНОЧНОЕ ИНВЕСТИРОВАНИЕ (или СТОИМОСТНОЕ ИНВЕСТИРОВАНИЕ) – Value Investing is about finding stocks that the market has not correctly priced. In other words, a stock that is worth more than is reflected in the current price. Value Investor:- the value investor, perhaps more than any other type of investor, is more concerned with the business and its fundamentals than other influences on the stock's price. Fundamentals, such as earnings growth, dividends, cash flow, and book value are more important than market factors on the stock's price. Value investors are also buy and hold investors who are with a company for the long term. If the fundamentals are sound, but the stock's price is below its obvious value, the value investor knows this is a likely investment candidate. The market has incorrectly valued the stock. When the market corrects that mistake, the stock's price should experience a nice rise. Stock XYZ is down 25% from its high of six months ago. Is it a candidate for a value investor? Maybe, but probably not. Value investors aren't usually interested in beaten up stocks unless there is no fundamental reason for the drop in price. The Market's Right:- this happens; however most of the time the market is right and a stock gets hammered because of any number of sound fundamental reasons (declining earnings, declining revenues, are good examples) or something fundamental changes in their market or product line. A pharmaceutical company has a top seller yanked off the market by the government – that fundamentally changes the company. On the other hand, other pharmaceutical companies may see their stock clipped also even though they are not part of the recall. That may make them worth a look by a value investor. Value Investing Guidelines:- What do value investors look for in a potential investment? Here are some guidelines gathered from a variety of value investors. Investors should settle on a formula that works for them, but it will probably include a minimum these elements:- (i) a Price Earnings Ratio (P/E) in the bottom 10 percent of its sector; (ii) a PEG (PEG = P/E / (Projected Growth In Earnings)) of less than one (the link will take you to an article that explains how to calculate PEG.); a PEG of less than one may indicate the stock is undervalued; (iii) a Debt to Equity Ratio of less than one; (iv) strong earnings growth over an extended period; a realistic number might be in the 6–8% range over 7 to 10 years; (v) a Price to Book ratio of one or less; and (vi) don't pay more that 60% to 70% of the stock's intrinsic per share price (see below for more on intrinsic price). A big challenge for the value investor, and all investors for that matter, is reconciling market value and book value. Intrinsic Value:- current accounting standards are adequate for measuring buildings and equipment (book value), but as our economy has moved to a more technology/knowledge-base, many of these intellectual assets never show up on financial statements. Value investors acknowledge that their target investment company is much more valuable as an ongoing business (expected cash flows, etc) than its assets (market value). In many cases, it is the intangibles – patents, trademarks, research and development, brand, and so on – that drives the expectations of future growth, not hard assets. How do you calculate the value of intangible assets? An article from Investopedia.com offers a step-by-step process to come up with a number. Coming up with the intrinsic value of a stock is a complicated process and there are a number of ways to get to the number. Finding Intrinsic Value:- fortunately, there are several places you can go on the Web to find the number. MorningStar.com calculates the number, which it calls 'fair value', on its site. However, you need to be a member. Take the two-week free trial to see if you like their service. Another good source is Reuters, which also requires a registration, but it is free. However you arrive at the intrinsic or fair value, give yourself a margin of error with the thought that if the calculation is wrong you might over pay. If you use one of the services mentioned above or another source to find the intrinsic value, determine if they have already factored in a margin of error. For example, if you believe the intrinsic value is USD40 per share, give yourself a margin of safety and lower the target to USD36 per share. Conclusion:- many people have made fortunes using a value-based approach to investing. This overview suggests a philosophy that works over time if you buy carefully and hold for the long term. Value Investing:- in the context of asset management, mutual funds, and hedge funds, the a style of investment that focuses on securities with low price to earnings ratios or low price to book ratios. Some of these securities are deemed cheap and are viewed by manager as having a lot of profit potential. Value Investing is an investment strategy where stocks are selected that trade for less than their intrinsic values. Value investors actively seek stocks they believe the market has undervalued. Investors who use this strategy believe the market overreacts to good and bad news, resulting in stock price movements that do not correspond with a company's long-term fundamentals, giving an opportunity to profit when the price is deflated. Undervalued stocks come about through investor irrationality. Typically, value investors seek to profit off this irrationality by selecting stocks with lower-than-average price-to-book ratios, lower-than-average price-to-earnings ratios and/or higher dividend yields. These numbers are compared to a company's intrinsic value, after which, a value investor invests if the comparative value is high enough. However, there is an issue with value investing in that estimating the intrinsic value of a stock is difficult. Two investors can be given the exact same information and place a different value on a company. For this reason, another central concept of value investing is that of 'margin of safety'. Value investors need to buy an equity at a big enough discount to allow some room for error in the estimation of value. Additionally, value investing is subjective. Some value investors only look at present assets and earnings and do not place any value on future growth. Other value investors base their strategies completely around the estimation of future growth and cash flows. Despite the different methodologies, the underlying logic is a value investor should buy something for less than he thinks it is currently worth. An Example of a Value Investment:- value investors seek to profit from market overreactions that usually come from the release of a quarterly earnings report. On May 04, 2016, Fitbit released its Q1 2016 earnings report, and saw a sharp decline in after-hours trading. After the flurry was over, the company lost nearly 19% of its value. However, while large decreases in a company's share price are not uncommon after the release of an earnings report, Fitbit not only met analyst expectations for the quarter but even increased guidance for 2016. The company earned USD505.4 million in revenue for the first quarter of 2016, up more than 50% when compared to the same time period from one year ago. Further, Fitbit expects to generate between USD565 million and USD585 million in the second quarter of 2016, which is above the USD531 million forecasted by analysts. The company looks to be strong and growing. However, since Fitbit invested heavily in research and development costs in the first quarter of the year, earnings per share (EPS) declined when compared to a year ago. This is all average investors needed to jump on Fitbit, selling off enough shares to cause the price to decline. However, a value investor looks at the fundamentals of Fitbit and understands it is an undervalued security, poised to potentially increase in the future. Value Investing is the philosophy of investing in a security when its share price undervalues its intrinsic worth. Proponents of this philosophy include Warren Buffet, Charlie Munger, and the late Benjamin Graham. Returns Of Value Investing:- Value Investing does not promise fantastic returns, or even market-beating returns. However, those who have practiced value investing consistently are considered by most to be among the greatest investors of this time; Warren Buffett, Peter Lynch, John Bogle, Mario Gabelli, Eddie Lampert, Charles Brandes, and quite a few others. Another point – in the last 20 years, the S&P 500 has obtained annualized returns of 13% per year. Over the same period, small-capitalization companies (market caps are less than 2 billion Dollars) that were considered value investments had annualized returns of 15%, better than all other types. USD1 000 invested in small-cap value investments 20 years ago, at an annual return of 15%, would yield about USD16 366 today. USD1 000 invested in the S&P 500 20 years ago, at an annual return of 13%, would yield about USD11 523. As you can see, the value investments would return almost USD5 000 more (on a USD1 000 investment)! Value Investing is an investment paradigm that (generally) involves buying securities whose shares appear underpriced by

some form of fundamental analysis. Examples are companies that:- (i) trade at discounts to book value or tangible book value; (ii) have high dividend yields; (iii) have low price-to-earning multiples; and/or (iv) have low price-to-book ratios. Value investing comes from the work that Ben Graham and David Dodd began teaching at Columbia Business School in 1928. They continued and refined this in their Security Analysis publication. Berkshire Hathaway chairman Warren Buffett is a strong advocate of value investing. He has argued that the essence of value investing is to buy stocks at less than their intrinsic value. The discount of the market price to the intrinsic value is what Benjamin Graham called the 'Margin Of Safety'. / Инвэстопидиа.дат.кам (Investopedia.com). МониньгСтар.дат.кам (MorningStar.com). Ройтас (Reuters). Фитбит (Fitbit). Ворэн Бафит (Warren Buffet), Чарли Мангё (Charlie Munger), и позже Бэньдьжемин Грэм (Benjamin Graham). Инвестирование В Недооцененные Акции (Value Investing):- технология инвестирования, основывающаяся на составлении портфеля из акций временно непопулярных и недооцененных компаний в расчёте на то, что в будущем рынок признает их потенциал и, соответственно, оценит их выше. Приверженцем именно этого стиля инвестирования является Ворэн Бафит. Противопоставляется инвестированию в акции быстрорастущих компаний (growth investing).

VALUE ITEM = СТОИМОСТНАЯ ПОЗИЦИЯ (или ХХ) – Value Item is a representation of a value meaning in a specific value domain – the actual value. See also Value Domain, and Value Meaning.

VALUELESS (WORTHLESS) SECURITIES = НИЧЕГО НЕ СТОЯЩИЕ (или БЕСПОЛЕЗНЫЕ) ЦЕННЫЕ БУМАГИ – Valueless Securities are non-performing securities which have lost all or most of their value, or which appear worthless due to specific circumstances. Such securities can, however, become attractive again at a later date, e.g., if the company is taken over or restructured. Worthless Securities are the securities that have a market value of zero. Worthless securities can include stocks or bonds that are either publicly traded or privately held. These securities result in a capital loss for the owner and can be claimed as such when filing taxes. The problem with declaring worthless securities as a loss for tax purposes is that you must sell securities before making this claim. Unfortunately, worthless securities are unsellable. Another difficulty comes from investors who own securities that they are not sure are totally worthless in a given year. If they go ahead and declare them as such and then they are deemed to have value the next year, taxpayers can file an amended return for the previous year and redeclare the loss the following year. / , например, если компания .

VALUE LINE, (INC.) = ВАЛЪЮ ЛАЙН, (ИНК.) – Founded in 1931 as Arnold Bernhard & Company, Inc. Value Line, Inc. (the Company), a New York corporation, was organized in 1982 and is the successor to substantially all of the operations of Arnold Bernhard & Company, Inc. (AB&Co.). As of 2007-June-30, AB & Co. owned approximately 86.5% of the Company's issued and outstanding common stock. The Company's primary businesses are producing investment related periodical publications through its wholly-owned subsidiary, Value Line Publishing, Inc. (VLP), and providing investment advisory services to mutual funds, institutions and individual accounts. VLP publishes in both print and electronic formats The Value Line Investment Survey®, one of the nation's major periodical investment services, as well as The Value Line Investment Survey – Small and Mid-Cap Edition, The Value Line 600, Value Line Select, The Value Line Mutual Fund Survey, The Value Line No-Load Fund Advisor, The Value Line Special Situations Service, The Value Line Daily Options Survey and The Value Line Convertibles Survey. VLP also provides current and historical financial databases which include DataFile, Estimates & Projections, Convertibles and Mutual Funds in standard computer formats. The Company also markets investment analysis software which includes The Value Line Investment Analyzer, Value Line Mutual Fund Survey for Windows®, Value Line Daily Options Survey, Value Line Electronic Convertibles and Value Line Research Center. These electronic products are available on CD-ROM and/or on the Company's internet site. The Company is the investment adviser for the Value Line Family of Mutual Funds (Value Line Funds), which on 2007-June-30 included 14 open-end investment companies with various investment objectives. In addition, the Company manages investments for private and institutional clients. The Company is registered with the Securities and Exchange Commission as an investment adviser under the Investment Advisers Act of 1940. In addition to Value Line Publishing, the Company's other wholly-owned subsidiaries include Value Line Securities, Inc., Vanderbilt Advertising Agency, Inc., Compupower Corporation and Value Line Distribution Center (VLDC). Value Line Securities, Inc. is a registered broker-dealer and distributor to the Value Line Funds. Vanderbilt Advertising Agency, Inc. places advertising on behalf of the Company and its subsidiaries' businesses. Compupower Corporation serves the subscription fulfillment needs of the VLP's publishing operations. VLDC primarily handles all of the mailings of the publications to VLP's subscribers. Additionally, VLDC is a disaster recovery site for the New York operations. The name 'Value Line', as used to describe the Company, its products, and its subsidiaries, is a registered trademark of the Company. Value Line® is a registered mark of Value Line, Inc., a New York corporation that provides financial services and publications. Since 1982, the Kansas City Board of Trade has been licensed to use the Value Line® mark in connection with its efforts to establish futures markets tied to the Value Line® index. The Kansas City Board of Trade and Value Line, Inc. are not affiliated corporate entities. Value Line, Inc. is the most trusted and prestigious name in the investment field. For seventy-five years Value Line has been synonymous with trust, reliability, objectivity, independence, accurate information and proven performance for investors. Value Line is:- (i) one of the largest independent research staffs of investment analysts and statisticians in the world; (ii) totally independent, objective and unbiased; (iii) a research company that collects data and analyzes performance of approximately 8 000 stocks, 13 000 mutual funds, 80 000 options and other securities; (iv) a company with 3/4 of a century of experience tracking, analyzing and ranking investments; (v) best known for The Value Line Investment Survey, one of the most widely read investment services in the world; and (vi) critically acclaimed:- 'I don't know any other system that's as good' – Warren Buffett. Value Line publishes more than a dozen print and electronic products which we think are used by more than half-a-million investors for timely information on stocks, mutual funds, special situations, options and convertibles. The Value Line Investment Survey is a comprehensive source of information and advice on approximately 1 700 stocks in 97 industries, the stock market, and the economy. It has three parts:- (i) The Ratings & Reports section contains one-page reports about approximately 1 700 companies and approximately 97 industries. Each company report contains, among other things, Value Line's Timeliness™, Safety, and Technical ranks, financial and stock price forecasts for the coming 3 to 5 years, an analyst's written commentary, and much more. (ii) The Summary & Index contains an index of all stocks in the Investment Survey as well as many up-to-date statistics to keep investors informed about the latest company results. It also contains a variety of stock 'screens' designed to help investors quickly identify companies with characteristics that match their investing goals. (iii) The Selection & Opinion section contains Value Line's latest economic and stock market forecasts, one-page write-ups about interesting and attractive stocks, model portfolios, and financial and stock market statistics. The most widely distributed independent investment information service, it tracks the performance of 1 700 common stocks. Value Line is an investment research company collecting data and analyzing performance of approximately 8 000 stocks, 15 000 mutual funds, and 80 000 options and other securities. Value Line is best known for their Investment Survey, one of the most widely read investment services in the world. The Value Line Investment Survey has three main parts:- (i) The Ratings & Reports section's one-page reports contain, among other things, Value Line's Timeliness, Safety, and Technical ranks, financial and stock price forecasts for the coming 3–5 years, an analyst's written commentary, and more. (ii) The Selection & Opinion section contains Value Line's latest economic and stock market forecasts, one-page write-ups about interesting and attractive stocks, model portfolios, and financial and stock market

statistics. (iii) The Summary & Index contains an index of all stock in the Investment Survey as well as many up-to-date statistics, keeping investors informed about the latest company results. Also here, you'll find a variety of stock 'screens' designed to help investors quickly identify companies with characteristics matching their investing goals. / Ворэн Эдвод Бафит (Warren Edward Buffett). Комиссия по Ценным Бумагам и Биржам (The Securities and Exchange Commission; сокращённо – КЦББ или СЭК (SEC), в Англоязычном произношении). Анолд Бёнад Энд Кампэни, Инк. (Arnold Bernhard & Company, Inc.) Валъю Лайн, Инк. (Value Line, Inc.). Вандёбилт Эдвётайзин Эйдьженси, Инк. (Vanderbilt Advertising Agency, Inc.), Компьюпавэ Корпорэйшэн (Compupower Corporation). Независимая, очень широко распространённая инвестиционно-информационная служба, отслеживающая поведение цен на обыкновенные акции 1 700 компаний. Инвестиционый Обзор от Валъю Лайн:- инвестиционная консультационная корпорация Валъю Лайн осуществляет оценку 1 700 акций с точки зрения 'соблюдения сроков' и безопасности. Используя компьютерную модель, основанную на показателе прибыльности компаний, Валъю Лайн прогнозирует, какие акции будут иметь лучшие или худшие относительные ценовые показатели в течение последующих 12 месяцев. Кроме того, каждой акции присваивается рэйтиньг по уровню риска, который указывает на лихорадочность (volatility) цен акций по отношению к средним показателям рынка. Это агентство также устанавливает рэйтиньги основных промышленных групп с точки зрения 'соблюдения сроков'. Система оценки (рэйтиньг) Валъю Лайн относительно 'соблюдения сроков' и безопасности конкретных акций выглядит следующим образом:- 1 – высший класс, 2 – класс выше среднего, 3 – средний класс, 4 – класс ниже среднего, 5 – низший класс. Еженедельные обзоры агентства, которые получают подписчики Валъю Лайн, включают детальную финансовую информацию о компании, а также такие данные, как решения о покупке и продаже ценных бумаг, сделанные лицами, имеющими доступ к внутренней информации (insider), и доле акций компании, которыми владеют институциональные инвесторы. Валъю Лайн предлагает подписчикам несколько специализированных финансовых обзоров. Value Line Convertibles Survey (Обзор Конвертируемых Ценных Бумаг от Валъю Лайн) – это издание, в котором публикуются рэйтиньги конвертируемых ценных бумаг. Value Line Mutual Fund (Обзор Взаимных Фондов от Валъю Лайн) публикует подробные предложения об инвестировании средств в фонды, даёт обзор их деятельности и ранжирует фонды с точки зрения ожидаемой доходности их деятельности. Кроме того, Валъю Лайн поддерживает свою собственную группу взаимных инвестиционных фондов. Валъю Лайн также рассчитывает несколько фондовых индексов и средних показателей, важным из которых является Survey Value Line Composite Average (Обзора о Сводном Усреднении от Валъю Лайн), который устанавливает индексы на рассматриваемые в Value Line Investment Survey (Инвестиционном Обзоре от Валъю Лайн) акции.

VALUE LINE ARITHMETIC COMPOSITE AVERAGE = АРИФМЕТИЧЕСКОЕ СВОДНОЕ УСРЕДНЕНИЕ ВАЛЪЮ ЛАЙН – The Value Line Arithmetic Composite Average is an equally weighted price index of all stocks in the Value Line Investment Survey. It is referred to as 'Arithmetic' because the index is computed by finding the mean or simple average.

VALUE LINE GEOMETRIC COMPOSITE AVERAGE = ГЕОМЕТРИЧЕСКОЕ СВОДНОЕ УСРЕДНЕНИЕ ВАЛЪЮ ЛАЙН – The Value Line Geometric Composite Average is an equally weighted price index of all stocks in the Value Line Investment Survey. It is referred to as 'Geometric' because the index is computed by finding the geometrical average. A geometrical average is calculated by taking the n^{th} root of the product of n terms. Of the two Value Line Composite Averages, the geometric version is referred to more often than the arithmetic version. On an absolute basis, the result of the geometric average will be less than the arithmetic average.

VALUE LINE INVESTMENT SURVEY® = ИНВЕСТИЦИОННЫЙ ОБЗОР ОТ ВАЛЪЮ ЛАЙН® – Have you ever opened the statement that your mutual fund company sent to you, then looked at the returns and thought, 'I could do better than that'? It's an increasingly common feeling, as the returns generated by many equity mutual funds often leave investors frustrated. If you want to try your hand at picking stocks but don't know where to start, the Value Line Investment Survey® can help. The Survey:- the Value Line Investment Survey® consists of professional research and recommendations on approximately 1 700 stocks. According to Value Line, this represents '… approximately 95% of the trading volume of all stocks traded in US markets …' The Survey also provides weekly updates on the financial markets, recommended portfolios, developments involving covered securities and special topical reports. For would-be stock pickers, Value Line provides an easy way to start your research. How to Get Started:- bearing in mind that conducting your own stock research is a time-consuming task, the first step in getting familiar with the tools Value Line offers is to set aside a few hours of reading time. You will need to study the materials closely in order to understand how to use them before you will be ready to invest any cash. Prior to delving into the literally thousands of pages of stock research at your fingertips, start by reviewing 'The Complete Guide to Using The Value Line Investment Survey®'. In roughly 40 pages, this slim volume explains Value Line's ranking system (stocks are rated from one to five in a variety of categories) provides line-by-line explanations for the information provided in each of the research reports. At the back of the booklet is a detailed glossary of investment terms that includes definitions for terms ranging from bond ratings to unit labor costs. Next, you'll want to read, 'A Quick Study Guide'. This guide explains the information included in the two binders that serve as primary research tools for investors using the hard copy version of Value Line. (An online service is also available.) The first binder contains the 'Summary and Index'and 'Ratings and Reports'. The second binder contains 'Selection and Opinion'. The Quick Study Guide also explains how to use the research to choose stocks for your portfolio. Binder 1:- Summary And Index:- starting with the first binder, the Summary and Index provides an overview of the stock screens Value Line provides, including lists of stocks with the lowest price-to-earnings ratio, the highest dividend yields, the highest annual total revenues and a host of other choices. These screens help investors identify stocks that align well with their personal investment goals. For example, investors seeking income may look for stocks that offer high dividend payments, while investors seeking growth may seek stocks that have the highest appreciation potential. If this is your first effort at picking stocks, this portion of the Survey could be of particular interest to you. In addition, the 'Summary and Index' catalogs all of the covered stocks and provides the page number where the research reports can be found. It also provides key statistics for the universe of covered stocks, including price-to-earnings ratio, dividend yields and appreciation potential. These statistics provide information about the 'universe' and the direction it has been moving in, as well as providing a baseline for comparing an individual stock against the universe. The 'Ratings and Reports' section provides stock research on approximately 1 700 companies. The research includes an analysts' report that provides a brief overview of the company, a review of its financial health and a recommendation regarding its attractiveness to investors. The data portion of the report provides a detailed statistical analysis, including a price target, transactions by company officials (buying/selling), transactions by institutions, chart of historical returns, sales figures, earnings data and much more. Perhaps the best thing about the research section, particularly if you are a novice, is its ranking system. Every stock in the survey is ranked on a scale of one to five in three different areas:- timeliness, safety and technical. A rank of one denotes stocks that are expected to outperform the rest of the Value Line universe. Timeliness refers to performance expectations for the next six to twelve months. Safety compares the security's price stability against its peers, and the Technical ranking compares 10 price trends to provide price return potential for a three to six month period. An alphabetical listing of all covered stocks, including key statistics and the ranking numbers, is particularly convenient for investors seeking a specific rating in one or more categories. Binder 2:- Weekly Selection And Opinion:- the second binder contains the 'Weekly Selection and Opinion' section, which includes an economic outlook, market commentary and research on selected topics. Additionally, it includes evaluations of four model portfolios, one targeting short-term growth, one for long-term growth, one for income and, lastly,

one for both growth and income. The evaluations highlight both successful selections and failures, which serves as an important reminder. While the Value Line Investment Survey® is a convenient, easy-to-use tool that is particularly helpful to novice investors, investing is not an endeavor that comes with any guarantees. The information you read in the Survey is well researched and impressively packaged, but there is no guarantee that it is correct. Like any other stock research, the insight provided by Value Line does not mean that you can't lose money on an investment that you make using the research. As with all security purchases, let the buyer beware. Using The Data:- taken as a whole, the Value Line Investment survey provides all the tools an investor needs to develop a picture of the current economic landscape, learn about stock analysis and identify securities that are appropriate for a variety of investment objectives. By matching the results of the research with your personal investment needs, you should be able to put together enough information to choose a stock or build an entire portfolio. How To Get It:- the Value Line Investment Survey® is available by subscription. A one-year subscription is just over USD500 for the online version and just under USD600 for the print version. For an additional fee, the firm also offers research on mutual funds, exchange traded funds, convertible securities and more. You can get them all for just under USD1 000. Interestingly, many large libraries receive the print version of the Value Line Investment Survey® and provide it to patrons for free. This provides an opportunity to learn about, use and thoroughly evaluate the materials before plunking down the cash for a personal subscription conveniently delivered to your house. Next Steps:- the Value Line Investment Survey® is not the only professional research that you can easily access. In fact, it is just the first in a long list of tools. After you have read, researched and mastered the Value Line tool set, you can expand your repertoire of investment tools by using the research reports provided through websites associated with online brokerage accounts. These sites provide access to research reports similar to those offered by Value Line. It is worth noting that reports from various research providers often contradict each other. The Bottom Line:- while these contradictions may be frustrating, think of research as data gathering. You can take in data from as many sources as possible and use that data to formulate your own opinion. Relying on any single source of data is unlikely to be a wise decision, as there are no guarantees that the researchers behind your data source will always make the right call. Of course, if reading these research reports is too time consuming, too scary or too frustrating, you can always buy a mutual fund or hire a professional financial advisor to provide investment recommendations. Value Line Investment Survey® is a proprietary service that ranks stocks for timeliness and safety. Value Line Investment Survey® provides you with proprietary research and analysis that can help you achieve your financial goals. / Инвестиционный Обзор От Валъю Лайн®:- инвестиционная консультационная служба, которая присваивает категории сотням ценных бумаг за своевременность платежей и надёжность. Категории рэйтиньга следующие:- 1 – высшая; 2 – выше средней; 3 – средняя; 4 – ниже средней; и 5 – низшая.

VALUE MANAGEMENT = УПРАВЛЕНИЕ СТОИМОСТЬЮ – Value Management is the application of established techniques to help define and refine business need, delivery strategy and the best value concept by setting customer objectives and values and determining success criteria for the project.

VALUE MANAGER = СТОИМОСТНОЙ УПРАВЛЯЮЩИЙ (или ДИСКОНТНЫЙ УПРАВЛЯЮЩИЙ, или XX) – Value Manager is a manager who seeks to buy stocks that are at a discount to their 'fair value' and to sell them at or in excess of that value. Often a value stock is one with a low price-to-book value ratio. Opposite of To Growth Stock. Also called Contrarians because they see value where many other market participants do not. Value Manager is an individual who looks for discounted stock prices so he or she can turn around and sell them at or for more than the purchase price.

VALUE MAXIMIZATION = МАКСИМИЗАЦИЯ СТОИМОСТИ – Value Maximization:- increases in owners' wealth achieved by maximizing of the value of a firm's common stock. Value Maximization is the process of increasing net worth through increased share prices on common stocks the investor has purchased.

VALUE MEANING = XX (или ЗНАЧЕНИЕ СТОИМОСТИ) – Value Meaning is the meaning or semantic content of a value. Context:- given a permissible value, representation of its value meaning shall be independent of (and shall not constrain) the representation of its corresponding value. The representation of value meanings in a registry shall be independent of (and shall not constrain) their representation in any corresponding value domain. Value meaning set is the relationship between a conceptual domain and a set of value meanings. Attributes of value meaning:- value meaning begin date is the effective date of this value meaning in the conceptual domain. A registration authority may determine whether this date is the date the value meaning becomes valid in a registry or the date the value meaning becomes part of the source domain or some other date. Value meaning description is a description of a value meaning. Value meaning end date is the date this value meaning became/becomes invalid. A registration authority may determine whether this date is the date the value meaning becomes no longer valid in a registry or the date the value meaning becomes no longer part of the source domain or some other date. Value meaning identifier is the unique identifier for a value meaning. See also Conceptual Domain, Permissible Value, and Value Item.

VALUE OF IMPROVEMENTS = СТОИМОСТЬ УЛУЧШЕНИЙ (или СТОИМОСТЬ БЛАГОУСТРОЙСТВ) – Value Of Improvements:- xxxxx. The Improvement Value is the Value Of The Improvements – an 'improvement' usually means a home/house/structure of some type. So, if you own a house for example, the land that the house sits on is the 'land value' and the house itself is the 'improvement'. Add the two together and you get the Total Value which is different from Assessment Value. Assessment Value is a somewhat arbitrary figure that your local property tax collector determines and then has a formula to calculate your annual real estate property taxes. The assessment value is usually significantly lower than the Total Value but this varies from state to state. / Стоимость Улучшений (Value Of Improvements):- стоимость, добавляемая к земле улучшениями, такими, как здания, сооружения или обогащения земли постоянного характера, включающие расходы труда и капитала и предполагающие повышение стоимости или полезности имущества. Улучшения обладают различным характером использования и экономические сроки службы. Смотрите также Улучшения.

VALUE OF MERCHANDISE = СТОИМОСТНОЙ ОБЪЁМ ТОВАРНОЙ МАССЫ (или XX) – Value Of Merchandise:- xxxxx. Valuation of Merchandise:- to ensure the proper matching of expenses and revenues, decreases in the value of inventory due to usage, damage, deterioration, obsolescence, and other factors must be recognized in the accounting period during which the decrease occurs rather than the period during which the merchandise sells. Inventory should never be valued at more than its net realizable value, which equals its expected sales price minus any associated selling expenses. For example, if a storm damages a car that cost an automobile dealer USD25 000, and if the car can now be sold for no more than USD23 000. Then the value of the car must be reported at USD23 000. This decrease in the value of inventory is recognized by debiting the loss on inventory write-down account, which is an expense account, and by crediting inventory. / Стоимостной Объём Товарной Массы, увеличивающих или уменьшающих национальное богатство страны. Стоимостной показатель, характеризующий величину всех видов движимого имущества, ввезённого или вывезенного из страны. Используется как при обобщении данных внешнеторговой (таможенной) статистики, так и при составлении платёжного баланса (balance of payments). В последнем учитывается в рыночных ценах. При внешнеэкономических расчётах под термином Товары подразумевается стоимость как самого товара, так и услуг в процессе доставки товаров до границы и погрузке их на борт транспортных средств в таможенном пункте. Иными словами, объём

вывоза (или экспорта) и привоза (или импорта) товаров, в соответствии с международными рекомендациями по составлению платёжного баланса, определяется на условиях ФОБ (Free On Board (FOB) Value) на таможенной границе страны-экспортёра.

VALUE OF PRODUCTION = СТОИМОСТЬ ПРОИЗВОДСТВА – Value Of Production:- generally as applied to crops, the multiplying of production by the estimated season average price received by producers for that part of production actually sold. For fruits and vegetables, quantities not harvested due to low prices or other factors are not included in the calculations.

VALUE OF PROPERTY ASSISTED = XX – Value Of Property Assisted:- monetary value of the distressed unit (including cargo) at the time assistance was rendered by the Coast Guard.

VALUE OF PROPERTY LOST = СТОИМОСТЬ ПОТЕРИ СОБСТВЕННОСТИ (или XX) – Value Of Property Lost:- monetary value of actual property lost as a result of the incident.

VALUE OF WORK PUT IN PLACE = СТОИМОСТЬ РАБОТЫ XX – The Value Of Work Put In Place (construction) is the value of work carried out on projects completed during the inquiry period, plus the value of work under construction at the end of the inquiry period minus the value at the beginning of the period. It includes construction work done as a main contractor and on own-account, plus work done as a subcontractor (minus the payments to sub-contractors for work done). See also Work Completed (Construction).

VALUE–ORIENTED INVESTING PHILOSOPHY = ФИЛОСОФИЯ ИНВЕСТИРОВАНИЯ, ОРИЕНТИРОВАННАЯ НА СТОИМОСТЬ (или XX) – Value-Oriented Investing Philosophy:- value investing is the philosophy of investing in a security when its share price undervalues its intrinsic worth. Proponents of this philosophy include Warren Buffet, Charlie Munger, and the late Benjamin Graham. Returns Of Value Investing:- Value Investing does not promise fantastic returns, or even market-beating returns. However, those who have practiced value investing consistently are considered by most to be among the greatest investors of this time; Warren Buffett, Peter Lynch, John Bogle, Mario Gabelli, Eddie Lampert, Charles Brandes, and quite a few others. Another point – in the last 20 years, the S&P 500 has obtained annualized returns of 13% per year. Over the same period, small-capitalization companies (market caps are less than 2 billion Dollars) that were considered value investments had annualized returns of 15%, better than all other types. USD1 000 invested in small-cap value investments 20 years ago, at an annual return of 15%, would yield about USD16 366 today. USD1 000 invested in the S&P 500 20 years ago, at an annual return of 13%, would yield about USD11 523. As you can see, the value investments would return almost USD5 000 more (on a USD1 000 investment)! / Ворэн Бафит (Warren Buffet), Чарли Мангё (Charlie Munger), и позже Бэндьжемин Грэм (Benjamin Graham). Ворэн Бафит (Warren Buffett), Питё Лынч (Peter Lynch), Дьжон Богл (John Bogle), Марио Габэлли (Mario Gabelli), Эди Лампат (Eddie Lampert), Чарлз Брандэс (Charles Brandes). / Философия Инвестирования, Ориентированная На Стоимость:- . VALUER = ОЦЕНЩИК – Valuer (or sometimes known as an Appraiser) is the person who determines what the value of something is. For instance:- property, jewellery and coins, boats and yachts, antiques, cars, etc. You often find Valuers working for insurance companies, estate agents, auctioneers, museums etc where the company needs to know exactly how much something is worth. This information is used to determine the price of insurance and payouts to claims, what a house/building should sell for etc. A Valuer's job is extremely important. If they don't get the price right, the client or company they are working for could suffer financially. What does a Valuer do? Depending who they are working for:- visits sites to see what needs appraising; takes photos and makes extensive notes; does research of current pricing of similar goods/services; compares pricing; write reports and advises client/company; and keeps up to date with the market trends. How do I become a Valuer? Well, this will depend on which field of appraising you'd like to work in. For instance:- property, antiques, art, etc. Whatever sector appeals to you, it would be an advantage to have some form of relevant qualification. You will need background skills and knowledge. Once you have your qualification, it would be advisable to get an entry level job in that sector. Once in, collect as much skills and experience as you can. Becoming a Valuer does not happen overnight. It's one of those jobs that requires years of hands-on experience and knowledge to be a good one. Xxxxx. Valuers and Appraisers establish the monetary worth of property, merchandise, business assets, objets d'art, precious stones, motor vehicles and household effects. In recent years the term 'Valuer' has been used to describe a person who determines the value of immovable property, while the term 'Appraiser' is used to describe a person who determines the value of any property, merchandise, goods and assets for purposes of managing deceased estates. Valuers and appraisers use the most readily available comparable facts and examine goods for condition and authenticity. They provide information for the parties concerned with the sale or expropriation of property. They may also be called upon to establish the value of security offered for a loan or mortgage. They assess the value of properties to enable local authorities to raise rates and taxes. They ascertain the value of company assets and shares. They evaluate the amount of cover and claims for insurance and estimate the value of plant and machinery. It is obvious that in every instance the good judgement of valuers is of cardinal importance to the parties concerned, because vast sums of money are at stake. The exact nature of valuers' work depends upon the employing organisation, such as building societies, banks, insurance companies, government departments, provincial administrations, local authorities or private practices. Their working conditions can vary widely from day to day, depending on the type of valuation required to be done. Valuers may find themselves in a very large office environment, whereas other colleagues may spend much of their time out-of-doors, inspecting properties. However, valuers can never be entirely office bound, because no valuation can be made without a physical inspection of the property and other comparable properties. Whatever field valuers may decide upon, they can expect to travel to some extent. / Оценщик (Valuer or Appraiser):- тот, кто обладает необходимой квалификацией, способностью и опытом для выполнения оценки. В некоторых государствах требуется лицензирование, прежде чем будет разрешено выступать в качестве оценщика. Смотрите также Профессиональный Оценщик Имущества.

VALUE RECEIVED = ПОЛУЧЕННАЯ СТОИМОСТЬ (или СТОИМОСТЬ ПОЛУЧЕНА) – Value Received:- this phrase is usually employed in a bill of exchange or promissory note, to denote that a consideration has been given for it. The expression value received, when put in a bill of exchange, will bear two interpretations:- (i) the drawer of the bill may be presumed to acknowledge the fact that he has received value of the payee; or (ii) when the bill has been made payable to the order of the drawer, it implies that value has been received by the acceptor. In a promissory note, the expression imports value received from the payee. Value Received is the term often used in a promissory note meaning that there has been a lawful consideration given for the note. Value Received:- this phrase is used on a bill of exchange to indicate that the bill is a means of paying for goods or services to the value of the bill. Value Received:- banking words used in a bill to show that the bill is a means of payment for goods supplied or services performed, to the value of the bill, and that it is not a means of transferring, e.g., a gift of money. / Стоимость Получена (Value Received):- слова на переводном векселе (bill of exchange), указывающие, что вексель является средством платежа за товары и услуги стоимостью, равной указанной в векселе. Однако в Великобритании нет необходимости писать на Британском векселе эти слова, так как каждый подписавший его рассматривается как уже уплативший (получивший) по векселю эквивалент.

VALUES AT CONSTANT EXCHANGE RATES OF PERIOD T0 = СТОИМОСТИ ПО ПОСТОЯННЫМ ОБМЕННЫМ КУРСАМ ПЕРИОДА T0 – Values At Constant Exchange Rates Of Period t0 are series at current domestic prices converted to a common currency by way of constant exchange rates of period t0. Context:- a value index of this kind corresponds to a weighted average of the value changes in domestic prices, as exchange rates are held fixed.

VALUES AT CONSTANT EXCHANGE RATES OF PERIOD T–1 = СТОИМОСТИ ПО ПОСТОЯННЫМ ОБМЕННЫМ КУРСАМ ПЕРИОДА Т–1 – Values At Constant Exchange Rates Of Period t-1 are series at current domestic prices converted to a common currency by way of constant exchange rates of period t-1. Context:- a value index of this kind corresponds to a weighted average of the value changes in domestic prices, as exchange rates are held fixed at their previous year's value. However, weights are continuously updated.

VALUES AT CONSTANT INTERNATIONAL PRICES OF PERIOD T0 (AT PPPs OF PERIOD T0) = СТОИМОСТИ ПО ПОСТОЯННЫМ МЕЖДУНАРОДНЫМ ЦЕНАМ ПЕРИОДА Т0 (ПРИ ППС ПЕРИОДА Т0) – Values At Constant International Prices Of Period t0 (At PPPs Of Period t0) are series at current domestic prices converted to a common currency by way of constant purchasing power parities (PPPs) of a given year. Context:- a value index of this kind corresponds to a weighted average of the value changes in domestic prices, as PPPs are held fixed.

VALUES AT CONSTANT INTERNATIONAL PRICES OF PERIOD T–1 (AT PPPs OF PERIOD T–1) = СТОИМОСТИ ПО ПОСТОЯННЫМ МЕЖДУНАРОДНЫМ ЦЕНАМ ПЕРИОДА Т–1 (ПРИ ППС ПЕРИОДА Т–1) – Values At Constant International Prices Of Period t-1 (At PPPs Of Period t-1) are series at current domestic prices converted to a common currency by way of purchasing power parities (PPPs) of year t-1. Context:- a value index of this kind corresponds to a weighted average of the value changes in domestic prices, as PPPs are held fixed at their previous year's value. However, weights are continuously updated.

VALUES AT CURRENT EXCHANGE RATES (AT CURRENT USD) = СТОИМОСТИ ПО ТЕКУЩИМ ОБМЕННЫМ КУРСАМ (ПРИ ТЕКУЩЕМ USD) – Values At Current Exchange Rates (At Current USD) are series at current domestic prices converted to a common currency by way of current exchange rates. Because exchange rates are price relatives of currencies, this expresses domestic values in terms of a foreign currency.

VALUES AT CURRENT INTERNATIONAL PRICES (AT CURRENT PPPs) = СТОИМОСТИ ПО ТЕКУЩИМ МЕЖДУНАРОДНЫМ ЦЕНАМ (ПРИ ТЕКУЩИХ ППС) – Values At Current International Prices (At Current PPPs) are series at current domestic prices converted to a common currency by way of current purchasing power parities (PPPs). Because PPPs are price relatives of goods and services, this implies substituting the set of domestic prices by a set of international prices.

VALUE STOCK = СТОИМОСТНАЯ АКЦИЯ (или ЦЕННАЯ АКЦИЯ) – Value Stock is a security that is currently selling at a price point lower than the issuing company's fundamentals would suggest. For example, its price might be selling at less than the book value of the business, or the price to earnings ratio is well under the ratio for competing firms. A value investor likes to invest in value stocks, on the assumption that their prices will eventually improve, providing a reasonable return on investment. A problem with the value stock concept is that there may be excellent reasons why the shares of a business are selling for such a low price, such as declining market share, the loss of a major customer contract, or the presence of a lawsuit that could go against the business. If these issues are present, it is entirely likely that the price of a value stock will remain low for a considerable period of time. Conversely, a value stock is already selling at a low price, so at least there is little risk of a deep additional decline in the stock price. Value Stocks are the stocks with low price/book ratios or price/earnings ratios. Historically, value stocks have enjoyed higher average returns than growth stocks (stocks with high price/book or P/E ratios) in a variety of countries. Value Stock is a stock that trades at a lower price relative to it's fundamentals, i.e. earnings, dividends, sales, etc; thereby being considered undervalued by a value investor. Common characteristics of such stocks include a high dividend yield, low price-to-book ratio and/or low price-to-earnings ratio.

VALUE STOCK FUND = ФОНД СТОИМОСТНЫХ АКЦИЙ – Value Stock Fund is a mutual fund that emphasizes stocks of companies whose growth opportunities are generally regarded as subpar by the market. A value stock company often pays regular dividend income to shareholders and sells at relatively low prices in relation to its earnings or book value. / взаимный фонд, который выделяет акции компаний, возможности роста которых .

VALUE STREAM MAPPING = КАРТИРОВАНИЕ ПОТОКА СТОИМОСТИ – Value Stream Mapping (VSM) reveals information about the process steps that a business uses to create value. It can be used to streamline process flows, thereby reducing non-value-added activities. Depending upon the format used, it can point out such information as:- (i) the work time and wait time required for each step in a process; (ii) the amount of labor needed for a work step, including the identification of overtime; (iii) the error rate by work step; and (iv) downtime by work step. VSM can be applied to the various accounting processes. The resulting charts can be used to pinpoint areas needing improvement, such as reductions in errors, automation to eliminate staff time, and altered controls to shorten process flows. The VSM concept is best explained with an example. In the following sample of the timekeeping process, we see that the accounting staff requires only a small amount of staffing and time to process two steps, which are issuing reminders to employees and verifying supervisory approval of time cards. However, the VSM indicates that the controller must allocate more staff to the tasks of reviewing received time cards and summarizing hours worked. These latter two tasks are so time-sensitive that they routinely require the use of overtime to be completed on time. The map also shows a high error rate. Further, the VSM reveals that a total of 25.5 hours are needed to complete this step, which is the lengthiest part of the payroll process. Given (the scheme) the issues shown in the map, it would be reasonable for a controller to implement a more automated method of time tracking, such as a computerized time clock. By doing so, the two bottlenecks in the process can be eliminated, along with overtime and the high error rate. Automation will also likely reduce the total processing time by a substantial amount. The controller might not have realized the severity of the problems with timekeeping without a VSM to clarify the issues. Value stream mapping is an especially effective tool when used to break down the elements of high-volume processes; these processes are completed many times in a typical year, so even small changes can yield large cumulative benefits. Conversely, there is little point in using VSM to analyze tasks that require little time and are only rarely completed, since there is only a modest opportunity for improvement.

VALUE SURCHARGE = ДОБАВОЧНЫЙ СБОР ЗА СТОИМОСТЬ (или XX) – Value Surcharge is a surcharge for the carriage of cargo having a value in excess of a specified amount per kilogram (aircargo).

VALUE UPDATING = ОБНОВЛЕНИЕ СТОИМОСТИ – Value Updating:- xxxxx. See also Price Updating.

VALUE WEIGHTS = ВЕСА СТОИМОСТИ (или СТОИМОСТНЫЕ ВЕСА, или ЦЕННОСТНЫЕ ВЕСА) – Value Weights:- the measures of the relative importance of products in the index. The weight reference-period values or shares of the various components of output (or input) covered by the index. Being commensurate and additive across different products, value weights can be used at aggregation levels above the detailed product level. See also Quantity Weights, and Weights. / меры относительной значимости продуктов в индексе.

VALUING NATURAL RESOURCES = ОЦЕНИВАНИЕ ПРИРОДНЫХ РЕСУРСОВ – Valuing Natural Resources:- the principles for valuing produced assets and calculating the decline in their value can be applied to natural resources in like manner. Natural resources provide a stream of services to the economy as they are used. The value of these services represents the resource rent of the asset.

The decline in value of the resource (ignoring price effects and disasters) can be called the consumption of natural capital, parallel to the consumption of fixed capital.

VALVATE = СТВОРЧАТОЕ (или ХХ) – Valvate (bud scales) (type):- with scales (usually two) meeting by the edges without overlapping. Compare with Imbricate. Valvate:- opening by valves; meeting by the edges without overlapping as leaves or petals in the bud.

VALVE = ВАЛЬВА (или СТВОРКА) – Valve is a segment into which a dry fruit dehisces. / Вальва или Створка:- сегмент, в который раскрывается сухой плод.

VALVE = КЛАПАН – (1) Valve:- in mechanical engineering, device for controlling the flow of fluids (liquids, gases, slurries) in a pipe or other enclosure. Control is by means of a movable element that opens, shuts, or partially obstructs an opening in a passageway. Valves are of seven main types:- globe, gate, needle, plug (cock), butterfly, poppet, and spool. In the globe valve shown in the Figure (far left), the movable element M may be a tapered plug or a disk that fits a seat on the valve body; the disk may carry a replaceable rubber or leather washer, as in a household water faucet. In a gate valve, the movable element is a wedge-shaped disk that seats against two tapered faces in the valve body. A needle valve has a long tapered needle fitting in a tapered seat. A plug valve, or cock, is a conical plug with a hole perpendicular to its axis fitting in a conical seat in the valve body at right angles to the pipe. By turning the plug the hole is either lined up with the pipe to permit flow or set at right angles to block the passage. A butterfly valve is a circular disk pivoted along one diameter; the solid lines in the Figure (left center), show one in the closed position. In the fully open position, shown dotted, the disk is parallel to the direction of flow. The damper in a stovepipe or a warm-air heating system is of this type, which is also used in the intake passage to carburetors on gasoline engines. On hydraulic turbines such valves may be 20 feet or more in diameter. Some valves operate automatically; check (or nonreturn) valves, for example, are self-acting and permit flow in one direction only. They are made in several types. If the movable element in the globe valve in the Figure were kept on its seat by gravity or a spring, it would permit flow from left to right but not from right to left. Safety valves, which are usually of the poppet type, open at a predetermined pressure. The movable element may be kept on its seat by a weighted lever or a spring strong enough to hold the valve closed until the pressure is reached at which safe operation requires opening. On gasoline engines, poppet valves are used to control the admission and rejection of the intake and exhaust gases to the cylinders. In the Figure (right center), the valve, which consists of a disk with a tapered edge attached to a shank, is held against the tapered seat C by a compressed spring. The valve is raised from its seat by the action of a rotating cam that pushes on the bottom of the shank, permitting gas flow between region A, which leads to the intake or exhaust pipes, and region B, which leads to the cylinder. In hydrostatic fluid-power systems, in which the working medium is usually pressurized oil, spool valves are employed to regulate the oil flow. The valve shown in the Figure provides two flow paths for the output from a pump. In the extreme upper position, as shown, active flow is from the pump port P to the working, or load, port B; discarded fluid from the load passes from port A to the tank or sump port T. In the extreme lower position, the functions of ports A and B are reversed. In the mid or neutral position of the spool, ports A and B are blocked. The movement of the spool may be manually or electrically controlled. Valve is a device which controls fluid flow direction, pressure, or flow rate. See also Bypass Valve; Differential Pressure Valve; Directional Control Valve; Directional Control Servo Valve; Flow Control Valve; Positive Crankcase Ventilation Valve; Pressure Control Valve; and Servovalve. / Смотрите также Перепускной Клапан (Bypass Valve); Клапан Перепада Давления или Дифференциальный Нагнетательный Клапан (Differential Pressure Valve); Клапан Контроля Направления или Клапан Распределительного Контроля (Directional Control Valve); Серво Клапан Контроля Направления или Серво Клапан Распределительного Контроля (Directional Control Servo Valve); Клапан Регулирования Расхода (Flow Control Valve); Клапан Принудительной Вентиляции Картера (Positive Crankcase Ventilation Valve); Клапан Контроля Давления или Редукционный Клапан или Уравнительный Клапан (Pressure Control Valve); и Сервоклапан (Servovalve). Под Клапаном, от Немецкого слова Klappe, означающее Заслонка или Крышка, понимается деталь или устройство, служащее для управления потоком газа или жидкости в машинах и трубопроводах путём изменения проходного сечения. В машинах – двигателях внутреннего сгорания, насосах, компрессорах, воздуходувках и другом – клапан является частью механизма распределения или механизма управления потоком газа или жидкости (смотрите Газораспределение). Клапан как разновидность трубопроводной арматуры служит для управления потоком газа, пара или жидкости. Клапан состоит из корпуса, встроенного в трубопровод, и затвора, перемещающегося внутри корпуса и изменяющего проходное сечение, а следовательно, и пропускную способность клапана. Применяются клапаны для:- (i) создания перепада давления (Дроссельные Клапаны); (ii) для предотвращения обратного потока жидкости (Обратные Клапаны); (iii) для частичного выпуска газа, пара или жидкости при повышении давления сверх установленного (Предохранительный Клапан); (iv) для управления давлением или расходом (Регулирующие Клапаны); (v) для понижения давления и поддержания его постоянным (Редукционные Клапаны). Кроме того, клапан широко применяется как запорная арматура для герметического отключения трубопроводов, технологических аппаратов, теплоэнергетических установок и другого. По конструкции корпуса клапаны разделяются на:- (i) проходные, (ii) угловые и (ii) трёх- или многоходовые. По способу присоединения к трубопроводу клапаны могут быть фланцевые, муфтовые и другие. Перемещение затвора в клапане может осуществляться вручную и от электрического, пневматического или гидравлического привода.

(2) Valve:- in anatomy, any of various membranous structures, especially in the heart, veins, and lymph ducts, that function to close temporarily a passage or orifice, permitting movement of a fluid in one direction only. A valve may consist of a sphincter muscle or two or three membranous flaps or folds. In the heart there are two valves that prevent backflow of blood from the ventricles into the atria. On the right side of the heart is the tricuspid valve, composed of three flaps of tissue; on the left is the two-piece mitral valve. Once blood has left the heart and entered the aorta, its return is prevented by the semilunar valves, which consist of membranous saclike flaps that open away from the heart. If the flow of blood reverses, the flaps fill and are pressed against each other, thus blocking the reentry of blood into the aorta. The valves in the venous system are of this same type. A valve unique to the lower vertebrates is the renal portal valve, which closes to shunt blood past the kidneys, increasing its supply elsewhere when necessary. In the digestive system of mammals the ileocecal valve, controlled by a sphincter muscle, prevents the return of the contents of the small intestine after they have passed into the colon.

VALVE LIFTER = ТОЛКАТЕЛЬ КЛАПАНА (или КУЛАЧОК ПОДЪЁМА КЛАПАНА, или СЪЁМНИК КЛАПАНА, или ЗАТВОР КЛАПАНА) – Valve Lifter:- sometimes called a Cam Follower, a component in engine designs that use a linkage system between a cam and the valve it operates. The lifter typically translates the rotational motion of the cam to a reciprocating linear motion in the linkage system. See also Valve.

VALVE OPERATOR = ОПЕРАТОР КЛАПАНА – Valve Operator is a part of automatic valve that activates the flow of gas to the main burner, usually powered electrically. Also known as Operator Head.

VAM = VESICULAR ARBUSCULAR MYCORRHIZA

VAMI = VALUE ADDED MONTHLY INDEX

VA MORTGAGE = VETERANS ADMINISTRATION MORTGAGE

VAN = HERL–RTP VAN SYSTEM = RESEARCH TRIANGLE PARK VAN SYSTEM

VAN = БАГАЖНЫЙ ВАГОН – Van is the railway vehicle without motor forming part of a passenger or goods train and used by the train crew as well as, if need be, for the conveyance of luggage, parcels, bicycles, etc. Context:- vehicles possessing one or more passenger compartments must not be counted as vans but as passenger carriages. Mail vans, belonging to railway enterprises, are included under vans when they do not have a passenger compartment. / Багажный Вагон – железнодорожное транспортное средство без локомотива (моторообразующей части) пассажирского или товарного поезда, используемый поездной бригадой, а также, если необходимо, для перевозки багажа, посылок, велосипедов, и так далее. Контекст:- транспортные средства, располагающие одним или более купе для пассажиров не должны рассматриваться в качестве багажных вагонов, а лишь в качестве пассажирских вагонов. Почтовые вагоны, принадлежащие железнодорожным предприятиям, подпадают под определение багажных вагонов, если они не имеют купе для пассажиров.

VAN = ГРУЗОПАССАЖИРСКИЙ АВТОМОБИЛЬ (или ФУРГОН, или ВЭН) – Van is a 20-foot long or shorter vehicle, usually with an automotive-type engine and limited seating normally entered directly through side or rear doors rather than from a central aisle, used for demand response, vanpool, and lightly patronized motorbus service. See also Motor Vehicle, and Vehicle. Van:- includes large vans. Exceptions are:- (1) Volkswagen vans are categorized as Minivans; and (2) all other pre-1983 vans are categorized as Vans. Van is a vehicle having a typical seating capacity of 5 to 15 passengers and classified as a van by vehicle manufacturers. A modified van is a standard van which has undergone some structural changes, usually made to increase its size and particularly its height. The seating capacity of modified vans is approximately 9 to 18 passengers. Van:- privately owned and/or operated vans and minivans designed to carry from 5 to 13 passengers or to haul cargo. / Вэн:- владеемые в частном порядке и/или эксплуатируемые вэны и минивэны, разработанные для перевозки от 5 до 13 пассажиров или для подвоза груза.

VANADATE MINERAL = МИНЕРАЛ ВАНАДАТ (или МИНЕРАЛЬНЫЙ ВАНАДАТ) – Vanadate Mineral is any of the many naturally occurring compounds of vanadium (V), oxygen (O), and various metals; most of these minerals are rare, having crystallized under very restricted conditions. Although vanadinite occasionally is mined as a vanadium ore and carnotite as a uranium ore, most vanadates have no economic importance; they are prized by mineral collectors, however, for their brilliant colors. The structures of the vanadate minerals are complex. Some vanadate minerals contain vanadate tetrahedra (VO_4), in which four oxygen atoms occupy the corners of a tetrahedron surrounding a central vanadium atom. Each vanadate tetrahedron has a net charge of -3, which is neutralized by large, positively charged metal ions (e.g., calcium, manganese, or ferrous iron) outside the tetrahedron. Unlike the similar silicate tetrahedra, which link to form chains, sheets, rings, or frameworks, vanadate tetrahedra are insular. The vanadates containing these tetrahedra are structurally and chemically similar to the phosphate and arsenate minerals; indeed, some vanadium in many of these vanadates often is replaced by phosphorus or arsenic, forming solid-solution series with both the phosphates and the arsenates. Like the phosphate and sulfate minerals, many vanadates are complexes of transition metals, particularly of ferrous iron, manganese, and copper. Other vanadates, particularly those that contain uranium, contain $V_2O_8^{6-}$ ions, in which two atoms of vanadium are surrounded by eight atoms of oxygen arranged in two square pyramids that share one edge. Very complex clusters also exist but are usually classed with the complex oxide minerals rather than with the vanadate minerals. / Ванадаты природные, группа минералов, представляющих различные по составу и сложности соли ортованадиевой кислоты $H_3(VO_4)$. Всего известно около 40 минеральных видов, большинство из них очень редки. Более распространёнными являются:- (i) пухерит $Bi(VO_4)$ – простой безводный ванадат; (ii) фольбортит $Cu_3(CVO_4)_2{\cdot}3H_2O$, (iii) карнотит $K_2(UO_2)_2\ (VO_4)_2{\cdot}3H_2O$, (iv) тюямунит $Ca(UO_2)_2(V_2O_8)_2{\cdot}8H_2O$, (v) метахьюэттит $Ca(V_6O_{16}){\cdot}3H_2O$ – простые и сложные ванадаты с кристаллизационной водой; (vi) ванадинит $Pb_6(VO_4)_3Cl$ и (vii) деклуазит $Pb(Zn,\ Cu)(VO_4)\ OH$ – ванадаты с добавочными анионами. Кристаллохимически ванадаты плохо изучены (по данным на 1969). Определённо устанавливаются островные структуры с тетраэдрами $(VO_4)^{3-}$, соединёнными только через катионы (Na^{1+}, K^{1+}, Ca^{2+}, Ba^{2+}, Cu^{2+}, Pb^{2+}, Zn^{2+}, Mn^{2+}, Bi^{3+}, Al^{3+}). Ванадаты кристаллизуются в гексагональной (ванадинит), ромбической, моноклинной и триклинной системах; обычно встречаются в виде порошков, налётов, корочек и редко в виде хорошо образованных кристаллов. Окраска преимущественно жёлтая, красная или буровато-красная за счёт аниона $(VO_4)^{3-}$. Влияние на цвет ванадатов оказывают также катионы; так, катион Cu придаёт им зелёные оттенки. Твёрдость по минералогической шкале 1–4, плотность порядка 2 500–7 000 килограммов на кубический метр (кг/м^3). Большинство ванадатов – вторичные минералы; по генезису они делятся на две группы:- (i) ванадаты, образовавшиеся в зоне окисления сульфидных месторождений (деклуазит, купродеклуазит, ванадинит, пухерит); и (ii) ванадаты осадочных эпигенетических месторождений (карнотит, тюямунит, фольбортит и другие), образовавшиеся позднее вмещающих их пород. Ванадаты в ряде случаев являются хорошими рудами для извлечения ванадия и иногда урана. Ванадаты, соли ванадиевых кислот, производных пятиокиси ванадия V_2O_5. Сами ванадиевые кислоты в свободном виде не выделены. Ванадаты образуются при растворении V_2O_5 в щёлочах:- $V_2O_5 + 2NaOH = 2NaVO_3 + H_2O$. Ванадаты играют важную роль в производстве ванадия (его выделяют из раствора в виде Ca $(VO_3)_2$ и NH_4VO_3). Ванадаты применяют в текстильной промышленности как протраву при крашении хлопчатобумажных тканей и для фиксации анилина на шёлке.

VANADIC ANHYDRIDE = ВАНАДИЕВЫЙ АНГИДРИД – Vanadic Anhydride is a vanadium pentoxide, a compound of vanadium and oxygen widely used as an oxidation catalyst, as in the oxidation of unburned hydrocarbons in automobile exhaust (see Vanadium). / Ванадиевый Ангидрид и ванадаты применяются в химической промышленности в качестве катализаторов при контактном способе получения серной кислоты и при некоторых органических синтезах. Соединения ванадия используются также в стекольной промышленности, в медицине, в фотографии. Под Ангидридом, от Греческих слов An, означающее Отрицательная Частица, и Hýdōr, означающее Вода, понимается химическое соединение какого-либо, элемента с кислородом, которое можно получить, отнимая воду от соответствующей кислоты.

VANADINITE = ВАНАДИНИТ (или ВАНАДИЕВОКИСЛЫЙ СВИНЕЦ) – Vanadinite is a vanadium mineral in the pyromorphite series of the apatite group of phosphates, lead chloride vanadate, $Pb_5(VO_4)_3Cl$. It is a source of vanadium and a minor source of lead. The mineral's typical occurrences are as orange, red, or brown hairlike or barrel-shaped crystals in the oxidized zone of lead deposits as in the Urals, Russia; Transvaal, South Africa; Chihuahua, Mexico; and Arizona, United States of America. Endlichite is a highly arsenious variety; the complete substitution of arsenic for vanadium in the crystal structure forms the mineral mimetite. For detailed physical properties, see Vanadate Mineral (table). / Ванадинит, минерал класса ванадатов состава $Pb_5(VO_4)_3Cl$ (78.3% PbO; 19.3% V_2O_5; 2.4% Cl). Кристаллизуется в гексагональной системе. Встречается в виде мелких призматических кристалликов, почковидных скоплений и землистых масс. Цвет жёлтый, бурый, красный. Твердость по минералогической шкале 2.75–3, плотность 6 500–7 100 кг/м^3. Ванадинит образуется в зоне окисления свинцово-цинковых и медных полиметаллических сульфидных месторождений. Используют для получения ванадия.

VANADIUM = ВАНАДИЙ – Vanadium (V) is a chemical element, silvery-white soft metal of Group Vb of the periodic table. It is alloyed with steel and iron for high-speed tool steel, high-strength low-alloy steel, and wear-resistant cast iron. A brief treatment of vanadium

follows. For information on the mining, recovery, and applications of vanadium, see Industries, Extraction and Processing. Vanadium was discovered (1801) by the Spanish mineralogist Andrés Manuel del Río Fernández (1764–1849), who named it erythronium but eventually came to believe it was merely impure chromium. The element was rediscovered (1830) by the Swedish chemist Nils Gabriel Sefström (1787–1845), who named it after Vanadis, the Scandinavian goddess of beauty and youth, a name suggested by the beautiful colors of vanadium's compounds in solution. The English chemist Sir Henry Enfield Roscoe (1833–1915) first isolated the metal in 1867 by hydrogen reduction of vanadium dichloride, VCl_2, and the American chemists John Wesley Marden and Malcolm N. Rich obtained it 99.7 percent pure in 1925 by reduction of vanadium pentoxide, V_2O_5, with calcium metal. Found combined in various minerals, coal, and petroleum, vanadium is the 22nd most abundant element in the Earth's crust. Some commercial sources are the minerals carnotite, vanadinite, and roscoelite. (Deposits of the important vanadium-bearing mineral patronite occurring in coal at Mina Ragra, Peru, have been materially depleted.) Other commercial sources are vanadium-bearing magnetite and flue dust from smokestacks and boilers of ships burning certain Venezuelan and Mexican oils. Vanadium is obtained from ores as vanadium pentoxide (V_2O_5) through a variety of smelting, leaching, and roasting processes. The pentoxide is then reduced to ferrovanadium or vanadium powder. Vanadium metal, sheet, strip, foil, bar, wire, and tubing have found use in high-temperature service, in the chemical industry, and in bonding other metals. Most of the vanadium produced is used with iron as ferrovanadium (about 85 percent vanadium) in making vanadium steels. Vanadium (added in amounts between 0.1 and 5.0 percent) has two effects upon steel:- it refines the grain of the steel matrix, and with the carbon present it forms carbides. Thus, vanadium steel is especially strong and hard, with improved resistance to shock. Vanadium compounds (pentoxide and certain vanadates) are used as catalysts in the contact process for manufacturing sulfuric acid; as oxidation catalysts in the syntheses of phthalic and maleic anhydrides; in the manufacture of polyamides such as nylon; and in the oxidation of such organic substances as ethanol to acetaldehyde, sugar to oxalic acid, and anthracene to anthraquinone. Natural vanadium consists of two isotopes:- stable vanadium-51 (99.76 percent) and weakly radioactive vanadium-50 (0.24 percent). Nine artificial radioactive isotopes have been produced. Vanadium dissolves in concentrated sulfuric acid, nitric acid, hydrofluoric acid, and aqua regia. It does not tarnish in air readily but when heated combines with nearly all nonmetals. The oxides corresponding to the four oxidation states are VO, V_2O_3, VO_2, and V_2O_5. The hydrogen-oxygen compounds of vanadium in the two lower oxidation states are basic; in the two higher, amphoteric (both acidic and basic). In aqueous solution the ions exhibit a lavender to blue color in the +2 to +4 states and a yellow color in the +5 state. Atomic Number – 23; Atomic Weight – 50.942; Melting Point – 1 890 °C (3 434 °F); Boiling Point – 3 380 °C (6 116 °F); Specific Gravity – 5.96 (20 °C); valence – 2, 3, 4, 5; electronic configuration – 2-8-11-2 or $(Ar)3d^34s^2$. Vanadium Processing:- preparation of the metal for use in various products. Vanadium (V) is a grayish silver metal whose crystal structure is a body-centered cubic (bcc) lattice, with a melting point of 1 926 °C (3 499 °F). The metal is used principally as an alloying addition to high-strength low-alloy (HSLA) steels and, to a lesser extent, in tool steels and iron and steel castings. It is also an important strengthener for titanium alloys. Vanadium alloys are promising candidates for applications in nuclear reactors. The metal is recognized as an industrial hazard, however, as breathing of particulate material with a high vanadium content has been observed to cause an intense, dry cough accompanied by irritation of the nose, eyes, and throat. History:- the discovery of vanadium was first claimed in 1801 by a Spanish mineralogist, Andrés Manuel del Río, who gave it the name erythronium, after the red color of one of its chemical compounds (Greek Erythros, 'Red'). In 1830 a Swedish chemist, Nils Gabriel Sefström, rediscovered the element and named it vanadium, after Vanadis, the Scandinavian goddess of beauty, because of the beautiful colors of its compounds in solution. The English chemist Henry Enfield Roscoe first isolated the metal by hydrogen reduction of vanadium dichloride in 1867, and the American chemists John Wesley Marden and Malcolm N. Rich obtained vanadium of 99.7 percent purity by a calcium reduction process in 1925. Since the early 1900s, vanadium has been used as an alloying element for steels and iron. In 1905 Antenor Riza Patron discovered a large asphaltite deposit containing rich vanadium ores in Mina Ragra, Peru. Two years later, the American Vanadium Company produced ferrovanadium on a commercial scale for the first time. After titanium became an aerospace construction material in the 1950s, vanadium saw wide use in titanium alloys. Ores:- the important vanadium minerals are patronite (VS_4), carnotite ($K_2(UO_2)_2(VO_4)_2$), and vanadinite, ($Pb_5(VO_4)_3Cl$). Ore deposits mined solely for vanadium are rare because much of the vanadium in igneous rocks occurs in the relatively insoluble trivalent state, substituting for ferric iron in ferromagnesium silicates, magnetite (an iron ore), ilmenite (a titanium ore), and chromite. The world's largest mines of vanadium are from titaniferous magnetite reserves in such regions as the Bushveld of South Africa, the Kachkanar Massif of the Ural Mountains, and China's Szechwan Province. Carnotite ores in the sandstones of the Colorado Plateau have been mined for vanadium and uranium. Other sources of vanadium include ash from the combustion of fossil fuel, slag from phosphate ore, the aluminum ore bauxite, and spent catalysts. Mining:- because vanadium is essentially the by-product of ores that are mined for other minerals, they are mined by methods peculiar to those ores. Extraction And Refining:- Vanadium Pentoxide:- titaniferous magnetite ore is partially reduced with coal in rotary kilns and then melted in a furnace. This produces a slag containing most of the titanium and a pig iron containing most of the vanadium. After removing the slag, the molten pig iron is blown with oxygen to form a new slag containing 12–24 percent vanadium pentoxide (V_2O_5), which is used in the further processing of the metal. Vanadium is extracted from carnotite as a coproduct with uranium by leaching the ore concentrate for 24 hours with hot sulfuric acid and an oxidant such as sodium chlorate. After removal of solids, the leachate is fed into a solvent extraction circuit where the uranium is extracted in an organic solvent consisting of 2.5-percent-amine–2.5-percent-isodecanol–95-percent-kerosene. Vanadium remains in the raffinate, which is fed into a second solvent extraction circuit. There vanadium in turn is extracted in the organic phase, stripped with a 10 percent soda ash solution, and precipitated with ammonium sulfate. The ammonium metavanadate precipitate is filtered, dried, and calcined to V_2O_5. Most other vanadium-bearing ores or slags are crushed, ground, screened, and mixed with a sodium salt such as sodium chloride or sodium carbonate. This charge is then roasted at about 850 °C (1 550 °F) to convert the oxides to sodium metavanadate, which can be leached in hot water. With the acidulation of the leachate with sulfuric acid, the vanadium is precipitated as sodium hexavanadate. This compound, known as Red Cake, can be fused at 700 °C (1 300 °F) to yield technical-grade vanadium pentoxide (at least 86 percent V_2O_5, or it can be further purified by dissolving it in an aqueous solution of sodium carbonate. In the latter case, the iron, aluminum, and silicon impurities in the red cake precipitate from solution upon adjustment of the acidity. The vanadium is precipitated as ammonium metavanadate by adding ammonium chloride. After filtration, the precipitate is calcined to produce V_2O_5 of a purity greater than 99.8 percent. Ferrovanadium:- the production of ferrovanadium, containing 35–80 percent vanadium, is carried out in an electric-arc furnace. Scrap iron is first melted, and a mixture of V_2O_5, aluminum, and a flux such as calcium fluoride or calcium oxide is added. In the ensuing reaction, the aluminum metal is converted to alumina, forming a slag, and the V_2O_5 is reduced to vanadium metal, which is dissolved in the molten iron. Since this oxidation-reduction reaction is exothermic, the heat supply need only develop the kindling temperature of 950 °C (1 750 °F). After kindling, the electrodes are withdrawn until the reaction is completed; they are then reinserted into the molten slag and the furnace reheated to improve settling. The aluminothermic process can also be carried out in a refractory-lined steel pot or water-cooled copper crucible. A charge of V_2O_5, iron oxide, and aluminum is ignited with a barium-peroxide fuse or a magnesium ribbon. Vanadium Metal:- in the production of pure metal, V_2O_5 is reduced metallothermically by calcium or aluminum. In the calcium reduction, the exothermic reaction is carried out in a sealed vessel using calcium chloride as a flux. The vanadium metal is recovered in the form of droplets or beads. (A massive regulus can be obtained by using iodine as both a flux and a thermal booster.) The calcium process requires a rather large amount of reductant and gives low metal yields – in the range of 75–80 percent. In the aluminothermic process, V_2O_5,

mixed with aluminum powder, is heated in an electric furnace or ignited in a refractory-lined vessel using barium peroxide as the booster. The vanadium regulus thus obtained may be further purified by electron-beam melting. To prepare aluminum-vanadium master alloys for the titanium industry, the aluminothermic method is also used. In this case, an amount of aluminum greater than that required for reduction is added to the charge. The Metal And Its Alloys:- in its pure form, vanadium is soft and ductile. It can be fabricated into mill forms, but it oxidizes readily at temperatures above 663 °C (1 225 °F) and is liable to pick up interstitial impurities. Because the metal has good corrosion resistance to liquid metal, a low absorption of neutrons, and a short half-life in its radioactive isotopic forms, vanadium-based alloys have potential as structural materials for fusion and liquid-metal fast-breeder fission reactors. Iron And Steel:- the addition of small amounts of vanadium (less than 0.2 percent) to structural steels improves their toughness, ductility, and strength owing to the grain-refining effect of vanadium carbide precipitates. These HSLA (short for the high-strength low-alloy) steels are used in automotive components, such as hoods and door panels, and in oil and gas pipelines. Almost all tool steels contain vanadium in amounts ranging from 0.10 to 5 percent. It is required to ensure the retention of hardness and cutting ability at high temperatures. In some cast irons, the addition of a small amount of vanadium controls the size and distribution of graphite flakes, thereby improving strength and wear resistance. Steel castings with vanadium additions also exhibit pronounced shock and wear resistance, which makes them useful in heavy-duty equipment and machinery. Titanium:- vanadium improves the strength of titanium alloys and promotes their thermal stability. Several important commercial titanium alloys contain between 2.5 and 15 percent vanadium. They are used in the undercarriages, wings, and engines of jet aircraft. Chemical Compounds:- Catalysts:- vanadium is used in the contact process for the manufacture of sulfuric acid. In this process, sulfur dioxide is oxidized to a trioxide by exposure to air in the presence of granular V_2O_5 or sodium metavanadate. Vanadium oxytrichloride and vanadium tetrachloride are catalysts in the production of special types of synthetic rubber. Ammonium metavanadate is employed as a catalyst for the synthesis of organic intermediates of nylon, polyester resins, and other synthetics, and it has also been used as a catalyst in the dyeing of leather and fur. Pigments:- in dye manufacturing, vanadium compounds are used in the production of aniline black. They are also employed as mordants in the dyeing and printing of cotton and for fixing aniline black on silk. Some modern quick-drying inks depend on the addition of ammonium metavanadate for their performance. Vanadium compounds are used in the ceramics industry for glazes and enamels. / Найлан[T3] (Nylon[TM]). Испанский минералог Андрэс Мануэль дэль Рио Фэрнандэс (Andrés Manuel del Río Fernández; 1764–1849). Шведским химиком Нильсом Габриэлем Сэфстрёмом (Nils Gabriel Sefström; 1787–1845), который назвал его в честь Ванадыс (Vanadis), Скандинавской богини красоты и молодости). Английский химик Сэр Хэнри Энфилд Раско (Sir Henry Enfield Roscoe; 1833–1915), и Американские химики Дьжон Вэсли Мадэн (John Wesley Marden) и Мэлком Эн. Рич (Malcolm N. Rich). В 1905 Антэнор Риса Патрон (Antenor Riza Patron). Амэрикэн Вэнэйдиэм Кампэни (American Vanadium Company). Ванадий (Vanadium), V, химический элемент V группы Периодической Системы Менделеева; атомный номер 23, атомная масса 50.942; металл серо-стального цвета. Природный ванадий состоит из двух изотопов:- ^{51}V (99.75%) и ^{50}V (0.25%); последний слабо радиоактивен (период полураспада $T_{1/2} = 10^{14}$ лет). Ванадий был открыт в 1801 Мексиканским минералогом Андрэсом Мануэлем дэль Рио Фэрнандэсом (Andrés Manuel del Río Fernández; 1764–1849) в Мексиканской бурой свинцовой руде и назван по красивому красному цвету нагретых солей эритронием (от Греческого слова Erythrós, означающее Красный). В 1830 Шведский химик Нильс Габриэль Сэфстрём (Nils Gabriel Sefström; 1787–1845) обнаружил новый элемент в железной руде из Таберга (Швеция) и назвал его Ванадием в честь древнескандинавской богини красоты Ванадис. Английский химик Сэр Хэнри Энфилд Раско (Sir Henry Enfield Roscoe; 1833–1915) в 1869 получил порошкообразный металлический ванадий восстановлением VCl_2 водородом. В промышленном масштабе ванадий добывается с начала XX века. Содержание ванадия в земной коре составляет $1.5 \cdot 10^{-2}$% по массе, это довольно распространённый, но рассеянный в породах и минералах элемент. Из большого числа минералов ванадия промышленное значение имеют патронит, роскоэлит, деклуазит, карнотит, ванадинит и некоторые другие (смотрите Ванадиевые Руды). Важным источником ванадия служат титаномагнетитовые и осадочные (фосфористые) железные руды, а также окисленные медно-свинцово-цинковые руды. Ванадий извлекают как побочный продукт при переработке уранового сырья, фосфоритов, бокситов и различных органических отложений (асфальтиты, горючие сланцы). Смотрите также Природные Ванадаты. Физические И Химические Свойства:- ванадий имеет объёмноцентрированную кубическую решётку с периодом a = 3.028 2 Å. В чистом состоянии ванадий ковок, легко поддаётся обработке давлением. Плотность 6.11 граммов на кубический сантиметр (г/см^3), $t_{пл}$ 1 900 ± 25 °C, $t_{кип}$ 3 400 °C; удельная теплоёмкость (при 20–100 °C) 0.120 кал/гград; термический коэффициент линейного расширения (при 20–1 000 °C) $10.6 \cdot 10^{-6}$ град$^{-1}$, удельное электрическое сопротивление при 20 °C $24.8 \cdot 10^{-8}$ Ом·м ($24.8 \cdot 10^{-6}$ Ом·см), ниже 4.5 К ванадий переходит в состояние сверхпроводимости. Механические свойства ванадия высокой чистоты после отжига:- модуль упругости 135.25 Н/м^2 (13 520 кгс/мм^2), предел прочности 120 Нм/м^2 (12 кгс/мм^2), относительное удлинение 17%, твёрдость по Бринеллю 700 МН/м^2 (70 кгс/мм^2). Примеси газов резко снижают пластичность ванадия повышают его твёрдость и хрупкость. При обычной температуре ванадий не подвержен действию воздуха, морской воды и растворов щёлочей; устойчив к неокисляющим кислотам, за исключением плавиковой. По коррозионной стойкости в соляной и серной кислотах ванадий значительно превосходит титан и нержавеющую сталь. При нагревании на воздухе выше 300 °C ванадий поглощает кислород и становится хрупким. При 600–700 °C ванадий интенсивно окисляется с образованием пятиокиси V_2O_5, а также и низших окислов. При нагревании ванадия выше 700 °C в токе азота образуется нитрид VN ($t_{пл}$ 2 050 °C), устойчивый в воде и кислотах. С углеродом ванадий взаимодействует при высокой температуре, давая тугоплавкий карбид VC ($t_{пл}$ 2 800 °C), обладающий высокой твёрдостью. Ванадий даёт соединения, отвечающие валентностям 2, 3, 4 и 5; соответственно этому известны окислы:- VO и V_2O_3 (имеющие основной характер), VO_2 (амфотерный) и V_2O_5 (кислотный). Соединения 2- и 3-валентного ванадия неустойчивы и являются сильными восстановителями. Практическое значение имеют соединения высших валентностей. Склонность ванадия к образованию соединений различной валентности используется в аналитической химии, а также обусловливает каталитические свойства V_2O_5. Пятиокись ванадия растворяется в щёлочах с образованием ванадатов. Получение И Применение:- Для извлечения ванадия применяют:- непосредственное выщелачивание руды или рудного концентрата растворами кислот и щёлочей; обжиг исходного сырья (часто с добавками NaCl) с последующим выщелачиванием продукта обжига водой или разбавленными кислотами. Из растворов методом гидролиза (при pH = 1–3) выделяют гидратированную пятиокись ванадия. При плавке ванадийсодержащих железных руд в домне ванадий переходит в чугун, при переработке которого в сталь получают шлаки, содержащие 10–16% V_2O_5. Ванадиевые шлаки подвергают обжигу с поваренной солью. Обожжённый материал выщелачивают водой, а затем разбавленной серной кислотой. Из растворов выделяют V_2O_5. Последняя служит для выплавки феррованадия (сплавы железа с 35–70% ванадием и получения металлического ванадия и его соединений. Ковкий металлический ванадий получают кальциетермическим восстановлением чистой V_2O_5 или V_2O_3; восстановлением V_2O_5 алюминием; вакуумным углетермическим восстановлением V_2O_3; магниетермическим восстановлением VC_{13}; термической диссоциацией йодида ванадия плавят ванадий в вакуумных дуговых печах с расходуемым электродом и в электроннолучевых печах. Чёрная металлургия – основной потребитель ванадия (до 95% всего производимого металла). Ванадий входит в состав быстрорежущей стали, её заменителей, малолегированных инструментальных и некоторых конструкционных сталей. При введении 0.15–0.25% ванадия резко повышаются прочность, вязкость, сопротивление усталости и износоустойчивость стали. Ванадий введённый в сталь, является одновременно

раскисляющим и карбидообразующим элементом. Карбиды ванадия распределяясь в виде дисперсных включений, препятствуют росту зерна при нагреве стали. Ванадий в сталь вводят в форме лигатурного сплава – феррованадия. Применяют ванадий и для легирования чугуна. Новым потребителем ванадия выступает быстро развивающаяся промышленность титановых сплавов; некоторые титановые сплавы содержат до 13% ванадия. В авиационной, ракетной и других областях техники нашли применение сплавы на основе ниобия, хрома и тантала, содержащие присадки ванадия. Разрабатываются различные по составу жаропрочные и коррозионностойкие сплавы на основе ванадия с добавлением Ti, Nb, W, Zr и Al, применение которых ожидается в авиационной, ракетной и атомной технике. Интересны сверхпроводящие сплавы и соединения ванадия с Ga, Si и Ti. Чистый металлический ванадий используют в атомной энергетике (оболочки для тепловыделяющих элементов, трубы) и в производстве электронных приборов. Соединения ванадия применяют в химической промышленности как катализаторы, в сельском хозяйстве и медицине, в текстильной, лакокрасочной, резиновой, керамической, стекольной, фото и кинопромышленности. Соединения ванадия ядовиты. Отравление возможно при вдыхании пыли, содержащей соединения ванадия. Они вызывают раздражение дыхательных путей, лёгочные кровотечения, головокружения, нарушения деятельности сердца, почек и тому подобное. Ванадий В Организме:- ванадий – постоянная составная часть растительных и животных организмов. Источником ванадия служат изверженные породы и сланцы (содержат около 0.013% ванадия), а также песчаники и известняки (около 0.002% ванадия), в почвах ванадия около 0.01% (в основном в гумусе); в пресных и морских водах $1 \cdot 10^{7}$–$2 \cdot 10^{7}$%. В наземных и водных растениях содержание ванадия значительно выше (0.16–0.2%), чем в наземных и морских животных ($1.5 \cdot 10^{-5}$–$2 \cdot 10^{-4}$%). Концентраторами ванадия являются:- Мшанка Plumatella, Моллюск Pleurobranchus Plumula, Голотурия Stichopus Mobii, некоторые Асцидии, из Плесеней – чёрный Аспергилл, из Грибов – Поганка (Amanita Muscaria). Биологическая роль ванадия изучена на Асцидиях, в кровяных клетках которых ванадий находится в 3- и 4-валентном состоянии, то есть существует динамическое равновесие $V^{III} \leftrightarrow V^{IV}$. Физиологическая роль ванадия у Асцидии связана не с дыхательным переносом кислорода и углекислого газа, а с окислительно-восстановительными процессами – переносом электронов при помощи так называемой Ванадиевой Системы, вероятно имеющей физиологическое значение и у других организмов.

VANCOMYCIN = ВАНКОМИЦИН – Vancomycin is an antibiotic used to treat a number of bacterial infections. It is recommended intravenously as a treatment for complicated skin infections, bloodstream infections, endocarditis, bone and joint infections, and meningitis caused by methicillin-resistant Staphylococcus Aureus. Blood levels may be measured to determine the correct dose. Vancomycin is also recommended by mouth as a treatment for severe Clostridium Difficile colitis. When taken by mouth it is very poorly absorbed. Common side effects include pain in the area of injection and allergic reactions. Occasionally, hearing loss, low blood pressure, or bone marrow suppression occur. Safety in pregnancy is not clear, but no evidence of harm has been found, and it is likely safe for use when breastfeeding. It is a type of glycopeptide antibiotic and works by blocking the construction of a cell wall. Vancomycin was first sold in 1954. It is on the World Health Organization's List of Essential Medicines, the most effective and safe medicines needed in a health system. It is available as a generic medication. The wholesale cost in the developing world of an intravenous dose is about USD1.70 to 6.00. In the United States, the pills are more expensive than the intravenous solution. The intravenous solution may be safely taken by mouth for the treatment of Clostridium Difficile colitis to reduce costs. Vancomycin is made by the soil Bacterium Amycolatopsis Orientalis. / Ванкомицин – антибиотик, продуцируемый Amycolatopsis Orientalis, против грам(+) Бактерий. Ванкомицин – антибиотик, получаемый из Бактерий Вида Streptomyces Orientalis; эффективен против большинства грамположительных организмов (особенно против стрептококков и стафилококков). Назначается во внутривенных вливаниях для лечения инфекционных заболеваний, вызванных устойчивыми к другим антибиотикам штаммами Бактерий. Данный препарат обладает низкой токсичностью, однако после его употребления у человека могут развиться такие побочные эффекты, как значительное снижение слуха или тромбофлебит. Торговое название:- Ванкоцин (Vancocin).

VANCOUVER STOCK EXCHANGE = ВАНКУВЕРСКАЯ ФОНДОВАЯ БИРЖА – Vancouver Stock Exchange (VSE) was one of Canada's junior company stock exchanges. On March 15, 1999, the VSE and the ASE (Alberta Stock Exchange) agreed to merge and form the CDNX – the Canadian Venture Exchange – which will also take on some junior Toronto and Montreal Exchange companies. The VSE got a bad reputation in the 1980's due to many unscrupulous scam artists manipulating VSE listed companies. New regulatory controls and surveillance systems which had been implemented on the VSE were transferred to the new CDNX. In 2002, the CDNX became the TSX-V (short for the Toronto Stock Exchange – Venture Exchange). Vancouver Stock Exchange (VSE) is a securities and options exchange in Vancouver, British Columbia, (Canada), specializing in venture capital companies. Canadian Venture Exchange (CDNX):- the former name of the TSX Venture Exchange, renamed when it was purchased by TMX Group Limited (then, the TSX Group Inc.) in 2001. The CDNX was created in Canada on November 29, 1999 as a result of an agreement among the Vancouver, Alberta, Toronto and Montreal Exchanges to restructure the Canadian capital markets along the lines of market specialization. The CDNX was created by the merger of the Vancouver Stock Exchange and the Alberta Stock Exchange. The focus of the CDNX was junior companies whose assets, business and market capitalization were too small to be listed on the Toronto Stock Exchange (TSX). These were mainly resource exploration companies, but also included new high technology ventures. The business of the Winnipeg Stock Exchange and the small-cap portion of the equities market of the Montreal Exchange (MX) were also merged into the CDNX in November 2000. / Ванкуверская Фондовая Биржа (ВФБ) (Vancouver Stock Exchange (VSE)) – биржа ценных бумаг и опционов в Ванкувере (Канада, Провинция Британская Колумбия). С 1907 специализируется на компаниях венчурного капитала. На этом рынке ценных бумаг обращаются акции, права участия акционеров, варранты и партии ценных бумаг, в то время как её опционный рынок фокусируется на опционах на золото и акции. Большая часть оборота приходится на акции компаний добывающей промышленности. Компании по добыче природных ресурсов привлекают через эту биржу миллиарды Долларов. Растёт число зарегистрированных на бирже компаний, работающих в сфере финансовых услуг, недвижимости, высоких технологий, фирм в области туризма, отдыха и развлечений. Традиционно 10–20% операций связано с компаниями США, 20–25% – стран Европы и Азии. Индекс от ВФБ (VSE Index) – Январь 1982 принят за 100, – взвешенный по капиталу, – составляется из трёх подиндексов:- торгово-промышленного индекса, индекса ресурсов и индекса венчурного капитала. После введения в 1990 системы Ванкуверской Компьютеризованной Торговли (ВКТ; Vancouver Computerized Trading (VCT)) ВФБ стала первой биржей в Северной Америке, полностью перешедшей от сделок путём прямого контакта продавца и покупателя на сделки через полностью автоматизированную систему торговли. Компьютеризованный клиринг проводится через компанию Западная Канадская Клиринговая Корп. (West Canada Clearing Corp.). Урегулирование происходит на третий рабочий день после сделки. Биржа работает с 09:00 до 17:00, кроме Субботы и Воскресенья.

VAN DER WAALS FORCES = ВАН ДЕР ВААЛЬСОВЫ СИЛЫ (или СИЛЫ ФАН ДЭР ВААЛСА) – Van Der Waals Forces are the intermolecular forces as a result of localization of electrical charge within molecules. A molecule considered as a whole is electrically neutral. Because of the way in which electrons are held, there may be local areas that appear to have positive or negative electric charge, either permanently or temporarily. These charges lead to attraction between molecules. Van der Waals forces are weak and easily broken, but they can be important in dyeing. They can be important in affinity, and hold dye molecules on the fiber near to where a much stronger bond may ultimately be formed. Van der Waals Forces are the relatively weak forces of attraction between molecules

that contribute to intermolecular bonding (i.e. binding-together two or more adjacent molecules). Historically, it was thought that van der Waals forces were always weaker than the hydrogen bond forces responsible for intramolecular bonding. However, in 1995, Dr. Alfred French discovered that van der Waals forces are primarily responsible for holding together a mass of cellulose molecules, with hydrogen bonding playing a lesser role. During 2000, Kellar Autumn discovered that Van der Waals forces (acting between foot skin hairs and the surface climbed) are responsible for enabling the Tokay Gecko (Gecko Gecko) to climb vertical surfaces and also to hang upside-down. These forces work (i.e. to 'adhere' a gecko's foot) even underwater or in a vaccuum. / Сродство (Affinity). Доктор Алфрэд Фрэнч (Dr. Alfred French). Келэ Отэм (Kellar Autumn). Под Ван Дер Ваальсовыми Силами, по имени Нидерландского физика Ёханэса Дидэрика фан дэр Ваалса (Johannes Diderik van der Waals; 1837–1923), понимаются силы межмолекулярного взаимодействия.

VANDYKE = ФАНДАЙК (или КЛИНЫШЕК) – Vandyke is a wide collar with a deeply indented edge. Vandyke Collar is a large collar with deep points standing high on the neck and falling onto the shoulders, usually trimmed with lace or reticella, worn in the second quarter of the XVII century, as seen in portraits by Anthony van Dyck. Sir Anthony van Dyck (many variant spellings; 22 March 1599 – 09 December 1641) was a Flemish Baroque artist who became the leading court painter in England, after enjoying great success in Italy and Flanders. He is most famous for his portraits of Charles I of England and his family and court, painted with a relaxed elegance that was to be the dominant influence on English portrait-painting for the next 150 years. He also painted biblical and mythological subjects, displayed outstanding facility as a draftsman, and was an important innovator in watercolor and etching. / кружевной или полотняный воротник с зубцами. Сэр Энтони фан Дайк (Sir Anthony van Dyck) .

VANILLA = ТИПОВОЙ (или ВАНИЛЬ) – (1) Vanilla is the normal option with no special or unusual features. A plain vanilla option is your plain run-of-the-mill option, with your standard expiry and strike price. Vanilla is sometimes used to mean Plain, Ordinary, or (US) Regular. A simple option whose terms and conditions do not include any provisions other than exercise style, expiry and strike. To compare with exotic options which have additional terms. See also Plain Vanilla Instrument. / В дословном переводе Ваниль на Англоязычном жаргоне биржевых дельцов относится к термину Типовой (например, типовой инструмент). порядки и условия .

(2) Vanilla is a term in the State's (Florida) Project Aspire, meaning the base package of PeopleSoft software – no customizations or modifications. Also known as As Delivered or Out-Of-The-Box.

VANILLA ISSUE = ВАНИЛЬНЫЙ ВЫПУСК – Vanilla Issue is an security issue that has no unusual features.

VANILLA OPTION = ТИПОВОЙ ОПЦИОН (или ОПЦИОН ВАНИЛЬ) – A Vanilla Option is an option with no unusual or special features or restrictions. It will have a standard strike price, standard expiration date and standard terms. The term Vanilla Option came about when options because the underlying contracts for further derivatives. For example, options on options. Options became more and more complex with more and more varying terms that a term had to be created to refer to the original option which because a Vanilla Option. Vanilla Option is a standard transaction that is not tailored to the needs of either party. A plain vanilla option pays out the difference between the strike price of the option and the spot price of the underlying at the time of the exercise. Vanilla Option is an option with standard features like a fixed strike price, expiration date and a single underlying asset. The option is effective at the current date and when exercised, its payoff equals the difference between the value of the underlying asset and the strike price. It is also known whether the option is a call or a put at the time the option is sold. See also Exotic Option; and Option. Vanilla Option is the date agreed between parties for the settlement of a transaction. Vanilla Option is a financial instrument that gives the holder the right, but not the obligation, to buy or sell an underlying asset at a predetermined price, within a given time frame. A vanilla option is a normal call or put option that has standardized terms and no special or unusual features. It is generally traded on an exchange such as the Chicago Board Options Exchange. Individual and institutional investors can take advantage of the versatility of options to design an investment that best meets their need to hedge or speculate on the price movement of an asset. If a vanilla option is not the right fit, they can explore exotic options such as barrier options, Asian options and digital options. Exotic options have more complex features and are generally traded over the counter. / Смотрите также Опцион (Option), и Экзотический Опцион (Exotic Option). Ванильный Опцион:- дата, согласованная между сторонами, для расчёта транзакции.

VANILLA TRANSACTIONS = ВАНИЛЬНЫЕ ТРАНЗАКЦИИ – Vanilla Transactions:- xxxxx. / Ванильные Транзакции (Vanilla Transactions):- ситуация, когда компания либо продаёт часть своей собственности в виде пакетов акций, либо выпускает облигации с целью привлечения денежных средств на срок до 30 лет по установленной процентной ставке.

VANISHING STRIPES = ПРОПАДАЮЩИЕ ПОЛОСКИ (или ИСЧЕЗАЮЩИЕ ПОЛОСЫ) – Vanishing Stripes:- Garment:- one pair of men's all-cotton slacks; Fabric Construction:- (i) Count:- 80 x 48; (ii) Warp:- 20/1 cotton; (iii) Filling:- same as warp. Complaint:- a customer claimed that the slacks originally contained dark-brown stripes, which disappeared after the first laundering. Analysis:- fabric analysis indicated that the material was essentially the same as that sold to the cutter, with the exception of the missing brown stripes. Reference head ends of the same style were checked in the laboratory and it was found that the brown warp yarns were dyed with sulphur colors. Sulphur colors do not resist chlorine bleaching, hence it was concluded that the slacks had been subjected to bleach in laundering. Although good commercial laundries do not normally bleach garments made of colored fabrics, certain articles which contain considerable white ground are often so badly soiled and stained that it is frequently necessary to risk bleaching rather than to have customers complain of improper cleansing. The supplier of the fabric assumed no responsibility for this complaint, since the garment manufacturer knew that sulphur colors had been used and was aware of their lack of fastness to bleaching. / Уточина:- такая же как основа.

VANITY = РИДИКЮЛЬ (или НЕСЕССЕР, или КОСМЕТИЧКА) – Vanity is a small case or handbag for toilet articles used by women. Vanity is a small box for cosmetics. Vanity is a fashionable trifle or knick-knack. / Дамская Сумочка. Ридикюль – устаревшее название ручной женской сумочки. Несессер или Нэсэсэр – размещённый в специальном футляре набор мелких предметов, необходимых для туалета, например, бритвенный несессер или маникюрный несессер. Под Несессером, от Французского слова Necessaire, означающее буквально Необходимый, понимается:- (1) дорожный футляр или небольшой чемодан с предметами туалета. (2) Шкатулка с набором принадлежностей для рукоделия или шитья.

VANNING = НАПОЛНЕНИЕ (или ЗАГРУЗКА) – Vanning is a term for stowing cargo in a container. Vanning:- the loading of cargo into a container. See also Stuffing. The act of packing a container. / Процесс загрузки контейнера.

VANPOOL = ПУЛ ВЭНОВ (или ПУЛ МИКРОАВТОБУСОВ, или ПУЛ ФУРГОНОВ) – Vanpool:- a voluntary commuter ridesharing arrangement, using vans with a seating capacity greater than 7 persons (including the driver) or buses, which provides transportation to a group of individuals traveling directly from their homes to their regular places of work within the same geographical area, and in which the commuter/driver does not receive compensation beyond reimbursement for his or her costs of providing the service. Vanpool:- an arrangement in which a group of passengers share the use and cost of a van in traveling to and from pre-arranged destinations together. Vanpool:- vans and/or Class C motor buses operating as a voluntary commuter ride sharing arrangement, which provides transportation to a group of individuals traveling directly between their homes and their regular places of work within the same

geographical area. The vans should have a seating capacity greater than seven persons, including the driver. Vanpool:- public sponsored commuter service operating under prearranged schedules for previously formed groups of riders in 8-to 18 seat vehicles. Drivers are also commuters who receive little or no compensation besides free transportation and use of the vehicle during off hours.

V ANTIGEN = АНТИГЕН ВИ. (или V АНТИГЕН, или АНТИГЕН V) – V Antigen (Vi Antigen) is an antigen contained in the sheath of a Bacterium, as Salmonella Typhosa (the Typhoid Bacillus), and thought to contribute to its virulence. / Под Антигенами, от Греческих слов Anti..., означающее Против, и Génos, означающее Происхождение или Рождение, понимаются высокомолекулярные коллоидные вещества, которые при введении в организм животных и человека вызывают образование специфических реагирующих с ними антител. Непременным условием антигенности является отличие антигенов от веществ, имеющихся в норме в организме реципиента. Антиген Ви. – многофункциональный белок Yersinia Pestis, выполняющий роль протективного антигена, вирулентного фактора и регуляторного белка вирусный антиген, структурный белок виринов, индуцирующий синтез протективных антител. V Антиген или Антиген Вирулентности:- термолабильный поверхностный соматический антиген, принадлежащий к группе К-антигенов (капсульных, оболочечных антигенов) брюшнотифозного микроба. Открыт в 1934 Асэ Филыксом (Arthur Felix; 1887–1956) и Ар. Магэрит Пит (R. Margaret Pitt) при изучении О-инагглютинабельных штаммов брюшнотифозных Бактерий. По химической природе V-антиген – высокомолекулярный полимер N-ацетиламиногексуроновой кислоты. Иммунизация Кроликов этими штаммами вызывала образование О-, Н- и Vi-агглютининов. Путём истощения иммунной сыворотки О- и Н-штаммами были получены чистые V-агглютинины, которые агглютинировали штаммы при наличии в них V-антигена. V-антиген не определяет в полной мере вирулентность брюшнотифозных Бактерий. Более высокая патогенность для мышей штаммов, содержащих V-антиген, объясняется их большей токсичностью. В зависимости от содержания V-антигена Немецко-Датский учёный Фритц Кауфман (Fritz Kauffmann; 1899–1978) различает следующие три варианта брюшнотифозной палочки:- V-форма, содержащая V-антиген; агглютинируется V-сывороткой и не агглютинируется О-сывороткой; W-форма, лишённая V-антигена; агглютинируется только О-сывороткой; VW-форма, содержащая V-антиген, но агглютинируемая обеими сыворотками. V-антиген присутствует в штаммах, выделенных в острый период болезни, и утрачивается в результате многократных пересевов. Оптимальная для его продукции t равна 37 °С. Нагревание в течение часа при 60 °С полностью разрушает агглютинабельность и резко снижает его агглютиногенность; агглютининсвязывающая способность V-антигена в культурах не изменяется даже при нагревании до 100 °С. Присутствие V-антигена в брюшнотифозных вакцинах имеет существенное значение для их иммуногенности, хотя эпидемиологический опыт в Югославии (Хорватский эпидемиолог Бранко Цветанович (Branko Cvjetanović; 1918–2002), 1957) не подтвердил предположения о том, что V-антиген играет главную роль в развитии иммунитета к брюшному тифу. Наличие V-антигена в свежевыделенных культурах брюшнотифозного микроба используется для их идентификации при помощи V-агглютинации и гемагглютинации, а также для определения их фаготипа посредством V-брюшнотифозных фагов. Реакции V-агглютинации и гемагглютинации с успехом используют для серодиагностики брюшного тифа и выявления бактерионосителей. Кроме брюшнотифозной палочки, V-антигены обнаружены у паратифозной Бактерии (Salmonella Paratyphi C), у некоторых паракишечных (S. Bailer up) и кишечных Бактерий (Escherichia Coli 5396/38).

VAPOR = ПАР – Vapor is the gaseous phase of substances that are liquid or solid at atmospheric temperature and pressure, e.g., steam. See also Water Vapor. Vapor is the gaseous product of evaporation. Vapor is a diffused matter (such as smoke or fog) suspended floating in the air and impairing its transparency. Vapor is a substance in the gaseous state as distinguished from the liquid or solid state. Vapor is a substance (such as gasoline, alcohol, mercury, or benzoin) vaporized for industrial, therapeutic, or military uses; also:- a mixture (such as the explosive mixture in an internal combustion engine) of such a vapor with air. Vapor (in physics) is a gas at a temperature below its critical temperature. Vapor is a visible exhalation, as fog, mist, steam, smoke, or noxious gas, diffused through or suspended in the air:- the vapors rising from the bogs. Vapor (in US) or Vapour (in UK) is a substance diffused or suspended in the air, especially one normally liquid or solid, e.g., ‘dense clouds of smoke and toxic vapour’. In physics a Vapor (American) or Vapour (British and Canadian) is a substance in the gas phase at a temperature lower than its critical temperature, which means that the vapor can be condensed to a liquid by increasing the pressure on it without reducing the temperature. A vapor is different from an aerosol. An aerosol is a suspension of tiny particles of liquid, solid, or both within a gas. For example, water has a critical temperature of 647 K (374 °C; 705 °F), which is the highest temperature at which liquid water can exist. In the atmosphere at ordinary temperatures, therefore, gaseous water (known as Water Vapor) will condense into a liquid if its partial pressure is increased sufficiently. A vapor may co-exist with a liquid (or a solid). When this is true, the two phases will be in equilibrium, and the gas-partial pressure will be equal to the equilibrium vapor pressure of the liquid (or solid). Properties:- Vapor refers to a gas phase at a temperature where the same substance can also exist in the liquid or solid state, below the critical temperature of the substance. (For example, water has a critical temperature of 374 °C (647 K), which is the highest temperature at which liquid water can exist.) If the vapor is in contact with a liquid or solid phase, the two phases will be in a state of equilibrium. The term Gas refers to a compressible fluid phase. Fixed gases are gases for which no liquid or solid can form at the temperature of the gas, such as air at typical ambient temperatures. A liquid or solid does not have to boil to release a vapor. Vapor is responsible for the familiar processes of cloud formation and condensation. It is commonly employed to carry out the physical processes of distillation and headspace extraction from a liquid sample prior to gas chromatography. The constituent molecules of a vapor possess vibrational, rotational, and translational motion. These motions are considered in the kinetic theory of gases. Vapor Pressure:- the vapor pressure is the equilibrium pressure from a liquid or a solid at a specific temperature. The equilibrium vapor pressure of a liquid or solid is not affected by the amount of contact with the liquid or solid interface. The normal boiling point of a liquid is the temperature at which the vapor pressure is equal to normal atmospheric pressure. For two-phase systems (e.g., two liquid phases), the vapor pressure of the individual phases are equal. In the absence of stronger inter-species attractions between like-like or like-unlike molecules, the vapor pressure follows Raoult’s law, which states that the partial pressure of each component is the product of the vapor pressure of the pure component and its mole fraction in the mixture. The total vapor pressure is the sum of the component partial pressures. Examples:- (i) perfumes contain chemicals that vaporize at different temperatures and at different rate in scent accords, known as Notes; (ii) atmospheric water vapor is found near the earth’s surface, and may condense into small liquid droplets and form meteorological phenomena, such as fog, mist, and haar; (iii) mercury-vapor lamps and sodium vapor lamps produce light from atoms in excited states; (iv) flammable liquids do not burn when ignited; it is the vapor cloud above the liquid that will burn if the vapor’s concentration is between the lower flammable limit (LFL) and upper flammable limit (UFL), of the flammable liquid; (v) E-Cigarettes allow users to inhale ‘e-liquid’ aerosol/vapor, rather than cigarette smoke. Measuring Vapor:- since it is in the gas phase, the amount of vapor present is quantified by the partial pressure of the gas. Also, vapors obey the barometric formula in a gravitational field, just as conventional atmospheric gases do. / Закон Раульта (Raoult’s Law; в честь установившего его Французского химика Фросуа-Мари Раульт (François-Marie Raoult); 1830–1901). Пар, название газообразного состояния веществ (смотрите Газы) в условиях, когда газовая фаза может находиться в равновесии с жидкой (твёрдой) фазой того же вещества. Как правило, термин Пар применяют в тех случаях, когда фазовое равновесие осуществляется при температурах T и давлениях p, характерных для обычных природных условий (говорят, например, о парах спирта, бензола, иода, нафталина и так далее). Как исключение, воду в газообразном состоянии

при T и p, превышающих критические значения, называют Паром, а CO_2, даже ниже критической температуры (31.04 °C), – газом. С точки зрения термодинамики фазовых превращений термины Пар и Газ эквивалентны. Различают следующие виды состояний пара химически чистых веществ:- (1) насыщенный пар (пар при T и p насыщения); (2) ненасыщенный пар, то есть пар при $T > T_{насыщ}$ для данного p и, следовательно, с плотностью меньшей, чем у насыщенного пара (в технике его называют перегретым паром или просто газом); (3) пересыщенный пар – пар, имеющий давление большее, чем $p_{насыщ}$, при той же температуре (смотрите также Водяной Пар).

VAPOR BARRIER = ПАРОВОЙ БАРЬЕР – Vapor Barrier is a thin layer of impermeable material, typically polythene sheeting, included in building construction to prevent moisture from damaging the fabric of the building. Vapor Barrier is a material with a permeance of one perm or less which provides resistance to the transmission of water vapor. Vapor Barrier is a layer of material (such as roofing paper or polyethylene film) used to retard or prevent the absorption of moisture into a construction (such as a wall or floor). / Под Барьером, от Французского слова Barriére, понимается заграждение, перегородка, препятствующие свободному проходу, проезду и так далее.

VAPOR CAPTURE SYSTEM = СИСТЕМА УЛАВЛИВАНИЯ ПАРА – Vapor Capture System is any combination of hoods and ventilation system that captures or contains organic vapors in order that they may be directed to an abatement or recovery device.

VAPOR DEPOSITION = ПАРОВОЕ ОСАЖДЕНИЕ (или ОСАЖДЕНИЕ ПАРА) – Vapor Deposition is a chemical process commonly used in the semiconductor industry to apply thin films of one substance onto a surface composed of another substance.

VAPOR DISPERSION = ДИСПЕРСИЯ ПАРА (или РАССЕЯНИЕ ПАРА) – Vapor Dispersion is the movement of vapor clouds in air due to wind, gravity spreading, and mixing.

VAPOR DISPLACEMENT = ЗАМЕЩЕНИЕ ПАРА (или ВЫТЕСНЕНИЕ ПАРА) – Vapor Displacement is the release of vapors that had previously occupied space above liquid fuels stored in tanks. These releases occur when tanks are emptied and filled.

VAPOR–DOMINATED GEOTHERMAL SYSTEM = ГЕОТЕРМАЛЬНАЯ СИСТЕМА С ДОМИНИРОВАНИЕМ ПАРА – Vapor-Dominated Geothermal System or Dry Steam Geothermal System is a conceptual model of a hydrothermal system where steam pervades the rock and is the pressure-controlling fluid phase. Vapor-dominated geothermal systems such as Larderello, Italy, The Geysers, California, and Matsukawa, Japan yield dry or superheated steam when exploited. Models for these systems are examined along with production data and the thermodynamic properties of water, steam and rock. It is concluded that these systems initially consist of a water and steam filled reservoir, a water-saturated cap rock, and a water or brine-saturated deep reservoir below a water table. Most liquid water in all parts of the system is relatively immobilized in small pores and crevices; steam dominates the large fractures and voids of the reservoir and is the continuous, pressure-controlling phase. With production, the pressure is lowered and the liquid water boils, causing massive transfer of heat from the rock and its eventual drying. Passage of steam through already dried rock produces superheating. After an initial vaporization of liquid water in the reservoir, the decrease in pressure produces increased boiling below the deep water table. With heavy exploitation, boiling extends deeper into hotter rock and the temperature of the steam increases. This model explains most features of the published production behavior of these systems and can be used to guide exploitation policies. Geothermal systems extract heat energy from the interior of the earth using a working fluid, typically water. Three components are required for a commercially viable geothermal system:- heat, fluid, and permeability. Current commercial electricity production using geothermal energy occurs where the three main components exist naturally. These are called hydrothermal systems. In the US, there is an estimated 30 GW of base load electrical power potential for hydrothermal sites. Next generation geothermal systems, named Enhanced Geothermal Systems (EGS), have an estimated potential of 4 500 GW. EGSs lack in-situ fluid, permeability or both. As such, the heat exchange system must be developed or engineered within the rock. The envisioned method for producing permeability in the EGS reservoir is hydraulic fracturing, which is rarely practiced in the geothermal industry, and not well understood for the rocks typically present in geothermal reservoirs. High costs associated with trial and error learning in the field have led to an effort to characterize fluid flow and fracturing mechanisms in the laboratory to better understand how to design and manage EGS reservoirs. Neutron radiography has been investigated for potential use in this characterization. An environmental chamber has been developed that is suitable for reproduction of EGS pressures and temperatures and has been tested for both flow and precipitations studies with success for air/liquid interface imaging and 3D reconstruction of precipitation within the core. / Лардэрэллё (Larderello; Италия), Зи Гайзёз (The Geysers; Калифорния, Соединённые Штаты Америки), и Мацукава (Matsukawa; Япония).

VAPOR DRIFT = СНОС ПАРА – A term Vapor Drift:- refers to the movement of pesticides as gaseous vapors from the target area. Some pesticides are volatile and can change readily from a solid or liquid into a gas under the right conditions. This most commonly occurs with high air temperatures. Pesticides that have volatilized into a vapor or gas may drift farther and for a longer time than they would have as spray droplets. Only those pesticides that are able to volatilize are susceptible to vapor drift. As air temperatures increase, the likelihood that these pesticides will volatilize and drift also increases. Whenever possible, choose a pesticide formulated as a low-volatility product. Avoid applying volatile pesticides on hot days. Some products can even volatilize several hours after application, so beware if high temperatures are predicted for later in the day. Many products carry precautions against applying these products when temperatures are above 85 °F or expected to reach 85 °F. Remember to check label precautions for product-specific concerns about vapor drift. See also Pesticide Drift.

VAPORIZATION = ИСПАРЕНИЕ (или ПАРООБРАЗОВАНИЕ) – Vaporization:- also called Evaporation, conversion of a substance from the liquid or solid phase into the gaseous (vapor) phase. If conditions allow the formation of vapor bubbles within a liquid, the vaporization process is called Boiling. Direct conversion from solid to vapor is called Sublimation. Heat must be supplied to a solid or liquid to effect vaporization. If the surroundings do not supply enough heat, it may come from the system itself as a reduction in temperature. The atoms or molecules of a liquid or solid are held together by cohesive forces, and these forces must be overcome in separating the atoms or molecules to form the vapor; the heat of vaporization is a direct measure of these cohesive forces. Condensation of a vapor to form a liquid or a solid is the reverse of vaporization, and in the process heat must be transferred from the condensing vapor to the surroundings. The amount of this heat is characteristic of the substance, and it is numerically the same as the Heat Of Vaporization. See also Sublimation. Vaporization is the change of a substance from a liquid to a gas. Vaporization:- an addition of thermal energy changing a liquid or semisolid to a vapor or gaseous state. Vaporization is the change from liquid or solid phase to the vapor phase. / Испарение, переход вещества из жидкого или твёрдого агрегатного состояния в газообразное – пар. Обычно под испарением понимают переход жидкости в пар, происходящий на свободной поверхности жидкости. Испарение твёрдых тел называется Возгонкой или Сублимацией. Вследствие теплового движения молекул испарение возможно при любой температуре, но с возрастанием температуры, то есть интенсивности теплового движения молекул, скорость испарения увеличивается. В замкнутом пространстве (закрытом сосуде) испарение происходит при заданной постоянной температуре до тех пор, пока пространство над оставшимся избытком жидкости (или твёрдого тела) не будет заполнено насыщенным паром. Давление насыщенного пара зависит только от температуры и повышается с её возрастанием. Кривая, изображающая давление насыщенного пара в зависимости от температуры, называется Равновесной Кривой Испарения. Если давление

насыщенного пара, заполняющего микрополости в жидкости, становится равным или несколько большим давления в газовой фазе над поверхностью жидкости, то испарение переходит в кипение. Наиболее высокой температурой кипения является Критическая Температура данного вещества. Критическая температура и давление определяют Критическую Точку – конечную точку на равновесной кривой испарения. Выше этой точки сосуществование в равновесии двух фаз – жидкости и пара – невозможно. При переходе из жидкости в пар молекула должна преодолеть силы молекулярного сцепления в жидкости. Работа против этих сил (работа выхода), а также против внешнего давления уже образовавшегося пара совершается за счёт кинетической энергии теплового движения молекул. В результате испарения жидкость охлаждается. Поэтому, чтобы процесс испарения был изотермическим, то есть протекал при постоянной температуре, необходимо сообщать каждой единице массы вещества определённое количество теплоты l (Дж/кг или Дж/моль), называемое Теплотой Испарения. Теплота испарения уменьшается с ростом температуры, особенно быстро вблизи критической точки, обращаясь в этой точке в нуль. Теплота испарения связана с производной давления насыщенного пара по температуре Уравнением Клапейрона–Клаузиуса (Clausius–Clapeyron Relation; в честь Французского инженера и физика Бэнуа Поля Эмиля Кляперо (Benoît Paul Émile Clapeyron; 1799–1864) и Немецкого физика и математика Рудольфа Юлиуса Эмануэля Кляусъюса (Rudolf Julius Emanuel Clausius; 1822–1888)), на основе которого определяются численные значения l для жидкостей. Скорость испарения резко снижается при нанесении на поверхность жидкости достаточно прочной плёнки нелетучего вещества. Испарение жидкости в газовой среде, например, в воздухе, происходит медленнее, чем в разреженном пространстве (вакууме), так как вследствие соударений с молекулами газа часть частиц пара вновь возвращается в жидкость (конденсируется). Испарение относится к фазовым переходам 1-го рода, которые характеризуются отличной от нуля теплотой фазового перехода. При процессе, обратном испарению, то есть при образовании из пара жидкой фазы (конденсации), происходит выделение теплоты испарения. Испарение применяется в технике как средство очистки веществ или разделения жидких смесей перегонкой. Испарение лежит в основе пароэнергетики, работы холодильных и других установок, а также всех процессов сушки материалов. В естественных условиях испарение является единственной формой передачи влаги с океанов и суши в атмосферу и основной составляющей круговорота воды на земном шаре. Парообразование, переход вещества из конденсированной фазы (жидкой или твёрдой) в газовую (фазовый переход I рода). Различают следующие виды парообразования:- испарение (парообразование со свободной поверхности конденсированной фазы, в случае твёрдого тела – Сублимация) и Кипение (парообразование, характеризующееся возникновением пузырьков насыщенного пара на поверхностях нагрева и ростом пузырьков в объёме жидкости). Испарение у растений, отдача растениями воды в окружающую атмосферу. Происходит по тем же законам, что и испарение с поверхности любого смоченного тела. Однако анатомическое строение испаряющей поверхности растений, покрытой мало проницаемой для воды кутикулой и снабжённой многочисленными устьицами, способными открываться и закрываться и тем регулировать отдачу воды, вносит существенные изменения в ход испарения, и из чисто физического процесса оно становится процессом физиологическим, называемым Транспирацией. Смотрите также Водный Режим Растений.

VAPORIZER = ВЫПАРИВАТЕЛЬ (или ИСПАРИТЕЛЬ, или ВЫПАРНОЙ АППАРАТ) – Vaporizer:- a heat transfer facility designed to introduce thermal energy in a controlled manner for changing a liquid or semisolid to a vapor or gaseous state. Vaporizer is a device that generates a particular substance in the form of vapour, especially for medicinal inhalation. / Выпарной Аппарат, аппарат для концентрирования растворов твёрдых веществ в жидких растворителях путём полного или частичного удаления растворителя в виде пара (смотрите Выпаривание). Выпарной аппарат для выпаривания воды, поступающей на питание котлов в котельных и ТЭЦ, а также для выпаривания хладоагента в холодильных установках, называются Испарителями. Испаритель, теплообменный аппарат для испарения жидкостей. В теплоэнергетике испаритель предназначен для выработки дистиллята, восполняющего потери конденсата в паросиловых установках. Обычно вертикальный трубчатый испаритель обогревается отработавшим в турбине паром, проходящим в межтрубном пространстве. Испаряемая предварительно умягчённая вода проходит внутри труб. Существуют также испарители, обогреваемые дымовыми газами, уходящими из котельных агрегатов. Получаемый в таких испарителях пар может быть использован как для восполнения потерь конденсата, так и для теплоснабжения. Испарители большой производительности находят применение на расположенных у морей и океанов атомных электростанциях для опреснения морской воды. Испарители, называемые иногда Опреснителями, устанавливают на морских судах. Испарители являются основными элементами холодильных установок, в которых испаряется холодильный агент, предназначенный для непосредственного (или посредством рассола) охлаждения холодильных камер. Испарителями являются также выпарные аппараты, аппараты для повышения концентрации различных растворов и другие. Испаритель или Эвапорометр (в метеорологии), прибор для измерения испарения с поверхности водоёмов и почвы. Для измерения испарения с поверхности водоёмов в бывшем Союзе Советских Социалистических Республик (СССР) применялся плавучий испаритель системы ГГИ-3000 (разработанный Государственным Гидрологическим Институтом). Он представлял собой металлический сосуд цилиндрической формы с конусообразным дном, наполненный водой; площадь испаряющей поверхности – 3 000 квадратных сантиметров ($см^2$). Во время наблюдений на трубку, укреплённую в центре сосуда, устанавливают объёмную бюретку с отверстием у дна, в которое проникает вода. По разности объёмов воды, взятых бюреткой в 2 последовательных срока, определяют количество испарившейся воды. В открытом море применяются испарители, которые дают возможность судить о величине испарения по изменению концентрации раствора солей морской воды или по изменению её температуры (Испаритель Шулейкина). Для измерения испарения с поверхности почвы наиболее распространён почвенный испаритель ГГИ-500. Он состоит из двух цилиндрических сосудов, входящих один в другой, и водосборного сосуда. Внутри цилиндр имеет дно с отверстиями; в него помещается почвенный монолит. Величина испарения определяется по разности массы монолита в два последовательных срока наблюдений. Для уменьшения влияния стенок и дна на данные измерений применяются испарительные бассейны, устроенные в грунте, площадью 20 квадратных метров ($м^2$) и более.

VAPOR LIQUID RATIO = СООТНОШЕНИЕ ПАР ЖИДКОСТЬ – Vapor Liquid (V/L) Ratio is a measure of the tendency of a fuel to vapor lock. Vapor Liquid (V/L) Ratio is another measurement of a fuel's volatility. The V/L Ratio is defined as the ratio of the volume of vapor formed at atmospheric pressure to the volume of liquid fuel. / соотношение паровой и жидкой фаз.

VAPOR LOCK = ПАРОВАЯ ПРОБКА – Vapor Lock is a condition caused when fuel fails to flow to an engine due to increased fuel vapor pressure in the inlet fuel line or internal fuel pump cavities. The increased fuel vapor pressure is caused by high temperatures or heat build-up. Vapor Lock or Vapour Lock:- partial or complete interruption of the fuel flow in an internal-combustion engine, caused by the formation of vapor or bubbles of gas in the fuel-feeding system. Vapor forms because of fuel boiling in the fuel lines, usually as a result of excessive heating of the engine in hot weather or operation of the vehicle in areas of high altitude, which lowers the boiling point of the fuel. In some engines the fuel line may be routed too close to the exhaust manifold or other parts of the engine which give off intense heat. Allowing the engine to cool usually enables the vapor to recondense and thereby clears the vapor lock.

VAPOR PLUMES = СТРУЙКИ ПАРА – Vapor Plumes:- flue gases that are visible because they contain water droplets. / которые становятся видимыми вследствие содержания в них капелек воды.

VAPOR PRESSURE = ДАВЛЕНИЕ ПАРА (или УПРУГОСТЬ ПАРА) – Vapor Pressure is a pressure of a confined vapor in equilibrium with its liquid at specified temperature thus, a measure of a liquid's volatility. The Vapor Pressure of a substance is the pressure which a vapor, in a closed container and in equilibrium with its solid or liquid form, exerts on the enclosing walls. Vapor Pressure or Vapour Pressure is a pressure exerted by a vapor when the vapor is in equilibrium with the liquid or solid form, or both, of the same substance – i.e. when conditions are such that the substance can exist in both or in all three phases. Vapor pressure is a measure of the tendency of a material to change into the gaseous or vapor state, and it increases with temperature. The temperature at which the vapor pressure at the surface of a liquid becomes equal to the pressure exerted by the surroundings is called the Boiling Point of the liquid. / Упругость Водяного Пара в атмосфере, парциальное давление водяного пара, находящегося в воздухе; выражается в миллибарах (мбар) или миллиметрах ртутного столба (мм рт. ст.). 1 мбар = 10^2 Н/м^2. Упругость водяного пара зависит от количества водяного пара в единице объёма и является одной из характеристик влажности воздуха. Упругость водяного пара у земной поверхности может быть около нуля (в Антарктиде, зимой в Якутии, иногда в пустынях) и до 30–35 мбар вблизи экватора. С высотой упругость водяного пара быстро убывает – в 2 раза в нижних 1.5 км и почти до нуля на верхней границе тропосферы.

VAPOR PRESSURE–REID = УПРУГОСТЬ ПАРА–ПО РИДУ (или ДАВЛЕНИЕ ПАРА–ПО РИДУ) – Vapor Pressure-Reid or Reid Vapor Pressure (RVP):- common measure of the pressure of vapor accumulated above a sample of gasoline or other volatile fuel in a standard bomb at 100 °F (37.8 °C). The higher the RVP, the more volatile the gasoline. Used to predict the vapor locking tendencies of the fuel in a vehicle's fuel system. Controlled by law in some areas to limit air pollution from hydrocarbon evaporation while dispensing. See also Volatility. New restrictions on vaporization loss os petroleum products give added emphasis to the measurement of vapor pressure for petroleum fractions and their blends. The common method for measuring vapor pressure is the Reid Vapor Pressure (RVP) test. Now an algorithm is available to calculate RVP without performing the actual test. The algorithm, based on air-and-water free model, uses the Gas Processors Association Soave-Redlich-Kwong equation of state and assumes liquid and gas volumes are additive. Since the calculations are iterative, they are incorporated into a general purpose process simulator to compare predicted values with experimental data. Good agreement is found between predicted and experimental values. Furthermore, the algorithm is fast and can be used to predict Rvp of any hydrocarbon mixture of known composition. Xxxxx. Reid Vapor Pressure (RVP) is a common measure of the volatility of gasoline. It is defined as the absolute vapor pressure exerted by a liquid at 37.8 °C (100 °F) as determined by the test method ASTM-D-323. The test method measures the vapor pressure of gasoline, volatile crude oil, and other volatile petroleum products, except for liquefied petroleum gases. RVP is stated in kilopascals and represents a relative pressure to the atmospheric pressure because ASTM-D-323 measures the gauge pressure of the sample in a non-evacuated chamber. All values are in SI units and are regarded as standards. Imperial units are for information only. The matter of vapor pressure is important relating to the function and operation of gasoline-powered, especially carbureted, vehicles. High levels of vaporization are desirable for winter starting and operation and lower levels are desirable in avoiding vapor lock during summer heat. Fuel cannot be pumped when there is vapor in the fuel line (summer) and winter starting will be more difficult when liquid gasoline in the combustion chambers has not vaporized. Thus, oil refineries manipulate the Reid Vapor Pressure seasonally specifically to maintain gasoline engine reliability. The Reid vapor pressure (RVP) differs slightly from the True Vapor Pressure (TVP) of a liquid due to small sample vaporization and the presence of water vapor and air in the confined space of the test equipment. That is, the RVP is the absolute vapor pressure and the TVP is the partial vapor pressure. / Рид (Reid). Суавэ-Рэдлихя-Квона (Soave-Redlich-Kwong equation; в честь Итальянского инженера Дьжёрдьжё Суавэ (Giorgio Soave; 1938–), Австрийского химика и инженера Ото Рэдлихя (Otto Redlich; 1896–1978) и Американского инженера Китайского происхождения Дьжозэфа Нэна Шана Квона (Joseph Neng Shun Kwong; 1916–1998)). Упругость Паров (бензина) по Риду, например, 10 psi RVP gasoline – бензин с упругостью паров по Риду 10 фунтов на квадратный дюйм.

VAPOR RETARDER = ПАРОВАЯ МЕМБРАНА (или ХХ) – Vapor Retarder is a material that retards the movement of water vapor through a building element (walls, ceilings) and prevents insulation and structural wood from becoming damp and metals from corroding. Often applied to insulation batts or separately in the form of treated papers, plastic sheets, and metallic foils.

VAPOR TRAIL = ПАРОВОЙ СЛЕД – Vapor Trail or Vapour Trail:- also called Condensation Trail, or Contrail, streamer of cloud sometimes observed behind an airplane flying in clear, cold, humid air. It forms upon condensation of the water vapor produced by the combustion of fuel in the airplane engines. When the ambient relative humidity is high, the resulting ice-crystal plume may last for several hours. The trail may be distorted by the winds, and sometimes it spreads outwards to form a layer of cirrus cloud. On rare occasions, when the air is nearly saturated with water vapor, air circulation at the wing tips of an airplane may cause sufficient pressure and temperature reductions to cause cloud streamers to form. / Конденсационный След (Condensation Trail) или След Инверсии (Contrail).

VAR = VALUE ADDED RATIO

VAR = VALUE–ADDED RESELLER

VaR = VALUE AT RISK

VAR = BAP – VAr is an abbreviation for Volt Ampere reactive. Unit of ac reactive power. VAr is a unit of the reactive electric power delivered by an alternating current (AC) circuit. In an AC circuit, the electric potential or Voltage (measured in Volts) and the current (in Amperes) alternate direction, varying smoothly according to sine curves. In a purely resistive circuit, current is in phase with Voltage. In a purely inductive circuit, the variations of the current would lag the variations in the Voltage by 1/4 cycle, or 90°. In real circuits, the current can be separated into two parts:- a part in phase with the Voltage, and the 'reactive' part, which lags the Voltage by 90°. The reactive part does no net work; it simply heats the conductor. Reactive current does perform important magnetizing and Voltage-regulation functions in real circuits. The reactive power is the product of the Voltage and the reactive part of the current. The name of the unit is an acronym for Volt-Ampere-reactive. / Под ВАром, сокращением от Вольт-Ампер Реактивный, обозначение допускаемой к применению единицы реактивной мощности переменного электрического тока. Отличается от Ватта множителем sinφ, где φ – сдвиг фаз между напряжением и током в цепи. 1 ВАр равен реактивной мощности при напряжении 1 В, силе тока 1 А и sin φ = 1. Обозначение:- ВАр. ВАр или Вольт-Ампер реактивный, единица реактивной мощности переменного тока Q = UIsinφ, где φ – сдвиг фаз между током I и напряжением U в цепи синусоидального переменного тока (смотрите также Вольт-Ампер). ВАр обозначается Вар или VAr. Различие в размерах Вара и Ватта (единицы электрической мощности) определяется сдвигом фаз φ.

VARDENAFIL = ВАРДЕНАФИЛ – Vardenafil (Levitra®) is a PDE5 Inhibitor drug. Vardenafil is a medicine used for the treatment of erectile dysfunction (ED) in men. Vardenafil works faster than Sildenafil (Viagra®) and it is less likely to have visual disturbance side effect. Vardenafil was co-marketed by Bayer Pharmaceuticals, GSK, and SP under the trade name Levitra®. / Лэвитчра® (Levitra®). Вайэгрэ® (или Виагра® (Viagra®)). Байа Фамэсютикэлз (Bayer Pharmaceuticals). Варденафил – препарат для лечения эректильной дисфункции, торговое название Лэвитчра® (Levitra®).

VARIABILITY = ВОЗМОЖНОСТЬ ИЗМЕНЧИВОСТИ (или ВАРИАБИЛЬНОСТЬ) – Variability (plant breeding):- genotypic differences. / Под Изменчивостью понимается разнообразие признаков и свойств у особей и групп особей любой степени родства. Присуща всем живым организмам. Различают изменчивость:- наследственную и ненаследственную; индивидуальную и групповую; качественную и количественную; направленную и ненаправленную. Наследственная изменчивость обусловлена возникновением мутаций, ненаследственная – воздействием факторов внешней среды. Явления наследственности и изменчивости лежат в основе эволюции.

VARIABILITY = ИЗМЕНЧИВОСТЬ (или ИЗМЕНЯЕМОСТЬ) – A term Variability refers to a distribution of measured properties within a given process. Variability can be measured in terms of geometrical, physical or mechanical response. Typically variability is used to describe some apparently random aspect of the manufacturing process.

VARIABLE = ИЗМЕНЯЕМОЕ (или ПЕРЕМЕННОЕ) – A Variable is a characteristic of a unit being observed that may assume more than one of a set of values to which a numerical measure or a category from a classification can be assigned (e.g., income, age, weight, etc, and 'occupation', 'industry', 'disease', etc. Context:- a variable in the mathematical sense, i.e. a quantity which may take any one of specified set of values. It is convenient to apply the same word to denote non-measurable characteristics, e.g., 'sex' is a variable in this sense since any human individual may take one of two 'values', male or female. It is useful, but far from being the general practice, to distinguish between a variable as so defined and a random variable. See also Characteristic, Data Item, and Observation.

VARIABLE = ПЕРЕМЕННОЕ (или ПЕРЕМЕННАЯ) – Variable is an element in a model. For example, in the model $RS\&P_{t+1} = a + b\ Tbill_t + e_t$, where $RS\&P_{t+1}$ is the return on the S&P in month t+1 and Tbill is the Tbill return at month t, both RS&P and Tbill are 'variables' because they change through time, i.e. they are not constant. See also Variables.

VARIABLE AIR VOLUME SYSTEM = СИСТЕМА С ИЗМЕНЯЕМЫМ ОБЪЁМОМ ВОЗДУХА – Variable Air Volume System (VAV System) is a mechanical Heating Ventilating and Air Conditioning system (HVAC system) capable of serving multiple zones which controls the temperature maintained in a zone by controlling the amount of heated or cooled air supplied to the zone.

VARIABLE AIR VOLUME SYSTEM ON THE HEATING AND COOLING SYSTEM = СИСТЕМА ИЗМЕНЯЕМОГО ОБЪЁМА ВОЗДУХА В СИСТЕМЕ ОТОПЛЕНИЯ И ОХДАЖДЕНИЯ (или ХХ) – Variable Air Volume (VAV) System On The Heating And Cooling System:- a means of varying the amount of conditioned air to a space. A variable air volume system maintains the air flow at a constant temperature, but supplies varying quantities of conditioned air in different parts of the building according to the heating and cooling needs.

VARIABLE ANNUITY = ИЗМЕНЯЕМЫЙ АННУИТЕТ (или ПЕРЕМЕННЫЙ АННУИТЕТ, или ПЛАВАЮЩИЙ АННУИТЕТ) – Variable Annuities products are investment-linked products with some form(s) of guarantee (accumulation, income, death or withdrawal) which are sold by life insurers into the retirement and investment market. In the United States, the most common guarantee offered is that on withdrawal. The customer's initial capital paid into such a product is invested in a sub-account at the customer's discretion. The customer can withdraw guaranteed periodic amounts up to the amount of the initial capital. The product terminates once the initial capital has been withdrawn with any remaining funds in the sub-account returned to the customer at maturity. So the sub-account value fluctuates with movements in the underlying assets and decreases with withdrawals. The product therefore effectively combines an annuity, in the form of guaranteed periodic withdrawals, with a call option on the underlying residual sub-account at maturity. So, while the customer who owns the sub-account carries much of the investment risk, the insurer is carrying the risk that the sub-account will not be adequate to fund the guaranteed withdrawal amounts. The US National Association of Insurance Commissioners (NAIC) has been developing its approach to the treatment of such products with complex guarantees in its capital adequacy requirements. In 2000, an internal models based approach was added to the previously factor-based capital approach to capture interest rate risk. This was refined in 2005 to capture equity risk. These changes have automatically been applied by all states, as the NAIC risk-based capital system is referenced in all state laws. Work is currently under way further to refine the reserving requirements for such products. Over the last few years, and especially since the financial crisis, insurers have reduced their writing of such products and scaled back the types and levels of guarantees offered. The term 'Insurance Commissioner' is used throughout this report to refer to the most senior official responsible for insurance regulation in each state, district, or territory. Actual titles vary. Variable Annuity is structured to be a retirement annuity, into which is integrated several additional features. The annuity usually offers a death benefit, under which the beneficiary of the investor is paid a certain amount (usually the greater of the amount thus far accumulated in the account or a guaranteed minimum) if the investor dies prematurely. Also, any investment income earned under the annuity plan is tax deferred until such time as the investor is paid (presumably at a much later date). The investment vehicle underlying the variable annuity is packaged with an insurance contract that is activated if there is a loss in capital, thereby protecting some or all of the investor's investment. Variable annuities are offered by insurance companies under an arrangement where an investor, who is planning for retirement, invests either a lump sump or a series of invested amounts with the insurer, who then invests the money and agrees to provide a variable annuity to the investor in exchange. A variable annuity can be structured in many ways, such as:- (i) there is a guaranteed minimum payment, with a variable additional amount that is based on the return from the underlying investment pool; (ii) there is no guaranteed payment, with the entire amount of the payment being derived from the return on an underlying investment pool; (iii) the investor has the option of being paid in an annuity format over a fixed period of time, or of withdrawing variable amounts at variable intervals (or all at once); and (iv) the investor can choose the payout period, such as larger payments over a short period, or smaller payments over a longer period. Variable annuities are generally not recommended, for three reasons:- (i) Fees:- this type of annuity is overloaded with both commission fees and ongoing account administration charges, which severely offset any investment gains. Further, each additional benefit built into the plan, such as the death benefit, is based on an integrated insurance plan that you are also paying for. (ii) Termination:- there are large termination fees that effectively lock up funds for a minimum of five years. You can still terminate the arrangement before that time, but only by paying a charge that can exceed 6% of the invested amount. (iii) Taxes:- gains on a variable annuity are taxes at the ordinary income tax rate, which is higher than the long-term capital gains rate. Because of the preceding issues, it is almost always more cost-effective to maximize your investment in a 401(k) pension plan and an individual retirement account (IRA) before placing any funds in a variable annuity. Variable Annuities are Investment contracts whose issuer pays a periodic amount linked to the investment performance of an underlying portfolio. Variable Annuity:- a life insurance policy where the annuity premium (a set amount of Dollars) is immediately turned into units of a portfolio of stocks. Upon retirement, the policyholder is paid accordingly to accumulated units, the Dollar value of which varies according to the performance of the stock portfolio. Its objective is to enhance, through stock investment, the purchasing value of the annuity which otherwise is subject to erosion through inflation. / Изменяемый Аннуитет (Variable Annuity):- контракт страхования жизни с плавающей (переменной) рентой. Контракт страхования жизни с регулярными платежами (рентой) (annuity), величина которой колеблется в момент исполнения в соответствии с котировками ценных бумаг, составляющих портфель вложений (portfolio), или другими показателями (index). Контракт страхования с регулярными взносами, по которому стоимость полиса варьирует, отличается от контракта с

фиксированными выплатами (fixed annuity), ставка дохода по которому постоянная и, следовательно, подвержена негативным последствиям инфляции. Доход по контракту страхования с варьирующей рентой может начисляться периодически, начиная непосредственно с начала срока действия полиса или с любого другого момента в будущем. Такой контракт может оплачиваться путём единовременного взноса или путём последовательной выплаты премий. Доход инвесторов может быть в форме периодических выплат, варьирующих в зависимости от рыночной стоимости (market value), портфеля вложений, или в форме фиксированных минимальных выплат; размеры доплат к этим скидкам зависят от скорости роста стоимости портфеля. Смотрите также Single Premium Deferred Annuity.

VARIABLE CONTRACT = ИЗМЕНЯЕМЫЙ ДОГОВОР (или ИЗМЕНЯЕМЫЙ КОНТРАКТ) – Variable Contracts are the contracts such as variable annuities or variable life insurance that contain an element of risk for the investor depending on the performance of the separate account backing the contract. Generally, these contracts are products of insurers but regulated by both state insurance departments and the federal government. Variable Contract is a type of contact that is regulated by both the state and federal governments. These contracts are riskier than the typical contract because they depend on the value of a separate account that serves as the backing for the contract. Variable Contracts:- thanks to biomedical advances and greater health awareness, people in the XXI century are living longer. Between 1950 and 2004 alone, individual life expectancy rose by 10 full years, from 68 to 78 years! This may not seem like a problem, but to investors it is an increasingly serious issue that should cause great concern. Put simply, people in developed countries now face the possibility of actually outliving their financial resources. But your clients can protect themselves from running out of money while enjoying a longer, healthier life by purchasing a variable annuity. There are actually two types of annuities:- fixed annuities and variable annuities. You will see below why a variable annuity protects against inflationary risk in ways that a fixed annuity does not. Like life insurance, a variable annuity (and a fixed annuity, for that matter) is a contract between an investor and an insurance company. In the case of life insurance, the investor puts money into the contract by paying a premium in return for payment of a certain face amount of money to a beneficiary if the investor dies. A variable annuity customer also puts money into an annuity contract, either all at once or periodically. However, that's where the similarities between life insurance and variable annuities end. Whereas life insurance protects a beneficiary against the untimely death of the policyholder, a variable annuity protects the annuity contract owner from the financial and emotional hazards of living too long! / Изменяемый Договор – договор страхования с переменной суммой.

VARIABLE CONTRIBUTION MARGIN = ИЗМЕНЯЕМАЯ КОНТРИБУЦИОННАЯ МАРЖА (или ПЕРЕМЕННАЯ КОНТРИБУЦИОННАЯ МАРЖА) – Variable Contribution Margin is the margin that results when variable production costs are subtracted from revenue. It is most useful for making incremental pricing decisions where an entity must cover its variable costs, though not necessarily all of its fixed costs. It is particularly useful when determining margins for short-term pricing decisions, such as pricing a single order to a customer. It is not advisable to set a price that results in a small or negative variable contribution margin, since the seller will be unable to earn a profit. The concept is least useful for long-term pricing decisions, where a company must set prices high enough to cover its fixed costs. The steps needed to calculate the variable contribution margin for a product or service are:- (i) Determine The Price:- this is the amount at which a product or service sells, minus any allowances for doubtful accounts or reductions for early payment discounts; (ii) Determine Variable Costs:- this includes only those costs that vary directly with the volume of units sold. If the calculation is being made for a product, this typically includes direct materials, commissions, and inbound and outbound shipping costs. If the calculation is being made for services, this typically includes the cost of labor, variable benefits, payroll taxes, and commissions. (iii) Subtract All Variable Costs From The Price:- this results in the variable contribution margin. Costs that should not be included in the variable contribution margin calculation include factory overhead (such as rent, supervisory salaries, and machine maintenance) and selling and administrative expenses (with the exception of commissions). The variable contribution margin differs from the gross margin in that the gross margin also incorporates factory overhead costs, which can result in significantly lower margins. A margin analysis using gross margin information is not as useful for incremental pricing decisions, since it includes allocated overhead costs that may not be relevant. Example of Variable Contribution Margin:- ABC International wants to determine the variable contribution margin associated with the sale of its green widget product. The widget sells for a net price of USD10. Its variable costs are USD3.50 for materials, USD0.25 for inbound freight, and USD0.50 for a sales commission. The calculation is:- USD10 Price – (USD3.50 Materials + USD0.25 Freight + USD0.50 Commission) = USD5.75 Variable Contribution Margin. The USD5.75 variable contribution margin represents margin that is available for the payment of fixed costs. Also known as Contribution Margin.

VARIABLE COST = ПЕРЕМЕННАЯ ЗАТРАТА (или ИЗМЕНЯЕМАЯ ИЗДЕРЖКА) – Variable Cost is a cost that changes in relation to variations in an activity. In a business, the 'activity' is frequently production volume, with sales volume being another likely triggering event. Thus, the materials used as the components in a product are considered variable costs, because they vary directly with the number of units of product produced. It is extremely useful to understand the proportion of variable costs in a business, since a high proportion means that a business can continue to function at a relatively low revenue level. Conversely, a high proportion of fixed costs requires that a business maintain a high revenue level in order to stay in business. Here are a number of examples of variable costs, all in a production setting:- (i) Direct Materials:- the most purely variable cost of all, these are the raw materials that go into a product; (ii) Piece Tate Labor:- this is the amount paid to workers for every unit completed (note:- direct labor is frequently not a variable cost, since a minimum number of people are needed to staff the production area; this makes it a fixed cost); (iii) Production Supplies:- things like machinery oil are consumed based on the amount of machinery usage, so these costs vary with production volume; (iv) Billable Staff Wages:- if a company bills out the time of its employees, and those employees are only paid if they work billable hours, then this is a variable cost; however, if they are paid salaries (where they are paid no matter how many hours they work), then this is a fixed cost; (v) Commissions:- salespeople are paid a commission only if they sell products or services, so this is clearly a variable cost; (vi) Credit Card Fees:- fees are only charged to a business if it accepts credit card purchases from customers; only the credit card fees that are a percentage of sales (i.e. not the monthly fixed fee) should be considered variable; and (vii) Freight Out:- a business incurs a shipping cost only when it sells and ships out a product; thus, freight out can be considered a variable cost. In most organizations, the bulk of all expenses are fixed costs, and represent the overhead that an organization must incur to operate on a daily basis. There tend to be far fewer variable costs. Variable Cost is a cost that is directly proportional to the volume of output produced. When production is zero, the variable cost is equal to zero. Variable Cost is a cost that varies in relation to changes in the volume of activity. The variable cost concept can be used to model the future financial performance of a business, as well as to set minimum price points. The most common variable costs are:- (i) Direct Materials, since the cost of materials are charged to expense when the associated products are sold; (ii) Commissions, since the sales staff earns commissions when sales transactions are completed; (iii) Billable Labor, since wages associated with billable hours are charged to expense when the associated sales transactions are completed; (iv) Piece Rate Labor, where employees are paid based on the number of units produced; and (v) Credit Card Fees, where a fee is not incurred unless a customer uses a credit card to pay for a purchase. Direct labor may not be a variable cost if labor is not added to or subtracted from the production process as production volumes change. This situation arises when a production line must be staffed, irrespective of the amount of production volume. Overhead is not a variable cost, since overhead costs will be incurred, irrespective of production levels. For example, both rent and machine depreciation, which are overhead costs, will be incurred even if there is no production activity. A

company with a high proportion of variable costs can usually generate a profit at a relatively low sales level, since there are few fixed costs that must also be paid for in each accounting period. Variable Cost is:- (1) costs that vary; (2) costs incurred from energy generation or transportation and delivery which change in proportion to the amount of energy used; and (3) include costs of fuel, operating expenses, equipment and facility maintenance charges, and depreciation from wear and tear on equipment among others. Variable Cost:- costs that vary directly with the level of activity within a short time. Examples include costs of moving cargo inland on trains or trucks, stevedoring in some ports, and short-term equipment leases. For business analysis, all costs are either defined as variable or fixed. For a business to break even, all fixed costs must be covered. To make a profit, all variable and fixed costs must be recovered plus some extra amount. Variable Cost is a cost that varies in relation to the level of operational activity.

VARIABLE COSTING = ИЗМЕНЯЕМОЕ НЕСЕНИЕ ИЗДЕРЖЕК (или ПЕРЕМЕННОЕ НЕСЕНИЕ ЗАТРАТ) – Variable Costing is a methodology that only assigns variable costs to inventory. This approach means that all overhead costs are charged to expense in the period incurred, while direct materials and variable overhead costs are assigned to inventory. There are no uses for variable costing in financial reporting, since the accounting frameworks (such as US Generally Accepted Accounting Principles (GAAP) and International Financial Reporting Standards (IFRS)) require that overhead also be allocated to inventory. Consequently, this methodology is only used for internal reporting purposes. However, it is quite commonly used in this role, where variable costs are used to:- (i) conduct breakeven analysis to determine the sales level at which a business earns a zero profit; (ii) establish the lowest possible cost at which a product can be sold; and (iii) formulate internal financial statements into a contribution margin format (which must be adjusted before they can be issued to outside parties). When variable costing is used, the gross margin reported from a revenue-generating transaction is higher than under an absorption costing system, since no overhead allocation is charged to the sale. Though this does mean that the reported gross margin is higher, it does not mean that net profits are higher – the overhead is charged to expense lower in the income statement instead. However, this is only the case when the level of production matches sales. If production exceeds sales, absorption costing will result in a higher level of profitability, since some of the allocated overhead will reside in the inventory asset, rather than being charged to expense in the period. The reverse situation occurs when sales exceed production. / Изменяемое Расходование или Директ Костинг (Variable Costing):- метод учёта переменных расходов; метод учёта затрат и калькулирования себестоимости, согласно которому только переменные производственные расходы включаются в себестоимость продукции и, следовательно, в оценку конечных запасов, а постоянные общепроизводственные расходы учитываются как периодические текущие расходы. Сравните с Методом Учёта Полных Расходов (Absorption Costing). Известно также как Прямое Расходование (Direct Costing); и Маржинальное Расходование (Marginal Costing).

VARIABLE COSTING INCOME STATEMENT = ОТЧЁТ О ДОХОДАХ ИЗМЕНЯЕМОГО НЕСЕНИЯ ИЗДЕРЖЕК (или ОТЧЁТ О ДОХОДАХ ПЕРЕМЕННОГО НЕСЕНИЯ ЗАТРАТ) – Variable Costing Income Statement is one in which all variable expenses are deducted from revenue to arrive at a separately-stated contribution margin, from which all fixed expenses are then subtracted to arrive at the net profit or loss for the period. It is useful to create an income statement in the variable costing format when you want to determine that proportion of expenses that truly varies directly with revenues. In many businesses, the contribution margin will be substantially higher than the gross margin, because such a large amount of its production costs are fixed, and very few of its selling and administrative expenses are variable. A variable income statement varies from a normal income statement in three respects:- (i) all fixed production costs are aggregated lower in the statement, after the contribution margin; (ii) all variable selling and administrative expenses are grouped with variable production costs, so that they are a part of the calculation of the contribution margin; and (iii) gross margin is replaced by the contribution margin. Thus, the format of a variable costing income statement is:- + Revenues; – Variable Production Expenses (such as materials, supplies, and variable overhead); – Variable Selling And Administrative Expenses; = Contribution Margin; – Fixed Production Expenses (including most overhead); – Fixed Selling And Administrative Expenses; = Net Profit Or Loss. In many cases, direct labor should be categorized as a fixed expense in this income statement format, rather than a variable expense, because this cost does not usually change in direct proportion to the amount of revenue generated. Instead, management needs to keep a certain number of employees in the production area within a certain production volume range. The key difference between gross margin and contribution margin is that fixed production costs are included in the cost of goods sold to arrive at the gross margin, whereas fixed production costs are not included in the same calculation for the contribution margin. This means that the variable costing income statement is sorted based on the variability of the underlying cost information, rather than by the functional areas or expense categories that are found in a more typical income statement. Under both the variable costing income statement and a normal income statement, the net profit or loss will be the same.

VARIABLE COST–PLUS PRICING = ИЗМЕНЯЕМОЕ ЦЕНООБРАЗОВАНИЕ С УЧЁТОМ ПРИПЛЮСОВЫВАНИЯ ИЗДЕРЖЕК (или ПЕРЕМЕННОЕ ЦЕНООБРАЗОВАНИЕ С УЧЁТОМ ПРИПЛЮСОВЫВАНИЯ ЗАТРАТ) – Variable Cost-Plus Pricing is a system for developing prices that adds a markup to the total amount of variable costs incurred. Examples of the variable costs incurred are direct materials and direct labor. For the seller to earn a profit under this pricing arrangement, the markup percentage must be sufficiently high to cover fixed costs and administrative costs, as well as a reasonable profit. This approach can work well when variable costs comprise the bulk of all costs incurred. However, it can result in unusual outcomes when variable costs comprise just a small proportion of total costs, since the markup multiplier may result in an unusually high or low price. Another situation in which variable cost-plus pricing can be used is when a company will not incur any additional fixed costs for each additional unit sold (a common occurrence when there is excess capacity). In this case, variable costs are the same as total costs, so the effect is the same as would be the case for cost-plus pricing. For example, a manufacturer uses variable cost-plus pricing to develop a quote for a purple widget. The variable cost to produce one of these widgets is USD20, and the firm uses a 40% markup percentage. This results in a quoted price of USD28, which is calculated as follows:- USD20 Variable Costs x 1.4 Markup Percentage = USD28 Price. The company has fixed costs that are allocated at USD6 per unit, which results in a total cost of USD26. Since the price is USD28, the company earns a USD2 profit on the sale of each unit. Variable Cost-Plus Pricing is a pricing method in which the selling price is established by adding a markup to total variable costs. The expectation is that the markup will contribute to meeting all or a part of fixed costs, and generate some level of profit. Variable cost-plus pricing is especially useful in competitive scenarios such as contract bidding, but is not suitable in situations where fixed costs are a major component of total costs. For example, assume total variable costs for manufacturing one unit of a product are USD10 and a markup of 50% is added. The selling price as determined by this variable cost-plus pricing method would be USD15. If contribution to fixed costs per unit is estimated at USD4, then profit per unit would be USD1.

VARIABLE COST PRICING = ЦЕНООБРАЗОВАНИЕ НА ОСНОВЕ ПЕРЕМЕННЫХ ИЗДЕРЖЕК (или ЦЕНООБРАЗОВАНИЕ НА ОСНОВЕ ИЗМЕНЯЕМЫХ ЗАТРАТ) – Variable Cost Pricing:- there are many ways to set prices based on costs, but one of the most flexible is variable cost pricing. In this lesson, we learn what it is and how to use it, and look at an example of it in action. What Is Variable Cost Pricing? When you are setting prices for a good or service, there are a number of different models that you can follow – you don't have to just make up a price and slap a sticker on the side of your good. For goods that have high fixed costs and low variable costs, variable cost pricing is a form that's worth considering. Variable cost pricing allows for a company to set the price directly from the variable cost, or the cost of producing that one extra unit. While the variable cost does not have to consider the

equipment or processing, since it is already taken into account, it does have to consider additional labor, materials, and processing, among other things. This is then added to the markup, which accounts for recouping any fixed costs in addition to the profit a company hopes to make. In this lesson, we'll see how variable cost pricing is calculated and look at an example of it in action. How Is it Used? In order to use variable cost pricing, we first must know three pieces of information. First, we should know our variable cost per item. No matter what, we will never sell a good for less than this. Second, we need to know the amount of profit that we want to make. Third, we should know the total fixed costs. Then, add the fixed cost to the total profit and divide by the number of units. Like I mentioned earlier, this gives us our markup. Ideally, we should always sell a variable cost priced good for the price of markup plus the variable cost. However, that is not always possible. Sometimes, it is to our advantage to simply sell the good at a price higher than the variable cost. Variable Cost Pricing is an approach to pricing which defines a cost base as all variable costs and excludes fixed manufacturing costs and fixed selling and administrative costs. / Изменяемое Ценообразование Расходов:- метод ценообразования на основе переменных расходов. Один из основных (расходных) подходов к установлению цены, согласно которому цена рассчитывается как определённый процент от суммы переменных производственных затрат на данный продукт.

VARIABLE COST RATIO = СООТНОШЕНИЕ С ИЗМЕНЯЕМЫМИ ИЗДЕРЖКАМИ (или СООТНОШЕНИЕ С ПЕРЕМЕННЫМИ ЗАТРАТАМИ) – Variable Cost Ratio reveals the total amount of variable expenses incurred by a business, stated as a proportion of its net sales. For example, if the price of a product is USD100 and its variable expenses are USD60, then the product's variable cost ratio is 60%. This ratio is useful at the product level, in order to understand the amount of margin remaining after variable costs have been deducted from a sale. This is known as the Contribution Margin, and is calculated as 1 minus the variable cost ratio. The variable cost ratio is also useful at the organizational level, to determine the amount of fixed costs that it incurs. A high variable cost ratio implies that a business can earn a profit at a relatively low sales level, since there are few fixed costs to pay for. A low variable cost ratio implies that the breakeven sales level is high, in order to pay for the large base of fixed costs.

VARIABLE COSTS = ПЕРЕМЕННЫЕ ИЗДЕРЖКИ (или ИЗМЕНЯЕМЫЕ ЗАТРАТЫ) – (1) Variable Costs:- business operating expenses that vary with the volume of output, as opposed to Fixed Costs. Variable costs fluctuate in direct proportion to the volume of production and sales. They primarily include raw materials, direct labor, energy used in production, and direct marketing expenses (delivery costs, brokerage fees, commissions and bonuses). Identifying fixed and variable costs is of fundamental importance in cost analysis to accurately compute cost of sales. Examples include costs of moving cargo inland on trains or trucks, stevedoring in some ports, and short-term equipment leases. For a business to break even, all fixed costs must be covered. To make a profit, all variable and fixed costs must be recovered plus some extra amount. Also known as Direct Costs. Variable Costs are those costs associated with production that changes directly with the amount of production, e.g., the direct material or labor required to complete the build or manufacturing of a product. The difference between Fixed Costs and Variable Costs is that fixed costs do not change with activity volumes, while variable costs are closely linked to activity volumes. When a cost contains elements of both fixed and variable costs, it is considered a mixed cost. This difference is a key part of understanding the financial characteristics of a business. If the cost structure is comprised mostly of fixed costs (such as an oil refinery), managers are more likely to accept low-priced offers for their products in order to generate sufficient sales to cover their fixed costs. This can lead to a heightened level of competition within an industry, since they all likely have the same cost structure, and must all cover their fixed costs. Once fixed costs have been paid for, all additional sales typically have quite high margins. This means that a high fixed-cost business can make very large profits when sales spike, but can incur equally large losses when sales decline. If the cost structure is comprised mostly of variable costs (such as a services business), managers need to turn a profit on every sale, and so are less inclined to accept low-priced offers from customers. These businesses can easily cover their small amounts of fixed costs. Variable costs tend to comprise a relatively high proportion of sales, so the profits generated on each individual sale once fixed costs have been covered tend to be lower than under a high fixed cost scenario. Examples of fixed costs are rent, insurance, depreciation, salaries, and utilities. Examples of variable expenses are direct materials, sales commissions, and credit card fees. Variable Costs are costs that vary with the amount produced. Examples are materials, fuel, production labour and maintenance. As the relevant time period is extended, more costs become variable. See also Costs, and Fixed Costs. Variable Cost is a cost of producing the product which a company sells. It would include such items as materials and labor that go directly into producing the shipped item. Another term for this is direct cost. These costs are usually shown directly under revenues on an income statement as the first costs associated with producing the revenues that are recorded. Variable Costs are the total costs incurred to produce energy, excluding fixed costs which are incurred regardless of whether the resource is operating. Variable costs usually include fuel, increased maintenance and additional labor. / Операционные расходы предприятия, изменяющиеся в зависимости от объёма выработки (выпуска) продукции, в противоположность Постоянным или Фиксированным Издержкам (или Затратам). Переменные Издержки:- совокупные издержки, понесённые при производстве электроэнергии, за исключением постоянных издержек, понесённых вне зависимости от того, эксплуатировался ли тот или иной ресурс. Переменные издержки, как правило, включают в себя стоимость топлива, дополнительные затраты на обслуживание и дополнительные трудозатраты. Переменные Издержки изменяются в прямой пропорции к объёму производства и продаж. К ним, главным образом, относятся материальные ресурсы или сырьё, рабочий труд, энергия, используемая для производства, и прямые расходы по реализации (затраты на доставку, брокерское вознаграждение, комиссионные или бонусы). Определение фиксированных или переменных издержек (или затрат) имеет принципиальное значение в анализе издержек для точного расчёта затрат на продажу. В качестве примера, можно выделить затраты на наземную перевозку грузов поездами или грузовиками, перевалка в некоторых портах, и краткосрочный лизинг оборудования. Чтобы предприятие самоокупалось, все фиксированные издержки (или затраты) должны покрываться. А для получения прибыли все переменные и фиксированные издержки (или затраты) должны быть перекрыты с лихвой. Известны также как Прямые Затраты или Прямые Издержки (Direct Costs). Переменные Расходы или Переменные Издержки или Переменные Затраты:- расходы, которые в сумме изменяются прямо пропорционально с изменением количества произведённой продукции (или другого объёмного показателя). В расчёте на единицу готовой продукции остаются постоянными; к ним относятся прямые расходы материалов, прямые затраты труда и отдельные виды общепроизводственных расходов и коммерческих расходов. Смотрите также Накладные Расходы (Overhead Costs). Переменные Издержки – издержки, напрямую зависящие от объёма производства, например, прямые расходы на материалы или оплату труда, необходимые для создания законченного продукта. Смотрите также Фиксированные Издержки (Fixed Costs).

(2) Variable Costs:- the total costs incurred to produce energy, excluding fixed costs which are incurred regardless of whether the resource is operating. Variable costs usually include fuel, increased maintenance and additional labor. / Совокупные издержки, понесённые при производстве электроэнергии, за исключением постоянных или фиксированных издержек (или затрат), понесённых вне зависимости от того, эксплуатируется ли тот или иной ресурс. Переменные издержки, как правило, включают в себя стоимость топлива, дополнительные затраты на обслуживание и дополнительные трудозатраты.

(3) Variable Costs:- (1) The portion of total cash production costs used for inputs needed to produce a specific yield of a specific crop. Variable costs typically include fertilizers, seed, pesticides, hired labor, fuel, repairs, and animal feed and drugs. (2) Costs that vary in

the aggregate with a change in output of a farm. In the short run, there are both fixed and variable costs; in the long run, all costs are variable. Variable Costs are the costs that change in direct proportion to output. For example, the cost of livestock feed is a variable cost because the amount of feed used varies in direct proportion to the number of livestock.

VARIABLE DISPLACEMENT PUMP = НАСОС С РЕГУЛИРУЕМЫМ ВЫТЕСНЕНИЕМ – A Variable Displacement Pump is a device that converts mechanical energy to hydraulic (fluid) energy. The displacement, or amount of fluid pumped per revolution of the pump's input shaft can be varied while the pump is running. Many variable displacement pumps are 'reversible', meaning that they can act as a hydraulic motor and convert fluid energy into mechanical energy. Types:- a common variable displacement pump used in vehicle technology is the Axial Piston Pump. This pump has several pistons in cylinders arranged parallel to each other and rotating around a central shaft. A swashplate at one end is connected to the pistons. As the pistons rotate, the angle of the plate causes them to move in and out of their cylinders. A rotary valve at the opposite end from the swashplate alternately connects each cylinder to the fluid supply and delivery lines. By changing the angle of the swashplate, the stroke of the pistons can be varied continuously. If the swashplate is perpendicular to the axis of rotation, no fluid will flow. If it is at a sharp angle, a large volume of fluid will be pumped. Some pumps allow the swashplate to be moved in both directions from the zero position, pumping fluid in either direction without reversing the rotation of the pump. An efficient variation is the Bent Axis Pump. Bending the axis reduces side loads on the pistons. Piston pumps can be made variable-displacement by inserting springs inline with the pistons. The displacement is not positively controlled, but decreases as back-pressure increases. Another variation is the Variable Displacement Vane Pump. Variable Displacement Pump is a pump in which the displacement per cycle can be varied. See also Pump. Variable Displacement Pumps:- in a variable-displacement pump, the flow rate and outlet pressure can be changed as the pump operates. This results in pumps that are:- (i) more complex; (ii) more expensive; and (iii) capable of doing a wider variety of jobs. The most common type of variable-displacement pump is the rotary vane pump, which is a variation of the gear pump in which the 'gear' is offset and the 'cogs' aren't fixed, but rather extend and retract as the gear turns, allowing the pump to increase the pressure of the fluid by compacting it as it pushes the fluid through. The top-tier pumps, however, are bent-axis piston-and-cylinder pumps, much like the ones that are used in an internal combustion engine. Simple, fixed-displacement pumps are perfect for single jobs that need to be repeated indefinitely over long periods of time; variable-displacement pumps can be used to power a wider variety of tools, but require more expense and more attention.

VARIABLE EXPENSES = ПЕРЕМЕННЫЕ РАСХОДЫ (или ИЗМЕНЯЕМЫЕ РАСХОДЫ) – Variable Expenses are those business expenses that usually fluctuate dependent upon production or sales volume. Contrast with Fixed Expenses. Variable Expense is a cost that alters in conjunction with some type of activity. For example, the direct materials expense increases as sales increase. Other variable expenses are commissions, billable labor, piece rate labor, and credit card fees. A business has few truly variable expenses. Many other expenses, such as rent expense, are fixed within a certain activity range. A business that has a high proportion of variable expenses can usually generate a profit on a low sales level. The reason is that there are few fixed expenses to be paid for in each month. When setting prices, one should ensure that at least the variable expenses are included in the price. That way, the business will not lose money when each unit of a product is sold. Variable Expenses:- expences that are related to the level of activity and vary with output. Examples of variable expenses are the cost of raw materials and of energy used in production. Variable Expenses are expenses that fluctuate with the amount of sales produced, typically as a predictable percentage of sales. Examples include sales commission, delivery expenses and advertising. See also Fixed Expense. / выработка (output).

VARIABLE FUEL VEHICLE = ТРАНСПОРТНОЕ СРЕДСТВО С ИЗМЕНЯЕМЫМ ТОПЛИВОМ (или ТРАНСПОРТНОЕ СРЕДСТВО С ИЗМЕНЯЕМЫМ ТОПЛИВОМ) – Variable Fuel Vehicle (VFV) is a vehicle that has the capacity of burning any combination of gasoline and an alternative fuel. Also known as Flexible-Fuel Vehicle. See also Flexible Fuel Vehicle.

VARIABLE GEOMETRY AIRFOILS = ПЕРЕМЕННЫЕ ГЕОМЕТРИЧЕСКИЕ КРЫЛЬЯ (или КРЫЛЬЯ С ИЗМЕНЯЕМОЙ ГЕОМЕТРИЕЙ, или КРЫЛЬЯ С МЕНЯЮЩЕЙСЯ ГЕОМЕТРИЕЙ) – Variable Geometry Airfoils:- use trailing edge flaps or tabs, or leading edge slats or pivoted nose droop, the position of which can be controlled in flight. A Variable Geometry Wingtip is comprised of two deformable yet relatively stiff airfoils that work in compression and tension against each other to change shape. There is only one moving part in the assembly with no internal mechanisms to facilitate morphing. The wingtip consists of a lower airfoil and an upper airfoil. The base of the lower airfoil is mounted horizontally to an under surface of an outboard end of a wing. The upper airfoil has a portion which is allowed to retract and extend from an upper surface of the outboard end of the wing. A single projecting wingtip is formed at an intersection of the lower and upper airfoils.

VARIABLE HEDGING = ИЗМЕНЯЕМОЕ ХЭДЬЖИРОВАНИЕ (или ПЕРЕМЕННОЕ ХЭДЬЖИРОВАНИЕ) – Variable Hedging:- xxxxx. / Переменное Хэдьжирование:- . Смотрите также Формирование Пропорциональной Курсовой Разницы (Ratio Spreading).

VARIABLE IMPORT LEVY = ИЗМЕНЯЕМЫЙ ПРИВОЗНОЙ СБОР (или ПЕРЕМЕННЫЙ ИМПОРТНЫЙ СБОР) – Variable (Import) Levy:- the difference between the price of a foreign product at the port and the official price at which competitive imports can be sold. Such levies are effectively a variable tax on imports or a variable subsidy to exports. Variable levies are used by the European Union and Switzerland. Variable Import Levy is employed to protect domestic price guarantees from being defeated by trade flows. A Variable Import Levy is a levy on imports that raises their price to a level at least as high as the domestic price. Such levies are adjusted frequently (hence variable) in response to changes in world market prices, and are imposed to defend administered prices set above world market prices. Under the Uruguay Round Agreement on Agriculture, the variable levies of the EU have been converted into fixed tariffs or tariff-rate quotas. / Изменяемый Сбор На Привоз или Переменная Импортная Пошлина:- налог, взимаемый с некоторых сельскохозяйственных продуктов (например, ряда Зерновых), который меняется таким образом, чтобы довести цену привоза (или импорта) в ЕС примерно до желательного в ЕС уровня. Во время переходного этапа эти налоги применяли в торговле между странами-членами, так что поставщики из Сообщества имели преимущество перед другими источниками снабжения. Налоги внутри ЕС упразднены на этапе реализации законченного Общего Рынка. Синоним – Изменяемый Сбор (Variable Levy).

VARIABLE INCOME STOCK = АКЦИЯ С ИЗМЕНЯЕМЫМ ДОХОДОМ (или АКЦИЯ С ПЕРЕМЕННЫМ ДОХОДОМ) – A term Variable Income Stock refers to investments that provide their owners with a rate of return that is dynamic and determined by market forces. Variable-income securities provide investors with both greater risks as well as rewards. Explanation:- variable-income securities, also known as Variable-Rate Securities, are typically valued by investors looking for higher returns than those offered by fixed-income securities. The classic example of a variable-income security is common stock, which can offer investors virtually unlimited up-side growth as well as the complete loss of principal. In exchange for this risk, investors in these securities demand higher returns than their fixed-income counterparts. In addition to common stocks, examples of variable-income securities include:- (i) Variable Rate Demand Obligations (VRDO):- municipal bonds that have long-term maturities that reset on a relatively short-term basis; and (ii) Floating Rate Notes (FRN):- bonds that feature a variable rate coupon, typically indexed to a money market rate such as federal funds or LIBOR plus a margin spread. The rate of interest on FRNs will increase or decrease quarterly based on the auction rates of 13-week

Treasury bills. / Акция С Переменным Доходом:- акция, как правило обыкновенная, дивиденд и доход по которой зависят от искусства фирмы реализовывать прибыль.

VARIABLE INTEREST ENTITY = ЮРИДИЧЕСКОЕ ЛИЦО С ИЗМЕНЯЕМЫМ ДОЛЕВЫМ УЧАСТИЕМ – Variable Interest Entity (VIE) is a legal entity in which an investor holds a controlling interest, despite not having a majority of its share ownership. A VIE has the following characteristics:- (i) the entity's equity is not sufficient to support its operations; (ii) residual equity holders do not control the VIE; and (iii) residual equity holders are shielded from the gains and losses normally associated with ownership. If an investor is the primary beneficiary of such an entity, the investor must consolidate its financial statements with those of the VIE. The primary beneficiary is the one that can direct the most significant economic activities of the VIE. Variable interest entities are used as special purpose vehicles to finance certain investments without putting the parent entity at risk of loss.

VARIABLE INTEREST RATE = ИЗМЕНЯЕМАЯ ПРОЦЕНТНАЯ СТАВКА (или ПЕРЕМЕННАЯ ПРОЦЕНТНАЯ СТАВКА, или ПЛАВАЮЩАЯ ПРОЦЕНТНАЯ СТАВКА) – Variable Interest Rate is the interest rate which may be changed during the term of a loan or a bond issue. Many international credits and bonds are periodically aligned to the London Euromoney market rate. See also Floating Rate Bond. Variable Interest Rate is an interest rate that moves up and down based on the changes of an underlying interest rate index, e.g., a credit card might have a variable rate that is a certain spread over the prime rate. Variable Interest Rate is an interest rate on a loan or security that fluctuates over time, because it is based on an underlying benchmark interest rate or index that changes periodically. The obvious advantage of a variable interest rate is that if the underlying interest rate or index declines, the borrower's interest payments also fall. Conversely, if the underlying index rises, interest payments increase. The underlying benchmark interest rate or index for a variable interest rate depends on the type of loan or security. Variable interest rates for mortgages, automobiles and credit cards may be based on a benchmark rate such as the prime rate in a country. Banks and financial institutions charge consumers a spread over this benchmark rate, with the spread depending on a number of factors, such as the type of asset and the consumer's credit rating. Variable Interest Rate Credit Cards:- variable interest rate credit cards have an annual percentage rate (APR) tied to a particular index, such as the prime rate. The prime rate most commonly changes when the Federal Reserve adjusts the federal funds rate, resulting in a change in the rate of the associated credit card. The rates on variable interest rate credit cards can change without advance notice to the cardholder. Within the 'terms and conditions' document associated with the credit card, the interest rate is most commonly expressed as the prime rate plus a particular percentage, with the listed percentage being tied to the credit worthiness of the credit card holder. An example of the format is the prime rate +11.9%. Variable Interest Rate Loans and Mortgages:- variable interest rate loans function similarly to credit cards except for the payment schedule. While a credit card is considered a revolving line of credit, most loans are installment loans, with a specified number of payments, leading to the loan being paid off by a particular date. As interest rates vary, the required payment will go up or down according to the change in rate and the number of payments remaining before completion. When a mortgage has a variable interest rate, it is more commonly referred to as an Adjustable Rate Mortgage (ARM). Additionally, many ARMs start with a low, fixed interest rate for the first few years of the loan, only adjusting after that time period has expired. Common fixed interest rate periods on an ARM are three or five years, expressed as a 3/1 or 5/1 ARM respectively. Variable Interest Rate Bonds:- for variable interest rate bonds, the benchmark rate may be the London Interbank Offered Rate (LIBOR). Some variable rate bonds also use the five-year, 10-year or 30-year US Treasury bond yield as the benchmark interest rate, offering a coupon rate that is set at a certain spread above the yield on US Treasuries. See also Adjustable Rate. / Изменяемая Процентная Ставка или Плавающая Процентная Ставка – ставка кредита, которая изменяется при изменении величины лежащего в её основе индекса процентных ставок. Например, плавающая процентная ставка по многим кредитным картам базируется на определённой курсовой разнице свыше Первоклассной Ставки (Prime Rate). Большинство плавающих ставок кредитов, предоставляемых внутри страны, также привязывается к Первоклассным Ставкам. Называется также Переоцениваемая Процентная Ставка (Adjustable Interest Rate).

VARIABLE INTEREST RATE US SAVINGS BOND = СБЕРЕГАТЕЛЬНАЯ ОБЛИГАЦИЯ США С ИЗМЕНЯЕМОЙ ПРОЦЕНТНОЙ СТАВКОЙ (или XX) – Variable Interest Rate US Savings Bond:- xxxxx. / Сберегательная Облигация США С Изменяемой Процентной Ставкой:- . Смотрите также Сберегательная Облигация США (US Savings Bond).

VARIABLE INTEREST SECURITIES = ЦЕННЫЕ БУМАГИ С ИЗМЕНЯЕМЫМ ПРОЦЕНТОМ (или ЦЕННЫЕ БУМАГИ С ПЕРЕМЕННЫМ ПРОЦЕНТОМ, или ЦЕННЫЕ БУМАГИ С ПЛАВАЮЩИМ ПРОЦЕНТОМ) – Variable Interest Securities:- where the amount of dividends/interest to be payable in future is not fixed and known in advance, e.g., ordinary shares like BP, Glaxo, Microsoft etc. / Би.Пи. (BP), Глаксо (Glaxo), Майкрософт (Microsoft).

VARIABLE LENGTH (OR BIAS CUT) STAPLE FIBERS = ШТАПЕЛЬНЫЕ ВОЛОКНА ИЗМЕНЯЕМОЙ ДЛИНЫ (или XX) – Variable Length (or Bias Cut) Staple Fibers are the staple fibers obtained by cutting in such a way as to deliberately introduce several lengths. Such fibers are specified by two finite nominal lengths corresponding to the limits of the cut length.

VARIABLE LEVY = ИЗМЕНЯЕМЫЙ СБОР (или ПЕРЕМЕННЫЙ СБОР) – Variable Levy is a tax on imports that varies over time so as to stabilize the domestic price of the imported good. Essentially, the tax is set equal to the difference between the target domestic price and the world price. Variable Levy is a tariff subject to alterations as world market prices change, the alterations are designed to assure that the import price after payment of the duty will equal a predetermined 'gate' price. Variable Levy is a tariff that changes in such a way that the domestic price of an imported good always remains the same (or almost the same). A variable levy increases when the raw price of the import drops and decreases when the raw price rises. See also Variable Import Levy. Variable Levy:- a tariff or import tax subject to change as world market prices change. The purpose is to assure that the import price after payment of duty will equal a predetermined set price.

VARIABLE LIFE INSURANCE = ИЗМЕНЯЕМОЕ СТРАХОВАНИЕ ЖИЗНИ (или ПЕРЕМЕННОЕ СТРАХОВАНИЕ ЖИЗНИ) – Variable Life Insurance is a permanent life insurance policy with an investment component. The policy has a cash value account, which is invested in a number of sub-accounts available in the policy. A sub-account acts similar to a mutual fund, except it's only available within a variable life insurance policy. I'm not a huge fan of this type of Life Insurance. I've found people can better serve their protection planning needs with Universal Life policies, with additional benefits for things like Terminal Illness and Chronic Illness riders. With a fully invested portfolio, there is just too much market risk for many people who actually need the underlying life insurance coverage. Bad few years in the market could cause the cash value to drop and put the death benefit in jeopardy when you need it the most. The investment return and principal value of variable sub-accounts will fluctuate. Your cash value, and perhaps the death benefit will be determined by the performance of the chosen sub-accounts. Variable universal life insurance policies typically include mortality and expense risk charges, administrative fees, and fund expense charges. Withdrawals may be taxable and subject to surrender charges. Policy Loans and withdrawal will reduce the policy's cash value and death benefit. Loans are subject to interest charges. Xxxxx. Variable Life Insurance is a permanent form of insurance that builds up cash value but allows you to invest the 'extra' in sub-accounts that are managed by many professional management firms. The process of buying a variable policy is to allow your agent or registered representative to run an illustration showing the premiums required to purchase x amount of insurance that will buildup x

amount of cash based on the sub-account illustrated performance. It sounds complicated, but it really is not. The key is running a policy that will sustain itself to age 95 to 100 with an interest rate of the sub-accounts that is reasonable, usually 7–8%. The sub-account is the insurance industry equivalent to mutual funds so do not get that confused. The market might average 9–10% for the last 100 years, but it is best to run your sub-account assumed performance a little lower than that for a little more security. A good, experienced registered representative should take into account if a variable policy makes sense for your insurance/investment portfolio as many times these types of polices can be abused. Consumers can pay into it for a certain period of time and then change their minds mid-stream causing them significant out of pocket expense and then a possible surrender charge on the cash that they did build up. If the consumer does not make the long term commitment to the plan, they likely will lose quite a bit not to mention the time lost. If kept, the policy can be a great tool for insurance protection and cash value options down the road. However, this plan takes many years to complete and insurance needs change over time. / Переменное Страхование Жизни или Изменяемое Страхование Жизни:- новый вид полного страхования жизни (или пожизненного страхования) вплоть до смерти владельца полиса (whole life insurance), который позволяет инвестировать налично-денежную часть стоимости полиса в акции, облигации или портфели. Инвесторы могут выбрать между возможностью перейти из одного портфеля вложений в другой и передачей средств в управление профессиональным управляющим, которые будут за них принимать эти решения. Как и при полном страховании жизни, ежегодная сумма страховых взносов является фиксированной, но часть этой суммы направляется в соответствующий инвестиционный портфель вложений (portfolio). Владелец страхового полиса принимает на себя риск инвестиций в ценные бумаги, в то время как страховая компания гарантирует минимальную страховую сумму в случае смерти страхователя, не зависящую от убытков по портфелю вложений. В том случае, если стоимость портфеля вложений значительно возрастает, часть увеличившейся наличной стоимости помещается в дополнительное страховое покрытие. Как и в случае полисов полного страхования жизни, страхователь может брать ссуды под обеспечение накопленных наличных средств или средства полиса могут быть обналичены. Так же, как и на индивидуальном пенсионном счёте (individual retirement account), доходы по этим полисам исключаются из налогообложения, пока не будут востребованы со счёта. Налогом облагается только доход, превышающий общую сумму уплаченных по полису страховых взносов. Страховая сумма, выплачиваемая в случае смерти, подлежит налогообложению не как индивидуальный доход, а как наследуемое имущество, исключение которого из налогообложения составляет до 600 000 Долларов США. Переменное страхование жизни отличается от универсального страхования жизни (universal life insurance). Универсальное страхование жизни позволяет владельцам полисов увеличивать или уменьшать размер страховых взносов, а также изменять размер страховых сумм, выплачиваемых в случае смерти. По этому полису также накапливается процентный доход – по ставке, привязанной к рыночной, за вычетом сборов на страхование и прочих расходов.

VARIABLE LIFE INSURANCE POLICY = ПОЛИС ИЗМЕНЯЕМОГО СТРАХОВАНИЯ ЖИЗНИ (или ПОЛИС ПЕРЕМЕННОГО СТРАХОВАНИЯ ЖИЗНИ) – A Variable Life Insurance Policy is a form of permanent life insurance. Variable life insurance provides permanent protection to the beneficiary upon the death of the policyholder. This type of insurance is generally more expensive than term insurance because it allows the insured to allocate a portion of the premium Dollars to a separate account comprised of various instruments and investment funds within the insurance company's portfolio, such as stocks, bonds, equity funds, money market funds and bond funds. Because of investment risks, variable policies are considered securities contracts and are regulated under the federal securities laws; therefore, they must be sold via a prospectus. As a securities product, fund performance may lead to declining cash value or death benefit over time. Variable life insurance policies have certain tax benefits made available to policyholders, such as the ability to utilize cash value on a tax-benefited basis. As long as premiums are paid and the policy remains in force, policyholders can access the cash value through a tax-free loan against the policy. Should cash value be withdrawn instead of borrowed, the policyholder faces tax implications on any realized earnings. Any loans taken out that are not repaid have the potential to decrease the death benefit paid to beneficiaries at the time the insured passes away. Variable Life Insurance Flexibility:- one of the aspects of variable life insurance that makes it stand out among other permanent life insurance policies is the flexibility it provides policyholders in terms of premiums paid and cash value accumulation. Premiums paid to a variable life insurance policy are not fixed as they are with traditional whole life insurance or term insurance. Instead, they can be shifted up or down over time, within certain limits, based on the insured's needs. For example, an insured with a variable life insurance policy may decide to reduce monthly premium payments from USD100 to USD50 because a major expense may have impeded cash flow for a period of time. The cash value within the policy can be used to make up the shortage in premium payments during the time lower premium payments are made. When cash flow returns to a comfortable level, the insured has the option to increase premiums back to the initial USD100 per month. Downsides of Variable Life Insurance:- unlike fixed life insurance products, variable life insurance may require policyholders to add premiums over time to ensure the death benefit remains guaranteed to a certain age. Paying more than the minimum cost of insurance for a variable life insurance policy is one method to ensure guarantees remain intact. Additionally, investment risks within the cash value of a variable life insurance policy fall completely on the policyholder, not the insurance company. As such, there are no guarantees as to how well the cash value may perform over time, making it difficult to plan for using accumulated earnings in the future. Like most life insurance policies, individuals are required to undergo full medical underwriting to obtain a variable life insurance policy. Variable Life Insurance Policy is a whole life insurance policy that provides a death benefit dependent on the insured's portfolio market value at the time of death. Typically the company invests premiums in common stocks, so variable life policies are referred to as Equity-Linked Policies.

VARIABLE LIMIT = ИЗМЕНЯЕМЫЙ ЛИМИТ (или ПЕРЕМЕННЫЙ ЛИМИТ) – Variable Limit is a price system that allows for larger than normal allowable price movements under certain conditions. In periods of extreme volatility, some exchanges permit trading at price levels that exceed regular daily price limits. Variable Limit:- according to the Chicago Board of Trade rules, an expanded allowable price range set during volatile markets. / Изменяемый Лимит:- расширенный допустимый ценовой диапазон в периоды высокой рыночной волатильности. Плавающие Лимиты (Variable Limits):- большинство бирж устанавливают лимит на максимальное дневное движение цены по некоторым фьючерсным контрактам. Они также оставляют за собой право расширить эти лимиты, если движение цены будет превышать лимит в одном направлении в течение двух или трёх торговых дней подряд. Если в таких случаях лимиты изменяются автоматически, они называются плавающими.

VARIABLE LIMIT MARGINS = МАРЖИ ПРИ ИЗМЕНЯЕМОМ ЛИМИТЕ (или МАРЖИ ПРИ ПЕРЕМЕННОМ ЛИМИТЕ) – Variable Limit Margins:- the performance deposit required whenever the daily trading limits on price of a commodity are raised in accordance with exchange rules. In periods of extreme price volatility, some exchanges permit trading at price levels that exceed regular daily limits. At such times, margins are also increased. / Гарантия исполнения, требуемая в соответствии с регламентом биржи всякий раз, когда лимиты изменения цены сырья для ежедневной торговли возрастают. В периоды экстремальной лихорадочности цен некоторые биржи разрешают торговлю по ценам, превосходящим обычные лимиты изменения цен в течение одного дня. В такие моменты ставки маржи также повышаются.

VARIABLE MANUFACTURING COSTS = ИЗМЕНЯЕМЫЕ РАСХОДЫ НА ИЗГОТОВЛЕНИЕ (или ПЕРЕМЕННЫЕ РАСХОДЫ НА ИЗГОТОВЛЕНИЕ, или ХХ) – Variable Manufacturing Costs:- small businesses and new start-ups must keep close watch on their

manufacturing costs to make a profit. The term Variable Manufacturing Cost applies to accounting methods to track business expenses and profits. Depending on the type of accounting system used, the specifics of the variable costs vary widely. Manufacturing Costs:- manufacturing costs include funds spent on direct costs, such as the amount your business spends for the materials and the amount you pay labor to make the items. Transportation of the goods to the marketplace also adds to manufacturing costs. Indirect costs add more to the product. Indirect fees include payments to manufacturing representatives to promote your products. Industrial researchers, including informal studies at Ford Motors and Rolls Royce, link between 70 percent and 90 percent of manufacturing costs to basic product design. Simple designs typically cost less to manufacture. Fixed Costs:- fixed manufacturing costs describe fees required to create the item, and manufacturers must pay these costs to produce the goods. Companies have little room to modify or change the fixed costs since the company must pay these standard costs to produce the goods. General accounting principals group the usual costs associated with the direct manufacture and the labor costs, although these costs do have some flexibility and vary somewhat over time. Variable Costs:- variable costs also include the amount of your company inventory on hand and the cost of storing or warehousing your goods. While the cost of marketing your items and the amount you spend to promote your products might appear to fall under the variable cost category, most accounting methods treat both selling and administrative expenses as period costs, not variable accounting costs. Period costs are paid at at certain times during the year. Your accountant may use period accounting methods in keeping your business books. Wide-Ranging Variables:- some small industries have unplanned cost increases due to fluctuations in certain raw product markets, such as oil. For small businesses, increases in manufacturing costs due to increased oil prices effectively reduce profits. This loss is linked to the limited scale of a small-business production. Large companies have a greater capacity to deal with price fluctuations. One way to control variable costs involves making long-term contracts with suppliers to lock in your prices. This allows your business a firm, fixed price for materials. Long-term labor agreements, if your company uses unionized workers, also provides stable manufacturing costs. Determining Variable Manufacturing Costs:- accounting variables also change with the type of bookkeeping accepted in your manufacturing industry. Absorption costing, a common accounting method, offers one method to artificially increase manufacturing profits by increasing production and storing the excess inventory. Small businesses start-ups have few opportunities to employ this cost accounting method used by large businesses to manipulate variable manufacturing costs. New and small firms have limited inventory and lack the investment money to increase production to the levels necessary to effectively use this accounting system. / Фод Мотоз (Ford Motors) и Ролз Ройс (Rolls Royce). Переменные Производственные Затраты:- виды производственных расходов, которые изменяются прямо пропорционально количеству произведённых единиц продукции. Они включают прямые материальные затраты и переменные общепроизводственные расходы.

VARIABLE OPERATING COST = ПЕРЕМЕННЫЙ ОПЕРАЦИОННЫЙ РАСХОД (или XX) – Variable Operating Cost:- in reference to passenger car operating cost, expenditures which are dependent on the amount of use of the car, such as the cost of gas and oil, tires, and other maintenance.

VARIABLE OVERHEAD = ИЗМЕНЯЕМЫЙ НАКЛАДНОЙ РАСХОД – Variable Overhead is those manufacturing costs that vary roughly in relation to changes in production output. The concept is used to model the future expenditure levels of a business, as well as to determine the lowest possible price at which a product should be sold. Examples of variable overhead are:- (i) Production supplies; (ii) Equipment Utilities; and (iii) Materials Handling Wages. For example, Kelvin Corporation produces 10 000 digital thermometers per month, and its total variable overhead is USD20 000, or USD2.00 per unit. Kelvin ramps up its production to 15 000 thermometers per month, and its variable overhead correspondingly rises to USD30 000, resulting in the variable overhead remaining at USD2.00 per unit. Variable overhead tends to be small in relation to the amount of fixed overhead. Since it varies with production volume, an argument exists that variable overhead should be treated as a direct cost and included in the bill of materials for products. Variable overhead is analyzed with two variances, which are:- (i) Variable Overhead Efficiency Variance:- this is the difference between the actual and budgeted hours worked, which are then applied to the standard variable overhead rate per hour; and (ii) Variable Overhead Spending Variance:- this is the difference between the actual spending and the budgeted rate of spending on variable overhead. The variable overhead concept can also be applied to the administrative side of a business. If so, it refers to those administrative costs that vary with the level of business activity. Since most administrative costs are considered to be fixed, the amount of administrative variable overhead is usually considered to be so small as to not be worth reporting separately. Similar Terms:- Variable Manufacturing Overhead is a subset of variable overhead, because it only includes those variable overhead costs incurred in the manufacturing process. / Келвин Корпорэйшэн (Kelvin Corporation).

VARIABLE OVERHEAD EFFICIENCY VARIANCE = ВАРИАНСА ЭФФЕКТИВНОСТИ ИЗМЕНЯЕМОГО НАКЛАДНОГО РАСХОДА (или XX) – Variable Overhead Efficiency Variance is the difference between the actual and budgeted hours worked, which are then applied to the standard variable overhead rate per hour. The formula is:- Variable Overhead Efficiency Variance = Standard Overhead Rate x (Actual Hours – Standard Hours). A favorable variance means that the actual hours worked were less than the budgeted hours, resulting in the application of the standard overhead rate across fewer hours, resulting in less expense incurred. However, a favorable variance does not necessarily mean that a company has incurred less actual overhead, it simply means that there was an improvement in the allocation base that was used to apply overhead. The variable overhead efficiency variance is a compilation of production expense information submitted by the production department, and the projected labor hours to be worked, as estimated by the industrial engineering and production scheduling staffs, based on historical and projected efficiency and equipment capacity levels. It is entirely possible that an improperly-set standard number of labor hours can result in a variance that does not represent the actual performance of an entity. Consequently, investigation of the variable overhead efficiency variance should encompass a review of the validity of the underlying standard. Variable Overhead Efficiency Variance Example:- the cost accounting staff of Hodgson Industrial Design calculates, based on historical and projected labor patterns, that the company's production staff should work 20 000 hours per month and incur USD400 000 of variable overhead costs per month, so it establishes a variable overhead rate of USD20 per hour. In May, Hodgson Industrial Design installs a new materials handling system that significantly improves production efficiency and drops the hours worked during the month to 19 000. The variable overhead efficiency variance is:- USD20 Standard Overhead Rate/Hour x (19 000 Hours Worked – 20 000 Standard Hours) = USD20 000 Variable Overhead Efficiency Variance. / Ходьжсэн Индэстриэл Дизайн (Hodgson Industrial Design).

VARIABLE OVERHEAD SPENDING VARIANCE = ВАРИАНСА НЕСЕНИЯ ИЗМЕНЯЕМОГО НАКЛАДНОГО РАСХОДА (или XX) – Variable Overhead Spending Variance is the difference between the actual and budgeted rates of spending on variable overhead. The variance is used to focus attention on those overhead costs that vary from expectations. The formula is:- Variable Overhead Spending Variance = Actual Hours Worked x (Actual Overhead Rate – Standard Overhead Rate). A favorable variance means that the actual variable overhead expenses incurred per labor hour were less than expected. The variable overhead spending variance is a compilation of production expense information submitted by the production department, and the projected labor hours to be worked, as estimated by the industrial engineering and production scheduling staffs, based on historical and projected efficiency and equipment capacity levels. There are a number of possible causes of a variable overhead spending variance. For example:- (i) Account Misclassification:- the variable overhead category includes a number of accounts, some of which may have been incorrectly classified

and so do not appear as part of variable overhead (or vice versa); (ii) Outsourcing:- some activities that had been sourced in-house have now been shifted to a supplier, or vice versa; and (iii) Supplier Pricing:- suppliers have changed their prices, which have not yet been reflected in updated standards. The variable overhead spending concept is most applicable in situations where the production process is tightly controlled, as is the case when large numbers of identical units are produced. The other component of the total variable overhead variance is the variable overhead efficiency variance. Variable Overhead Spending Variance Example:- the cost accounting staff of Hodgson Industrial Design calculates, based on historical and projected cost patterns, that the company should experience a variable overhead rate of USD20 per labor hour worked, and builds this figure into the budget. In April, the actual variable overhead rate turns out to be USD22 per labor hour. During that month, production employees work 18 000 hours. The variable overhead spending variance is:- 18 000 Actual Hours Worked x (USD22 Actual Variable Overhead Rate – USD20 Standard Overhead Rate) = USD36 000 Variable Overhead Spending Variance. / Ходьжсэн Индэстриэл Дизайн (Hodgson Industrial Design).

VARIABLE PLAN = ИЗМЕНЯЕМЫЙ ПЛАН (или ПЕРЕМЕННЫЙ ПЛАН) – Variable Plan is a plan in which either the number of shares and/or the price at which they will be issued is not known on the grant date.

VARIABLE PRICE LIMIT = ИЗМЕНЯЕМЫЙ ЛИМИТ ЦЕНЫ (или ПЕРЕМЕННЫЙ ЛИМИТ ЦЕНЫ) – Variable Price Limit is a price limit schedule, determined by an exchange, that permits variations above or below the normally allowable price movement for any one trading day.

VARIABLE–PRICE SECURITY = ЦЕННАЯ БУМАГА С ИЗМЕНЯЕМОЙ ЦЕНОЙ (или ЦЕННАЯ БУМАГА С ПЕРЕМЕННОЙ ЦЕНОЙ) – Variable-Price Security is a security with a constantly changing or periodically changing price based on market forces. Most stocks, bonds and derivatives are variable-price securities, while most certificates of deposit have a price that doesn't change, in comparison. Variable-Price Security is a security that sells at a fluctuating market-determined price stocks and bonds are example.

VARIABLE PRICING = ИЗМЕНЯЕМОЕ ЦЕНООБРАЗОВАНИЕ (или ПЕРЕМЕННОЕ ЦЕНООБРАЗОВАНИЕ) – Variable Pricing is a system for altering the price of a product or service based on the current levels of supply and demand. It is commonly employed in environments where supply and demand information is easily available. For example, the price of an item that is being sold through an auction will change depending upon the amount of demand for it, as evidenced by bid prices. The same principle works in a stock market, where the sale of new shares by a company will increase the supply, thereby dropping the stock price; conversely, intense demand to own a company's shares will increase the price of the shares on the market. Yet another example is airline seats, where an airline can adjust its pricing based on the number of seats that have already been sold. Variable pricing also follows the business cycle. For example, the price of lawn mowers is high as the summer season approaches, since this is when demand spikes. Once the summer season is over, prices decline because there is little demand and sellers want to clear out their excess inventories. Some companies refuse to use variable pricing, because they find that it annoys customers. For example, someone who paid a high price for a seat on an airplane will be annoyed if he finds that the person sitting next to him spent a fraction of that amount. Variable pricing also does not work in situations where pricing is physically fixed, such as when prices are manually affixed to goods. Variable Pricing (or Variable Rate):- (i) a price for a product or service that changes over time; (ii) a price for a given quantity of that product or service that change over time; and (iii) used to insure that customer billings reflect the actual value of energy at the time it is consumed.

VARIABLE PRODUCTION OVERHEADS = ИЗМЕНЯЕМЫЕ ПРОИЗВОДСТВЕННЫЕ НАКЛАДНЫЕ РАСХОДЫ – Variable Production Overheads:- those indirect costs of production that vary directly, or nearly directly, with the volume of production, such as indirect materials and indirect labour. Variable Manufacturing Overhead Cost:- the indirect manufacturing costs that will change in proportion to the change in an activity such as machine hours. For example, a portion of a manufacturer's electricity cost will vary with the change in the number of machine hours worked. Variable Overhead is those manufacturing costs that vary roughly in relation to changes in production output. The concept is used to model the future expenditure levels of a business, as well as to determine the lowest possible price at which a product should be sold. / Переменные Производственные Накладные Расходы (Variable Production Overheads):- те косвенные производственные затраты, которые изменяются прямо, или почти прямо пропорционально объёму производства, такие как косвенные затраты на материалы и на оплату труда.

VARIABLE QUOTATION = ИЗМЕНЯЕМАЯ РАСЦЕНКА (или ИЗМЕНЯЕМАЯ КОТИРОВКА, или ИЗМЕНЯЕМЫЙ КУРС) – Variable Quotation is a continuous quotation. For high-volume stocks, usually of large companies, continuous market prices are determined (quoted) on each trading day, rather than a single cash quotation or cash price. The initial price is referred to as the Starting or Opening Price, while the closing price refers to the last price. The quotation of a stock in continuous trading is a condition for inclusion in one of the selection indices of Deutsche Börse AG. / Немецкая Биржа АО или Дойчэ Бёрзэ А.Ге. (Deutsche Börse AG).

VARIABLE RATE = ИЗМЕНЯЕМАЯ СТАВКА (или ПЕРЕМЕННАЯ СТАВКА) – Variable Rate:- a variable-rate agreement, as distinguished from a fixed-rate agreement, calls for an interest rate that may fluctuate over the life of the loan. The rate is often tied to an index that reflects changes in market rates of interest. A fluctuation in the rate causes changes in either the payments or the length of the loan term. Limits are often placed on the degree to which the interest rate or the payments can vary. Variable Rate is an interest rate that changes periodically in relation to an index, such as the prime rate. Payments may increase or decrease accordingly. A Variable Rate is an interest rate that may fluctuate over the life of the loan, unlike a fixed rate. A change in the variable rate will affect either the size of the re-payment or the length of the loan. / Флуктуация (колебание) ставки вызывает изменения либо в платежах, либо в длительности срока ссуды.

VARIABLE–RATE AGREEMENT = СОГЛАШЕНИЕ С ИЗМЕНЯЕМОЙ СТАВКОЙ (или СОГЛАШЕНИЕ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable-Rate Agreement, as distinguished from a fixed-rate agreement, calls for an interest rate that may fluctuate over the life of the loan. The rate is often tied to an index that reflects changes in market rates of interest. A fluctuation in the rate causes changes in either the payments or the length of the loan term. Limits are often placed on the degree to which the interest rate or the payments can vary.

VARIABLE–RATE APPLICATION TECHNOLOGY = ТЕХНОЛОГИЯ ВНЕСЕНИЯ С ИЗМЕНЯЕМОЙ СТАВКОЙ (или ТЕХНОЛОГИЯ ВНЕСЕНИЯ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable-Rate Application Technology:- xxxxx. See also Precision Agriculture; and Precision Farming. In precision agriculture, Variable Rate Application (VRA) refers to the application of a material, such that the rate of application is based on the precise location, or qualities of the area that the material is being applied to. Variable Rate Application can be, Map Based or Sensor Based:- (i) Map Based VRA is pre-planned, and applications are based on VRA Prescription Maps that an Agronomist or Advisor prepares based on data sources; or (ii) Sensor Based VRA is calculated realtime, based on sensors that are local to the Variable Rate Applicator. Applications Of VRA:- In precision agriculture, VRA is known to be used in the following areas:- (i) seeding; (ii) weed control; (iii) fertilizer; (iv) lime; and (v) soil cultivation intensity.

VARIABLE RATE BOND = ОБЛИГАЦИЯ С ИЗМЕНЯЕМОЙ СТАВКОЙ (или ОБЛИГАЦИЯ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable Rate Bond is a bond whose stated interest rate varies as a percentage of a baseline indicator, such as the prime rate. Jumps in the baseline indicator can lead to substantial increases in interest rates, so this is a riskier form of financing for the issuer. The risk of

higher interest rate costs can be mitigated by adding a redemption option to the bond agreement, whereby the issuer can choose to buy back bonds if interest rates increase to an excessive degree. Variable Rate Bond is a bond whose interest payments are linked to a reference index (for example, LIBOR), or the price of a specific commodity, or the price of a specific financial instrument that normally changes over time in a continuous manner in response to market pressures. Variable-Rate Bond is a security or tranche with interest rates that change over time, but for which the schedule of changes is published in the prospectus. Not the same as a floating-rate note. / (более известная в Англоязычном звучании как ЛАЙБО или ЛИБО (LIBOR)).

VARIABLE–RATE CERTIFICATE = СЕРТИФИКАТ С ПЕРЕМЕННОЙ СТАВКОЙ (или СВИДЕТЕЛЬСТВО С ИЗМЕНЯЕМОЙ СТАВКОЙ) – Variable-Rate Certificate is a specific type of Certificate of Deposit (CD), characterized by the fact that its interest rate varies depending upon the value of some other item. Some certificates have their interest rates fluctuate based on a given stock index, others based on the prime rate. Typically these rates are adjusted quarterly. / Сертификат С Плавающей Ставкой:- депозитные сертификаты (certificate of deposit (CD)), по которым установлены плавающие ставки, периодически изменяющиеся вместе с движением такой базы, как ставка прайм рэйт или фондовый индекс. Сертификат С Изменяемой Ставкой:- сберегательный сертификат, ставка выплачиваемого процента по которому меняется в зависимости от условий обеспечения денег. Процентная ставка устанавливается правительственными регулирующими агентствами.

VARIABLE–RATE CERTIFICATES OF DEPOSITS = ДЕПОЗИТНЫЕ СЕРТИФИКАТЫ С ПЕРЕМЕННОЙ СТАВКОЙ (или СВИДЕТЕЛЬСТВА О ВКЛАДАХ С ИЗМЕНЯЕМОЙ СТАВКОЙ) – A Variable-Rate Certificate Of Deposit (CD) is a CD with an interest rate that can change. How It Works (Example):- a CD is an investment whereby the investor deposits a certain amount of money with a bank orcredit union, which agrees to pay interest on that deposit for the duration of the deposit. Generally, the depositor cannot access the investment again until the term of the CD is up, which can be anywhere from one month to several years long. Most investors opt for fixed-rate CDs, which pay a flat rate of interest. However, some institutions also offer variable-rate CDs, which offer interest rates based on Treasury bills, market indexes, the prime rate, or other market rates. Often, the interest an institution will pay on a variable-rate CD equals the percentage change in the associated index or rate over the duration of the CD. For example, if the CD is based on the changes in the prime rate and the prime rate increases from 5% to 8% over the duration of the CD, the difference is the interest rate on the variable rate CD – in this case, the difference in the prime rate is 3%, which is what the investor will earn. Why It Matters:- CDs are one of the most conservative investments there are, and the interest rates on them tend to be very low. Variable-rate CDs offer investors the opportunity to receive higher returns if interest rates in other areas of the markets go up. Of course, the opposite is true:- if rates go down, the interest rate on a variable CD can also decrease. Variable-Rate Certificates Of Deposits (CDs):- short-term certificate of deposits that pay interest periodically on roll dates. On each roll date, the coupon on the CD is adjusted to reflect current market rates. Variable-Rate Certificate Of Deposit is a certificate of deposit (CD) with a variable interest rate. The rate can be determined by a number of mediums, such as the prime rate, consumer price index, treasury bills or a market index. The amount paid out is usually based on a percentage difference between the beginning index and the final index. A certificate of deposit is generally considered to be one of the safer ways to invest your money. It is the perfect choice for the conservative investor, or to diversify the risk of your portfolio. When looking to step up the risk just a little bit, considering a variable rate CD may be a good place to start. / Депозитные Сертификаты С Изменяемой Ставкой:- введённые в 1975 депозитные сертификаты с обычным минимальным сроком погашения 360 дней. Процентная ставка поддерживается банком-эмитентом с определённой разницей по сравнению с текущей ставкой банка по 90-дневным депозитным сертификатам и корректируется каждые 90 дней.

VARIABLE–RATE DEMAND BOND = ОБЛИГАЦИЯ С ИЗМЕНЯЕМОЙ СТАВКОЙ НА ПРЕДЪЯВИТЕЛЯ (или ОБЛИГАЦИЯ С ПЕРЕМЕННОЙ СТАВКОЙ НА ПРЕДЪЯВИТЕЛЯ) – Variable Rate Demand Bond is a bond with floating coupon payments that are adjusted at specific intervals. The bond is payable to the bondholder upon demand following an interest rate change. Generally, the current money market rate is what is used to set the interest rate, plus or minus a set percentage. As a result of this, the coupon payments can change over time. Although a demand bond can be redeemed at any time, bondholders are often encouraged to keep the bonds in order to continue receiving coupon payments. The floating rate of the coupon payment contributes to higher uncertainty in coupon cash flows compared to generic bonds. Some of this risk is mitigated by the redemption option. Variable-Rate Demand Bond (VRDB) is the floating-rate bond that periodically can be sold back to the issuer.

VARIABLE–RATE DEMAND NOTE = НОТА С ПЕРЕМЕННОЙ СТАВКОЙ НА ПРЕДЪЯВИТЕЛЯ (или БИЛЕТ С ИЗМЕНЯЕМОЙ СТАВКОЙ НА ПРЕДЪЯВИТЕЛЯ, или ПРЕДЪЯВИТЕЛЬСКИЙ ВЕКСЕЛЬ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable-Rate Demand Notes (VRDNs) are longer-term municipal securities that feature both a periodic coupon reset and a demand feature that allows an investor to periodically tender, or put, the securities at par plus accrued interest. (1) Periodic Coupon Resets:- the interest rate on VRDNs is generally reset daily or weekly based on the Securities Industry and Financial Markets Association (SIFMA) Municipal Swap Index. (The SIFMA Municipal SWAP Index is a seven-day high-grade market index composed of tax-exempt VRDO reset rates that are reported to the Municipal Securities Rulemaking Board's SHORT reporting system. You cannot invest directly in an index). This reset feature ensures that VRDN yields reflect the current interest-rate environment. (2) Demand Feature:- VRDNs also generally have a one-day or seven-day demand feature, or put option, which enables an investor to tender the securities to a financial intermediary – such as a remarketing agent, tender agent, or trustee – after providing a one-day or seven-day notification. This feature allows VRDNs to be considered under US Securities and Exchange Commission (SEC) Rule 2a-7 as having a maturity equal to the next put date rather than its final maturity date. (3) Credit And Liquidity Enhancement:- virtually all VRDNs benefit from third-party credit and liquidity enhancements, ensuring payment of principal and interest on tendered securities. The main types of credit enhancement include letters of credit and standby bond purchase agreements, both of which are typically provided by a highly rated bank or other financial institution. Letters of credit offer a somewhat higher degree of security as they obligate the credit provider to pay principal and interest to bondholders within a certain time frame if the underlying issuer is unable to fulfill its obligation. Variable-Rate Demand Notes (VRDNs) have historically been a core holding in municipal money market funds because of their effectiveness as a tool for managing a fund's liquidity and average maturity. The relative safety and soundness of the VRDN structure has been demonstrated through various market conditions and economic cycles, most notably during the 2008 financial crisis. In recent years, VRDNs have become a popular investment alternative for prime money market funds due to their ability to provide liquidity and enhance principal preservation. Variable Rate Versus Auction Rate:- What's The Difference? VRDNs are sometimes confused with auction-rate securities because the interest rate on both of these types of investments resets periodically. One key difference is that VRDNs have contractual features that enable an investor to put back the security at par. In contrast, auction-rate securities failed as the financial crisis unfolded because there was no backup to the auction or remarketing mechanism on which the liquidity of these securities depended. It is important to note that auction-rate securities have never been an allowable investment for money market funds. Key Features Make VRDNs Attractive For Money Market Funds:- there are four features that make VRDNs a desirable investment for money market funds:- (i) eligible securities under SEC Rule 2a-7; (ii) highly liquid with a stable value; (iii) short term to repayment; and (iv) high credit quality. SEC Rule 2a-7 requires a money market fund to maintain at least 30% of its total assets in weekly liquid assets, which includes 'securities that mature or are subject to a demand feature that is exercisable and payable within five business days'. The demand

feature not only ensures liquidity but also promises repayment at par, which means the value of a VRDN remains stable. Further, VRDNs used in our money market funds are analyzed by our credit specialists to determine that they present minimal credit risk. Market Overview:- the VRDN market is approximately USD224 billion in size and is composed of more than 10 000 individual securities. (Thomson Reuters (TM3), 'US Municipal VRDO Update, September 2015'). The vast majority of issuers are public entities. As shown in Chart 1 below, the amount of VRDNs outstanding increased in 2008 as failed auction-rate securities were repackaged as VRDNs. More recently, outstandings have declined as issuers have sold long-term bonds in order to lock in historically low interest rates. Additionally, many issuers have continued to have an austerity mindset several years post the Great Recession, which has resulted in only modest amounts of new issuance across both short- and long-term municipal supply. As the Federal Reserve has continued an accommodative monetary policy, all interest rates have fallen, including yields on VRDNs. However, nontraditional buyers have remained attracted to VRDNs due to the principal stability and liquidity features inherent in VRDNs. Pricing remains extremely stable because VRDNs can be put back at par on a daily or weekly basis. However, investors can expect differences in the yield offered on specific issues. Relative supply and demand for an issue will vary based on many factors, such as rates in other related sectors (for example, commercial paper and government repurchase agreements). Other factors include the relative credit quality of the liquidity or credit support provider, whether the issue is subject to state taxes or the Alternative Minimum Tax or is fully taxable, and dealer inventory levels. VRDNs And Wells Fargo Money Market Funds:- prior to the purchase of any security in one of our money market funds, our team of credit analysts conducts a thorough analysis of its credit quality, including the underlying issuer, the terms and conditions of any credit or liquidity enhancement, and the credit quality of any provider of enhancement. In the VRDN sector, this analysis is performed by our dedicated team of municipal credit specialists. Only after a determination is made that a security presents minimal credit risk can it be added into one of our money market funds. Variable-Rate Demand Note is a note that is payable on demand and bears interest tied to a money market rate. Variable-Rate Demand Note is a debt instrument that represents borrowed funds that are payable on demand and accrue interest based on a prevailing money market rate, such as the prime rate. The interest rate applicable to the borrowed funds is specified from the outset of the debt, and is typically equal to the specified money market rate plus an extra margin. Because money market interest rates, such as the bank prime rate, are variable over time, the interest rate applicable to this type of demand note is variable as well. Every time the prevailing money market rate changes, a variable rate demand note's interest rate is adjusted accordingly. As the name implies, these debt instruments are payable on demand. This means that the lender of the funds can request repayment of the entire debt amount at its discretion, and the funds must be repaid once the demand has been made. Libor is an interest rate at which banks can borrow funds, in marketable size, from other banks in the London interbank market. The Libor is fixed on a daily basis by the British Bankers' Association. The Libor is derived from a filtered average on the world's most creditworthy banks' interbank deposit rates for larger loans with maturities between overnight and one full year. VRDNs are debt securities commonly held within the Wells Fargo Money Market funds. Like all bonds, VRDN values fluctuate in response to the financial condition of individual issuers, general market and economic conditions, and changes in interest rates. Changes in market conditions and government policies may lead to periods of heightened volatility in the bond market and reduced liquidity for certain bonds. In general, when interest rates rise, bond values fall and investors may lose principal value. Interest-rate changes can be sudden and unpredictable. In addition to credit and interest-rate risk, VRDNs are subject to municipal securities risk. An investment in a money market fund is not insured or guaranteed by the Federal Deposit Insurance Corporation or any other government agency. Although the Wells Fargo Money Market Funds seek to preserve the value of your investment at USD1.00 per share, it is possible to lose money by investing in a money market fund. Carefully consider a fund's investment objectives, risks, charges, and expenses before investing. For a current prospectus and, if available, a summary prospectus, containing this and other information, visit wellsfargofunds.com. For variable net asset value (NAV) money market funds:- You could lose money by investing in the fund. Because the share price of the fund will fluctuate, when you sell your shares they may be worth more or less than what you originally paid for them. The fund may impose a fee upon sale of your shares or may temporarily suspend your ability to sell shares if the fund's liquidity falls below required minimums because of market conditions or other factors. An investment in the fund is not insured or guaranteed by the Federal Deposit Insurance Corporation or any other government agency. The fund's sponsor has no legal obligation to provide financial support to the fund, and you should not expect that the sponsor will provide financial support to the fund at any time. For retail money market funds:- You could lose money by investing in the fund. Although the fund seeks to preserve the value of your investment at USD1.00 per share, it cannot guarantee it will do so. The fund may impose a fee upon sale of your shares or may temporarily suspend your ability to sell shares if the fund's liquidity falls below required minimums because of market conditions or other factors. An investment in the fund is not insured or guaranteed by the Federal Deposit Insurance Corporation or any other government agency. The fund's sponsor has no legal obligation to provide financial support to the fund, and you should not expect that the sponsor will provide financial support to the fund at any time. For government money market funds:- You could lose money by investing in the fund. Although the fund seeks to preserve the value of your investment at USD1.00 per share, it cannot guarantee it will do so. An investment in the fund is not insured or guaranteed by the Federal Deposit Insurance Corporation or any other government agency. The fund's sponsor has no legal obligation to provide financial support to the fund, and you should not expect that the sponsor will provide financial support to the fund at any time. SIFMA Municipal Swap Index produced by Municipal Markets Data (MMD), is a 7-day high-grade market index comprised of tax-exempt VRDNs from MMD's extensive database. Variable Rate Demand Notes (VRDNs) are variable rate securities issued by municipalities with features that help investors in money market funds meet their needs for liquidity, flexibility, and competitive short-term rates, particularly in this low yield environment. A VRDN is a long-term (20- to 30-year) municipal bond which is offered in a variable interest rate mode – meaning it adjusts to changes in the prevailing money market interest rate, usually adjusting every one to seven days – and provides investors with an option to tender the securities (or 'put') back to the fi nancial intermediary in return for repayment of the entire debt amount with as little as one up to seven days notice. How Do VRDNs Work? VRDNs are comprised of three distinct features that may make them an attractive vehicle for short-term money market investors:- (i) Variable Interest Rate:- the interest rate on VRDNs is reset usually every one to seven days off the Securities Industry and Financial Market Association (SIFMA) Municipal Swap Index, which is the municipal equivalent of seven-day Libor, allowing you to continually earn the market interest rate, and reducing risk associated with rising interest rates. During 2011, SIFMA posted index levels ranging from 29 to seven basis points, with an average of 19 basis points for the year. (ii) The 'Demand' Feature:- it is the VRDN's 'put' or 'demand' feature that makes it eligible for purchase by money market mutual funds that are required to follow special maturity guidelines under SEC Rule 2a-7. Bond holders have the right to put their bonds back to the financial intermediary for payment at par plus accrued interest at any time with appropriate notice. (iii) Liquidity Support/Credit Support:- to mitigate the risk associated with loss of principal due to issuer default ('credit risk'), VRDNs are generally supported by external credit enhancements in the form of a Letter of Credit (LOC) from a highly rated financial institution. By providing an irrevocable and unconditional LOC, a financial institution serves as the liquidity provider of last resort, committed to supporting timely payment of principal and interest. One basis point equals one one-hundredth of a percentage point. / Томсэн Ройтас (Thomson Reuters). Вэлз Фарго (Wells Fargo). Облигация На Предъявителя С Изменяемой Ставкой – облигация, представляющая займы (обычно из коммерческих банков) на предъявителя, по которой выплачивается ставка процента, привязанная к процентной ставке финансового рынка, обычно банковской ставке – первичной ставке (prime rate). Процентная ставка по облигации корректируется в направлении повышения

или понижения каждый раз при изменении базовой процентной ставки. Предъявительский Вексель С Изменяемой Ставкой – вексель, представляющий заём, выплачиваемый по требованию и приносящий проценты, привязанные к ставке рынка краткосрочного капитала, часто к банковской базисной ставке. Ставка по векселю корректируется вверх или вниз каждый раз с изменением базисной ставки.

VARIABLE–RATE LOAN = ЗАЙМ С ИЗМЕНЯЕМОЙ СТАВКОЙ (или ЗАЁМ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable Rate Loan is a loan made at an interest rate that fluctuates depending on a base interest rate, such as the prime rate or LIBOR. / (более известная в Англоязычном звучании как ЛАЙБО или ЛИБО (LIBOR)).

VARIABLE RATE MORTGAGE = ЗАКЛАДНАЯ С ИЗМЕНЯЕМОЙ СТАВКОЙ (или ЗАКЛАДНАЯ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable Rate Mortgage (VRM) is a type of home loan in which the interest rate is not fixed. The two most common types of mortgages in the United States are fixed rate and variable rate (also called Adjustable Rate). With a fixed rate mortgage, the interest rate does not change for the entire loan term. Borrowers know with certainty what the interest and principal payment on their mortgage will be each month for as long as they carry the mortgage. With a variable rate mortgage, the interest rate adjusts periodically. Monthly principal and interest payments change according to a predetermined schedule throughout the life of the loan. Variable rate mortgages are attractive because they usually have a low interest rate for an initial period of a few years, and that initial rate is usually less than the rate on a fixed rate mortgage. This interest-rate difference can yield significant savings for borrowers at the beginning of the mortgage term. However, once the introductory period ends, the rate will move up or down as market interest rates change. Interest rate increases can be problematic for borrowers with variable rate mortgages. In a worst-case scenario, the mortgage payments can become so unaffordable that the homeowner defaults and eventually loses the home to foreclosure. In general, the more money the homeowner has borrowed, the more a change in interest rate will affect the monthly payment amount. / Смотрите также Закладная С Переоцениваемой Ставкой (ЗПС; Adjustable Rate Mortgage (ARM)). Закладная С Изменяемой Ставкой:- тип закладной, первоначально применявшийся в Калифорнии и ныне признанный в национальном масштабе, который позволяет процентным взносам по ссуде повышаться или понижаться автоматически в соответствии с заранее установленным индексом, например, индексом стоимости кредитных средств для банков. Процентная ставка может изменяться каждые шесть месяцев, но она не может быть поднята более чем на 2½ процентных пункта в течение периода действия закладной. Кроме того, банки обязаны предоставить клиентам право выбора между закладными с изменяемой ставкой и обычными закладными. Смотрите также Закладная С Пересматриваемой Ставкой (Renegotiable-Rate Mortgage); Переоцениваемая Закладная От Ваковиа (Wachovia Adjustable Mortgage). Закладная С Изменяемой Ставкой – документ по ипотечной ссуде (под жилые дома) со ставкой процента, изменяющейся в течение срока действия закладной обычно в соответствии с изменением основной ставки на выбранном рынке.

VARIABLE–RATE NOTE = НОТА С ПЕРЕМЕННОЙ СТАВКОЙ (или БИЛЕТ С ИЗМЕНЯЕМОЙ СТАВКОЙ) – Variable-Rate Note (VRN) is a floating-rate note (FRN) where the margin over the reference rate is fixed by the issuer and the remarketing agent several days before the following interest period. The holders, during a predetermined period of time, have the right to either bid for the new applicable margin over the reference rate or (under certain conditions) put the notes to the arranger (but not the issuer) on the following interest payment date. Variable Rate Notes (VRNs):- these securities adopted the standard characteristics of a variable-rate bond. However, whereas a standard characteristic of a variable-rate bond is that it carries a fixed spread over a referral index, the spread over LIBOR on a VRN varies over time depending on the change in the perceived credit risk of the issuer. The spread is reset at each rollover date – normally every three months – by means of negotiation between the issuer and arranging house. Context:- VRNs are usually issued with no maturity date (perpetual VRNs) but fixed five-year and longer-dated issues are in existence. VRNs generally have a put option for the existing holders of notes to sell the issue back to the lead manager of the issuing syndicate, at par, at any interest payment date. / (более известная в Англоязычном звучании как ЛАЙБО или ЛИБО (LIBOR)).

VARIABLE RATE PREFERRED STOCK = ПРИВИЛЕГИРОВАННАЯ АКЦИЯ С ИЗМЕНЯЕМОЙ СТАВКОЙ (или ПРИВИЛЕГИРОВАННАЯ АКЦИЯ С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable Rate Preferred Stock is a preferred stock paying a dividend that varies from time to time. Usually, the dividend rate is based on an index or on the interest rate on a Treasury security. They may also be backed by mortgages or mortgage-backed securities. Variable rate preferred stocks sound like a good idea, especially during a period of low rates. The idea is that preferred stock investors will be able to ride the wave up when rates start to rise in the future. In addition to increasing income, this mechanism also offers a degree of principal protection since such securities would theoretically maintain their value as rates go higher. See also Adjustable Rate Preferred Stock (ARP). Variable-Rate Preferred Stock is a type of a share on which dividends are paid before dividends on other ordinary shares are paid and the dividends issued will vary according to a benchmark, most often a US Treasury note rate. / будут изменяться в соответствии с эталоном, наиболее часто ставкой билета Казначейства США.

VARIABLE RATE TENDER = КОНКУРС С ИЗМЕНЯЕМОЙ СТАВКОЙ (или КОНКУРС С ПЕРЕМЕННОЙ СТАВКОЙ) – Variable Rate Tender is a bidding procedure, in particular for the tender of securities repurchase transactions. The bidding bank must specify both the interest rate at which it wishes to participate and the volume it is prepared to transact. While, under the US-style rate tender, allocations are made to the bank according to the interest rate offered, a uniform interest rate is determined in the Dutch-style rate tender which corresponds to the most favorable allocated interest rate and is applied to all participating banks. In addition to the variable rate tender procedure there is the fixed-rate tender procedure. Variable Rate Tender is a tender procedure whereby the counterparties bid both the amount of money they want to transact with the central bank and the interest rate at which they want to enter into the transaction.

VARIABLE–RATIO PLAN = ПЛАН С ИЗМЕНЯЕМЫМ СООТНОШЕНИЕМ (или ПЛАН С ПЕРЕМЕННЫМ СООТНОШЕНИЕМ) – Variable-Ratio Plan is a variation on the constant ratio plan. The allocation of assets is modified in response to or in anticipation of changing conditions in the various markets. The goal of buying low and selling high is built into this strategy, but, like the constant Dollar plan, prolonged movements in a given direction can harm returns. Variable-Ratio Plan is a more flexible variation of constant ratio plan. Under the variable ratio plan, it is provided that if the value of aggressive portfolio changes by certain percentage or more, the initial ratio between the aggressive portfolio and conservative portfolio will be allowed to change as per the pre-determined schedule. Some variations of this plan provide for the ratios to vary according to economic or market indices rather than the value of the aggressive portfolio. Still others use moving averages of indicators. / План С Изменяемым Соотношением:- инвестиционная программа, согласно которой средства разделяются в определённый момент времени, как правило, на две равные части:- средства на акции для покупки различных обыкновенных акций и наличные средства, сохраняемые в ликвидной форме. Когда цены повышаются, акции продаются для сохранения соотношения стоимости средств на акции и наличных средств; обратные действия производятся в случае снижения цен. Это предполагает наличие постоянных колебаний вокруг нормального соотношения, которые могут периодически корректироваться с целью поддержания данного соотношения при долгосрочной тенденции.

VARIABLE RATIO WRITE = ВЫПИСКА С ИЗМЕНЯЕМЫМ СООТНОШЕНИЕМ (или ВЫПИСКА С ПЕРЕМЕННЫМ СООТНОШЕНИЕМ) – Variable Ratio Write is an option strategy in which an investor holds a long position in the underlying asset and writes multiple call options at varying strike prices. Variable ratio writes have limited profit potential because the trader is only looking to capture the premiums paid for the call options. This strategy is best used on stocks with limited volatility. In ratio call writing, the ratio represents the number of options sold for every 100 shares owned in the underlying stock. This strategy is similar to a ratio call write, but instead of writing at-the-money calls, the trader will write both in the money and out of the money calls. For example, in a 2:1 variable ratio write, the trader will be long 100 shares of the underlying stock. Two calls are written:- one is out of the money and one is in the money. The payoff in a variable ratio write resembles that of a reverse strangle. Variable Ratio Write is an option strategy in which the investor owns 100 shares of the underlying security and writes two call options against it, each option having a different striking price. The Variable Ratio Write is a variant of the ratio write strategy in which the options trader owns a holding of the underlying stock and sells more calls than shares owned. Variable Ratio Write Construction:- (1) Long 100 Shares, (2) Sell 1 ITM Call (short for the in-the-money call), and (3) Sell 1 OTM Call (short for the out-of-the-money call). Like the ratio write, it is a limited profit, unlimited risk options trading strategy that is taken when the options trader thinks that the underlying stock price will experience little volatility in the near term. Unlike the 2:1 ratio call write, which involves writing two at-the-money calls, the 2:1 variable ratio write involves writing one out-of-the-money call and one in-the-money call. As such, the variable ratio write has a lower profit potential but the profit zone is wider. (1) Limited Profit Potential:- maximum gain for the variable ratio write is limited and is made when the underlying stock price at expiration is anywhere between the strike prices of the options sold. At this price range, the higher striking short call expires worthless while the lower striking short call expires in the money. Any loss resulting from the gain in the intrinsic value of the short call is offset by the premiums earned for selling this call while any profit from the drop in intrinsic value of this short call is completely negated by the corresponding depreciation of the long stock position. As a result, the options trader gets to keep as profit the time value of the premiums received when putting on the trade. The formula for calculating maximum profit is given below:- (i) Max Profit = Net Premium Received + Strike Price of Lower Strike Short Call – Purchase Price of Underlying – Commissions Paid; and (ii) Max Profit Achieved When Price of Underlying is in between the Strike Prices of the Short Calls. (2) Unlimited Risk Potential:- loss occurs for the variable ratio write when the stock price makes a strong move to the upside or downside beyond the upper and lower breakeven points. There is no limit to the maximum possible loss. The formula for calculating loss is given below:- (i) Maximum Loss = Unlimited; (ii) Loss Occurs When Price of Underlying < Strike Price of Lower Strike Short Call – Max Profit OR Price of Underlying > Strike Price of Higher Strike Short Call + Max Profit; and (iii) Loss = Price of Underlying – Strike Price of Higher Strike Short Call – Max Profit OR Strike Price of Lower Strike Short Call – Price of Underlying – Max Profit + Commissions Paid. (3) Breakeven Point(s):- there are 2 break-even points for the variable ratio write position. The breakeven points can be calculated using the following formulae:- (i) Upper Breakeven Point = Strike Price of Higher Strike Short Call + Points of Maximum Profit; and (ii) Lower Breakeven Point = Strike Price of Lower Strike Short Call – Points of Maximum Profit. Referring to the graph shown above, since the maximum profit is USD400, points of maximum profit is therefore equals to 4. Therefore, upper breakeven is at USD54 while lower breakeven is at USD36. Example:- Suppose XYZ stock is trading at USD45 in June. An options trader executes a 2:1 variable ratio write by buying 100 shares of XYZ stock for USD4 500, selling one in-the-money JUL 40 call for USD700 and selling another out-of-the-money JUL 50 call for USD200. The total premiums received for putting on the trade is USD900. On expiration in July, if XYZ stock is still trading at USD45, the long stock position is still worth USD4 500, the JUL 50 call expires worthless while the JUL 40 call expires in the money with USD500 in intrinsic value. With USD900 in premiums earned, buying back the short JUL 40 call for USD500 still results in a USD400 profit. This is the maximum profit and can be made when XYZ stock price is anywhere between USD40 and USD50. If XYZ stock rallies and is trading at USD54 on expiration in July, all the call options will expire in the money. The JUL 40 call is now worth USD1 400 while the JUL 50 call is worth USD400. This USD1 800 loss is completely offset by the USD900 appreciation of his long stock position and the USD900 in premiums he received earlier. Therefore, he achieves breakeven at USD54. Beyond USD54 though, there will be no limit to the loss possible. For example, at USD70, the written JUL 40 call will be worth USD3 000 while the JUL 50 call will be valued at USD2 000, resulting in a combined loss of USD5 000 on the short position. Meanwhile, his long stock position has only appreciated by USD2 500 and together with the USD900 in premium received, the options trader still need to come up with another USD1 600 to close the position. Using the formula for computing the breakeven point, we calculated the lower breakeven point to be USD36. At USD36, all the call options expire worthless. However, his long stock position also suffers a loss of USD900 in value but this loss is offset by the USD900 in premiums earned. Therefore, there is breakeven at USD36. Below USD36 however, there is no limit to the potential loss. For example, if the stock price is trading at USD20 on expiration, while all the call options expire worthless, the long stock position suffers a USD2 500 drop in value. Even with the USD900 in premiums to offset the loss, the options trader still suffers a USD1 600 loss. Note:- while we have covered the use of this strategy with reference to stock options, the variable ratio write is equally applicable using ETF options, index options as well as options on futures. Commissions:- for ease of understanding, the calculations depicted in the above examples did not take into account commission charges as they are relatively small amounts (typically around USD10 to USD20) and varies across option brokerages. However, for active traders, commissions can eat up a sizable portion of their profits in the long run. If you trade options actively, it is wise to look for a low commissions broker. Traders who trade large number of contracts in each trade should check out OptionsHouse.com as they offer a low fee of only USD0.15 per contract (+USD4.95 per trade). Variable Ratio Write is an options strategy in which a trader writes multiple option contracts per 100 shares of stock owned or shorted, with varying strike prices. A variable ratio write is a conservative strategy that seeks to minimize losses rather than maximizing gains. The Variable Ratio Write strategy is a relatively safe way of trading a stock that one expects will experience little volatility in the near future. It's closely related to other ratio write strategies that combine stock ownership with the sale of more call options than shares owned. But there's one essential difference. Whereas a simple 2-to-1 ratio write strategy might involve the sale of two at-the-money calls against the underlying stock, the variable ratio write strategy entails the sale of one in-the-money and one out-of-the-money call. The resulting profit/loss profile is thereby diminished, with the variable ratio write trader affording himself less profit potential – but, at the same time, buying wider price range from which to profit. In options writing, Variable Ratio Write is an option strategy in which an investor owns 100 shares of the underlying security and writes two call options against it with each option having a different striking price. / В выписывании опционов Выписка С Изменяемым Соотношением или Выписка С Переменным Соотношением – это опционная стратегия, в которой инвестор владеет 100 акциями по соответствующей ценной бумаге и выписывает два опциона на покупку против них, причём каждый из этих опционов имеет различную сходную цену. Данная стратегия является консервативной и нацелена скорее на минимизацию убытков, нежели на максимизацию прибылей.

VARIABLE RATIO WRITING = ВЫПИСЫВАНИЕ С ИЗМЕНЯЕМЫМ СООТНОШЕНИЕМ (или ВЫПИСЫВАНИЕ С ПЕРЕМЕННЫМ СООТНОШЕНИЕМ) – Variable Ratio Writing is the same as Variable Ratio Write. / Выписывание С Изменяемым Соотношением:- то же самое, что . Синоним термина Пропорциональное Выписывание (Ratio Write).

VARIABLE REGION = ИЗМЕНЧИВЫЙ РЕГИОН (или ИЗМЕНЯЕМЫЙ РЕГИОН, или ПЕРЕМЕННЫЙ РЕГИОН) – Variable Region:- a configuration in the upper branches of the Y of an antibody molecule, unique in each antibody type, that binds with the determinant of a specific antigen. See also Antibody. Variable Region:- the portion of the amino (NH_2) terminal of an antibody's heavy

and light chains having a variable amino acid sequence. The structure of the variable region determines the antigenic specificity of the antibody. Compare Constant Region. Variable Region:- the part of the polypeptide chain of a light or heavy chain of an antibody that ends in a free amino group $–NH_2$, that varies greatly in its sequence of amino acid residues from one antibody to another, and that probably determines the conformation of the combining site which confers the specificity of the antibody for a particular antigen – called also Variable Domain.

VARIABLES = ПЕРЕМЕННЫЕ (или ИЗМЕНЧИВЫЕ) – Variables:- data or some characteristics that show variability. The characteristic may be numerical (quantitative) or non-numerical (qualitative). See also Variable. / Переменные:- данные или какие-то характеристики, которые отображают изменчивость. Характеристика может быть цифровой (количественной) или нецифровой (качественной). В логике под Переменной понимается неопределённое имя предмета из некоторой выделенной предметной области – области значений этой переменной. Переменная или Переменное, одно из основных понятий математики и логики. Начиная с работ Французского математика Пьера дё Фэрма (или Пьера Ферма; Pierre de Fermat; 1601–1665), Французского философа и математика Рэне Дэкярта (или Рене Декарта; René Descartes; 1596–1650), Английского физика и математика Айзэка Ньютчэна (или Исаака Ньютона; Isaac Newton; 1643–1727), Немецкого философа-идеалиста, математика, физика и изобретателя Готфрида Вильхэльма (фон) Ляйбница (или Готфрида Вильгельма (фон) Лейбница; Gottfried Wilhelm (von) Leibniz; 1646–1716) и других основоположников ‘высшей’ математики под Переменной или Переменным понимали некоторую ‘величину’, которая может ‘изменяться’, принимая в процессе этого изменения различные ‘значения’. Тем самым переменные противопоставлялись ‘постоянным’ (или константам) – числам или каким-либо другим ‘величинам’, каждая из которых имеет единственное, вполне определённое значение (смотрите Переменные И Постоянные Величины). По мере развития математики и в ходе её обоснования представления о ‘процессах’, ‘изменении величин’ и тому подобном тщательно изгонялись из математического арсенала как ‘внематематические’, в результате чего переменная стала пониматься как обозначение для произвольного элемента рассматриваемой предметной области (например, области натуральных чисел или действительных чисел), то есть как родовое имя всей этой области (в отличие от констант – ‘собственных имён’ для чисел или других конкретных предметов рассматриваемой области). Этот пересмотр взглядов на понятие Переменной был тесно связан с перестройкой математики на базе теории множеств, завершившейся в конце XIX века. При всей простоте и ‘естественности’ такой перестройки она существенным образом опирается на так называемую абстракцию актуальной бесконечности, позволяющую рассматривать произвольные бесконечные множества в качестве ‘данных’ (‘завершённых’, ‘готовых’, ‘актуальных’) объектов и применять по отношению к ним любые средства классической логики, отвлекаясь от незавершённости и принципиальной незавершимости процесса образования такого множества. Трудности решения логических проблем, связанных с принятием этой абстракции, делают понятной частичную ‘реабилитацию’ старинных представлений о ‘переменных величинах’; при построении математических теорий представители некоторых школ (смотрите Математический Интуиционизм, Конструктивное Направление) предпочитают обходиться боле (слабой, но зато менее уязвимой в логическом отношении абстракцией потенциальной осуществимости, с точки зрения которой с бесконечными множествами как раз связываются представления о процессах их ‘порождения’, – сколь угодно далеко заходящих, но никогда не завершающихся (смотрите Бесконечность в математике). При исследовании вопроса непротиворечивости различных областей математики на такую позицию фактически встаёт значительное большинство математиков и логиков (смотрите Метаматематика). В формализованных языках (исчислениях, формальных системах) математической логики Переменными называются символы строго фиксированного вида, могущие при определённых условиях заменяться выражениям данного исчисления. Это относится к так называемым свободным (или значащим) переменным, примером которых может служить переменная в неравенстве $x > 5$, обращающемся при подстановке вместо x, скажем, цифры 7 (то есть обозначения для числа) 7 в истинное высказывание, а при подстановке цифры 2 – в ложное высказывание. Что касается так называемых связанных (или фиктивных) переменных, то они сами по себе вообще ничего не означают, несут чисто синтаксические функции и могут (при соблюдении некоторых элементарных предосторожностей) ‘переименовываться’, то есть заменяться другими переменными. Такова, например, переменная y в записях $\sum_{y=5}^{25} y$ или $”yP(y)$, в интерпретации (прочтения) которых она вообще не входит и может быть заменена любой другой переменной. Так, первая из них (читаемая как ‘сумма целых чисел от 5 до 25’) может быть заменена на $\sum_{x=5}^{25} x$ или $\sum_{z=5}^{25} z$, а вторая (‘все числа обладают свойством P’) на $”tP(t)$. Различают индивидные, пропозициональные, предикатные, функциональные, числовые и другие виды переменных, вместо которых можно (согласно специальным правилам подстановки) подставлять соответственно обозначения предметов из рассматриваемой области (‘термы’), обозначения для конкретных высказываний, предикатов, функций, чисел и другого. Таким образом, переменную можно содержательно понимать как ‘пустое место’ в формуле, снабжённое указанием, чем это ‘место’ может быть ‘заполнено’ (своего рода ‘тара под строго определённый товар’). Свободные вхождения переменной в выражения содержательных научных теорий и формулы логико-математических исчислений (соответствующие употреблению неопределённых местоимений в обычной речи) допускают различные интерпретации. Первая (соответствующая применению всякого рода процедур подстановок) – так называемая предикатная интерпретация:- формула $A(x_1, ..., x_n)$ какого-либо исчисления понимается как некоторый местный предикат. Та же формула может интерпретироваться и как предложение (высказывание), а именно как предложение $”x_1 \dots ”x_n\ A(x_1 \dots x_n)$, являющееся её ‘замыканием’, – это так называемая интерпретация всеобщности (употребительная, например, при формулировке аксиом различных научных теорий). Свободным переменным могут, наконец, приписываться значения, постоянные в пределах некоторого контекста (например, вывода из данной совокупности формул), их тогда называют параметрами этого контекста и говорят об их условной интерпретации. Например, переменная x в выражении $\cos x$, взятом изолированно, имеет предикатную интерпретацию, в тождестве $\sin^2 x + \cos^2 x = 1$ – интерпретацию всеобщности, в уравнении $\cos x = 1$ (в процессе его решения, когда эта переменная именуется ‘неизвестным’) – условную интерпретацию. Таким образом, на различных уровнях формализации понятие Переменной выступает как уточнение средств, общеупотребительных в обычных разговорных языках (неопределённые местоимения, неопределённые артикли), и различных способов использования этих средств.

VARIABLE SAMPLING = ИЗМЕНЯЕМАЯ ВЫБОРКА (или ИЗМЕНЯЕМЫЙ ОТБОР ПРОБ) – Variable Sampling is used for measurement of hardness, tensile strength, resistance and other physical properties of the desired sample. The variables used for measurement are on a continuous scale and the limits for rejection are clearly demarcated for the entire range. The sample which is tested from the complete lot is said to be its representative. It is a much more descriptive of the type of defect and the gives the measure of deviation from the accepted standard. The reason for declaring the product to be defective can easily be inferred from the result. It is preferred to an attribute sampling where the product is categorized as ok or defective. The attribute sampling does not indicate the exact reason for failure of a sample. It usually takes a large sample size so that there is at-least a couple of defective pieces and the failure rate can be expressed as a percentage. It is considered to be a wasteful activity because after 100% testing we end up classifying them as tested ok or faulty. Example:- the sample size selected for testing is between 4–25. The sample size is kept low because a homogenous quality is ensured during designing and unnecessary expenditure is not done on testing. All the indicative parameters have to be recorded for the selected samples which makes it all the more time consuming. In the sample set for variable

sampling the original values are taken as reference values and the measured values are compared with them and the acceptance limits is decided by the confidence interval restricted by the normal distribution curve and all the values lying outside them are rejected. The curve is divided into three zones. Zone 1 and 3 are short zones and Zone 2 is known as Long Zone. The upper limits and lower limits of deviation are kept as +3 sigma and –3 sigma respectively. Hence it not only saves a lot of inspection cost it also keeps a check on controlling all the risk levels.

VARIABLE SAMPLING FRACTION = ИЗМЕНЯЕМАЯ ФРАКЦИЯ ОТБОРА ПРОБ (или ПЕРЕМЕННАЯ ФРАКЦИЯ ОТБОРА ПРОБ) – Variable Sampling Fraction:- if from a stratified population a simple random selection is selected from each stratum in such a way that the proportion of units sampled in each stratum varies from stratum to stratum, the sample is said to be selected with variable sampling fraction. Applicability of the term to other sampling schemes rests upon the general definition of sampling fraction.

VARIABLE SELECTION = ИЗМЕНЯЕМЫЙ ВЫБОР (или ПЕРЕМЕННЫЙ ВЫБОР) – Variable Selection:- the problem of selecting subsets of variables, in regression or multivariate statistics, that contain most of the relevant information in the full data set.

VARIABLE–SPEED WIND TURBINES = ТУРБИНЫ ДЛЯ ИЗМЕНЯЕМЫХ СКОРОСТЬ ВЕТРОВ – Variable-Speed Wind Turbines are the turbines in which the rotor speed increases and decreases with changing wind speed, producing electricity with a variable frequency.

VARIABLE SPREAD = ИЗМЕНЯЕМАЯ КУРСОВАЯ РАЗНИЦА (или ПЕРЕМЕННЫЙ СПРЭД) – Variable Spread tends to fluctuate in a range depending on the market conditions; that is, it would be low sometimes and high at other times. When the liquidity in a market increases, such as the overlap between the London and New York sessions, variable spread increases. And, during low market times, such as at 06:00 pm Eastern time (ET), when New York is closed and Asia is not yet fully opened, the difference between the bid price and ask price decreases. Therefore, this makes your trading through variable spreads less expensive on the whole. Worth mentioning, trading variable spreads come with the risk of fluctuating market conditions that can widen them almost instantly. For instance, during low market conditions, the spread for the above-mentioned USD/JPY pair can be lower than three pips, maybe two pips, which makes for less expensive trading costs that is always advantageous. Conversely, during times of important news releases, variable spreads increases as the quantity of orders reduces in the marketplace. As an example, during the monthly release of the US Non-Farm Payroll data, you can observe that the EURO/USD pair has a spread of ten pips. Therefore, this makes variable spreads difficult to trade with especially when you want to trade during unpredictable market conditions, as it would mean incurring more transaction costs. If the number of options purchased is not equal to the number sold, the position may be called a Ratio Spread or a Variable Spread. / В случае когда число приобретённых опционов не равно числу проданных позиция может именоваться Пропорциональной Курсовой Разницей или Пропорциональным Спрэдом или Изменяемой Курсовой Разницей или Изменяемым Спрэдом. Изменяемая Курсовая Разница или Изменяемый Спрэд:- техника акционерного опционного спрэда, предусматривающая одновременную покупку и продажу опционов на одну и ту же лежащую в основе акцию, при этом число проданных контрактов зависит от числа купленных контрактов. Смотрите также Сделки С Пропорциональной Курсовой Разницей (Ratio Spreading).

VARIABLE STOCKING = ИЗМЕНЯЕМОЕ ПОГОЛОВЬЕ (или ИЗМЕНЯЕМАЯ ЧИСЛЕННОСТЬ) – Variable Stocking is the practice of allowing a variable number of animals on a fixed area of land during the time when grazing is allowed.

VARIABLE SURFACE GLYCOPROTEIN = ВАРИАБЕЛЬНЫЙ (или ИЗМЕНЯЕМЫЙ, или ПЕРЕМЕННЫЙ) ПОВЕРХНОСТНЫЙ ГЛИКОПРОТЕИН – Variable Surface Glycoprotein (VSG):- an antigen expressed on the surface of an microorganism that changes over time and helps the organism evade host antibodies. See also Glycoprotein. / Вариабельный Поверхностный Гликопротеин – образование на поверхности микроорганизма, направленное на уклонение от иммунной системы поражаемого хозяина.

VARIABLY SEROTINOUS = ПЕРЕМЕННО ЗАПОЗДАЛОЕ (или ХХ) – Variably Serotinous (seed cones) (serotiny):- having some cones that open when the seeds ripen and others that remain closed long after the seeds are ripe.

VARIANCE = ВАРИАНСА (или ОТКЛОНЕНИЕ, или РАСХОЖДЕНИЕ, или РАССЕИВАНИЕ, или НЕСООТВЕТСТВИЕ, или ДИСПЕРСИЯ) – Variance is a statistical measure of the risk exposure of an investment (bond, share, etc) or portfolio. Variance is the amount by which individual earnings positions deviate from average earnings over a set period. High variance is an indication of high risk. In statistics, square of the standard deviation of several items. Variance is a measure of dispersion which is the mean of the squares of deviations of the observations from the population mean. Estimated as the ratio of a sum of squares to the corresponding number of degrees of freedom. Variance is a deviation or difference between an estimated value and the actual value. Variance is the difference between an actual measured result and a basis, such as a budgeted amount. In many accounting applications, a variance is considered to be the difference between an actual cost and a standard cost. Variance reporting is used to maintain a tight level of control over a business. The amount of a variance can be manipulated by adjusting the baseline upon which it is calculated. For example, if the purchasing manager wants to generate a favorable materials purchase price variance, he or she can lobby for a high baseline cost. With the standard so high, it is an easy matter to actually purchase at a lower price point, resulting in favorable performance under the variance calculation. For this reason, the formulation of variances should be carefully controlled. There are a multitude of possible variances that can be reported to management, so the person reporting this information should be selective in only forwarding those variances that management can take action to correct. If a variance is insignificant or cannot be corrected in the future, there is less reason to present the information. Variance is a measure of dispersion of a set of data points around their mean value. The mathematical expectation of the average squared deviations from the mean. The square root of the variance is the standard deviation. Variance, in accounting, is the difference between a projected number and the actual number, e.g., (1) a budget variance is spending either more or less from the amount that was budgeted; and (2) a cost variance is the difference between actual cost and standard cost in the categories of direct material, direct labor, and direct overhead. The Variance is the mean square deviation of the variable around the average value. It reflects the dispersion of the empirical values around its mean. Variance is the Government permission for a delay or exception in the application of a given law, ordinance, or regulation. Under the Clean Water Act, variances from surface water quality standards must be reviewed as part of the triennial review of water quality standards. Variance is a measure of volatility, risk or statistical dispersion. It is the square of the standard deviation. Variance:- in statistics, the square of the standard deviation of a sample or set of data, used procedurally to analyze the factors that may influence the distribution or spread of the data under consideration. See also Mean. / Под Дисперсией, от Латинского слова Dispersio, означающее Рассеяние, понимается:- (1) в математической статистике и теории вероятностей – мера рассеивания (отклонения от среднего). В статистике, квадрат стандартного расхождения нескольких значений. Отклонением является разница, на которую результаты отдельных позиций расходятся с усреднёнными результатами за установленный период. Значительное отклонение является признаком высокого риска. Рассеивание естественное, разбрасывание (отклонения от цели) артиллерийских снарядов, мин, гранат, пуль, ракет и бомб относительно цели при выстрелах (пуске ракет, бомбометании) из одного и того же оружия в практически одинаковых условиях. Естественное рассеивание происходит под влиянием случайных причин:- различий в массе боевых зарядов и качестве пороха, в массе, форме и размерах снарядов (ракет), в степени нагрева и качественном состоянии ствола

(направляющей); неоднообразия вертикальной и горизонтальной наводки при повторных выстрелах (пусках ракет, бомбометании), разнообразия углов вылетов; изменения скорости и направления ветра, плотности и температуры воздуха и другого. Рассеивание подчиняется нормальному закону случайных ошибок (смотрите Нормальное Распределение), который в отношении рассеивания снарядов (ракет, бомб) называется Законом Рассеивания. При дистанционной (неконтактной) стрельбе по воздушным или подводным целям рассеивание снарядов (ракет и другого) в пространстве ограничивается объёмом, называемым Эллипсоидом Рассеивания. При стрельбе по плоским целям соответствующая область называется Эллипсом Рассеивания. В отличие от естественного рассеивания, имеется искусственное рассеивание, которое применяется при стрельбе из пулемётов по широким и глубоким целям. Смотрите также Стрельба. Дисперсия, в математической статистике и теории вероятностей, наиболее употребительная мера рассеивания, то есть отклонения от среднего. В статистическом понимании Дисперсия есть среднее арифметическое из квадратов отклонений величин xi от их среднего арифметического. В теории вероятностей Дисперсией случайной величины X называется математическое ожидание $E (X – m_x)^2$ квадрата отклонения X от её математического ожидания $mx = E (X)$. Дисперсия случайной величины X обозначается через D (X) или через s^2_X. Квадратный корень из дисперсии (то есть s, если дисперсия есть s^2) называется Средним Квадратичным Отклонением (смотрите Квадратичное Отклонение). Об оценке дисперсии по результатам наблюдения смотрите Статистические Оценки. В теории вероятностей большое значение имеет теорема:- дисперсия суммы независимых слагаемых равна сумме их дисперсии. Не менее существенно Неравенство Чебышева, позволяющее оценивать вероятность больших отклонений случайной величины X от её математического ожидания. Погрешность Измерения – характеристика результата измерения, представляющая собой отклонение найденного значения величины от её истинного значения. Различают:- (i) абсолютную погрешность измерения, выражаемую в единицах измеряемой величины; и (ii) относительную погрешность измерения, представляющую собой отношение абсолютной погрешности измерения к истинному значению измеряемой величины (в долях единицы, в процентах и так далее). Погрешность измерения – результат воздействия на средство измерения и измеряемую величину неблагоприятно влияющих факторов (колебаний температуры, электромагнитных помех и так далее), несовершенства метода и самого средства измерений (неточность его начальной градуировки, нестабильность во времени и другое). Различают случайные и неучтённые систематические составляющие погрешности измерения. Случайная погрешность измерения характеризуется средним квадратичным отклонением, то есть рассеиванием результата при повторных измерениях с учётом задаваемого уровня доверительной вероятности. Отклонение:- величина, на которую фактические издержки отличаются от нормативных при системе калькуляции издержек производства по нормативным (standard costing). Отклонения могут анализироваться по причинам, их породившим, например, ценовые отклонения, количественные отклонения, отклонения эффективности, отклонения ассортимента и так далее. Отклонение:- разница между фактическим и нормативным (плановым, бюджетным) значением показателя за отчётный период. Отклонения, которые оказывают положительный эффект на прибыль, называются Благоприятными Отклонениями (Favorable Variance), в случае отрицательного эффекта – Неблагоприятными Отклонениями (Unfavorable Variance; в Великобритании – Adverse Variance). Отклонение или Несоответствие или Дисперсия (Variance):- В бухгалтерском учёте:- разница между реальными расходами и стандартными расходами (standard cost) по таким категориям, как прямые расходы на материалы, прямые расходы на оплату труда и прямые накладные расходы (direct overhead). Позитивное отклонение (когда реальные расходы ниже стандартных или ожидаемых расходов) выразится в более высокой прибыли, если не будет перекрыто негативным отклонением где-либо ещё. В финансах:- (1) разница между соответствующими статьями в балансовой ведомости (balance sheet) и отчёте о прибылях и убытках (profit and loss statement) (в балансовом отчёте); (2) разница между реальными расходами и бюджетными сметами или прогнозируемыми расчётами по любой финансовой категории. Например, если объём продаж на определённый период прогнозировался в размере 2 миллионов Долларов, а реально составил 2.5 миллиона Долларов, то будет иметь место позитивное отклонение в размере 500 000 Долларов, или 25%. В недвижимости:- разрешённое исключение из правил зонирования. Если определённый квартал был построен как зона исключительно жилых домов, а кто-то захочет открыть там магазин, то ему придётся добиваться того, чтобы в порядке исключения районный совет разрешил не применять это решение. В статистике:- мера дисперсии распределения; равна сумме квадратов отклонений от среднего. Смотрите также Standard Deviation. Варианса (Variance) – показатель дисперсии набора точек данных вокруг их средней величины.

VARIANCE ACCOUNTING = РАСЧЁТ ВАРИАНСЫ (или РАСЧЁТ ДИСПЕРСИИ) – Variance Accounting:- there is usually no need to account for variances. A variance arises when actual results differ from expected results. There are detailed procedures available for reporting variances to management, along with the reasons for the variances. But this is simply internal reporting that does not impact the general ledger. For nearly all transactions, actual revenues and expenditures are being recorded, and accounting standards require that the actual monetary amounts associated with transactions be recorded and reported. When there is a variance from a budgeted amount, there is no need to record this variance, since the only number that matters is the one relating to the actual transaction, not the budget being used for comparison purposes. The exception is when transactions are initially recorded at their standard costs in the accounting records. This only happens when inventory is recorded at its standard cost, rather than its actual cost. If such is the case, and there is a variance from the standard cost, how do you account for the variance? The answer depends upon how well standard costs have been constructed. If the standards are well-researched and have been updated recently, any variances should be outside of the costing expectations of the business, and so should be recognized in the current period. Since the original transaction was already recorded at its standard cost, this means that there is no need to account for the variance. What about the alternative, where the standard cost used to record a transaction is likely incorrect? If so, it is entirely possible that the standard should be adjusted to reflect recent conditions, which means that there should be no variance. If the accountant recognizes that this type of variance is based on an incorrect standard, then there should be a journal entry to adjust the standard cost of the inventory item. This type of adjustment is only likely to arise if there is an ongoing program of actively investigating why variances are occurring.

VARIANCE ANALYSIS = АНАЛИЗ ВАРИАНСЫ (или ДИСПЕРСИОННЫЙ АНАЛИЗ) – Variance Analysis:- the total variation displayed by a set of observations, as measured by the sums of squares of deviations from the mean, may in certain circumstances be separated into components associated with defined sources of variation used as criteria of classification for the observations. Such an analysis is called an Analysis Of Variance, although in the strict sense it is an analysis of sums of squares. Many standard situations can be reduced to the variance analysis form. Variance Analysis is the analysis of performance by means of variances. Used to promote management action at the earliest possible stages. After a budget (based on standard costs) has been set, its usefulness lies in the review procedures which compare actual results against the budget. Variance analysis is the process of examining in detail each variance between actual and budgeted/expected/standard costs to determine the reasons why budgeted results were not met (material costs too high, sales prices too low, etc). Variance Analysis is the quantitative investigation of the difference between actual and planned behavior. This analysis is used to maintain control over a business. For example, if you budget for sales to be USD10 000 and actual sales are USD8 000, variance analysis yields a difference of USD2 000. Variance analysis is especially effective when you review the amount of a variance on a trend line, so that sudden changes in the variance level from month to month are more readily

apparent. Variance analysis also involves the investigation of these differences, so that the outcome is a statement of the difference from expectations, and an interpretation of why the variance occurred. To continue with the example, a complete analysis of the sales variance would be:- 'Sales during the month were USD2 000 lower than the budget of USD10 000. This variance was primarily caused by the loss of ABC customer at the end of the preceding month, which usually buys USD1 800 per month from the company. We lost ABC customer because we had several instances of late deliveries to it over the past few months'. This level of detailed variance analysis allows management to understand why fluctuations occur in its business, and what it can do to change the situation. Here are the most commonly-derived variances used in variance analysis (they are linked to more complete descriptions, as well as examples):- (i) Purchase Price Variance:- the actual price paid for materials used in the production process, minus the standard cost, multiplied by the number of units used; (ii) Labor Rate Variance:- the actual price paid for the direct labor used in the production process, minus its standard cost, multiplied by the number of units used; (iii) Variable Overhead Spending Variance:- subtract the standard variable overhead cost per unit from the actual cost incurred and multiply the remainder by the total unit quantity of output; (iv) Fixed Overhead Spending Variance:- the total amount by which fixed overhead costs exceed their total standard cost for the reporting period; (v) Selling Price Variance:- the actual selling price, minus the standard selling price, multiplied by the number of units sold; (vi) Material Yield Variance:- subtract the total standard quantity of materials that are supposed to be used from the actual level of use and multiply the remainder by the standard price per unit; (vii) Labor Efficiency Variance:- subtract the standard quantity of labor consumed from the actual amount and multiply the remainder by the standard labor rate per hour; and (viii) Variable Overhead Efficiency Variance:- subtract the budgeted units of activity on which the variable overhead is charged from the actual units of activity, multiplied by the standard variable overhead cost per unit. It is not necessary to track all of the preceding variances. In many organizations, it may be sufficient to review just one or two variances. For example, a services organization (such as a consulting business) might be solely concerned with the labor efficiency variance, while a manufacturing business in a highly competitive market might be mostly concerned with the purchase price variance. In other words, put most of the variance analysis effort into those variances that make the most difference to the company if the underlying issues can be rectified. There are several problems with variance analysis that keep many companies from using it. They are:- (i) Time Delay:- the accounting staff compiles the variances at the end of the month before issuing the results to the management team. In a fast-paced environment, management needs feedback much faster than once a month, and so tends to rely upon other measurements or warning flags that are generated on the spot (especially in the production area). (ii) Variance Source Information:- many of the reasons for variances are not located in the accounting records, so the accounting staff has to sort through such information as bills of material, labor routings, and overtime records to determine the causes of problems. The extra work is only cost-effective when management can actively correct problems based on this information. (iii) Standard Setting:- variance analysis is essentially a comparison of actual results to an arbitrary standard that may have been derived from political bargaining. Consequently, the resulting variance may not yield any useful information. Many companies prefer to use horizontal analysis, rather than variance analysis, to investigate and interpret their financial results. Under this approach, the results of multiple periods are listed side-by-side, so that trends can be easily discerned. / Анализ Отклонений:- процесс определения величины отклонений фактических показателей от нормативных (бюджетных) и выявления причин их образования. Используется руководством для контроля исполнения бюджетов, оценки результатов деятельности в системе Стандарт-Кост.

VARIANCE ESTIMATION = ОЦЕНКА ВАРИАНСЫ (или ОЦЕНКА ДИСПЕРСИИ) – Variance Estimation:- the task of estimating the value of the variance of an estimate. Context:- methods employed are commonly classified as:- (i) analytic methods:- use and compute the proper formulae of the variance; (ii) approximate methods:- methods that use approximations for complex and muti-stage sample designs. These methods can be classified in three categories:- (i) simplifying assumptions:- setting assumptions which allow use of straightforward formulae (as if an analytic method could be applied); (ii) Taylor's linearization techniques:- estimation of non-linear statistics is simplified in using a Taylor's development of the concerned statistics; (iii) replication or re-sampling methods: a large number of sub-samples are derived from the initial sample and variance is estimated from the variability of the results in this set of sub-samples. Several methods are based on re-sampling, such as the jack-knife, the bootstrap and the balanced repeated replication methods. See also Estimate, and Variance. / Тэйлор (Taylor).

VARIANCE–MINIMIZATION APPROACH TO TRACKING = ПОДХОД МИНИМИЗАЦИИ ВАРИАНСЫ ПРИ ОТСЛЕЖИВАНИИ (или XX) – Variance-Minimization Approach To Tracking is an approach to bond indexing that uses historical data to estimate the variance of the tracking error. Variance Minimization Approach To Tracking:- a bond indexing approach in which the tracking error's variance is estimated using historical data.

VARIANCE REPORT = ОТЧЁТ О ВАРИАНСЕ (или ОТЧЁТ О ДИСПЕРСИИ, или ОТЧЁТ О РАСХОЖДЕНИИ) – Variance Report compares actual to expected results. The typical format is to first present the actual results, followed by the expected results (in the form of a budgeted or standard number), after which the variance amount and variance percentage are stated. This report allows management to gauge the performance of an organization against expectations. The report is most commonly used to calculate revenue and expense variances from a baseline forecast or budget. The best variance reports highlight the most significant variances and downplay minor ones, so that management attention is directed towards material issues that are most in need of investigation and correction.

VARIANCE RULE = ПРАВИЛО ВАРИАНСЫ (или ПРАВИЛО ДИСПЕРСИИ, или ПРАВИЛО РАСХОЖДЕНИЯ) – Variance Rule specifies the permitted minimum or maximum quantity of securities that can be delivered to satisfy a TBA (short for the To Be Announced) trade. For Ginnie Mae, Fannie Mae, and Freddie Mac pass-through securities, the accepted variance is plus or minus 2.499 999% per million of the par value of the TBA quantity. / Дьжини Мэй (Ginnie Mae), Фэни Мэй (Fannie Mae), и Фрэди Мэк (Freddie Mac).

VARIANCE SWAP = СВОП НА ВАРИАНСУ (или XX) – Variance Swap:- this is a kind of volatility swap in which the return is dependant on variance instead of volatility. The payout in a variance swap is bigger than that in a volatility swap, as the returns depend on variance and not standard deviation, which is the usual measure of volatility.

VARIANT = ВАРИАНТ (или ВАРИАНТА) – (1) Variant is a plant that is different from the majority or from normal plants. / Под Вариантом, от Французского слова Variante, от Латинского слова Varians, родительный падеж Variantis, означающее Изменяющийся или Меняющий, понимается:- (1) видоизменение, разновидность чего-либо. (2) Одна из возможных реализаций, например, одна из нескольких редакций какого-либо произведения (литературного, музыкального и тому подобного) или официального документа; видоизменение какой-либо части произведения (документа). (3) В шахматной или шашечной игре – одна из возможных при данном положении комбинаций ходов.

(2) In computing terms, a Variant is a type of virus or malware program. Viruses and malware are potentially dangerous programs or pieces of programming code that can cause massive amounts of damage to your computer if it becomes infected with them, in some cases even resulting in a complete system crash. The term Variant refers specifically to new or modified strains of an existing virus or malware program. Antivirus software is constantly being updated to recognize common viruses. Because of this, a single virus strain

might only have a relatively short life span before it is recognized and neutralized. By creating a variant, malware programmers can increase the longevity of the virus's original code while still technically generating a new, unrecognizable virus. See also Virus. / Вариант вируса, штамм, модификация (Variant) – модифицированный вариант одного и того же вируса. Изменения в вирусный код могут вноситься как автором вируса, так и третьим лицом.

(3) Variant is a manufactured fiber modified in polymer configuration or by additive during manufacture, resulting in a change in the properties of the fiber. Examples are flame-retardant variants, deep-dyeing variants, high-tenacity variants, low-pilling variants, and cotton-blending or wool-blending variants.

VARIANT CREUTZFELDT–JACOB DISEASE = ВАРИАНТ БОЛЕЗНИ КРОЙЦФЭЛЬДА–ЯКОБА – Variant Creutzfeldt-Jakob Disease (vCJD) is a variant form of Creutzfeldt-Jakob disease believed to be caused by eating contaminated beef products from BSE-affected cattle. The variant form in the United Kingdom predoninantly affected younger persons and had atypical clinical features, including prominent psychiatric or sensory symptoms early in the course of the illness, delayed onset of neurologic abnormalities, duration of illness of at least 6 months, and a diffusely abnormal non-diagnostic electroencephalogram. German neuropathologist Hans Gerhard Creutzfeldt (1885–1964) and German neurologist Alfons Maria Jakob (1884–1931). Creutzfeldt-Jakob Disease (CJD):- A degenerative, invariably fatal brain disorder. It affects about one person in every one million people per year worldwide; in the United States there are about 200 cases per year. CJD usually appears in later life and runs a rapid course. Typically, onset of symptoms occurs about age 60, and about 90% of patients die within a year. In the early stages of disease, patients may have failing memory, behavioral changes, lack of coordination and visual disturbances. As the illness progresses, mental deterioration becomes pronounced and involuntary movements, blindness, weakness of extremities, and coma may occur. There are three major categories of CJD:- (i) Sporadic CJD:- in sporadic CJD, the disease appears even though the person has no known risk factors for the disease. This is by far the most common type of CJD and accounts for at least 85% of cases. (ii) Hereditary CJD:- in hereditary CJD, the person has a family history of the disease and/or tests positive for a genetic mutation associated with CJD. About 5 to 10% of cases of CJD in the United States are hereditary. (iii) Acquired CJD:- in acquired CJD, the disease is transmitted by exposure to brain or nervous system tissue, usually through certain medical procedures. There is no evidence that CJD is contagious through casual contact with a CJD patient. Since CJD was first described in 1920, fewer than 1% of cases have been acquired CJD. CJD belongs to a family of human and animal diseases known as the Transmissible Spongiform Encephalopathies (TSEs). Spongiform refers to the characteristic appearance of infected brains, which become filled with holes until they resemble sponges under a microscope. CJD is the most common of the known human TSEs. Other human TSEs include kuru, fatal familial insomnia (FFI), and Gerstmann-Straussler-Scheinker disease (GSS). Kuru was identified in people of an isolated tribe in Papua New Guinea and has now almost disappeared. Fatal familial insomnia and GSS are extremely rare hereditary diseases, found in just a few families around the world. Other TSEs are found in specific kinds of animals. These include bovine spongiform encephalopathy (BSE), which is found in cows and often referred to as 'Mad Cow' Disease, scrapie, which affects sheep and goats, mink encephalopathy, and feline encephalopathy. Similar diseases including chronic wasting disease (CWD) occur in elk, deer, and exotic zoo animals. Symptoms:- CJD is a rapidly progressive dementia. Initially, patients experience problems with muscular coordination; personality changes, including impaired memory, judgment, and thinking; and impaired vision. People with the disease also may experience insomnia, depression, or unusual sensations. CJD does not cause a fever or other flu-like symptoms. As the illness progresses, the patients' mental impairment becomes severe. They often develop involuntary muscle jerks called Myoclonus, and they may go blind. They eventually lose the ability to move and speak and enter a coma. Pneumonia and other infections often occur in these patients and can lead to death. There are several known variants of CJD. These variants differ somewhat in the symptoms and course of the disease. For example, a variant form of the disease – called new variant or variant (nv-CJD or v-CJD), described in Great Britain and France – begins primarily with psychiatric symptoms, affects younger patients than other types of CJD, and has a longer than usual duration from onset of symptoms to death. Another variant, called the panencephalopathic form, occurs primarily in Japan and has a relatively long course, with symptoms often progressing for several years. CJD causes unique changes in brain tissue which can be seen at autopsy. Diagnosis:- There is currently no single diagnostic test for CJD. When CJD is suspected, the first concern is to rule out treatable forms of dementia such as encephalitis (inflammation of the brain) or chronic meningitis. A neurological examination and spinal tap are often performed to rule out more common causes of dementia. An electroencephalogram (EEG) to record the brain's electrical pattern can be particularly valuable because it shows a specific type of abnormality in CJD. Computerized tomography (CT) of the brain can help rule out the possibility that the symptoms result from other problems such as stroke or a brain tumor. Magnetic resonance imaging (MRI) brain scans also can reveal characteristic patterns of brain degeneration that can help diagnose CJD. At present, the only sure way to confirm a diagnosis of CJD is by brain biopsy or autopsy. In a brain biopsy, a neurosurgeon removes a small piece of tissue from the patient's brain so that it can be examined by a neuropathologist. This procedure may be dangerous for the patient, and the operation does not always obtain tissue from the affected part of the brain. Because a correct diagnosis of CJD does not help the patient, a brain biopsy is discouraged unless it is needed to rule out a treatable disorder. In an autopsy, the whole brain is examined after death. More tests for CJD are under development. Treatment:- There is no treatment that can cure or control CJD. Researchers have tested many drugs, including amantadine, steroids, interferon, acyclovir, antiviral agents, and antibiotics. However, none of these treatments has shown any consistent benefit. Current treatment for CJD is aimed at alleviating symptoms and making the patient as comfortable as possible. Cause(s):- The agent that causes CJD has several characteristics that are unusual for well-known organisms such as Viruses and Bacteria. It is difficult to kill, it does not appear to contain any genetic information in the form of nucleic acids (DNA or RNA), and it usually has a long incubation period before symptoms appear. In some cases, the incubation period may be as long as 40 years. The leading scientific theory at this time maintains that CJD and the other TSEs are caused not by an organism but by a type of protein called a 'prion'. Prions occur in both a normal form, which is a harmless protein found in the body's cells; and in an infectious form, which causes disease. The harmless and infectious forms of the prion protein are nearly identical, but the infectious form takes a different folded shape than the normal protein. Sporadic CJD may develop because some of a person's normal prions spontaneously change into the infectious form of the protein and then alter the prions in other cells in a chain reaction. Once they appear, abnormal prion proteins stick together and form fibers and/or clumps called Plaques that can be seen with powerful microscopes. Fibers and plaques may start to accumulate years before symptoms of CJD begin to appear. It is still unclear what role these abnormalities play in the disease or how they might affect symptoms. About 5 to 10% of all CJD cases are inherited. These cases arise from a mutation, or change, in the gene that controls formation of the normal prion protein. While prions themselves do not contain genetic information and do not require genes to reproduce themselves, infectious prions can arise if a mutation occurs in the gene for the body's normal prions. If the prion gene is altered in a person's sperm or egg cells, the mutation can be transmitted to the person's offspring. Several different mutations in the prion gene have been identified. The particular mutation found in each family affects how frequently the disease appears and what symptoms are most noticeable. However, not all people with mutations in the prion gene develop CJD. This suggests that the mutations merely increase susceptibility to CJD and that other, still-unknown factors also play a role in the disease. Transmission:- CJD is not a contagious disease in the usual sense. Although it can be transmitted to other people, the risk of this happening is extremely small. CJD cannot be transmitted through the air or through touching or most other forms of casual contact.

Spouses and other household members of sporadic CJD patients have no higher risk of contracting the disease than the general population. However, direct or indirect contact with brain tissue and spinal cord fluid from infected patients should be avoided to prevent transmission of the disease through these materials. In a few very rare cases, CJD has spread to other people from grafts of dura mater (a tissue that covers the brain), transplanted corneas, implantation of inadequately sterilized electrodes in the brain, and injections of contaminated pituitary growth hormone derived from human pituitary glands taken from cadavers. Doctors call these cases that are linked to medical procedures iatrogenic cases. Since 1985, all human growth hormone used in the United States (US) has been synthesized by recombinant DNA procedures, which eliminates the risk of transmitting CJD by this route. The appearance of the new variant of CJD (nv-CJD or v-CJD) in several younger than average people in Great Britain and France has led to concern that BSE may be transmitted to humans through consumption of contaminated beef. Although laboratory tests have shown a strong similarity between the prions causing BSE and v-CJD, there is no direct proof to confirm this theory. Furthermore, BSE has never been found in the US, and importation of cattle and beef from countries with BSE has been banned in the US since 1989 to reduce the risk that it will occur in this country. Some animal studies suggest that contaminated blood and related products may transmit the disease, although this has never been shown in humans. If there are infectious agents in these fluids, they are probably in very low concentrations. Scientists do not know how many abnormal prions a person must receive before he or she develops CJD, so they do not know whether these fluids are potentially infectious or not. They do know that, even though millions of people receive blood transfusions each year, there are no reported cases of someone contracting CJD from a transfusion. Even among hemophiliacs, who sometimes receive blood plasma concentrated from thousands of people, there are no reported cases of CJD. This suggests that, if there is a risk of transmitting CJD through blood or plasma, it is extremely small. Precautions:- To reduce the already very low risk of CJD transmission from one person to another, people should never donate blood, tissues, or organs if they have suspected or confirmed CJD, or if they are at increased risk because of a family history of the disease, a dura mater graft, or other factor. Normal sterilization procedures such as cooking, washing, and boiling do not destroy prions. Caregivers, health care workers, and undertakers should take the following precautions when they are working with a person with CJD:- (i) Wash hands and exposed skin before eating, drinking, or smoking; (ii) Cover cuts and abrasions with waterproof dressings; (iii) Wear surgical gloves when handling a patient's tissues and fluids or dressing the patient's wounds; (iv) Avoid cutting or sticking themselves with instruments contaminated by the patient's blood or other tissues; (v) Use disposable bedclothes and other cloth for contact with the patient; (vi) If disposable materials are not available, regular cloth should be soaked in undiluted chlorine bleach for an hour or more, then washed in a normal fashion after each use; (vii) Use face protection if there is a risk of splashing contaminated material such as blood or cerebrospinal fluid; (viii) Soak instruments that have come in contact with the patient in undiluted chlorine bleach for an hour or more, then use an autoclave (pressure cooker) to sterilize them in distilled water for at least one hour at 132–134 degrees Centigrade. / Кройцфэльд-Якоб (Creutzfeldt-Jakob). Немецкий невропатолог Ханс Герхад Кройцфэльд (Hans Gerhard Creutzfeldt; 1885–1964) и Немецкий невролог Альфонс Мариа Якоб (Alfons Maria Jakob; 1884–1931).

VARIATE = СЛУЧАЙНАЯ ВЕЛИЧИНА – In statistics, Variate is a random variable with a numerical value that is defined on a given sample space. Variate:- in contradistinction to a variable, a variate is a quantity which may take any of the values of a specified set with a specified relative frequency or probability. The variate is therefore often known as a Random Variable. It is to regarded as defined, not merely by a set of permissible values like an ordinary mathematical variable, but by an associated frequency (probability) function expressing how often those values appear in the situation under discussion. Variate is a single observation or measurement. A Variate is a generalization of the concept of a random variable that is defined without reference to a particular type of probabilistic experiment. It is defined as the set of all random variables that obey a given probabilistic law. It is common practice to denote a variate with a capital letter (most commonly X). The set of all values that X can take is then called the Range, denoted R_X (Evans et al. 2000, p. 5). Specific elements in the range of X are called Quantiles and denoted x, and the probability that a variate X assumes the value x is denoted P (X = x). / В теории вероятностей под Случайной Величиной понимается величина, принимающая в зависимости от случайного исхода испытания те или иные значения с определёнными вероятностями. Так, число очков, выпадающее на верхней грани игральной кости, представляет собой случайную величину, принимающую значения 1, 2, 3, 4, 5, 6 с вероятностью 1/6 каждое. Если случайное число принимает конечную или бесконечную последовательность различных значений, то её распределение вероятностей (закон распределения) задаётся указанием этих значений:- $x_1, x_2, ..., x_n, ...$ и соответствующих им вероятностей:- $p_1, p_2, ..., p_n, ...$ Случайные величины указанного типа называются дискретными. В других случаях распределение вероятностей задаётся указанием для каждого отрезка D = [a, b] вероятности P_x (a, b) неравенства a £ x < b. Особенно часто встречаются случайные величины, для которых существует такая функция px (x) (плотность вероятности), что $P_x (a, b) = \int_a^b px (x)dx$. Случайные величины этого типа называются непрерывными. Ряд общих свойств распределения вероятностей случайных величин достаточно полно описывается небольшим количеством числовых характеристик. Наиболее употребительными среди этих последних являются математическое ожидание EX, случайная величина X и её дисперсия DX. Менее употребительны медиана, мода, квантили и тому подобные. Смотрите также Теория Вероятностей.

VARIATE TRANSFORMATION = ТРАНСФОРМАЦИЯ СЛУЧАЙНОЙ ВЕЛИЧИНЫ – Variate Transformation is the transformation of one variate into another, usually by a mathematical equation connecting them. The object is, as a rule, to transform the distribution function of one variate exactly or approximately into a distribution function of known form and properties.

VARIATION = ВАРИАЦИЯ (или ИЗМЕНЧИВОСТЬ) – Variation:- in biology, any difference between cells, individual organisms, or groups of organisms of any species caused either by genetic differences (genotypic variation) or by the effect of environmental factors on the expression of the genetic potentials (phenotypic variation). Variation may be shown in physical appearance, metabolism, fertility, mode of reproduction, behaviour, learning and mental ability, and other obvious or measurable characters. Genotypic variations are caused by differences in number or structure of chromosomes or by differences in the genes carried by the chromosomes. Eye color, body form, and disease resistance are genotypic variations. Individuals with multiple sets of chromosomes are called Polyploid; many common plants have two or more times the normal number of chromosomes, and new species may arise by this type of variation. A variation cannot be identified as genotypic by observation of the organism; breeding experiments must be performed under controlled environmental conditions to determine whether or not the alteration is inheritable. Environmentally caused variations may result from one factor or the combined effects of several factors, such as climate, food supply, and actions of other organisms. Phenotypic variations also include stages in an organism's life cycle and seasonal variations in an individual. These variations do not involve any hereditary alteration and in general are not transmitted to future generations; consequently, they are not significant in the process of evolution. Variations are classified either as continuous, or quantitative (smoothly grading between two extremes, with the majority of individuals at the center, as height in human populations); or as discontinuous, or qualitative (composed of well-defined classes, as blood groups in man). A discontinuous variation with several classes, none of which is very small, is known as a Polymorphic Variation. The separation of most higher organisms into males and females and the occurrence of several forms of a butterfly of the same species, each colored to blend with a different vegetation, are examples of polymorphic variation. Variation is the occurrence of differences among cultivars due to differences in their genetic composition and/or the environment in which they were cultivated. / Под

Вариацией, от Латинского слова Variatio, означающее Изменение, понимается возникновение различий между . Под Вариацией понимается таксономическая категория; то же, что Вариетет. Под Изменчивостью понимается разнообразие признаков и свойств у особей и групп особей любой степени родства. Присуща всем живым организмам. Различают изменчивость:- наследственную и ненаследственную; индивидуальную и групповую; качественную и количественную; направленную и ненаправленную. Наследственная изменчивость обусловлена возникновением мутаций, ненаследственная – воздействием факторов внешней среды. Явления наследственности и изменчивости лежат в основе эволюции.

VARIATION (MAINTENANCE) MARGIN = ВАРИАЦИОННАЯ (ПОДДЕРЖИВАЕМАЯ) МАРЖА – Variation (Maintenance) Margin is the additional funds called in by a broker or bank for a futures contract in order to meet the margin requirements. See also Initial Margin; and Variation Margin. What is the difference between initial margin and maintenance margin? Buying securities on margin can be advantageous for an investor. Profit is magnified if there is a gain, and losses are as well if there is a loss. Margin is much like buying stocks on loan. An investor borrows funds from a brokerage firm to purchase stocks and pays interest on the loan. The stocks themselves are held as collateral by the brokerage firm. There are many set rules the brokerage firm and the investor must follow. The Federal Reserve Board sets the rules for margin requirements. There is an initial margin requirement and a maintenance margin requirement. The Federal Reserve Regulation T states that an initial margin must be at least 50%, although many brokerage firms set their requirements higher at 70%. This means that an investor must pay 50%, or more if the brokerage firm requires it, of the security's purchase price up front. The brokerage firm must provide the remainder of the funds. After the initial purchase, a maintenance margin is set. Regulation T sets this requirement at 25%, although many brokerage firms require more, such as 30 to 40%. A maintenance margin at 25% means that there must be a minimum amount of equity valued at 25% or more of the total value of the margin account. If one or more securities in the account falls below a certain price and these requirements are not met, the investor receives a Margin Call, sometimes known as a 'Fed Call'. In this situation, a brokerage firm then requires the investor to deposit funds to bring the account back up to the minimum maintenance requirement.

VARIATION MARGIN = ВАРИАЦИОННАЯ МАРЖА – Variation Margin:- the collateral exchanged to cover the gains or losses associated with the change in the price of a centrally cleared or bilaterally margined contract. Variation margin may be prescribed for exchange-traded deals, as well as bilateral deals and those that are cleared. On a periodic basis – often daily – collateral is exchanged to reflect the change in mark-to-market of a deal or portfolio of deals. See also Collateral; and Initial Margin. Variation Margin is an additional margin required to be deposited by a clearing member firm to the exchange clearinghouse during periods of great market volatility or in the case of high-risk accounts. The Variation Margin is a variable margin payment made by clearing members to their respective clearing houses based on adverse price movements of the futures contracts these members hold. Variation margin is paid by clearing members on a daily or intraday basis to reduce the exposure created by carrying highly risky positions. By demanding variation margin from their members, clearing organizations are able to maintain a suitable level of risk and cushion against significant devaluations. A variation margin is used to bring an equity account up to the margin level. This margin, and the associated initial and maintenance margin, must be sustained by liquid funds associated with the investor's account, allowing it to function as collateral against the other activities in which the investor participates. This is more likely to be required when investments experience significant movement and price changes in the associated shares. The amount required at any point when the variation margin is requested varies depending on the exact market conditions and price movement experienced at the end of the day. It can be affected by market conditions, especially high volatility, or any other activity that presents higher risk but is not necessary when risks are lowered. The variation margin payment of additional funds may be deemed necessary by a broker when the equity account balance falls below the maintenance margin or initial margin requirement. This request for funds is referred to as a Margin Call. The margin call involves the brokerage requiring the investor to contribute the additional funds to meet the required minimum. It is enacted when the value of the securities purchased falls below the initial margin. If the investor is not able to meet the margin call requirement, the brokerage can then sell off securities held in the account by the investor until the amount is met. The maintenance margin requirement refers to the amount of money an investor must keep in his margin account. This requirement gives the investor the ability to borrow from a brokerage. This fund functions as collateral against the amount borrowed by the investor. Maintenance margins may be set to any amount as required by the brokerage. For example, the Financial Industry Regulatory Authority (FINRA) requires the maintenance margin to be set at a minimum of 25%. Other brokerages can set higher minimums, such as 50%, depending on the level of risk and the investor involved. Additional margin payments to bring original margin deposits up to the required levels in relation to changing prices. See also Margin Call. Variation Margin is an additional margin, or collateral payable by an investor, resulting from an adverse movement in the price of the underlying asset in a forward, futures or options contract. Variation Margin:- profits and losses calculated on a daily basis in open futures contracts and options, resulting in the counterparty to the bilateral trade making a payment to the relevant clearing house or vice versa. Variation Margin is an additional required deposit to bring an investor's equity account up to the margin level when the balance falls below the maintenance margin requirement. See also Initial Performance Bond, Maintenance Performance Bond, and Margin Call. Variation Margin:- funds that are paid to (or received from) a counterparty (clearing house or clearing member) to settle any losses (gains) that are implied by marking open positions to market. Variation Margin:- during periods of great market volatility or in the case of high-risk accounts, additional margin deposited by a clearing member firm to an exchange clearinghouse. Variation Margin is the settlement via the clearinghouse of daily or intraday gains and losses between clearing member firms. Variation Margin is the minimum funds required by an FX brokerage firm to support an open position. Variation Margin:- profits and losses on open positions which are calculated daily by the mark-to-market process, which are then paid or collected daily. What is Maintenance Margin? It is important to note that the value of all contracts for difference positions is constantly being monitored and re-assessed by brokers. As a trader an important part of the contract is that you must agree to maintain the positions at the required deposit value on an ongoing basis. Maintenance margin also sometimes referred to as variation margin is the amount of margin that is needed to maintain a position (remain invested in a trade). Initial margin is always higher than maintenance margin, so for as long as the initial margin is covered you do not have to worry about the maintenance margin. Usually, maintenance margin is about 75% of initial margin. When the available monies in your margin account are reduced by losses to below a certain level, known as the Maintenance Margin Requirement, you will be required to deposit additional funds to bring the account back to the level of the initial margin. Or, you may also be asked for additional margin if the exchange raises its margin requirements. Variation Margin refers to the difference between the initial margin and the margin needed to keep the position open as the position value changes. For instance, if the initial margin for gold is USD2 000 and the maintenance margin is USD1 500, you would need to have USD2 000 allocated from your account as initial margin to trade the gold contract. Positions are marked-to-market every day meaning that every position is valued at the close of each business day with any profits credited to your trading account and losses deducted. This means that the current price is compared to the previous day's price and should losses on the position amount to, say, USD600, the value of your initial margin would be reduced to USD1 400, which is below the USD1 500 maintenance margin requirement. Therefore, extra funds in the amount of USD600 from your account would be automatically allocated towards bringing the initial margin figure back to USD2 000. If there were not excess funds in the account to bring the initial amount back up to USD2 000, the trader would have to meet the margin call promptly as otherwise the position would be liquidated by the broker which means having your investments sold by the

provider because you can't meet the margin top up requirements. Note that margins are computed on an intraday basis to ensure a sufficient level of margin cover is maintained. This means that you may have to pay more if the market moves against you. If the market moves in your favor, your margin requirement may be reduced. Variation Margin Share Trade Example:- Let's take the case where you bought 5 000 share CFDs in ABC stock at USD4.20 giving you a total position value of 5 000 x USD4.20 = USD21 000. Assuming an initial margin of 10%, you would need to deposit at least USD2 100 with the CFD broker to open this trade. If ABC's share price goes down to say, USD4.10, you will now incur a loss of USD500 (USD0.10 x 5 000). This running loss referred to as variation margin is subtracted from your initial margin of USD2 100, which leaves a deposit of USD1 600. Since you still hold 5 000 share contracts at USD4.10 you will have a margin requirement of USD2 050 (i.e. 5 000 x 4.10 x 10%). Since there's now a paper loss of USD500, the initial margin has now been reduced to USD1 600 which is USD450 lower than the margin required to retain the position open and more margin is needed to top-up the account. This deficit in margin is sometimes referred to as a 'Shortage In Equity'. If you cannot maintain the margin requirement you will not be able to extend your position but you can always reduce or close the position. Variation Margin is the payment required upon margin call. A Variation Margin is the amount that you are required to pay into your account to bring the Maintenance Margin back to its minimum level. Your broker (or the clearing house) may require that you pay in more to than the minimum amount to get you to the Maintenance Margin. Variation margin is paid on a daily or intraday basis in order to reduce the exposure created by a position moving adversely against the trader. Brokers will issue a Margin Call against the trader requesting that they pay in a Variation Margin. Variation Margin is a payment made on a daily or intraday basis by a clearing member to the clearing organization based on adverse price movement in positions carried by the clearing member, calculated separately for customer and proprietary positions. / Вариационная Маржа:- прибыли и убытки по открытым позициям, рассчитываемые ежедневно в процессе переоценки по текущей рыночной стоимости и затем выплачиваемые или взыскиваемые также на ежедневной основе. Вариационная Маржа:- дополнительная маржа, которая должна быть внесена фирмой членом клиринговой палаты на её счёт в клиринговой палате данной биржи в периоды значительной лихорадочности рынка или в случае повышенного риска для счёта по операциям данного клирингового члена. Производимый клиринговым членом клиринговой палате на посуточной или внутрисуточной основе платёж зависит от уровня изменения цен по его открытым позициям. Такой платёж рассчитывается отдельно по позициям заказчиков и по собственным позициям этого клирингового члена. Вариационная Маржа – дополнительное гарантийное обеспечение, ежедневно уплачиваемое сторонами срочной сделки при неблагоприятном движении цен. Вариационная Маржа:- денежные средства, уплачиваемые контрагенту/или получаемые от контрагента (клиринговой палаты или участника клиринга) для осуществления расчёта в размере любых убытков (прибылей), возникших вследствие переоценки открытых позиций по рыночным ценам. Вариационная Маржа:- доходы или убытки по открытым контрактам на фьючерсных рынках, рассчитываемые на основе цены закрытия в конце каждого дня. Клиринговая Палата (Clearing House) записывает их в кредит счетов своих членов, а эти члены клиринговой палаты в свою очередь записывают их на счета своих клиентов. Вариационная Маржа:- дополнительное внесение средств по марже, необходимость которого возникает в результате колебаний цены на товар. Вариационная Маржа или Переменная Маржа:- сумма прибылей/убытков по открытым позициям участника срочного рынка, рассчитываемая ежедневно расчётной палатой по результатам торговой сессии. Вариационная маржа может увеличивать или уменьшать сумму гарантийных обязательств. При положительной вариационной марже прибыль зачисляется на биржевой счёт клиента. При отрицательной вариационной марже сумма убытка списывается со счёта клиента, и расчётная палата предъявляет требование о внесении дополнительного гарантийного обеспечения. В результате перерасчёта открытых позиций сумма выигрыша переводится со счёта проигравшей стороны на счёт выигравшей стороны. Смотрите также (Initial Performance Bond), (Maintenance Performance Bond), и (Margin Call). Вариационная Маржа:- сумма прибылей и/или убытков по всем открытым позициям участника срочного рынка биржи, определяемая при проведении корректировки по рынку. Вариационная маржа по одной позиции – прибыль или убыток по этой позиции при пересчёте её стоимости по расчётной цене текущего торгового дня. Вариационная маржа по позиции равна:- (а) для длинной позиции:- ВМ = (Цр – Цт) х Сим / Им; или (б) для короткой позиции:- ВМ = – (Цр – Цт) х Сим / Им, где:- ВМ – вариационная маржа по данной позиции; Цр – расчётная цена данного торгового дня по соответствующей серии срочного инструмента; Цт – текущая цена данной позиции; Им – минимальное изменение цены в соответствии со спецификацией срочного инструмента; Сим – стоимостная оценка минимального изменения цены (в Рублях) в соответствии со спецификацией срочного инструмента. Вариационная Маржа (Variation Margin) – изменение маржи за прошедший день.

VARIATION MARGINING = ВАРИАЦИОННЫЙ ПЕРЕРАСЧЁТ МАРЖИ – Variation Margining is a daily clearing of profits and losses resulting from futures and options on futures. To this end, individual positions are valued at their daily settlement price. The difference compared to the position's value on the previous trading day is debited or credited to the market participant.

VARIEGATED = ПЁСТРОЕ – Variegated:- with patches or stripes of different colors, often yellow or reddish. Hence variegata – of a plant exhibiting variegation. Variegated (leaf lower surface, leaf upper surface) (color variegation):- the color disposed in various irregular, sinuous, spaces. / Пёстрое:- с пятнами или полосками разного цвета, часто жёлтыми или красноватыми. пестролистность (variegation).

VARIETAL DIVERSITY = СОРТОВОЕ РАЗНООБРАЗИЕ (или МНОГООБРАЗИЕ РАЗНОВИДНОСТИ) – Varietal Diversity is the measurable differences among varieties grown in a particular area or the genetic diversity among varieties of, e.g., the Rice plant. Loss of varietal diversity is a worldwide challenge to crop species at risk for genetic erosion, while the loss of biological resources may hinder future breeding objectives. Loss of varieties has been mostly investigated in traditional agricultural systems where variety numbers are dramatically high, or for most economically important crop species for which comparison between pre-intensive and modern agriculture was possible. Varietal dynamics, i.e. turnover, or gains and losses of varieties by farmers, is nevertheless more rarely studied and while we currently have good estimates of genetic or varietal diversity for most crop species, we have less information as to how on farm agro-diversity changes and what cause its dynamics. We therefore investigated varietal dynamics in the agricultural yam system in the Caribbean island of Guadeloupe. We interviewed producers about varieties they cultivated in the past compared to their current varieties, in addition to characterizing yam cropping characteristics and both farm level and producers socio-economic features. We then used regression tree analyses to investigate the components of yam agro-diversity, varietal dynamics and impact of anthracnose on varieties. Our data demonstrated that no dramatic loss of varieties occurred within the last decades. Cultivation changes mostly affected widespread cultivars while frequency of uncommon varieties stayed relatively stable. Varietal dynamics nevertheless followed sub-regional patterns, and socio-economic influences such as producer age or farm crop diversity. Recurrent anthracnose epidemics since the 1970s did not alter varietal dynamics strongly, but sometimes translated into transition from Dioscorea Alata to less susceptible species or into a decrease of yam cultivation. Factors affecting changes in agro-diversity were not relating to agronomy in our study, and surprisingly there were different processes delineating short term from long term varietal dynamics, independently of disease risk. Our results highlighted the importance of understanding varietal dynamics, an often overlooked component of agriculture sustainability, in addition to evolutionary forces shaping agro-diversity and genetic diversity distribution within crops. It is also crucial to understand how processes involved do scale up worldwide and for different crop species, so as not to mislead on-farm conservation efforts and efficacy of agro-diversity preservation.

VARIETAL IMPROVEMENT = УЛУЧШЕНИЕ СОРТОВ (или УЛУЧШЕНИЕ РАЗНОВИДНОСТЕЙ) – Varietal Improvement is the process of improving varieties to meet the standards required. For example, there are several varieties of Rice available in the market. Similarly, there are many varieties of Mangoes and Brinjal. Each variety is unique in its colour, size, shape and taste. Thus, one type of plant has many varieties. A lot of research has gone into creating these varieties. They have been tailor made to satisfy the different needs of man. Producing many varieties has not only brought about an improvement in the quality but also has brought about an increase in production. Let us study the production of Wheat and Rice in our country. The yield of Wheat and Rice which stood at 668 kg and 663 kg per hectare respectively in 1952 increased to 1 851 and 1 468 kg per hectare in eighties. The production has tripled in thirty years. This increase in food production has marked a turning point in Indian agriculture, which has led to Green Revolution in our country. The revolution is called green because it led to unprecedented greenery of crops everywhere. It is because of the green revolution that our country has become self sufficient in food production and a large stock of food grains has been created for use in the times of natural calamities like drought, floods and famine. The various factors, which collectively led to the green revolution in our country, are:- (i) introduction of high yielding varieties of Mexican Wheat; (ii) proper irrigation; (iii) increased use of fertilizers, weedicides and pesticides; (iv) more land under cultivation; and (v) improved soil practices and agricultural implements. Need For Varietal Improvement:- Population grows in geometrical proportions but food grows in only arithmetical proportion. With the ever increasing demand on food grains, fodder, fibre, vegetables, fruit, sugar and oil, there is an urgent need to increase crop production, as our land resources are limited. Our natural resources (soil, water and weather) are being deteriorated and depleted. So there is an urgent need for improvement in crop plants. The variety developed should be superior to its predecessor. The Reasons For Crop Improvement Are:- (i) Improved Yield:- here the aim is to increase crop production. High yielding crops should be developed for this purpose. (ii) Better Quality:- the public is aware and so it looks out for better quality crops. The quality would mean better size, colour, shape and taste. The health conscious public also wants better nutritive value in the food crop. (iii) Biotic And Abiotic Resistance:- varieties that are biotic (diseases, insects and pests) and abiotic (drought, salinity, water logging, heat, cold, frost) resistant can be developed by an increase in crop production. (iv) Early And Uniform Maturity:- in certain long duration crops, early maturity can make the crop double or triple cropping system. This will reduce the cost of crop production. Along with early maturity if the crop also has the quality of uniform maturity it will make the harvesting process easy and reduce the loss of crop during harvesting. (v) Photo And Thermo Insensitivity:- crop plants are sensitive to light and temperature. The required exposure to sunlight and the right temperature determines the healthy growth of the plant and ensures a good yield. Developing varieties insensitive to these factors will help in overcoming these constraints. Then these crops can be grown in areas, which might not have been ideally suited for the growth of these varieties. This ensures spread of new crops. Desirable Agronomic Traits:- good height, high tillering and profuse branching are traits, desirable for fodder crops. Cereal crops should be short, for better productivity. Developing varieties with agronomic traits that are tailor – made will ensure higher yield. Wider Adaptability:- developing varieties of wider adaptability will help stabilize crop production under unfavourable environmental conditions.

VARIETAL RELEASE = СОРТОВОЙ ВЫПУСК – Varietal Release is the procedure for releasing varieties from breeding stations to farmers for commercial cultivation. The purpose of registration and release of new crop varieties is to ensure that credible and best cultivars are introduced to the public for general cultivation in the region in which they are adapted. It is also to ensure that crops that are introduced to farmers have no harmful effects on the consumer and the environment at large. This enables the farmers to choose varieties of interest for cultivation in the regions in which they are suitable. The process also helps to know the number of crop varieties available to farmers in a particular region and at a given period of time. Lastly, the process helps to identify the gaps and areas of need among breeders, farmers and consumers/industries. Generally, the broad goal of registration and release of new crop varieties is to maximize public benefit. Reasons For Breeding New Crop Varieties:- plant breeding aims to improve the characteristics of plants so that they become more desirable agronomically and economically. Generally, a successful variety is one with total balance of traits that makes it more profitable for the growers and acceptable to the consumers than any other one they might choose. Some of the reasons for breeding a new crop variety may be as follows:- (1) Higher yields; (2) Improved quality:- like baking in Wheat, cooking in Rice, malting in Sorghum, vitamin fortified in Cassava, quality protein in Maize, etc; (3) Resistance/tolerance to Pests; (4) Resistance/tolerance to diseases; (5) Tolerance to abiotic stress like drought, flood, salt and iron toxicity; (6) Early maturity; (7) Good agronomic characteristics like dwarfness in cereals; (8) Photo-insensitivity; (9) Elimination of anti-nutritional factors; (10) Good storability For the purpose of registration and release; if a crop variety is bred for other characteristic apart from yield, in such case(s), it must be of economic importance and also, the yield factor must not be compromised. Requirements For Registration And Release Of Crop Varieties:- for a crop to be registered and released as a new variety in Nigeria it must have passed the test for Distinctiveness, Uniformity and Stability (DUS) and as well as for Value for Cultivation and Use (VCU). (1) The Distinctiveness, Uniformity and Stability (DUS) is an acronym for:- (i) Distinctiveness:- new variety should be clearly distinguishable from any other existing varieties in Nigeria; (ii) Uniformity:- individual plant of new variety should be sufficiently uniform at the same growth stages in the expression of their characteristic; and (iii) Stability:- the genetic traits of the new variety should be stable through generations. The DUS test is an internationally recognised procedure standardized mainly for plant variety protection. The test is used to assess novelty of new varieties and also used to gather information regarding the botanical description of new varieties. In DUS test plots, candidate varieties are compared with similar existing varieties (check varieties) where agronomic characteristics (like yield, maturity date, height), morphological characteristics (like colour, shape, and size), physio-genetical characteristics (like tolerance to pest and disease) and general tolerance to biotic and abiotic stresses are evaluated following the International Union for the Protection of New Varieties of Plants (UPOV) guidelines. The DUS test is to be carried out at the On-station or at any designated DUS testing sites for at least 2 years/ two different giving seasons. (2) Value for Cultivation and Use (VCU):- implies that for a crop to be registered as new variety, it must be beneficial to farming and industrial communities. The objective of VCU test for a candidate variety to be registered are to know:- (i) the adaptation and stability across varied environments; (ii) agronomic performance; (iii) reaction to pests and diseases; and (iv) resistant/tolerant to abiotic stresses, when compared with existing varieties. The VCU test is to be carried out during the multi-locational trial for two years in different environments. (3) The variety must have superior/trait performance over the existing ones with the farmers or currently registered variety in Nigeria. (4) The variety or its progeny is not detrimental to human or animal health and safety of the environment when grown and used as intended. (5) The variety name is not likely to be confused with the name of a variety that had previously been or currently being registered. (6) The variety name is not likely to offend the public. (7) The variety meets the standard for variety purity established by the International Seed Testing Association (ISTA) for a variety of that specie. (8) The variety was monitored by representatives of the Registrar and Technical Sub-Committee on crops during the on-farm trial. (9) The variety is officially nominated to the Technical Sub-Committee (Crops) for registration and release and defended by the developing scientist. (10) No false statement or misleading information is submitted in support of the nomination for variety registration and release. To ascertain that a crop variety meet the DUS and VCU tests, the following trials must be conducted:- (a) On-Station Trial:- the on-station trial is conducted by the breeder responsible for the development of the candidate variety within the premises of the research institute/institution. In the On-station trial, the preliminary yield trial is carried out on the candidate's varieties along with the existing ones. Simultaneously, these lines are given to entomologist/pathologist to study the reaction to pests and diseases of economic importance. The food quality and post-harvest traits are also evaluated at this stage. The principal breeder should also carry out the

DUS test at this stage according to UPOV guidelines. Only lines that qualify from DUS test, yield, pests and diseases, quality and any other novel traits of interest point of view are recommended for multi-locational trial. On-station trial can take more than a year. (b) Multi-Locational Trials:- these trials are carried out for at least two years across different agroecological zones in Nigeria or at several appropriate locations in case the variety is bred for a particular agro-ecology. During the multi-locational trial, the VCU test is examined. These include adaptability, stability, agronomic performance, resistance/tolerant to biotic and abiotic stresses. It must be carried out in not less than 10 testing sites per year for comparison. (c) On-Farm Trial:- the on-farm trials are used to test a new technology on farmer's field. The purpose is to validate the perception of farmers about the candidate variety whether it will be accepted or not, whether it is better than what they have or not and whether it can be adaptable or not. This trial is carried out on farmer's field for a year/a growing season. The trial is to be supervised by appropriate government extension organisation for the crop and farmer's varieties are compared with the candidate varieties in the process. A year data from at least 10 farmer's field across different agro-ecology is required. Exceptional Case In Perenial Crop Species:- In the case of perennial/long gestation crop species (for example, Cocoa, oil-palm, rubber, Mango, citrus, etc), it is recommended that the multi-locational and on-farm trials should be combined through a farmer's participatory varietal selection. Minimum of two years production data in addition to on-station data should be presented for registration and release of the proposed varieties. Note:- All data from these trials should be analysed and presented inform of tables and figures in order of execution along with other relevant documents to the technical committee for registration and release. See also Variety Release. Procedure For Release Of A Variety (in the Tamil Nadu Agricultural University (TNAU), India):- (i) Identification of best cultures from the segregating generation; (ii) Row Yield Trial (RYT); (iii) Replicated Row Yield Trial (RRYT); (iv) Preliminary Yield Trial (PYT); (v) Comparative Yield Trial (CYT); (vi) Multi Location Trial (MLT); (vii) Adaptive Research Trial (ART); (viii) Variety Release Proposal; (ix) State Variety Release Committee (SVRC); (x) Release of State variety; (xi) Notification; and (xii) Certified Seed Production. After identification of the best cultures from the segregating generation or any other source it has to undergo the following trials:- (1) Row Yield Trial (RYT):- For every 10 row, there will be a check entry and the trial will be non replicated. (2) Replicated Row Yield Trail (RRYT):- From the row yield trial, the best cultures will be tested in RRYT along with appropriate check. The best entries from RRYT will be carried forward to preliminary yield trial. (3) Preliminary Yield Trial (PYT):- Replicated trial conducted with appropriate checks. PYT will be conducted normally for two seasons. While conducting, PYT, the best entries will be nominated to All India trials also. Screening for biotic and abiotic stresses will be done during PYT stage. The best entry will be carried to comparative yield trial. The entries entered into All India trial will be given project number. For, e.g., Sorghum entry will be given SPV (Sorghum Project Variety), Rice – IET (Initial Evaluation Trial), etc. (4) Comparative Yield Trial (CYT):- CYT is replicated one conducted with more than one check. The trial will be repeated for 3 seasons. The entry proved to be superior in all the 3 seasons will be proposed for multilocation trial (MLT). (5) Multilocation Trial (MLT):- The entries for MLT will be decided at Crop scientists meet held once in a year. Each station will propose its own entry. Based on discussion of merits and demerits of each culture, the entries will be nominated. The MLT will be conducted at Research Stations of TNAU spread over the State. The best entries will be proposed for Adaptive Research Trial (ART). (6) Adaptive Research Trial (ART):- ART will be conducted at farmers' field by the Agricultural Department Staff. The entries for ART will be decided during Scientific Workers Conference (SWC) which will be held once in a year at TNAU. Both scientists of TNAU and Agri. Dept. Staff will participate. At SWC, the entries will be fixed and each Joint Director of Agriculture will fix number of trials for his division. The entries performing well in ART will be proposed for release as a variety. Each culture has to be tested at least in a minimum of 50 centres spread all over the state. If a culture is non season bound, it will be tested in all the three seasons. If it is not so, one or two seasons result is enough. (7) Variety Release Proposal:- The scientist incharge of the culture will propose the culture for release as a variety. There is a proforma for variety release. This proforma will contain all the information about the culture viz., parentage, parent's morphology, cultures morphology, key characters of the culture for identification, agronomic practices, pest and disease resistance, quality characters and yield trial results. The variety release proposal will be discussed by Director of Research and Scientists. After approval the proposal will be presented before Variety Release Committee. (8) Variety Release Committee:- It will be headed by Commissioner and Secretary, Agrl. Dept. members will be Director of Agriculture Joint Directors of Agriculture and TNAU scientists. Besides these, two leading farmers of the state will also be the members. After discussion, based on merit the VRC will approve it for release. Then the culture will be released for general cultivation. (9) Notification Of The Variety:- For certified seed production, the variety is to be notified by the central variety release committee, Delhi. After release of the variety for notification purpose the information will be furnished in the prescribed proforma. At that time details about All India trial will also be furnished. After notification only, a variety can be multiplied under certified seed production.

VARIETY = РАЗНОВИДНОСТЬ (или СЕЛЕКЦИОННЫЙ СОРТ, или СОРТ РАСТЕНИЙ) – Variety is a group of animals or plants related by descent, but distinguished from other similar groups only by characters considered too inconsistent or trivial to entitle it to recognition as a species. The term Variety means a subdivision of a kind which is characterized by growth, plant, fruit, seed, or other characters by which it can be differentiated from other sorts of the same kind. Variety:- development of Cotton Varieties that produce both high yields and excellent fiber quality has long challenged Cotton breeders. Consistent high yields of varieties are hampered by annual variation in the environment – challenging breeders to find types that are able to yield well over highly contrasting environments. Fiber quality is also affected by variation in environment, but probably hampered more by poor associations with high yield and early maturation, the relative breeding priority on yield, and by changing definitions of excellent quality. Variety is a group of strains or a single strain that can be differentiated from another group by its structural or functional characteristics. The most important criteria to consider when selecting a variety is yield potential. The second most important criteria in variety selection is yield stability. Variety selection is one of the first decisions – perhaps the single most important decision – a cotton producer makes each season. Variety:- subdivision of a species for taxonomic classification. Used interchangeably with the term Cultivar to denote a group of individuals that are distinct genetically from other groups of individuals in the species. An agricultural Variety is a group of similar plants that by structural features and performance can be identified from other varieties within the same species. Variety selection is a critical step in crop production. Cotton breeders attempt to get many 'monkeys' (traits) into one tree (variety). Combining high yielding ability and excellent fiber quality into one variety has been an allusive trick. Biotechnology is clearly making a big impact in the marketplace as dozens of new Cotton varieties have become available in the last few years. Variety is a naturally occurring subdivision of a species representing individuals with distinct but minor variations in their characteristics. The taxonomic rank between Subspecies and Form. Wheat Varieties are categorized by NABIM (short for the National Association of British and Irish Millers) Groups 1 to 4. Groups 1 and 2 are used for most breadmaking grists while Group 3 is used for a range of biscuit, cake and batter flours. See also Class, Cultivar, Division, Family, Genus, Kingdom, Order, Phylum, Specie, and Type. / Смотрите также Вид (Specie), Класс (Class), Культивар или Сорт Растений (Cultivar), Отдел (Division), Отряд (Phylum), Порядок (Order), Род (Genus), Семейство (Family), Тип (Type), и Царство (Kingdom). Сорт Хлопчатника, имеющий своё название и характеризующийся специфическими характеристиками качества получаемого из него волокна или созреваемостью в данных климатических условиях. Разновидность (Varietas), в ботанической номенклатуре группа особей или популяция, отличающаяся от типичных особей Вида второстепенными, слабо наследуемыми признаками (степень опушённости, характер роста, окраска и тому подобное) и не имеющая чётко отграниченного ареала. Разновидность – таксономическая категория рангом ниже Подвида и выше Формы. Появление Разновидности связано с обитанием вида в различных экологических условиях. Так, у Можжевельника Туркестанского

(Juniperus Turkestanica) иногда выделяют высокогорную низкорослую Разновидность – Varietas Fruticosa. Современные систематики обычно избегают понятия разновидности вследствие его неопределённости. В зоологической номенклатуре Разновидности соответствует Вариетет. Под биологической Разновидностью понимается таксономическая категория (ранг) ниже Подвида в систематике растений. Разновидность – группа особей, отличающихся от типичных для Вида особей какими-либо второстепенными признаками (характером роста, окраски). Под Культиваром или Сортом Растений, от Французского слова Sorte, от Латинского слова Sors, означающее Вид или Разновидность, понимается совокупность растений, созданная в результате селекции и обладающая определёнными, передающимися по наследству морфологическими, физиологическими, хозяйственными признаками и свойствами; низшая классификационная единица для культурных растений. Различают местные и селекционные сорта растений. (i) Местные Сорта Растений создаются в результате длительного действия естественных и простейших приёмов искусственного отбора при возделывании той или иной культуры в определённой местности; часто служат исходным материалом в селекции. (ii) Селекционные Сорта Растений создаются в научно-исследовательских учреждениях на основе научных методов селекции. Различают:- (a) Линейные Сорта Растений – генетически однородное потомство одного самоопыляющегося растения, полученное методом индивидуального отбора; (b) Сорта-Популяции – генетически неоднородная совокупность перекрёстно- или самоопыляющихся растений, полученная путём массового отбора (все местные сорта перекрёстно- или самоопыляющихся культур – сорта-популяции); (c) Сорта-Клоны – отобранное потомство одного вегетативно размножаемого растения (отличается высокой степенью выравненности, нарушающейся только под влиянием естественного мутагенеза); (d) особое положение занимают Гибриды, отличающиеся повышенной урожайностью (явление гетерозиса) в 1-м поколении. Родственные сорта растений, имеющие сходные хозяйственные и биологические признаки, для удобства изучения и инвентаризации объединяют в группы – Сортотипы. Использование лучших Сортов – одно из эффективных средств повышения урожайности сельскохозяйственных культур и улучшения качества продукции. В производственных условиях Сорта ухудшаются и нуждаются в сортообновлении. Старые Сорта растений периодически заменяют новыми, более урожайными и дающими лучшую продукцию, то есть проводят сортосмену. В бывшем Союзе Советских Социалистических Республик (СССР) все Сорта растений проходили государственное Сортоиспытание в целях отбора лучших для внедрения в производство. Размножением их занимается Семеноводство. Определение подлинности Сорта растений осуществляет Сортовой Контроль.

(1) Variety is a group of cultivated plants within a Species which is distinguished from another Variety (Group) by any characters (morphologic, physiological, biochemical, or other) of significance to agriculture and which, when reproduced, retains its distinguishing characters. A Variety may be derived from several pure lines which have many common features and are reasonably uniform in appearance (but not necessarily genetically pure). / Виды (Species).

(2) Variety is a group of similar plants which, by structural features and performance, may be identified from other Varieties (Groups) in the same Species. It differs from a breeding line in that it has been named and made commercially available to farmers. / Виды (Species).

(3) Variety is a subdivision of a Species; a group of individuals within a Species which are distinct in form or function from other similar arrays of individuals in commercial production. Variety is synonymous with Cultivar. Variety (as a botanical unit) is a sub-division of the Species composed of individuals differing from other members of the Species in certain minor characters which are usually perpetuated through generations by seed. / Виды (Species).

VARIETY GROUP = СОРТОВАЯ ГРУППА (или ГРУППА РАЗНОВИДНОСТИ) – Variety Group is the classification of accessions into groups based mainly on the morphological features of the adult Rice Plant and on grain appearance.

VARIETY ORDER LIST = ПЕРЕЧЕНЬ ЗАПРАШИВАЕМЫХ СОРТОВ – The Variety Order List lists the varieties of seeds that have been registered for production in Canada under the authority of the Canada Seeds Act. Section 28 of the Canada Grain Act authorizes the grading of varieties not included under the Order into the lowest grade established by regulation for that kind of grain.

VARIETY RELEASE = ВЫПУСК РАЗНОВИДНОСТИ – Variety Release is the release for public consumption of crop seeds as either public varieties, nonexclusive branded varieties, or licensed exclusive varieties. Releases may be made through public institutions, nonprofit foundations, or private companies or marketing agencies. See also Varietal Release.

VARIETY TRIAL = СОРТОИСПЫТАНИЕ (или ИСПЫТАНИЕ РАЗНОВИДНОСТИ) – Variety Trial is a trial in which treatments are different in the varieties that are grown and all other factors are treated equally and in a uniform system. / Под Сортоиспытанием понимается изучение, оценка сортов и гибридов сельскохозяйственных культур (в сравнении со стандартным сортом) и установление их пригодности для выращивания в производственных условиях. В бывшем Союзе Советских Социалистических Республик (СССР) проводились ежегодно (с 1929) на основании данных государственного сортоиспытания. На 1984 было районировано около 6 000 сортов и гибридов. Сортоиспытание, изучение, оценка сортов и гибридов сельскохозяйственных культур (в сравнении со стандартным сортом) и установление их пригодности для возделывания в условиях производства. В бывшем СССР проводили станционное и государственное сортоиспытания. При станционном сортоиспытании сорта изучали 2–3 года на полях учреждения (оригинатора), в котором выведен сорт. Одновременно проводили производственное испытание (1–2 года) в колхозе или совхозе. В государственное сортоиспытание – конкурсное и расширенное, которым занимались сортоиспытательные участки Государственной Комиссии по Сортоиспытанию Сельскохозяйственных Культур при Министерстве Сельского Хозяйства СССР, включали лучшие сорта, прошедшие станционное сортоиспытание, а также сорта зарубежной селекции. В конкурсном сортоиспытании сравнивают урожайность сортов и гибридов, длину их вегетационного периода, зимостойкость, засухоустойчивость, устойчивость к полеганию, осыпанию, болезням и вредителям, отзывчивость на удобрения и орошение, пригодность к механизированной уборке и тому подобное. Задача расширенного сортоиспытания – выявить сорта и гибриды, пригодные для конкурсного сортоиспытания в других областях. Наиболее перспективные сорта проходили производственное сортоиспытание (на полях колхозов и совхозов). Качество урожая (например, содержание белка, жира, сахара, выход волокна) оценивали Центральная Лаборатория Государственной Комиссии по Сортоиспытанию, лаборатории межобластные, сортоучастков, научно-исследовательских учреждений и других. Для государственного сортоиспытания каждой культуры была разработана единая методика. В СССР государственное сортоиспытание было начато в 1923–24 (РСФСР, УССР). До 1931 сортоиспытательная сеть делилась на Северные (7 сортоучастков) и Южные (17). К 1933 работало 346 сортоучастков, на которых испытывали более 1 700 сортов 116 культур. В 1937–38 число сортоучастков увеличилось до 1 055, а в 1976 было более 1 500 (в 1974 провели сортоиспытания 11 455 сортов 184 культур). На основании данных государственного сортоиспытания ежегодно в производственные посевы включали сорта и гибриды, наиболее урожайные и приспособленные к местным условиям, снимали с производства старые, не отвечавшие требованиям практики, то есть проводили сортовое районирование. Смотрите также Селекция и Семеноводство.

VARIOLATION = ВАРИОЛЯЦИЯ (или ОСПОПРИВИВАНИЕ) – Variolation is the obsolete method of immunizing patients against smallpox by infecting them with substance from the pustules of patients with a mild form of the disease (variola minor). The disease

then usually occurs in a less-dangerous form than when contracted naturally. The method was popularized in England in 1721–22 by Lady Mary Wortley Montagu; it has long been known by the Turks, Chinese, and other peoples. In America, Cotton Mather learned of its use in Africa from his slave, Onesimus, who himself had been inoculated. Its use spread in America after 1721, and in 1728 it was introduced into South America. Variolation continued to be opposed by some religious groups and most physicians, who were not convinced of the safety of the method. It was supplanted by vaccination after 1798. In 1842 an act of Parliament in England made the practice of variolation a felony in that country. / Лэйди Мэри Вотли Монтэгю (Lady Mary Wortley Montagu). Онисимас (Onesimus). Под Вариоляцией, от позднелатинского слова Variola, означающее Оспа, понимается. Оспопрививание, метод профилактики натуральной оспы путём искусственного заражения человека вирусом оспенной вакцины; вид активной иммунизации. В древности в Китае, Индии, Африке применялся метод вариоляции:- здоровому человеку подкожно (или на слизистую оболочку носа) вводили содержимое оспенных пузырьков и гнойничков (или высушенный оспенный гной), возникало заболевание, обычно лёгкой формой оспы, после чего приобретался иммунитет. В XVIII веке вариоляция применялась и в Европейских странах, в том числе в России. Однако после неё иногда развивалась тяжёлая форма заболевания; кроме того, больной лёгкой формой мог стать источником инфекции для окружающих; наконец, при вариоляции возможно заражение и другими инфекционными заболеваниями. В 1796 Английский врач и учёный Эдвод Дьженё (Edward Jenner; 1749–1823), основываясь на наблюдении, согласно которому доярки, заразившиеся от больных коров и перенёсшие лёгкую, местную (высыпания только на руках) форму заболевания, в последующем не болели натуральной оспой, предложил иммунизировать людей содержимым пузырьков коровьей оспы (cow pox). Метод был назван вакцинацией (от Латинского слова Vaccinum, означающее Коровий). Современную вакцину готовят, заражая телят вирусом осповакцины (вирус натуральной оспы, многократно перевивавшийся телятам и получивший при этом все свойства вируса коровьей оспы). Содержимое оспин заражённого телёнка растирают и смешивают с глицерином, который, не разрушая вакцинный вирус, убивает посторонние микроорганизмы. Специальные правила регламентируют основные требования к производству, контролю и хранению осповакцины. Внедрение оспопрививания в практику здравоохранения резко снизило заболеваемость оспой. Однако во многих странах оспопрививание не является обязательным. По действовавшим в бывшем Союзе Советских Социалистических Республик (СССР) правилам, оспопрививание проводилось всем детям, начиная с одного-двух лет, а при угрозе эпидемий оспы и ранее. Повторные прививки проводили в 8 и 16 лет и каждые 5 лет медицинским работникам, работникам сферы коммунального обслуживания и некоторым другим. Оспопрививанию также подлежат выезжающие в неблагополучные по оспе страны или общавшиеся с больными. Прививки проводят накожно (на кожу после её дезинфекции наносят вакцину и делают насечки). Купание запрещается до отпадения корочек. Если после отпадения корочки рубец не образуется (кожа остаётся гладкой), прививка не считается успешной и повторяется. После прививки иногда наблюдаются сильные реакции (повышение температуры, резко выраженные местное покраснение и отёк), которые вскоре самостоятельно проходят. При возникновении (в редких случаях) осложнений применяется противооспенный гамма-глобулин.

VARISCITE = ВАРИСЦИТ (или СИНЯЯ ЖЕЛЕЗАЯ РУДА) – Variscite is a phosphate mineral, hydrated aluminum phosphate ($AlPO_4 \cdot 2H_2O$), which is valued as a semiprecious gemstone and an ornamental material. Both variscite and strengite, a similar mineral in which iron replaces aluminum in the crystal structure, occur as glassy nodules, veins, or crusts, in near-surface deposits:- variscite is produced by the action of phosphate-rich waters on aluminous rocks, and strengite by alteration of iron-containing phosphates. Variscite is usually green; strengite, red. Variscite occurs in Germany, Austria, Czech Republic, Congo (Kinshasa), and Australia and in commercially important quantities near Fairfield, Utah, the United States. It also occurs with apatite on islands where phosphatic solutions from guano (seafowl excrement) have altered aluminous igneous rocks. Strengite deposits are known in Germany, Portugal, Sweden, and the United States. For detailed physical properties, see Phosphate Mineral (table). Variscite is cut en cabochon (with a round, convex, polished surface) for brooches, earrings, and beads and is frequently substituted for turquoise. It also is carved into bowls or other decorative objects. Because of its porosity, it tends to absorb grease and oil, which discolor it.

VAR MODEL = VALUE–AT–RISK MODEL

VARNISH = ОЛИФА (или ЛАК) – Varnish:- when applied to lubrication, a thin, insoluble, nonwipeable film deposit occurring on interior parts, resulting from the oxidation and polymerization of fuels and lubricants. Can cause sticking and malfunction of close-clearance moving parts. Similar to, but softer, than lacquer. Varnish:- thin, insoluble non-wipeable layer on the internal parts of the engine. It can cause the sticking and breakdown of internal moving engine parts. Varnish is a preparation consisting of resinous matter, as copal or lac, dissolved in an oil (oil varnish) or in alcohol (spirit varnish) or other volatile liquid. When applied to the surface of wood, metal, etc, it dries and leaves a hard, more or less glossy, usually transparent coating. Varnish is the sap of certain trees, used for the same purpose (natural varnish). Varnish is a liquid coating material containing a resin that dries to a hard transparent film. Most varnishes are a blend of resin, drying oil, drier, and volatile solvent. When varnish dries, its solvent portion evaporates, and the remaining constituents oxidize or polymerize to form a durable transparent film. Varnishes provide protective coatings for wooden surfaces, paintings, and various decorative objects. Varnish protects and enhances the appearance of wooden floors, interior wood paneling and trim, and furniture. The early varnishes were solutions of natural resins that are the secretions of plants. Among these natural resins are copal, dammar, and rosin. The natural varnishes are produced by heating the resins, adding natural oils such as linseed oil, cooking the mixture to the desired viscosity, and then diluting it with turpentine. The resultant coating took three to four days to harden, had a yellow tint, and eventually developed cracks as it aged. Natural varnishes have largely been replaced by varnishes containing synthetic resins, chief among which are the alkyd, polyurethane, phenolic, vinyl, and epoxy resins. The first synthetic resins used in varnishes, developed by the Belgian-American chemist Leo Hendrik Baekeland, were phenolic resins similar to Bakelite. Improved through the 1930s and 1940s, phenolics were displaced in many uses by alkyds, which eventually became the single most important resin class in the coatings industry, though phenolics continue to be used in marine and floor varnishes. Alkyds are made with an alcohol such as glycerol, a dibasic acid, such as maleic or phthalic acid, and an oil, such as castor, coconut, linseed, or soybean, or a fatty acid. Unlike natural resins, synthetic resins can be manufactured in large quantities and can be chemically tailored with great precision for particular uses. For example, the molecular structure of alkyd resins can be manipulated to vary their viscosity, their hardness, their solubility in water or other substances, and their capacity to mix successfully with various pigments. A paint coating which lacks pigment and which gives a transparent or translucent finish to wood. / Фенольное (Phenolic). твёрдость (hardness). Бельгийско-Американским химиком Лейо Хэндриком Бакэлёдом (Leo Hendrik Baekeland). Покрытие из краски, которая не имеет пигмента и которая при заключительной обработке древесины придаёт ей прозрачность или просвечиваемость. Под Лаком, от Немецкого слова Lack, понимаются:- (i) растворы плёнкообразующих веществ в органических растворителях. Тонкие слои лака высыхают с образованием твёрдых, блестящих, прозрачных покрытий, назначение которых – защита изделий от агрессивных агентов, декоративная отделка поверхности или электроизоляционная пропитка различных материалов. Служат также основой грунтовок, шпатлёвок и эмалевых красок. Лаки могут содержать пластификаторы, катализаторы и инициаторы плёнкообразования (соли металлов, органические пероксиды). И (ii) органические красящие вещества, которые, подобно пигментам, не растворяются в воде и в окрашиваемых материалах. Получаются переводом растворимых красителей (антрахиноновых и других) в их нерастворимые соединения, например,

бариевые соли. Применяются в производстве непрозрачных окрашиваемых материалов, например, бумаги, пластмасс или резины. По типу плёнкообразователя лаки делят на:- алкидные лаки, масляные лаки, эфироцеллюлозные лаки и другие. Под Лаками, от Немецкого слова Lack; первоисточник – Санскр. Лакша, понимаются растворы плёнкообразующих веществ в органических растворителях, которые после нанесения тонким слоем на металлическую, деревянную или другую поверхность и высыхания образуют твёрдые блестящие прозрачные плёнки, прочно удерживаемые на поверхности силами адгезии. Назначение этих плёнок – защита изделий от разрушающего действия атмосферных агентов и других агрессивных сред, а также декоративная отделка поверхности. Некоторые лаки используют в качестве электроизоляционных материалов (смотрите, например, Кремнийорганические Лаки, Битумные Лаки, Масляные Лаки, Эпоксидные Лаки). В наибольшем количестве лаки применяют как основу для приготовления пигментированных лакокрасочных материалов – эмалевых красок, грунтовок, шпатлёвок. Лаки известны с древнейших времён. Так, ещё во 2-м тысячелетии до Нашей Эры в Китае изготовляли лаки на основе сока Лакового Дерева. За несколько веков до Нашей Эры в Египте готовили лаки на основе природных смол – янтаря, мастикса и других. В VIII веке Нашей Эры были хорошо известны лаки, изготовляемые на основе высыхающих растительных масел – льняного, конопляного, макового, орехового. До 1930-х природные смолы и растительные масла были основными плёнкообразующими веществами (плёнкообразователями) для приготовления лаков. В 1920-х начался постепенный переход к производству лаков на основе эфиров целлюлозы (смотрите Эфиро-Целлюлозные Лаки), а в 1930-х – к получению лаков из синтетических продуктов - алкидных смол, фенолоальдегидных смол и других. Лаки готовят растворением плёнкообразователей в органических растворителях – спирте, уайт-спирите, этилацетате, ксилоле и другом. В зависимости от типа плёнкообразователей различают масляные лаки, алкидные лаки, полиуретановые лаки, эпоксидные лаки и другие. Большинство лаков бесцветно. При необходимости получения окрашеных лаков в их состав вводят растворимые органические красители, позволяющие сохранить прозрачность плёнки. Чёрные лаки могут быть изготовлены на основе битумов. Для повышения эластичности плёнок (прочности при изгибе) в состав лаков вводят пластификаторы, например, дибутилфталат или невысыхающие растительные масла. Лаки наносят на поверхность распылением, окунанием, обливанием и другими способами (смотрите Лакокрасочные Покрытия). Высыхание лака в простейшем случае сводится к улетучиванию растворителя с образованием обратимых (плавких и растворимых) плёнок. Достоинство таких лаков – быстрое высыхание при комнатной температуре. Во многих случаях улетучивание растворителя сопровождается глубокими химическими превращениями плёнкообразователя (полимеризацией или поликонденсацией), что приводит к образованию необратимых (нерастворимых) плёнок, превосходящих обратимые по стойкости к повышенным температурам и действию агрессивных сред. В некоторых случаях для получения необратимых плёнок в состав лаков вводят отвердители (смотрите Отверждение Полимеров). Ускорение высыхания лаков на основе маслосодержащих плёнкообразователей достигается введением сиккативов, а также сушкой покрытий при повышенных температурах. Всё более широкое применение находят лаки, которые содержат реакционноспособные растворители. Примером таких лаков могут служить полиэфирные лаки – растворы ненасыщенных полиэфиров в стироле или в другом растворителе, который сополимеризуется в условиях сушки с плёнкообразователем, образуя при однократном нанесении покрытие толщиной до 300 мкм (при нанесении лаков, содержащих нереакционноспособные растворители, толщина одного слоя покрытия составляет обычно 10–20 мкм). Свойства лака характеризуются показателями вязкости, содержания сухого остатка, растекаемости по поверхности (‘розлив’), скорости высыхания. Важнейшие показатели лаковых плёнок – адгезия к подложке, твёрдость, прочность при изгибе и ударе, атмосферо- и светостойкость (для повышения этого показателя в состав лаков вводят светостабилизаторы), стойкость к действию воды, бензина, минеральных масел, электроизоляционные свойства. Лаки используют во всех областях народного хозяйства и в быту. В наибольшем объёме, как в бывшем Союзе Советских Социалистических Республик (СССР), так и за рубежом выпускают алкидные лаки, что объясняется доступностью и сравнительной дешевизной исходного сырья, а также хорошими технологическими свойствами лаков. Всё возрастающее значение приобретают также лаки на основе эпоксидных смол, полиуретанов, полиакрилатов, кремнийорганических полимеров. Лаки В Искусстве:- Различные виды лаков применяют в декоративно-прикладном искусстве (смотрите Художественные Лаки), в гравюре – для покрытия металлических досок перед их травлением, в живописи – для образования защитного слоя на красочной поверхности и придания равномерного блеска масляным краскам (покровные лаки для устранения пожухлостей в масляной живописи (лаки для ретуши). Лаки для живописи изготовляют растворением чистых, по возможности бесцветных природных смол – даммары, мастикса, сандарака – в высыхающих растительных маслах, спирте, скипидаре и другом. Художественные Лаки:- изделия из дерева, папье-маше или металла, покрытые лаком и нередко украшенные декоративно-плоскостной росписью, рельефной резьбой, инкрустацией, гравировкой. Главные художественные особенности художественных лаков – блеск зеркальной полированной поверхности, контрасты цветов фона, росписи и инкрустации, а у резных лаков – мягкая светотеневая игра и сочность форм. Художественные лаки известны со 2-го тысячелетия до Нашей Эры в Китае, где в качестве материала для покрытий используется сок Лакового Дерева. Китайские художественные лаки (чашки, вазы, шкатулки, мебель, архитектурные детали) из папье-маше, дерева, оклеенные материей или бумагой, проходят длительные операции грунтования, многократного покрытия лаком, сушки и полирования, чем достигается прочность и водонепроницаемость покрытия. В Китайских художественных лаках распространены многоплановая резьба по красному лаку (в Пекине), тончайшая роспись полихромными и золотыми (в состав которых входит золотой порошок) лаками по чёрному или цветному фону, роспись в прорезях чёрного фона (‘коромандельские лаки’), инкрустация перламутром, оловом или серебром. Для Китайских художественных лаков характерны изображения пейзажей, цветов, бытовых сцен. К Китайским близки художественные лаки Кореи, Японии, Индокитая. Во Вьетнаме и Лаосе наряду с декоративной лаковой живописью на бытовых изделиях получила распространение и станковая. В Иране, Индии и Центральной Азии (Герат) известны (особенно в XV–XVII века) миниатюры, исполненные темперными красками на изделиях (шкатулки, пеналы) из папье-маше и покрытые лаком, главной составной частью которого является сандарак. В Индии распространены также ‘нирмальские лаки’ – изделия из дерева или металла, покрытые так называемым золотым лаком из сока зёрен Тамаринда, по которому выполнялась яркая полихромная роспись (фигурки людей, цветы, птицы). Восточные художественные лаки известны с XV века в Европе, где собственное производство лаковых изделий (декорация дворцовых интерьеров, мебель, бытовые предметы) из дерева, папье-маше начало развиваться в XVII–XVIII века. В Европейских художественных лаках техника производства была упрощена, введены горячая сушка в печах, применение масляных красок и масляных лаков. В XVIII веке техническим и художественным мастерством выделялись Французские художественные лаки фирмы Мартен и Немецкие фабрики И. Штобвассера (шкатулки, табакерки, украшенные миниатюрами). С XVIII века производство лаковых изделий из дерева (декорация дворцовых интерьеров, мебель), папье-маше (шкатулки, табакерки), металла (подносы) с росписями масляными красками (пейзажи, цветы, жанровые сценки, портреты) началось в России, где с начала XIX века стали возникать народные промыслы (смотрите Федоскинская Миниатюра, Жостовская Роспись). В Советское время наряду со старыми промыслами возникло тончайшее искусство темперной живописи на лаковых изделиях (Палехская Миниатюра, Мстёрская Миниатюра, Холуйская Миниатюра). Под Олифой, от Греческого слова Áleipha, означающее Жир или Мазь или Масло, понимается плёнкообразующее вещество на основе растительных масел, например, льняного (натуральные, полунатуральные, комбинированные олифы), или алкидных

смол (глифталевые, ксифталевые, пентафталевые олифы). Олифы применяются для приготовления и разбавления масляных красок, а также для пропитки древесины перед её отделкой этими красками. Олифы – жидкие материалы на основе растительных масел или маслосодержащих (жирных) алкидных смол. Хорошо смачивают дерево и металл. При нанесении на поверхность тонким слоем высыхают в результате полимеризации масла с образованием эластичной плёнки, нерастворимой в воде и в органических растворителях. Высыхание ускоряется при введении в состав олиф сиккативов (веществ, растворимых в растительных маслах и служащих катализаторами их высыхания). Применяются для приготовления масляных красок (густотёртых и разбавленных до рабочей вязкости), грунтовок, шпатлёвок, а также для пропитки поверхности дерева и других пористых материалов перед их окраской. Под Олифами, от Греческого слова Áleipha, означающее Жир или Мазь или Масло, понимаются плёнкообразующие вещества на основе масел растительных или жирных алкидных смол. Олифы – прозрачные жидкости от жёлтого до вишнёвого цвета, хорошо смачивающие дерево и металл. При нанесении тонким слоем на поверхность они высыхают в результате полимеризации масла под действием кислорода воздуха с образованием эластичных плёнок, не растворимых в воде и органических растворителях. Высыхание может быть ускорено введением в состав олиф сиккативов – солей Pb, Mn, Co (0.01–0.1% металла в расчёте на массу масла). Время полного высыхания плёнок при комнатной температуре и относительной влажности воздуха 60–70% не превышает 24 часов (ч). Получение олифы включает химическую обработку масел (например, частичную полимеризацию при 270–280 °C), введение сиккатива, а в некоторых случаях также разбавление олифы растворителем. Выбор типа олифы (Натуральной, Комбинированной, Полунатуральной, Алкидной (Глифталевой или Пентафталевой)) определяется требованиями к покрытиям и экономическим соображениями. Наиболее атмосферостойкие и долговечные покрытия образуют материалы на основе алкидных олиф; их важное экономическое преимущество перед олифами других типов – меньшее содержание масла.

VARNISH TREE = ЛАКОВОЕ ДЕРЕВО (или СУМАХ ЛАКОНОСНЫЙ) – Varnish Tree:- also called Japanese Varnish Tree, Lacquer Tree, or Wood Oil Tree, any of various trees whose milky juice is used to make a varnish or lacquer. The term is applied particularly to an Asian tree (Rhus Verniciflua), related to poison ivy, that is highly irritating to the skin. On being tapped, the tree exudes a thick, milky emulsion that was possibly used as the first drying oil; it has the peculiar property of drying only in a moist atmosphere. From this exudate comes the lacquer used to produce the highly polished woodenware of China and Japan with hard and durable coats unaffected by water. / Сумах Лаконосный (Japanese Varnish Tree). Лаковое Дерево или Сумах Лаконосный (Rhus Verniciflua), дерево высотой до 20 метров (м) Семейства Сумаховых. Листья непарноперистые. Цветки мелкие, желтовато-белые, в метёлках. Плод – жёлто-зелёная костянка. Растёт в Японии и Китае, где имеет большое хозяйственное значение. При надрезах коры выделяет ядовитую, вызывающую ожоги кожи, вязкую лаконосную смолу, из которой изготовляют Японский Лак. В плодах содержится около 25% жира; из них получают так называемый Японский Воск. Даёт ценную лимонно-жёлтую древесину с красивым рисунком, стойкую против гниения.

VARROA MITE = КЛЕЩ ВАРРОА – Varroa Mite is an external parasite that sucks blood out of developing and adult bees, thereby weakening or killing honeybees. No contamination of honey occurs. Varroa Mite is a reddish-brown, oval Mite (Varroa Destructor) that parasitizes honeybees and can cause the death of colonies. The Varroa Mite has spread to and become a major pest of honey bees since their introduction into Florida in the mid 1980's. They were first reported in the Bluegrass Region of the Commonwealth in 1991 and now occur throughout the state (State of Kentucky). Varroa Mites are external parasites that attack both honey Bees and brood. They suck the blood from both the adults and developing brood, especially drone brood. This weakens and shortens the Bee's life. Emerging brood may be deformed with missing legs or wings. Untreated infestations of Varroa Mites will increase and may kill colonies. If the colonies are not examined for Mites, losses may be mistaken for winter mortality or queenlessness. The adult female Mites have eight legs and reddish-brown flattened oval bodies about 1 to 1.5 mm across. They are large enough to be seen with the unaided eye on the Bee's thorax or abdomen. Their flat shape allows them to fit between the Bee's abdominal segments. This mite is often confused with the Bee louse. However, the Bee louse, an insect, has only six legs. Its body is more circular and slightly larger. Mites develop on the Bee brood. A female Mite will enter a brood cell about a day before it is capped so it is sealed in with the larva. Immature Mites that emerge from the eggs she lays feed and develop on the maturing Bee larva. By the time the adult Bee emerges from the cell, several of the Mites will have become adults, mated, and are ready to begin searching for other Bees or larvae to parasitize. Inspection of the drone brood in their capped cells will often indicate whether or not a colony is infested. The dark Mites are easily seen on the white pupae when the comb is broken or the pupae are pulled from their cells. Mites spread from colony to colony by drifting workers and drones. Honey Bees can also acquire these Mites when robbing smaller colonies. It is best to isolate captured swarms, package Bees, and other new colonies from older colonies and examine them for Mites before placing them in an apiary. Early detection of low levels of Mite infestation is key to successful management. It is easier to detect infestations that are well-developed than those that are just getting started. Apistan is a product available that will kill the Mites and cause the Mites to drop from the Bees. Two strips should be hung in the brood nest area of the colony for about 4 weeks. This is to be used with sticky paper and a fine-mesh screen on the bottom board of a colony to capture any Mites that may have been present. A considerable amount of cell cappings and other debris will also collect on the sticky paper so it is best to inspect the sticky paper carefully for Mites after its removal. This method is able to detect low level infestations. Apistan strips, which contain the miticide fluvalinate, are available from most large beekeeping suppliers and can be used both for detection and treatment of Varroa infestations. If an infested colony is found, all colonies at the site should be treated with Apistan strips in the same manner. The strips are not to be used during honey flow, or when there is surplus honey present in the colony that may be removed later for human consumption. Therefore, late fall, after removal of surplus honey, or early spring, prior to honey flow, are the best times to treat for Varroa Mites. Always carefully follow all label instructions with regard to the storage, use and disposal of pesticides. Caution! Pesticide recommendations in this publication are registered for use in the State of Kentucky, USA ONLY! The use of some products may not be legal in your state or country. Please check with your local county agent or regulatory official before using any pesticide mentioned in this publication. Varroa Mite is any parasitic Mite of the Genus Varroa that causes disease in honeybees. Varroa Mite:- one of the biggest problems for honey bee colonies is the Varroa Mite (Varroa Destructor). The small Mite will attach to a foraging worker Bee and catch a ride into the hive. Once there, it will burrow into a cell containing a larva and lay its eggs on it. When the larva pupates the eggs will hatch and the Bee will leave the cell, taking the parasites with it. The Mites feed on the Bee's blood, weakening its immune system and transmitting diseases such as Deformed Wing Virus which leaves the Bee with short and useless wings. The Bees bitten by Varroa Mites are often weak and don't usually live for more than a couple of days. Varroa Mites have spread to most of the world, and only Australia and areas near it seem to be free of them. Australia has even sent some of its healthy Bees over to the USA by plane to try and boost its honeybee population. Once a Varroa Mite enters a hive the whole colony can be destroyed in 2 to 4 years, and most wild Bee colonies have died out because of them. Varroa Mite is a microscopic Mite which is a debilitating parasite of the honeybee, causing loss of honey production.

VASCAR = VISUAL AVERAGE SPEED COMPUTER AND RECORDER

VASCULAR = ВАСКУЛЯРНОЕ (или СОСУДИСТОЕ) – Vascular:- pertaining to, or having vessels that convey fluids. Vascular:- with vessels or ducts. Vascular:- of tissues containing vessels for conveying fluids and minerals. / или имеющее сосуды, которые

проводят жидкости. Васкулярное или Сосудистое:- о тканях, содержащих сосуды для проводки жидкостей и минералов. , от Латинского слова Vasculum, означающее Сосудик, понимается .

VASCULAR BUNDLE = СОСУДИСТЫЙ ПУЧОК (или ПРОВОДЯЩИЙ ПУЧОК) – Vascular Bundle is a compact group of conducting bundles composed of xylem and phloem and surrounding tissues, occurring in stem, leaf and flower. In Cactaceae a clear ring of vascular tissue is on a cross section cut across the stem. This woody material also has a structural function and forms the supporting skeletons of many cacti. Vascular Bundle is a strand of conducting tissues and associated cells within a stem or connected structure. / У Кактусовых (Cactaceae). , от Латинского слова Vasculum, означающее Сосудик, понимается . Сосудистый Пучок у растений, то же, что Проводящий Пучок. Проводящий Пучок у растений, совокупность элементов проводящих тканей. В побеге проводящий пучок возникает из меристемы его конуса нарастания, точнее из прокамбия. Проводящий пучок включает флоэму (луб) и ксилему (древесину), механические ткани и клетки живой паренхимы. Проводящие пучки бывают полными или неполными, то есть состоят из одной флоэмы или ксилемы; открытыми – часть прокамбия не дифференцируется в проводящие ткани и сохраняется в виде камбия (у Двудольных), или закрытыми – без камбия (у Однодольных). Различают коллатеральные пучки – флоэма располагается по одну сторону – кнаружи от ксилемы; биколлатеральные пучки – флоэма располагается по обе стороны от ксилемы; концентрические пучки – амфивазальные (ксилема окружает флоэму) и амфикрибральные (флоэма окружает ксилему). Структура проводящих пучков на разных уровнях стебля может меняться. В корнях растений формируются радиальные пучки, состоящие из отдельных чередующихся участков ксилемы и флоэмы, расположенных по радиусам проводящего цилиндра.

VASCULAR ENDOTHELIAL GROWTH FACTOR = ФАКТОР РОСТА СОСУДИСТОГО ЭНДОТЕЛИЯ (или ХХ) – Vascular Endothelial Growth Factor (VEGF) is a human growth factor (GF) that causes angiogenesis, i.e. growth/proliferation of blood vessels/endothelium and also endothelial cells. Discovered in 1989 by an Italian-American molecular biologist Napoleone Ferrara (1956–). / Наполеонэ Феррара (Napoleone Ferrara).

VASCULAR ENDOTHELIUM = СОСУДИСТЫЙ ЭНДОТЕЛИЙ – Vascular Endothelium is an interface between the blood stream and the vessel wall. Changes in this single cell layer of the artery wall are believed of primary importance in the pathogenesis of vascular disease/atherosclerosis. The endothelium responds to humoral, neural and especially hemodynamic stimuli and regulates platelet function, inflammatory responses, vascular smooth muscle cell growth and migration, in addition to modulating vascular tone by synthesizing and releasing vasoactive substances. Compromised endothelial function contributes to the pathogenesis of cardiovascular disease; endothelial 'dysfunction' is associated with risk factors, correlates with disease progression, and predicts cardiovascular events. Therapies for atherosclerosis have been developed, therefore, that are directed towards improving endothelial function. / Сосудистый Эндотелий – слой эпителиальных клеток внутри сосудистых органов организма. Под Эндотелием, от Греческих слов Éndon, означающее Внутри (часть сложных слов, означающая 'внутренний', 'внутри', например, эндогамия, эндоскопия), и Thele, означающее Сосок, понимаются специализированные клетки животных и человека, выстилающие внутреннюю поверхность кровеносных и лимфатических сосудов, а также полостей сердца. Эндотелий образуется из мезенхимы. Представлен однослойным пластом тесно прилежащих друг к другу плоских клеток, обычно отграниченных от подлежащих тканей базальной мембраной; у эндотелия лимфатических сосудов базальная мембрана отсутствует. Цитоплазма клеток эндотелия некоторых капилляров может иметь поры, способствующие проницаемости веществ через стенку капилляра (например, в сосудистых клубочках почки). Особенность эндотелия расширенных капилляров (синусоидов) кроветворных органов, а также печени, коры надпочечников и некоторых других органов – высокая способность к фагоцитозу. Эти эндотелиальные клетки относятся к ретикуло-эндотелиальной системе.

VASCULAR SYSTEM = СОСУДИСТАЯ СИСТЕМА – Vascular System is the system of vessels that carries water and mineral salts within the plant, i.e. from the roots to the leaves and shoots and from the leaves to the fruiting structures. A Vascular Wilt is an infection of the vascular system. The system of plant tissues that conducts water, mineral nutrients form the roots (xylem), and products of photosynthesis through the plant (phloem). Vascular System:- in plants, assemblage of conducting tissues and associated supportive fibers. Xylem tissue transports water and dissolved minerals to the leaves, and phloem tissue conducts food from the leaves to all parts of the plant. The condition of the xylem, the woody elements in the stem, defines several categories. The protostele has a solid xylem core; the siphonostele has an open core or one filled with generalized tissue called Pith. The discontinuous vascular system of monocots (e.g., grasses) consists of scattered vascular bundles; the continuous vascular system of dicots (e.g., roses) surrounds the central pith. Vascular bundles run longitudinally along the stem. Vascular rays extend radially across the stem, assisting in conduction from the vascular bundles to tissues alongside them. The vascular tissues and supporting tissues constitute the stele. Several kinds of vascular bundles are recognized. In the collateral pattern, the phloem lies only on one side of the xylem, usually toward the stem exterior. This arrangement is typical of the dicots, the majority of flowering plants, such as roses, apples, oaks, pines, etc. If phloem is on the outer and inner faces of the xylem, the bundle is bicollateral. A concentric bundle has xylem entirely surrounded by phloem (amphicribal condition) or phloem entirely surrounded by xylem (amphivasal condition). Closed bundles lack cambium and are unable to continue growth laterally. They are typical of monocots, such as grasses, lilies, and palms, in which they are scattered in two or more rings in the stem. / Тканевая система растения, которая проводит воду, минеральные питательные вещества от корней (через ксилемы), и осуществляет фотосинтез у растения (через лубья). У растений под Сосудами (трахеями) понимаются проводящие элементы ксилемы в виде длинных полых трубок, образованных одним рядом клеток (членников) со сквозными отверстиями (перфорациями) между ними. Сосуды (или Трахеи) у растений, проводящие элементы ксилемы (или древесины), представляющие собой длинные полые трубки, образованные одним рядом клеток (члеников) со сквозными отверстиями (перфорациями) на поперечных стенках. Характерны для покрытосеменных, кроме некоторых Многоплодниковых (Троходендрон, Дримис) и Лилейных (Ландыш, Драцена, Агава), встречаются у Папоротников (Орляк), Селагинелл, Хвощей, Оболочкосеменных (Эфедра, Гнетум, Вельвичия). По строению боковых стенок различают кольчатые, спиральные, лестничные и пористые сосуды. У первых двух вторичная оболочка имеет вид колец или спирально закрученных лент. Они возникают на ранних этапах развития органов растения и способны растягиваться. Остальные типы сосудов с более мощными отложениями вторичной оболочки и окаймлёнными порами в стенках формируются у органов, закончивших рост в длину. После одревеснения оболочек протопласты клеток отмирают, полость сосудов заполняется водой. Для примитивных сосудов характерны большая длина (до 1.3 миллиметра (мм)), малый диаметр, угловатое поперечное сечение члеников с лестничными перфорациями на скошенных поперечных стенках, лестничная поровость боковых стенок (Тюльпанное Дерево). Высокоспециализированные сосуды сложены короткими, в сечении округлыми широкопросветными (до 0.5 мм в диаметре) члениками с простыми перфорациями на поперечных стенках и мелкими очередными порами на боковых стенках (Ясень, Дуб). О сосудах у животных и человека смотрите в статьях Артерии, Вены, Кровеносная Система, Лимфатическая Система. Смотрите также Проводящий Пучок.

VASCULAR WILT = ВАСКУЛЯРНЫЙ ВИЛТ (или СОСУДИСТЫЙ ВИЛТ, или ВИЛТ СОСУДИСТОЙ СИСТЕМЫ) – Verticillium Dahliae and Fusarium Oxysporum f. sp. (Formae Speciales) Vasinfectum cause Verticillium Wilt and Fusarium Wilt of Cotton. These

fungi infect plants via the roots and then invade the water conducting (vascular) tissue, blocking water uptake and causing yellowing, leaf mottle and sometimes wilting and death of plants. Brown discoloration of the root and stem vascular tissues becomes apparent. See also Wilt. Vascular Wilt is a viral or bacterial disease that deprives the plant of water and nutrients by blocking the passage through conductive tissue, thus causing the plant to droop, wilt, and die. / Несовершенные Грибы Вертициллиозные Георгины или Далии (Verticillium Dahliae) и Фусариум Оксиспорум Васинфэктум (Fusarium Oxysporum f. sp. Vasinfectum) вызывают Вертициллиозный Вилт и Фузариозный Вилт Хлопчатника. Эти Грибы заражают растения через корни, а затем наполняют водоносную (сосудистую) ткань, блокируя поглощение воды и вызывая пожелтение, крапчатость листьев, а иногда увядание и смерть растений. Становится очевидным изменение цвета корня и стебля до бурого.

VASI = VISUAL APPROACH SLOPE INDICATOR

VASODILATOR = ВАЗОДИЛЯТОР (или СОСУДОРАСШИРЯЮЩИЕ НЕРВНЫЕ ВОЛОКНА) – Vasodilators are medications that open (dilate) blood vessels. They affect the muscles in the walls of your arteries and veins, preventing the muscles from tightening and the walls from narrowing. As a result, blood flows more easily through your vessels. Your heart doesn't have to pump as hard, reducing your blood pressure. Some drugs used to treat hypertension, such as calcium channel blockers – which prevent calcium from entering blood vessel walls – also dilate blood vessels. But the vasodilators that work directly on the vessel walls are hydralazine and minoxidil. Uses For Vasodilators:- Doctors prescribe vasodilators to prevent, treat or improve symptoms in a variety of conditions, such as:- high blood pressure, high blood pressure during pregnancy or childbirth (preeclampsia or eclampsia), heart failure, and high blood pressure that affects the arteries in your lungs (pulmonary hypertension). Side Effects And Cautions:- Direct vasodilators are strong medications that generally are used only when other medications haven't controlled your blood pressure adequately. These medications have a number of side effects, some of which require taking other medications to counter. Side effects include:- rapid heartbeat (tachycardia), heart palpitations, fluid retention (edema), nausea, vomiting, flushing, headache, excessive hair growth, joint pain, and chest pain. Vasodilator is an agent (such as a parasympathetic nerve fiber or a drug) that induces or initiates vasodilation. Vasodilators are highly effective antihypertensive agents that dominated the management of hypertension in the 1950s and 1960s. However, treatment with these agents is associated with an unacceptable level of adverse reactions. With the advent of newer and better-tolerated antihypertensive agents, their use has declined dramatically. Many vasodilators can now be considered only of historical interest. In developed countries, vasodilators have a limited clinical role. Some direct-acting vascular smooth muscle relaxants continue to have utility in the management of hypertensive emergencies (notably sodium nitroprusside) and in severe hypertension refractory to other antihypertensive agents (notably minoxidil). In developing countries, however (where the cost of newer agents may be prohibitive), vasodilators continue to be prescribed more widely. The safe and effective long-term use of these drugs requires careful attention to adverse reactions with concomitant administration of beta blockers and diuretics to avoid the consequences of reflex cardiac stimulation and salt and water retention. Vasodilators are potent antihypertensive agents that can cause a significant reduction in blood pressure in their own right. Vasodilators are used in children to control blood pressure during and after surgery, to treat systemic and pulmonary hypertension, and to decrease afterload on either the systemic or pulmonary ventricle, thereby improving pump function. Vasodilators are also given during cardiopulmonary bypass to reduce systemic vascular resistance to improve regional perfusion and facilitate rapid and even core cooling and rewarming. Several different types of vasodilators are currently employed in children for these purposes. The most common are direct-acting nitrosovasodilators such as sodium nitroprusside and nitroglycerin. These drugs directly relax vascular smooth muscle to cause vasodilation. Hydralazine is another direct-acting smooth muscle vasodilator that is occasionally given to children to reduce blood pressure. α-Adrenergic blockers, such as phentolamine and phenoxybenzamine, are also used occasionally to acutely reduce blood pressure and systemic vascular resistance in the perioperative period. The latter blockers are more frequently employed during cardiopulmonary bypass. Angiotensin-converting enzyme (ACE) inhibitors may also be useful to help control blood pressure. Prostaglandin E_1 (PGE_1) is a direct-acting vasodilator with the unique property of being able to dilate the ductus arteriosus and maintain its patency. Prostacyclin and inhaled nitric oxide are further additions that possess relatively selective pulmonary vasodilating capabilities. / Вазодилятор:- агент (такой как . Под Вазодилятаторами, от Латинских слов Vas, означающее Сосуд, и Dilato, означающее Расширяю, понимается то же, что сосудорасширяющие нервные волокна. Смотрите также Сосудодвигательные Нервные Волокна. Сосудорасширяющие Средства, фармакологические вещества, вызывающие расслабление гладких мышц кровеносных сосудов, что сопровождается увеличением их просвета. По механизму действия и химическому строению выделяют несколько групп сосудорасширяющих средств. Препараты миотропного действия оказывают непосредственное влияние на мышечные элементы сосудистой стенки, изменяя в них обменные процессы и понижая их тонус (производные пурина – кофеин, теофиллин; изохинолина – папаверин, но-шпа, сальсолин; хромона – келлин и так далее). Сосудорасширяющие средства нейротропного действия вызывают сосудорасширяющий эффект, влияя на нервную регуляцию тонуса кровеносных сосудов. Они могут быть периферического или центрального действия. К 1-й подгруппе принадлежат вещества, блокирующие адренергические рецепторы кровеносных сосудов, – адренолитики (например, фентоламин), и вещества, блокирующие передачу возбуждения с окончаний симпатических нервов, иннервирующих кровеносные сосуды, – симпатолитики (октадин, орнид). Сосудорасширяющим действием обладают также холиномиметические вещества (ацетилхолин, карбахолин), облегчающие передачу возбуждения с парасимпатических нервов на эффекторные органы, в том числе кровеносные сосуды, и ганглиоблокаторы (тетамон, гексоний, пентамин и другие), затрудняющие передачу возбуждения в симпатических ганглиях, в результате чего снижается тонус кровеносных сосудов. На центральную регуляцию сосудистого тонуса влияют производные гидразинофталазина (апрессин), фенотиазина (аминазин) и другие. Некоторые препараты имеют смешанный механизм действия – центральный нейротропный и периферический миотропный; в эту группу входят, в частности, нитриты и нитраты (амилнитрит, нитроглицерин, нитранол и другие) и резерпин (алкалоид тропического растения раувольфин), который ослабляет центральную и периферическую адренергическую иннервацию кровеносных сосудов, в связи с чем происходит расширение их просвета и снижение артериального давления. Сосудорасширяющие средства применяют главным образом для лечения ишемической болезни сердца (смотрите Стенокардия, Инфаркт Миокарда), гипертонической болезни и нарушений мозгового кровообращения. Кроме того, сосудорасширяющие средства используют при хирургических операциях с целью уменьшения кровотечений (путём снижения артериального давления). Многие сосудорасширяющие средства вызывают и другие фармакологические эффекты. Смотрите также Сердечно-Сосудистые Средства.

VASSAL = ВАССАЛ – Vassal:- in feudal society, one invested with a fief in return for services to an overlord. Some vassals did not have fiefs and lived at their lord's court as his household knights. Certain vassals who held their fiefs directly from the crown were tenants in chief and formed the most important feudal group, the barons. A fief held by tenants of these tenants in chief was called an Arrière-Fief, and, when the king summoned the whole feudal host, he was said to summon the Ban Et Arrière-Ban. There were female vassals as well; their husbands fulfilled their wives' services. Under the feudal contract, the lord had the duty to provide the fief for his vassal, to protect him, and to do him justice in his court. In return, the lord had the right to demand the services attached to the fief (military, judicial, administrative) and a right to various 'incomes' known as Feudal Incidents. Examples of incidents are relief, a tax paid when a fief was transferred to an heir or alienated by the vassal, and scutage, a tax paid in lieu of military service. Arbitrary

arrangements were gradually replaced by a system of fixed dues on occasions limited by custom. The vassal owed fealty to his lord. A breach of this duty was a felony, regarded as so heinous an offense that in England all serious crimes, even those that had nothing to do with feudalism proper, came to be called Felonies, since, in a way, they were breaches of the fealty owed to the king as guardian of the public peace and order. The vassals' rights over the fiefs grew larger and larger in course of time, and soon fiefs became hereditary in the sense that investiture could not be withheld from an heir who was willing to do homage. The rules of inheritance tended to safeguard an undivided fief and preferred the eldest among the sons (primogeniture). This principle was far from absolute; under pressure from younger sons, parts of an inheritance might be set apart for them in compensation (appanage). Vassals also acquired the right to alienate their fiefs, with the proviso, first, of the lord's consent and, later, on payment of a certain tax. Similarly, they obtained the right to subinfeudate, that is, to become lords themselves by granting parts of their fiefs to vassals of their own. If a vassal died without heir or committed a felony, his fief went back to the lord (see Escheat). / Арьэр-Фьеф (Arrière-Fief), Бо И Арьэр-Бо (Ban Et Arrière-Ban). Под Вассалом, от позднелатинского слова Vassalus, означающее Вассал, от Vassus, охначающее Слуга, в средние века в Западной Европе понимался . Смотрите также Вассалитет. Под Вассалитетом, от Французского слова Vassalité, от Vassal, позднелатинского слова Vassallus, от Vassus, означающее Слуга, понимается система отношений личной зависимости одних феодалов (вассалов) от других (сеньоров) в средние века. В странах Западной Европы вассалитет как развитый институт сформировался в VIII–IX веках во Франкском государстве, где короли и крупные феодалы давали за службу землю, движимость или какой-либо другой источник дохода. Переворот в аграрных отношениях в этот период создал предпосылки для всё более широкой раздачи вассалам земельных владений. Таким образом, материальной основой личных отношений вассалитета стали в большинстве случаев поземельные отношения, служба вассалов начала сводиться, как правило, к военной. Земли, предоставлявшиеся вначале пожизненно, то есть в качестве бенефиция (от Латинского слова Beneficium, означающее Благодеяние, понимается какая-либо льгота или условное срочное пожалование или вознаграждение должностью)), постепенно превратились в условное наследственное владение (феод (от позднелатинского слова Feodum, Feudum) или фьеф (от Французского слова Fief) или фи (от Английского слова Fee) или лен (от Немецкого слова Lehn), означавшее в странах Западной Европы в средние века земельное владение или фиксированный доход (в деньгах или в натуре), пожалованные сюзереном своему вассалу в наследственное владение под условием несения последним в пользу первого феодальных служб:- прежде всего военной, а также придворной (участие в суде, в управлении сеньорией и другой) и уплаты предусмотренных обычаем денежных платежей). Крупные феодалы, становясь вассалами верховного сеньора (сюзерена) – короля и получая от него земли, в свою очередь имели вассалов – более мелких феодалов – и жаловали им земельные владения. Главной обязанностью вассала было несение за свой счёт военной службы в течение определённого срока (обычно – 40 дней в году). Вассал должен был участвовать в суде и совете (курии) сеньора, содержать его со свитой (в известных случаях) и вносить некоторые платежи экстраординарного характера, прежде всего 'помощь' (auxilium) для выкупа сеньора, попавшего в плен, и другие, а также уплачивать рельеф (при смене владельца феода). Сеньор был обязан, кроме передачи феода, защищать вассала и его имущество. Договор о вассалитете оформлялся особым обрядом – оммажем и сопровождавшей его клятвой верности (фуа) вассала сеньору. Неисполнение обязанностей со стороны вассала или сеньора влекло за собой расторжение договора и нередко войну. С распространением отношений вассалитета, покоившихся на иерархической структуре земельной собственности, оформилась феодальная иерархическая лестница (от короля до мелких феодалов) – политическая, в первую очередь военная, организация господствующего класса. Подобная организация была обусловлена главным образом необходимостью охранять в период слабости центральной власти монопольную собственность класса феодалов на землю и осуществлять внеэкономическое принуждение по отношению к феодально-зависимому крестьянству. С образованием централизованных феодальных государств, постепенным вытеснением вассальной военной службы системой наёмных отрядов, многочисленными переходами феодов (в условиях роста товарно-денежных отношений) в руки новых владельцев вассалитет постепенно утратил военное и политическое значение. Наиболее завершённые формы вассалитета и феодальная иерархическая лестница получили в странах Западной Европы. В странах Востока он в общем был менее развит (хотя в некоторых из них, например, в Японии, в странах, подвергшихся Монгольским завоеваниям, также сложилась многоступенчатая иерархическая лестница внутри господствующего класса). На Руси вассальные отношения существовали лишь между великими и удельными князьями.

VAST = СТОП (или ОГРОМНОЕ) – Vast is an order to cease (stop). / Стоп – распоряжение на прекращение (останов).

VAT = VALUE ADDED TAX

VAT = VATICAN CITY STATE = HOLY SEE

VAT AND DUTIES TRIBUNAL = ТРИБУНАЛ ПО НДС И ПОШЛИНАМ – VAT And Duties Tribunal (in the United Kingdom) is an independent body that provides a method of dealing with disputes concerning VAT, and both Customs and excise duties. / Под Трибуналом, от Латинского слова Tribunal, означающее Судилище, (основное значение:- возвышение, на котором в Древнем Риме восседали важнейшие должностные лица – консулы, преторы – при исполнении служебных обязанностей), понимается особый суд. (1) Во Франции – революционный чрезвычайный суд периода Великой Французской Революции. (2) В бывшем Союзе Советских Социалистических Республик (СССР) – суды, учреждённые Декретом Совета Народных Комиссаров О Суде от 22 Ноября (05 Декабря) 1917 для борьбы с контрреволюцией и наиболее опасными преступлениями (см отрите Революционные Трибуналы), а также суды, рассматривающие дела о воинских и иных преступлениях, отнесённых законом к их ведению (смотрите Военные Трибуналы). (3) Международный судебный орган по преследованию и наказанию главных военных преступников 2-й Мировой Войны 1939–45 (смотрите Международный Военный Трибунал). (4) В судебных системах некоторых буржуазных стран (например, Франции, Италии) суд первой инстанции и апелляционная инстанция для дел, рассмотренных мировыми судьями.

VAT BONDS = ОБЯЗАТЕЛЬСТВА В ОТНОШЕНИИ НДС – In the United Kingdom, VAT Bonds:- provided to HM Customs and Excise and allows the applicant to import goods from outside of the European Union (EU) without the immediate payment of duty/tax, which is then settled on a monthly basis by Direct Debit. Liability under the guarantee is 200% of the face value and remains valid until HM Customs confirm to HSBC Bank that no liability is outstanding, following the giving of a notice termination. HM Customs provide their own paperwork for this type of guarantee. Also known as Duty Deferment Bonds. / Эйч.Эс.Би.Си. (HSBC).

VATDEC = VALUE ADDED TAX MESSAGE

VAT DYEING = КУБОВОЕ КРАШЕНИЕ – Vat Dyeing refers to the type of dye rather than to the way in which the dyeing is done. This process uses an insoluble dye made soluble in its application. It is put on the fiber and oxidized to its original insoluble form. Exeellent colorfastness to washing and sunlight. / Кубовое Крашение, окраска текстильных материалов кубовыми красителями. Смотрите также Крашение.

VAT DYES = КУБОВЫЕ КРАСИТЕЛИ – Vat Dyes have excellent fastness properties when properly selected and are often used for fabrics that will be subjected to severe washing and bleaching conditions (towelling, industrial and military uniforms, etc). Vat dyes are

normally insoluble in water, but they become water-soluble and substantive for the fiber after reduction in alkaline conditions (vatting). They are then converted again to the original insoluble form by oxidation and in this way they remain fixed into the fiber. When applying vat dyes in batch processes the textile is dyed very rapidly and unevenly due to the high affinity of the dye. Nevertheless, level dyeing can be achieved by:- (i) adding levelling agents; (ii) increase of the temperature under a controlled profile ('High Temperature' process and 'Semi-pigmention' method); and (iii) impregnation of the textile with the dye as water-insoluble dispersion, followed by addition of the reductive agent in a subsequent step (pre-pigmentation process). In all cases, oxidation and after-treatment follow. After-treatment consists in washing the material in a weakly alkaline bath with a detergent at boiling temperature. Continuous processes are used almost exclusively for dyeing woven fabrics and to only a small extent for knitwear. The most commonly applied continuous process is the pad-steam process. The textile is padded with the aqueous dye dispersion in the presence of anti-migrant (polyacrylates, alginates, etc.) and dispersing/wetting agents, if required. After drying, the fabric is passed through a chemical padder, which contains the required amount of alkali and reducing agent and is fed immediately to a steamer. The material is finally rinsed, oxidised and soaped in an open-width washing machine. A more rapid, one-step process is also possible, but only for pastel to pale shades. Voluminous open fabrics can be dyed according to a wet-steam process. Unlike the pad-steam process, this process does not require intermediate drying before steaming. The following chemicals and auxiliaries are applied in vat dyeing:- (i) reducing agents:- mainly sodium dithionite (hydrosulphite) and sulphoxylic acid derivatives (Zn-sulphoxylate). The latter, in particular, is used when the pad-steam process is applied. Sulphur-free organic reducing agents such as hydroxyacetone are also now available for some applications; (ii) oxidising agents, such as hydrogen peroxide, perborate, or 3-nitrobenzenesulphonic acid; (iii) alkali (caustic soda); (iv) salt; (v) dispersing agents:- they are already present in the dye formulation and are further added in the subsequent steps of the dyeing process; and (vi) levelling agents:- they form adducts with the dye, thus retarding its absorption onto the fiber. Vat Dyes is a class of water-insoluble dyes which are applied to the fiber in a reduced, soluble form (leuco compound) and then reoxidized to the original insoluble form. Vat dyes are among the most resistant dyes to both washing and sunlight. They are widely used on cotton, linen rayon, and other cellulosic fibers. Vat Dyes:- this class includes two natural dyes of great antiquity, indigo and Tyrian purple, but all the rest are synthetic. Their name derives from the ancient practice of fermenting indigo in a vat to render it fit for use. As with the ingrain dyes these dyes are insoluble in water. For application, the insoluble vat dye is first treated with a reducing agent in alkaline solution (usually sodium hydrosulphite in aqueous sodium hydroxide). This is the process of vatting and replaces the older fermentation method. It converts the vat dye into its so-called leuco-compound, which is soluble in the alkaline solution. The material is then dyed with this solution. On exposing the dyed material to the atmosphere, oxidation of the leuco-compound occurs and the insoluble vat dye is re-formed, now within the fiber. Finally, washing and soaping treatments, which remove surplus dye and usually brighten the shade of fixed dye, complete the process. This method is used mainly for cellulosic materials, since the conditions are detrimental to many other fibers. Modified methods of application are often used. Thus, in textile printing, formaldehyde-sulphoxylate is used as the reducing agent. This delays the formation of the leuco-compound until the prints are steamed, this process being an essential one in printing. A different kind of modification is in the preparation, by the manufacturer, of stable, soluble derivatives of the leuco-compounds. These require no chemical treatment by the dyer before use, and may be applied to cellulosic fibers in the same way as direct dyes of low substantivity or to basic fibers as acid dyes. They are reconverted, on the fiber, to the insoluble vat dye by treating the dyed goods with an acidic oxidizing agent, most commonly sodium nitrite in sulphuric acid, but more complex systems are used for printing. The vat dyes as a class show good all-round fastness properties. The yellow and orange dyes, however, may bring about degradation of the material on which they are dyed if this is exposed for long periods to sunlight. Vat Dyes are insoluble in water and cannot dye fibers directly. However, They can be made soluble by reduction in alkaline solution which allows them to affix to the textile fibers. Subsequent oxidation or exposure to air restore the dye to its insoluble form. Indigo is the original vat dye. These dyes are the fastest dyes for cotton, linen and rayon. They are used with mordants to dye other fabrics such as wool, nylon, polyesters, acrylics and modacrylics. Vat Dye is a classification of dyes that are converted from a water-insoluble pigment form to a soluble leuco form (using a reducing agent), applied by immersion to fabric, then converted back to the insoluble form (by oxidation). The name comes from 'Vatting' which once meant using natural fermentation processes in a vat to produce the reducing conditions to make the dye soluble. Indigo, the blue of blue jeans, is a common vat dye. Vat dyes, with the notable exception of indigo, are generally very lightfast and washfast. Many have very good resistance to chlorine bleach. Multiple applications of dye may be required to build strong shades because of limited substantivity. Sulfur dyes use processes similar to vat dyes, but are distinguished by their sulfur content. Some modern vat dyes are supplied in already-reduced soluble form. Occasionally art dyes will say something is vat dyed when they mean it has been dyed with any dye type in a large volume of solution, as opposed to by direct application of dye or other techniques. This use should be avoided. Vat Dye is any of a large class of water-insoluble dyes, such as indigo and the anthraquinone derivatives, that are used particularly on cellulosic fibers. The dye is applied in a soluble, reduced form to impregnate the fiber and then oxidized in the fiber back to its original insoluble form. Vat dyes are especially fast to light and washing. Brilliant colors can be obtained in most shades. Originated in medieval Europe, vat dyes were so named because of the vats used in the reduction of indigo plants through fermentation. / Найлан^{T3} (Nylon^{TM}). хлорный отбеливатель (chlorine bleach). Субстантивность (Substantivity). Под Кубовыми Красителями понимаются нерастворимые в воде органические красители – антрахиноновые, индигоидные, тиоиндигоидные и другие полициклические, отличающиеся наличием в молекуле не менее 2 карбонильных групп (=CO), соединённых системой сопряжённых связей. Восстановление кубовых красителей в щелочной среде приводит к образованию растворимого лейкосоединения, которое, в отличие от исходного красителя, хорошо сорбируется волокном. При крашении волокон кубовые красители предварительно восстанавливают до лейкосоединений. При последующем окислении, например, кислородом воздуха, лейкосоединение вновь превращается на волокне в нерастворимый краситель, образующий яркие, чистые и прочные окраски. Применяются главным образом для крашения целлюлозных волокон и их смесей с полиэфирными волокнами. Кубовые Красители – одна из важнейших групп красителей; нерастворимы в воде, содержат карбонильные группы, которые при крашении восстанавливаются гидросульфитом $Na_2S_2O_4$ в енольные $^{3}C - ONa$; образующиеся при этом растворимые лейкосоединения кубовых красителей адсорбируются субстратом (например, целлюлозным волокном) и при последующем окислении воздухом переходят в исходные нерастворимые кубовые красители. По химическому строению делятся на полициклические, индигоидные и тиоиндигоидные. Кубовые красители выпускаются всех цветов, кроме ярко-красного. Полициклические кубовые красители очень прочны. Они широко применяются в текстильной промышленности для крашения целлюлозных волокон, а также в качестве пигментов. Смотрите также Крашение.

VAUCHERIA = ВОШЕРИЯ – Vaucheria is a Genus of yellow-green Algae characterized by oil food reserves and multinucleate tubular branches lacking cross walls except in association with reproductive organs or an injury. Asexual reproduction is by motile zoospores and nonmotile aplanospores; sexual reproduction also occurs. The spherical female sex organ (oogonium) and the slender hook-shaped male sex organ (antheridium) are usually produced on branches close to each other. After the nonmotile egg is fertilized by a biflagellate sperm, the zygote may enter a resting phase for several weeks before germinating into a new plant. Although most species occur in fresh water or are terrestrial, some are marine and others live in ice. / Вошерия – Род жёлтозелёных Водорослей. Вошерия (Vaucheria, по имени Швейцарского ботаника Жо Пьера Этьена Воше, Jean Pierre Étienne Vaucher, 1763–1841), Род жёлто-зелёных (по другим данным, зелёных) Водорослей. Около 40 Видов, обитающих на почве, в пресных и морских водах.

Вошерия – тонкие зелёные стелющиеся нити неклеточного строения. Хлоропласты дисковидные без пиреноидов. Запасный продукт – масло. Вегетативное размножение осуществляется обрывками нитей, бесполое – многоядерными многожгутиковыми зооспорами, апланоспорами или цистами. Половой процесс – оогамия.

VAULT = СВОД – Vault:- in building construction, a structural member consisting of an arrangement of arches, usually forming a ceiling or roof. The basic barrel form, which appeared first in ancient Egypt and the Middle East, is in effect a continuous series of arches deep enough to cover a three-dimensional space. It exerts the same kind of thrust as the circular arch and must be buttressed along its entire length by heavy walls with limited openings. Roman architects discovered that two barrel vaults that intersected at right angles formed a groin vault, which, when repeated in series, could span rectangular areas of unlimited length. Because the groin vault's thrusts are concentrated at all four corners, its supporting walls need not be massive and require buttressing only where they support the vault. The groin vault, however, requires great precision in stone cutting, an art that declined in the West with the fall of Rome. Vaulting was continued and improved in the Byzantine Empire and in the Islamic world. Medieval European builders developed a modification, the rib vault, a skeleton of arches or ribs on which the masonry could be laid. The medieval mason used pointed arches; unlike round arches, these could be raised as high over a short span as over a long one. To cover rectangular areas, the mason used two intersecting vaults of different widths but of the same height. XIX-century builders, using new materials, could construct large iron skeletons as frameworks for vaults of lightweight materials – for example, the glass-vaulted Crystal Palace of the 1851 Great Exhibition in London. Because the new materials eliminated weight and thrust problems, the simple barrel vault returned to favor for such structures as railroad terminals and exhibition halls. In many modern frame systems the vault has lost its functional significance and become a thin skin laid over a series of arches. The reinforced-concrete shell vault, a bent or molded slab, is an important innovation. The steel-reinforced shell exerts no lateral thrust and may be supported as if it were a beam. / Свод в архитектуре, пространственная конструкция, перекрытие или покрытие сооружений, имеющее геометрическую форму, образованную выпуклой криволинейной поверхностью. Под нагрузкой своды, подобно арке, работают преимущественно на сжатие, передавая на опоры вертикальные усилия, а также во многих типах сводов горизонтальные (распор). Простейшим и наиболее распространённым является цилиндрический свод, опирающийся на параллельно расположенные опоры (стены, ряды столбов, аркады и тому подобное); в поперечном сечении он представляет собой часть окружности, эллипса, параболы и тому подобного. Два цилиндрических свода одинаковой высоты, пересекающиеся под прямым углом, образуют крестовый свод, который может опираться на свободностоящие опоры (столбы) на углах. Части цилиндрических сводов – лотки, или щёки, опирающиеся по всему периметру перекрываемого сооружения на стены (или арки, балки), образуют сомкнутый свод. Зеркальный свод отличается от сомкнутого тем, что его верхняя часть (плафон) представляет собой плоскую плиту. Производной от свода конструкцией является купол. Отсечением вертикальными плоскостями частей сферической поверхности купола образуется купольный (парусный) свод (свод на парусах). Многочисленные разновидности этих основных форм определяются различием кривых их сечений, количеством и формой распалубок и прочим (своды – стрельчатые, ползучие, бочарные, сотовые и другие). Древнейшими являются так называемые ложные своды, в которых горизонтальные ряды кладки, нависая один над другим, не передают усилий распора (например, своды казематов Акрополя Тиринфа, XIII век до Нашей Эры). В 4–3-м тысячелетиях до Нашей Эры в Египте и Месопотамии появились цилиндрические своды, распространившиеся в архитектуре Древнего Рима, где также употреблялись сомкнутые своды (своды в галерее Табулария, 79 до Нашей Эры) и крестовые своды (Базилика Максенция (Константина; около 315 Нашей Эры) – обе постройки в Риме). В Византийской архитектуре применялись цилиндрические, парусные, крестовые своды, в частности, в крестово-купольных храмах. В архитектуре Азербайджана, Индии, Китая, народов Средней Азии и Ближнего Востока использовались преимущественно стрельчатые своды. В Западной и Северной Европе в средневековый период распространились крестовые своды, которые в архитектуре готики приобрели стрельчатый характер с основным конструктивным элементом – нервюрой. С древности своды выполнялись преимущественно из природного естественного камня и кирпича. Величина прочности камня на изгиб ограничивала примерно на 5 метров (м) ширину пролёта в стоечно-балочной конструкции. Применение сводов (в которых камень, работая не на изгиб, а на сжатие, обнаруживает более высокую прочность) позволило значительно превысить эти размеры. Со 2-й половины XIX века своды нередко создавались из металлических конструкций. В XX веке появились различные типы монолитных и сборных железобетонных тонкостенных сводов-оболочек сложной конструкции, которые применяются для покрытий большепролётных зданий и сооружений. С середины XX века распространяются также деревянные клеёные сводчатые конструкции.

VAULT = ХРАНИЛИЩЕ – Vault is a room or compartment (at a bank) for the safekeeping of valuables. Also known as Strong Room. See also Safe Deposit Box. / Комната или помещение (в банке) для хранения ценностей. Известно также как Укреплённое Хранилище (Strong Room). Смотрите также Индивидуальная Сейфовая Ячейка (Safe Deposit Box).

VAULT CASH = НАЛИЧНОСТЬ В ХРАНИЛИЩЕ – Vault Cash is the cash kept on hand in a depository institution's vault to meet day-to-day business needs, such as cashing checks for customers. Can be counted as a portion of the institution's required reserves.

VAULT RECEIPT = СОХРАННАЯ РАСПИСКА (или ХРАНИЛИЩНАЯ РАСПИСКА) – Vault Receipt is a document indicating ownership of a commodity stored in a bank or other depository and frequently used as a delivery instrument in precious metal futures contracts. / Документ, отражающий владение товаром, хранящимся в банке или ином депозитарии, и часто используемый в качестве инструмента поставки по фьючерсным контрактам на благородные металлы. Сохранная Расписка, документ, выдаваемый при принятии имущества на хранение.

VAV SYSTEM = VARIABLE AIR VOLUME SYSTEM

VAWT = VERTICAL–AXIS WIND TURBINE

VB = VASCULAR BUNDLES

V–BED FLAT–KNITTING MACHINE = XX ПЛОСКОВЯЗАЛЬНАЯ МАШИНА – V-Bed Flat-Knitting Machine is a latch-needle weft-knitting machine with two needlebeds at a 90° angle to each other in the form of an inverted V. Each needlebed is at a 45° angle to the horizontal. These machines are used primarily to produce collars, sleeves, sweater strips, and rib trims.

V–BELT = ВИ.–ОБРАЗНЫЙ ПОЯС (или КЛИНООБРАЗНЫЙ ПОЯС) – V-Belt is a belt for transmitting power, commonly used in agricultural equipment.

V–BELT SEEDER = СЕЯЛКА С ВИ.–ОБРАЗНЫМ ПОЯСОМ (или СЕЯЛКА С КЛИНООБРАЗНЫМ ПОЯСОМ) – V-Belt Seeder is a seeding device where seeds are metered by the size of the hole in a belt.

VBG = VERY BIG GRIN

VBOK = EMSL–VEGAS LIBRARY BOOK SYSTEM = ENVIRONMENTAL MONITORING SYSTEMS LABORATORY – VEGAS LIBRARY BOOK SYSTEM

VBSCRIPT = ВИ.БИ.СКРИПТ (или ВИ.БИ.СЦЕНАРИЙ) – VBScript:- Visual Basic Script (VBScript) is a component-based scripting language developed by Microsoft. It is a light version of Visual Basic with a fast interpreter for use on Microsoft platforms. VBScripts use the Component Object Model (COM) to access the features of the environment where they are running. VBScripts are executed in the host environment. VBScript consists of procedures, control structures, constants, variables, date/time functions, etc. Procedures are the main construct of a VBScript, which allows codes to be divided into small modules. Control structures in VBScript use iterative and conditional do-loop construct, if-then-else statements, case statements, etc. Variables in VBScript have a variant type by default. VBScript works like JavaScript, when used for client-side web development. It is also used for server-side processing of web pages, for example, the Microsoft Active Server Pages (ASP). While there are uses for IE only environments (say, for example, an Intranet), all other major browsers support JavaScript. As such, JavaScript is the preferred scripting language on a public facing website. / VBScript – язык программирования сценариев, созданный компанией Майкрософт (Microsoft). Представляет собой подмножество языка Visual Basic, предназначенное для написания встроенных в тело Web-страниц сценариев. Поддерживается браузером MS Internet Explorer.

VDAX® = ФДАКС® – The VDAX®, the DAX® volatility index, expresses the fluctuation of the DAX® expected by market participants over the next 45 days. The basis of calculation are the DAX® option prices and implied volatility, i.e. the intensity of future price fluctuations currently expected by the market. A high VDAX® is a sign of an unstable market, low values suggest a development without major price swings. The VDAX® is therefore also referred to as the 'Fear Barometer'. It gives no indication of the direction of the change, i.e. whether share prices will rise or fall.

VDVM = VERBAND DEUTSCHER VERSICHERUNGSMAKLER E.V.

VE = VENEZUELA

VE = VISUAL EMISSIONS

VEAL = ТЕЛЯТИНА – Veal is a meat of calves slaughtered between 3 and 14 weeks, delicate in flavour, pale grayish white in color, firm and fine-grained, with velvety texture. It has no marbling, and the small amount of fat covering is firm and white. In modern livestock farming, calves bred to yield high-quality veal are raised indoors under controlled temperatures (60–65 °F (16–18 °C)) and intensively fed on milk, high-protein calf meal, or both. Herbaceous foods are excluded, resulting in an iron deficiency producing the desirable light color in the meat. Although the meat of an animal from 15 weeks to one year is technically called Calf, it is frequently marketed as Veal. Wholesale cuts, usually smaller than comparable beef cuts, vary in different countries. Because of its high amount of connective tissue and low fat content, large cuts of veal require long, slow cooking. Fat in the form of lard or salt pork may be added to avoid dryness. Veal is often served rare in European countries but is usually thoroughly cooked in the United States. Cuts such as the leg, loin, shoulder, and breast are usually roasted, often boned and stuffed, or braised. Schnitzel, pan-fried cutlets coated with bread crumbs, are a specialty of Germany and Austria. Scallops, small thin slices – called Scallopine in Italy and Escalopes or Médaillons in France – may be cooked in wine or other sauces. Veal:- meat from a calf that weighs about 150 pounds. Those that are mainly milk-fed usually are less than three months old. The difference between veal and baby beef is based on the color of their meat, which is determined almost entirely by diet. Veal is pale pink and contains more cholesterol than beef. / Скалопин (Scallopine) в Италии и Эскалёп (Escalopes) или Медайю (Médaillons) во Франции.

VEAL CALVES = XX (или ТЕЛЯТА–МОЛОЧНИКИ) – Veal Calves are the immature cattle, including beef and dairy breeds, that lack a functional rumen and are intended for meat production. Veal calves are recognized as a distinct regulatory class from suckling calves because of their handling, housing, and proximity to slaughter. Veal Calves, for the most part, are unwanted male calves from dairy

breeds – primarily the offspring of Holstein cows. With the advent of artificial insemination, only highly bred pedigree bulls who sire high producing cows are kept for breeding and consequently, and male calves have little value to the dairy farmer. Four categories of veal calves:- (i) Bob Veal Calves are newborns, some with umbilical cords still hanging from their abdomens, up to three weeks of age. About 15% of veal calves are marketed as Bob Veal. Meat from these calves goes into hot dogs and prepared sandwich meats. (ii) Milk Fed Veal Calves are often anemic. The calves are fed a low iron diet to produce the most desired white meat. They are fed milk replacer, which can be laced with antibiotics in order to control the diarrhea that is caused by an inadequate diet. These calves are restricted from moving and spend their lives in small stalls or hutches. They are slaughtered at 18 to 20 weeks of age. Calves can be so crippled from confinement that they have to be helped into the truck or trailer on the way to the slaughter plant. (iii) Red Veal Calves are fed milk replacer plus grain and hay. They are allowed to move about in large pens. The meat is thought to be less desirable because it is more red and not the highly desired white meat. These calves have a healthier diet, including grain and hay, and are able to freely move. (iv) Free Raised Veal Calves stay with their mothers in the pasture. They get their mother's milk and grass. They are healthy because they get colostrum from the dams over a longer period of time which gives them a stronger immune system. They get the food they need for optimum health. They are slaughtered at 24 weeks. They account for about 20% of the veal market. / Телята-Молочники:- Крупный Рогатый Скот, независимо от пола, в возрасте от 14 дней до 3 месяцев, выпоенный молоком.

VEB = VENEZUELAN BOLIVAR

VEBA = VOLUNTARY EMPLOYEES' BENEFITS ASSOCIATION

VECTOR = ВЕКТОР – (1) Vector:- in mathematics, a quantity that has both magnitude and direction but not position. Examples of such quantities are velocity and acceleration. In their modern form, vectors appeared late in the XIX century when Josiah Willard Gibbs and Oliver Heaviside (of the United States and Britain, respectively) independently developed vector analysis to express the new laws of electromagnetism discovered by the Scottish physicist James Clerk Maxwell. Since that time, vectors have become essential in physics, mechanics, electrical engineering, and other sciences to describe forces mathematically. Vectors may be visualized as directed line segments whose lengths are their magnitudes. Since only the magnitude and direction of a vector matter, any directed segment may be replaced by one of the same length and direction but beginning at another point, such as the origin of a coordinate system. Vectors are usually indicated by a boldface letter, such as v. A vector's magnitude, or length, is indicated by |v|, or v, which represents a one-dimensional quantity (such as an ordinary number) known as a Scalar. Multiplying a vector by a scalar changes the vector's length but not its direction, except that multiplying by a negative number will reverse the direction of the vector's arrow. For example, multiplying a vector by 1/2 will result in a vector half as long in the same direction, while multiplying a vector by −2 will result in a vector twice as long but pointed in the opposite direction. Two vectors can be added or subtracted. For example, to add or subtract vectors v and w graphically (see the diagram), move each to the origin and complete the parallelogram formed by the two vectors; v + w is then one diagonal vector of the parallelogram, and v − w is the other diagonal vector. There are two different ways of multiplying two vectors together. The cross, or vector, product results in another vector that is denoted by v · w. The cross product magnitude is given by |v · w| = vw sin θ, where θ is the smaller angle between the vectors (with their 'tails' placed together). The direction of v · w is perpendicular to both v and w, and its direction can be visualized with the right-hand rule, as shown in the figure. The cross product is frequently used to obtain a 'normal' (a line perpendicular) to a surface at some point, and it occurs in the calculation of torque and the magnetic force on a moving charged particle. The other way of multiplying two vectors together is called a Dot Product, or sometimes a Scalar Product because it results in a scalar. The dot product is given by v · w = vw cos θ, where θ is the smaller angle between the vectors. The dot product is used to find the angle between two vectors. (Note that the dot product is zero when the vectors are perpendicular.) A typical physical application is to find the work W performed by a constant force F acting on a moving object d; the work is given by W = Fd cos θ. / Дьжосайа Вилод Гибз (Josiah Willard Gibbs) и Оливэ Хэвисайд (Oliver Heaviside) (из Соединённых Штатов и Британии, соответственно) независимо друг от друга разработали векторный анализ для выражения новых законов электромагнетизма, открытых Шотландским физиком Дьжеймзом Клаком Максвэлом (James Clerk Maxwell). Под Вектором, от Латинского слова Vector, означающее буквально Несущее или Перевозящее, в геометрическом смысле понимается направленный отрезок, то есть отрезок, у которого указаны начало (называемое также Точкой Приложения Вектора) и конец. Для обозначения вектора используются либо жирные Латинские буквы α, b, либо буквы обычного алфавита с чёрточками или стрелками наверху:- ā, , ... Вектор, имеющий начало в точке A и конец в точке B, обозначается AB. Прямая, на которой расположен вектор, называется Линией Действия Данного Вектора. Понятие Вектор возникло в связи с изучением величин, характеризуемых численным значением и направленностью (например, перемещение, скорость и ускорение движущейся материальной точки, действующая на неё сила и тому подобные). В механике и физике рассматривают свободные, скользящие и связанные векторы. Вектор называется Свободным, если его значение не меняется при произвольном параллельном переносе. Свободным вектором является, например, скорость движения материальной точки. Вектор называется Скользящим, если его значение не меняется при любом параллельном переносе вдоль линии его действия. Примером скользящего вектора может служить сила, действующая на абсолютно твёрдое тело (две равные и расположенные на одной прямой силы оказывают на абсолютно твёрдое тело одинаковое воздействие). Вектор называется Связанным, если фиксировано его начало. Например, сила, приложенная к некоторой точке упругого тела, представляет собой связанный вектор. Свойства свободных векторов изучаются средствами векторной алгебры (смотрите Векторное Исчисление). Общее понятие Вектор как элемента, так называемого, векторного пространства определяется аксиоматически.

(2) Vector is a self-replicating DNA molecule that serves to transfer a DNA segment into a host cell in recombinant DNA technology. Vector is an object that is used to transport genes into a host cell (vectors can be plasmids, viruses, or other bacterial). A gene is placed in the vector, the vector then 'infects' the bacterium. / в технологии рекомбинантных ДНК. Под Вектором, от Латинского слова Vector, означающее Несущее, понимается . Вектор (Vector) – переносчик генетического материала в генной инженерии (бактериофаг, вирус или плазмида со вставкой чужеродной ДНК).

VECTOR = ПЕРЕНОСЧИК – Vector is an organism that carries a pathogen from an infected plant to a healthy plant. Insects, nematodes, man, parasitic plants, etc may act as vectors for plant pathogens while remaining unaffected by their presence. An organism able to transport and transmit a pathogen to a host. Vector is:- (1) an organism that carries pathogens from one host to another; (2) an insect that transmits a disease. Vector is a pathogen-carrying insect or animal. Vector is the agent used (by researchers) to carry new genes into cells. Plasmids currently are the biological vectors of choice; though viruses and other biological vectors such as Agrobacterium Tumefaciens. Vector is an organism, often an insect or rodent, that carries disease. / Организм, способный переносить и передавать патоген хозяину. Переносчики возбудителей инфекций, членистоногие, осуществляющие перенос возбудителей инфекционных и инвазионных болезней между людьми и животными. К переносчикам возбудителей инфекций относят кровососущих Насекомых (Блохи, Вши, Комары, Москиты, Мошки, Слепни и другие), Клещей и некровососущих Насекомых (Мухи, Тараканы, Муравьи). Различают специфический перенос, при котором возбудитель заболевания проходит в теле переносчика определённые стадии развития и размножения (например, плазмодий малярии в организме Комара), и механический, при котором такого развития и размножения не происходит (например, возбудители

кишечных инфекций). Кровососущие переносчики возбудителей инфекций передают возбудителя при кровососании (передача малярии и жёлтой лихорадки Комарами, клещевого энцефалита Клещами, чумы Блохами); возбудитель инфекции может проникнуть в организм человека при попадании экскрементов кровососущих на повреждённую кожу (передача сыпного тифа Вшами) или при попадании на повреждённую кожу крови раздавленных переносчиков (например, при возвратном тифе). Для передачи инфекции кровососущий переносчик возбудителей инфекций должен предварительно насосаться крови больного, являющегося источником инфекции. Таким источником при некоторых заболеваниях (малярия, сыпной тиф) является только человек, при других (клещевые энцефалиты, возвратный тиф, флеботомная лихорадка, лейшманиозы и другие) – в основном животные (Грызуны, Волки, Птицы, Собаки, Коровы, Козы и другие). Заболевания, передающиеся кровососущими переносчиками возбудителей инфекций, называют Трансмиссивными Болезнями. Ряд переносчиков передают вирус своим потомкам из поколения в поколение (например, Клещи передают вирус клещевого энцефалита). Наличие резервуара инфекции среди диких животных и циркуляция возбудителя между ними и переносчиками возбудителей инфекций обусловливает природную очаговость болезней. Некровососущие Насекомые переносят возбудителя на лапках, волосках; он может также содержаться в их экскрементах. Для борьбы с переносчиками возбудителей инфекций применяют инсектициды, в целях защиты от укусов – репелленты, накомарники, противоклещевые комбинезоны.

VECTOR ANALYSIS = ВЕКТОРНЫЙ АНАЛИЗ – Vector Analysis:- a user-definable prepayment model for mortgage-backed securities. The vector-analysis model lets you define up to 10 different prepayment speeds over the life of the security. For example, you can define a model with a 600 PSA (short for the Public Securities Association standardized prepayment model) for the first year, a 100 PSA for the next year, a 700 PSA for the third, and so on. You can also use the vector model to flatten out seasonality, if desired.

VECTOR BORNE = ПЕРЕДАВАЕМАЯ ПЕРЕНОСЧИКОМ – Vector Borne:- a Vector is a living organism that transmits an infectious agent from an infected animal to a human or another animal. Vectors are frequently arthropods, such as mosquitoes, ticks, flies, fleas and lice. Vectors can transmit infectious diseases either actively or passively:- (i) Biological Vectors, such as mosquitoes and ticks may carry pathogens that can multiply within their bodies and be delivered to new hosts, usually by biting. (ii) Mechanical Vectors, such as flies can pick up infectious agents on the outside of their bodies and transmit them through physical contact. Diseases transmitted by vectors are called Vector-Borne Diseases. Many vector-borne diseases are zoonotic diseases, i.e. diseases that can be transmitted directly or indirectly between animals and humans. These include for example Lyme disease, tick-borne encephalitis, West Nile virus, Leishmaniosis and Crimean-Congo haemorrhagic fever. Many vector-borne diseases are considered as emerging infectious diseases in the European Union:- (i) a disease that appears in a population for the first time; or (ii) that may have existed previously but is rapidly increasing in incidence or geographic range. Some vectors are able to move considerable distances. This may affect the transmission ranges of vector-borne zoonotic diseases. Vectors can be introduced to new geographic areas for example by:- (i) travel of humans and international trade; (ii) animal movement, for instance of livestock; (iii) migratory birds; (iv) changing agricultural practices; or (v) the wind. Other factors may play a role in their establishment and persistence in new areas, including climatic conditions. / Передаваемая Переносчиком:- трансмиссивная передача болезни.

VECTOR CONVERSION = ВЕКТОРНАЯ КОНВЕРСИЯ (или ВЕКТОРНОЕ ПРЕОБРАЗОВАНИЕ, или ВЕКТОРНАЯ КОНВЕРТАЦИЯ) – Vector Conversion is the art of converting raster images to vector format. Bitmap images are made up of pixels, and cannot be scaled up effectively. Vector images are created by the numerical coordinates that are contained within the file. Vector images can be scaled up or down infinitely without the loss of resolution and are much smaller files compared to bitmap files. Vector images also allow you to change color and edit individual elements with ease. Vector artwork is simply comprised of lines (wireframe) that represent the objects. Vector images are usually created with the drawing program such as Corel Draw, Adobe Illustrator or Freehand.

VECTOR RATE = ВЕКТОРНАЯ СТАВКА (или XX) – Vector Rate:- xxxxx. See also Two Dimensional Vector Rate; and Three Dimensional Vector Rate.

VECTOR SPACE = ВЕКТОРНОЕ ПРОСТРАНСТВО – Vector Space:- a set of multidimensional quantities, known as Vectors, together with a set of one-dimensional quantities, known as Scalars, such that vectors can be added together and vectors can be multiplied by scalars while preserving the ordinary arithmetic properties (associativity, commutativity, distributivity, and so forth). Vector spaces are fundamental to linear algebra and appear throughout mathematics and physics. The idea of a vector space developed from the notion of ordinary two- and three-dimensional spaces as collections of vectors {u, v, w, …} with an associated field of real numbers {a, b, c, …}. Vector spaces as abstract algebraic entities were first defined by the Italian mathematician Giuseppe Peano in 1888. Peano called his vector spaces ‘Linear Systems’ because he correctly saw that one can obtain any vector in the space from a linear combination of finitely many vectors and scalars – av + bw + … + cz. A set of vectors that can generate every vector in the space through such linear combinations is known as a Spanning Set. The dimension of a vector space is the number of vectors in the smallest spanning set. (For example, the unit vector in the x-direction together with the unit vector in the y-direction suffice to generate any vector in the two-dimensional Euclidean plane when combined with the real numbers.) The linearity of vector spaces has made these abstract objects important in diverse areas such as statistics, physics, and economics, where the vectors may indicate probabilities, forces, or investment strategies and where the vector space includes all allowable states. / Итальянский математик Дьжузэппэ Пэано (Giuseppe Peano) в 1888. Векторное Пространство, математическое понятие, обобщающее понятие совокупности всех (свободных) векторов обычного трёхмерного пространства. Определение Векторного Пространства:- Для векторов трёхмерного пространства указаны правила сложения векторов и умножения их на действительные числа (смотрите Векторное Исчисление). В применении к любым векторам x, y, z и любым числам a, b эти правила удовлетворяют следующим условиям (условия A):- (1) $x + y = y + x$ (перестановочность сложения); (2) $(x + y) + z = x + (y + z)$ (ассоциативность сложения); (3) имеется нулевой вектор 0 (или нуль-вектор), удовлетворяющий условию $x + 0 = x$: для любого вектора x; (4) для любого вектора x существует противоположный ему вектор y такой, что $x + y = 0$, (5) $1 \cdot x = x$, (6) $a(bx) = (ab)x$ (ассоциативность умножения); (7) $(a + b)x = ax + bx$ (распределительное свойство относительно числового множителя); (8) $a(x + y) = ax + ay$ (распределительное свойство относительно векторного множителя). Векторным (или Линейным) Пространством называется множество R, состоящее из элементов любой природы (называемых Векторами), в котором определены операции сложения элементов и умножения элементов на действительные числа, удовлетворяющие условиям A (условия 1–3 выражают, что операция сложения, определённая в векторное пространство, превращает его в коммутативную группу). Выражение:- $a_1e_1 + a_2e_2 + ... + a_ne_n$ (1), называется Линейной Комбинацией Векторов $e_1, e_2, ..., e_n$ с коэффициентами $a_1, a_2, ..., a_n$. Линейная комбинация (1) называется Нетривиальной, если хотя бы один из коэффициентов $a_1, a_2, ..., a_n$ отличен от нуля. Векторы $e_1, e_2, ..., e_n$ называются Линейно Зависимыми, если существует нетривиальная комбинация (1), представляющая собой нулевой вектор. В противном случае (то есть если только тривиальная комбинация векторов $e_1, e_2, ..., e_n$ равна нулевому вектору) векторы $e_1, e_2, ..., e_n$ называется Линейно Независимыми. Векторы (свободные) трёхмерного пространства удовлетворяют следующему условию (условие B):- существуют три линейно независимых вектора; любые четыре вектора линейно зависимы (любые три ненулевых вектора, не лежащие в одной плоскости, являются линейно независимыми). Векторное пространство

называется n-мерным (или имеет ‘размерность n’), если в нём существуют n линейно независимых элементов $e_1, e_2, ..., e_n$, а любые n + 1 элементов линейно зависимы (обобщённое условие B). Векторное пространство называется бесконечномерным, если в нём для любого натурального n существует n линейно независимых векторов. Любые n линейно независимых векторов n-мерного векторного пространства образуют базис этого пространства. Если $e_1, e_2, ..., e_n$ – базис векторного пространства, то любой вектор x этого пространства может быть представлен единственным образом в виде линейной комбинации базисных векторов:- $x = a_1e_1 + a_2e_2 + ... + a_ne_n$. При этом числа $a_1, a_2, ..., a_n$ называются Координатами Вектора x в данном базисе. Примеры Векторных Пространств:- Множество всех векторов трёхмерного пространства образует, очевидно, векторное пространство. Более сложным примером может служить так называемое n-мерное арифметическое пространство. Векторами этого пространства являются упорядоченные системы из n действительных чисел:- $l_1, l_2, ..., l_n$. Сумма двух векторов и произведение на число определяются соотношениями:- $(l_1, l_2, ..., l_n) + (m_1, m_2, ..., m_n) = (l_1 + m_1, l_2 + m_2, ..., l_n + m_n)$; $a(l_1, l_2, ..., l_n) = (al_1, al_2, ..., al_n)$. Базисом в этом пространстве может служить, например, следующая система из n векторов $e_1 = (1, 0, ..., 0)$, $e_2 = (0, 1, ..., 0)$, ..., $e_n = (0, 0, ..., 1)$. Множество R всех многочленов $a_0 + a_1u + ... + a_nu^n$ (любых степеней n) от одного переменного с действительными коэффициентами $a_0, a_1, ..., a_n$ с обычными алгебраическими правилами сложения многочленов и умножения многочленов на действительные числа образует векторное пространство. Многочлены $1, u, u_2, ..., u_n$ (при любом n) линейно независимы в R, поэтому R – бесконечномерное векторное пространство. Многочлены степени не выше n образуют векторное пространство размерности n + 1; его базисом могут служить многочлены $1, u, u_2, ..., u_n$. Подпространства Векторных Пространств:- Векторное пространство R” называется Подпространством R, если R” Í R (то есть каждый вектор пространства R” есть и вектор пространства R) и если для каждого вектора v Î r” и для каждых двух векторов v_1 и v_2 (v_1, v_2 Î R”) вектор lv (при любом l) и вектор $v_1 + v_2$ один и тот же независимо от того, рассматриваются ли векторы v, v_1, v_2 как элементы пространства R” или R. Линейной оболочкой векторов $x_1, x_2, ..., x_p$ называется множество всевозможных линейных комбинаций этих векторов, то есть векторов вида $a_1x_1 + a_2x_2 + ... + a_px_p$. В трёхмерном пространстве линейной оболочкой одного ненулевого вектора x_1 будет, очевидно, совокупность всех векторов, лежащих на прямой, определяемой вектором x_1. Линейной оболочкой двух не лежащих на одной прямой векторов x_1 и x_2 будет совокупность всех векторов, расположенных в плоскости, которую определяют векторы x_1 и x_2. В общем случае произвольного векторного пространства R линейная оболочка векторов $x_1, x_2, ..., x_p$ этого пространства представляет собой подпространство пространства R размерности p. В n-мерном векторном пространстве существуют подпространства всех размерностей, меньших p. Всякое конечномерное (данной размерности k) подпространство R” векторного пространства R есть линейная оболочка любых k линейно независимых векторов, лежащих в R”. Пространство, состоящее из всех многочленов степени £ n (линейная оболочка многочленов $1, u, u_2, ..., u_n$), есть (n + 1)-мерное подпространство пространства R всех многочленов. Евклидовы Пространства:- Для развития геометрических методов в теории векторного пространства нужно указать пути обобщения таких понятий, как длина вектора, угол между векторами и тому подобное. Один из возможных путей заключается в том, что любым двум векторам x и y из R ставится в соответствие число, обозначаемое (x, y) и называемое Скалярным Произведением Векторов x и y. При этом требуется, чтобы выполнялись следующие аксиомы скалярного произведения:- (1) (x, y) = (y, x) (перестановочность); (2) $(x_1 + x_2, y) = (x_1, y) + (x_2, y)$ (распределительное свойство); (3) (ax, y) = a(x, y), (4) $(x, x)^3 0$ для любого x, причём (x, x) = 0 только для x = 0. Обычное скалярное произведение в трёхмерном пространстве этим аксиомам удовлетворяет. Векторное пространство, в котором определено скалярное произведение, удовлетворяющее перечисленным аксиомам, называется Евклидовым Пространством; оно может быть как конечномерным (n-мерным), так и бесконечномерным. Бесконечномерное Евклидово пространство обычно называют Гильбертовым Пространством. Длина |x| вектора x и угол (xy) между векторами x и y Евклидова пространства определяются через скалярное произведение формулами:- $|x| = \sqrt{(x,x)}$, $\cos(xy) = (x,y) / \sqrt{((x,x)(y,y))}$. Примером Евклидова пространства может служить обычное трёхмерное пространство со скалярным произведением, определяемым в векторном исчислении. Евклидово n-мерное (арифметическое) пространство En получим, определяя в n-мерном арифметическом векторном пространстве скалярное произведение векторов $x = (l_1, ..., l_n)$ и $y = (m_1, ..., m_n)$ соотношением:- $(x, y) = l_1m_1 + l_2m_2 + ... + l_nm_n$ (2). При этом требования (1)–(4), очевидно, выполняются. В Евклидовых пространствах вводится понятие Ортогональных (Перпендикулярных) Векторов. Именно векторы x и y называются ортогональными, если их скалярное произведение равно нулю:- (x, y) = 0. В рассмотренном пространстве En условие ортогональности векторов $x = (l_1, ..., l_n)$ и $y = (m_1, ..., m_n)$, как это следует из соотношения (2), имеет вид:- $l_1m_1 + l_2m_2 + ... + l_nm_n = 0$ (3). Применение Векторного Пространства:- Понятие Векторное Пространство (и различные обобщения) широко применяется в математике и её приложениях к естествознанию. Пусть, например, R – множество всех решений линейного однородного дифференциального уравнения $y^n + a1(x)\ y^{(n+1)} + ... + an\ (x)\ y = 0$. Ясно, что сумма двух решений и произведение решения на число являются решениями этого уравнения. Таким образом, R удовлетворяет условиям A. Доказывается, что для R выполнено обобщённое условие B. Следовательно, R является векторным пространством. Любой базис в рассмотренном векторном пространстве называется Фундаментальной Системой Решений, знание которой позволяет найти все решения рассматриваемого уравнения. Понятие Евклидова Пространства позволяет полностью геометризовать теорию систем однородных линейных уравнений:- $\alpha_{11}u_1 + ... + \alpha_{1n}u_n = 0$, $\alpha_{m1}u_1 + ... + \alpha_{mn}u_n = 0$ (4). Рассмотрим в Евклидовом пространстве E^n векторы $a_i = (a_{i1}, a_{i2}, ..., a_{in})$, i = 1, 2, ..., n и вектор-решение $u = (u_1, u_2, ..., u_n)$. Пользуясь формулой (2) для скалярного произведения векторов En, придадим системе (4) следующий вид:- $(a_i, u) = 0$, i = 1, 2, ..., m (5). Из соотношений (5) и формулы (3) следует, что вектор-решение u ортогонален всем векторам a_i. Иными словами, этот вектор ортогонален линейной оболочке векторов ai, то есть решение u есть любой вектор из ортогонального дополнения линейной оболочки векторов ai. Важную роль в математике и физике играют и бесконечномерные линейные пространства. Примером такого пространства может служить пространство C непрерывных функций на отрезке с обычной операцией сложения и умножения на действительные числа. Упомянутое выше пространство всех многочленов является подпространством пространства C.

VECTRAN® FIBER = ВОЛОКНО ВЭКТРЭН® (или ВОЛОКНО ВЕКТРАН®) – Vectran® Fiber is a manufactured fiber spun from a liquid crystal polymer. These fibers have high-temperature resistance, high strength and modulus, and a high resistance to moisture and chemicals, with good property retention in hostile environments. Vectran® is a high-performance multifilament yarn spun from liquid crystal polymer (LCP). Vectran® fiber exhibits exceptional strength and rigidity. It is 5 times stronger than steel and 10 times stronger than aluminum. Vectran® is used in industrial rope and cord because of it’s superior abrasion resistance, excellent moisture resistance and exceptional property retention over a broad range of temperatures and chemical environments. Properties of Vectran®:- (i) high strength and modulus; (ii) excellent creep resistance; (iii) high abrasion resistance; (iv) excellent flex/fold characteristics; (v) minimal moisture absorption; (vi) excellent chemical resistance; (vii) low coefficient of thermal expansion (CTE); (viii) high dielectric strength; (ix) outstanding cut resistance; (x) excellent property retention at high and low temperatures; (xi) outstanding vibration damping characteristics; and (xii) high impact resistance. Applications:- (i) parachute cords; (ii) helicopter sling legs; (iii) astronaut safety tethers; (iv) aerial camera tethers; (v) balloon tethers; (vi) helicopter rescue ropes; (vii) tow ropes; (viii) cargo tie-downs; (ix) running rigging; (x) standing rigging; and (xi) mountaineering ropes.

VEEP = VICE PRESIDENT

VEEP = VOLUNTARY ENERGY EFFICIENCY PROGRAMME

VEER = ТРАВИТЬ (или МЕНЯТЬ НАПРАВЛЕНИЕ) – Veer:- to slack off or move off; also said of a change of direction of wind, when the wind shifts to a different direction. / Травить канат или якорную цепь.

VEF = VENEZUELAN BOLIVAR

VEGA = ВЕГА – Vega represents the amount that the price of an option will change compared to a 1% change in volatility. Vega:- option prices are exposed not only to market movements in the direction of the spot price of the underlying, but also to market movements in the implied volatility used to price the option. Thus, the sensitivity of an option price with respect to volatility of the underlying security price is called Vega. Vega is the sensitivity of an option's value to a change in volatility. Vega is an indicator that meaures the change in the price of an option resulting from a one percent change in the volatility of the underlying, all other things being equal. A high Vega means that the price of the option responds relatively strongly to changes in the volatility of the underlying. Vega is a measure of how much an option's price will change as the volatility of the underlying fluctuates. Measures the change in an option's price caused by changes in volatility. Vega is at its highest when an option is at-the-money. It decreases the more the market and strike prices diverge. Options closer to expiration have a lower Vega than those with more time to run. Positions with positive Vega will generally have positive Gamma. To be long Vega (to have a positive Vega) is achieved by purchasing either put or call options. Positions that are long Vega benefit from increases in implied volatility but also from actual volatility if the option is being Delta hedged. They will also lose from reductions in volatility. Spread options can be an exception:- a reduction in the volatility of one of the assets may actually increase the price of the option because the correlation between the two assets decreases. Vega is sometimes known as Kappa or Tau. Vega is a term that describes the sensitivity of the option price to a one-percent change in volatility. Vega is a measure of the rate of change in an option's theoretical value for a one-unit change in the volatility assumption. See also Delta, Gamma, and Kappa. Vega is a measure of the sensitivity of an option's price to a change in volatility. Vega:- the change in the price of an option associated with a 1% change in implied volatility. This is technically the first derivative of the option price with respect to volatility. You may also see Vega referred to as Eta, Epsilon, Omega and Kappa. The terms that refer to the component calculations of options are often know as 'The Greeks'. A large price movement in the underlying asset will cause a change in Vega (i.e. increased volatility). The value of Vega will also change if volatility is expected to increase. In other words, the underlying asset's price does not need to change, just the expectation that it will change is sufficient to change the value of Vega. All the Greeks:- Delta, Gamma, Vega, Theta, and Vomma. Vega is the option risk parameter that measures the sensitivity of the option price to changes in the price volatility of the underlying instrument. / Чувствительность стоимости опциона к изменению лихорадочности. Вега:- показатель изменения цены опциона в зависимости от изменения его подразумеваемой лихорадочности. Например, если Вега опциона на акции XYZ составляет 0.25, то цена опциона будет изменяться на 25 центов при каждом изменении подразумеваемой лихорадочности опциона на один процентный пункт.

VEGETABLE = ОВОЩ (или ОВОЩНАЯ КУЛЬТУРА, или ОВОЩНОЕ) – Vegetable:- in the broadest sense, any kind of plant life or plant product, namely 'Vegetable Matter'; in common, narrow usage, the term Vegetable usually refers to the fresh edible portion of a herbaceous plant – roots, stems, leaves, flowers, or fruit. These plant parts are either eaten fresh or prepared in a number of ways. Virtually all of the more important vegetables were cultivated among the ancient civilizations of either the Old or the New World. Some, such as the Cucumber, Potato, sweet Corn (Maize), and Onion, have been so changed by cultivation that their wild ancestors can no longer be identified with certainty. Vegetables are usually classified on the basis of the part of the plant that is used for food. The root vegetables include Beets, Carrots, Radishes, and Turnips. Stem vegetables include Asparagus and Kohlrabi. Among the edible tubers, or underground stems, are Potatoes. The leaf and leafstalk vegetables include Brussels Sprouts, Cabbage, Celery, Lettuce, Rhubarb, and Spinach. Among the bulb vegetables are Garlic, Leeks, and Onions. The head, or flower, vegetables include Artichokes, Broccoli, and Cauliflower. The fruits commonly considered vegetables by virtue of their use include Beans, Cucumbers, Eggplant, Okra, Sweet Corn, Squash, Peppers, and Tomatoes. Most fresh vegetables have a water content in excess of 70 percent, with only about 3.5 percent protein and less than 1 percent fat. Vegetables, however, are good sources of minerals, especially calcium and iron, and vitamins, principally A and C. Modern vegetable farming ranges from small-scale production for local sale to vast commercial operations utilizing the latest advances in automation and technology. Most vegetables are planted by seeding in the fields where they are to be grown, but occasionally they are germinated in a nursery or greenhouse and transplanted as seedlings to the field. During the growing season herbicides, pesticides, and fungicides are commonly used to inhibit damage by Weeds, Insects, and diseases, respectively. Harvesting operations are usually mechanized in well-developed nations, but the practice of harvesting by hand is still employed in some areas or is used in conjunction with machine operations. Another concern of the vegetable farmer is postharvest storage, which may require refrigerated facilities. Vegetables may be washed, sorted, graded, cut, and packaged for sale as fresh products. Fresh vegetables are subject to quick aging and spoilage, but their storage life can be extended by such preservation processes as dehydration, canning, freezing, fermenting, or pickling. Vegetable is a herbaceous plant grown for eating, usually eaten as part of a meal. / Под Овощами понимаются сочные части травянистых растений, употребляемые в пищу в свежем или переработанном виде. В качестве овощей используют продуктивные органы Овощных культур – завязи, клубни, корнеплоды, кочаны, листья, плоды, недозрелые семена, соцветия, утолщённые стебли, черешки и другие. Выращиванием Овощных культур для получения овощей занимается овощеводство. Приятный вкус и пищевые достоинства овощей обусловлены содержанием в них сахаров (0.5–2.5%), органических кислот, ароматических веществ, зольных элементов (0.4–3%), витаминов (5–50 мг% С, а также каротин, B_1, B_2, РР и другие). Овощи почти не содержат жиров, в них мало белка (1–2%, кроме Бобовых, в которых 5–6%), но много воды – 65–96%. Поэтому энергетическая ценность овощей невелика – 2–2 000 кДж/кг. Однако в овощах содержатся биологически активные соединения (соли калия, кальция, магния, железа, фосфора), микроэлементы. Минеральные вещества овощей при пищеварении образуют соединения со щелочными свойствами, что способствует поддержанию кислотно-щелочного равновесия в организме, нейтрализации содержащихся в хлебе, мясе, жирах веществ с кислыми свойствами. Важная физиологическая особенность овощей – их способность возбуждать аппетит, улучшать усвояемость других продуктов. Овощи широко применяют в диетическом питании. Издавна известны и лечебные свойства овощей. В Луке, Хрене, Чесноке и других накапливаются фитонциды – вещества, обладающие бактерицидными свойствами. Состав и питательная ценность овощей зависит от вида продукта, условий выращивания, хранения и переработки. Биологическая ценность овощей значительно снижается при кулинарной обработке. При квашении, быстром замораживании, сублимационной сушке (в вакууме) в овощах в значительной степени сохраняются витамины и другие вещества. Овощи, сочные части травянистых Растений, употребляемые в пищу человеком в свежем или переработанном виде. Для пищевкусовых целей используют плоды или завязи их, молодые побеги, корни, корневища, клубни, соцветия, семена, листья, черешки листьев, кочаны, луковицы, утолщённые стебли овощных Растений. Овощи играют важную роль в питании Человека. Приятный вкус и пищевые достоинства овощей обусловлены разнообразным сочетанием в них сахаров, органических кислот, ароматических и минеральных веществ. Многие овощи применяются как лечебные средства и в диетическом питании. Овощи должны включаться в пищевой рацион (смотрите Питание) взрослого здорового Человека в количестве не менее 600 граммов

(г) в сутки. Состав и питательная ценность овощей колеблются в широких пределах и зависят от вида продукта, условий выращивания, хранения и так далее. Овощи не содержат жиров. По содержанию белков овощи значительно уступают продуктам животного происхождения. Основная ценность овощей заключается в том, что они – источники пищевых биологически активных веществ:- витаминов (С, каротина, фолиевой кислоты), минеральных веществ, органических кислот, клетчатки в комплексе с пектиновыми веществами. Важное физиологическое свойство овощей – их способность возбуждать аппетит и влиять на секреторную функцию пищеварительных желёз. Выращиванием овощей занимается овощеводство. Овощи в большом количестве перерабатывают различными методами (подробнее смотрите в статьях Консервирование, Квашение, Маринование, Замораживание Пищевых Продуктов, Сушка Пищевых Продуктов). Биологическая ценность овощей значительно снижается при тепловой кулинарной обработке, а также при неправильном хранении. При квашении, быстром замораживании, сублимационной сушке в овощах в большей степени сохраняются витамины. Овощные Растения, культивируемые или дикорастущие травянистые растения, у которых в пищу используются сочные части – овощи. К овощным Растениям относятся более 1 200 Видов, принадлежащих к 78 Семействам, из них примерно половину возделывают, остальные используют в дикорастущем состоянии. У различных овощных Растений в пищу употребляются плоды (плодовые овощные Растения – Томат, Баклажан, Перец, Огурец, Арбуз, Горох, Фасоль и другие), побеги, листья и их черешки, кочаны (листовые овощные Растения – Капуста, Салат, Шпинат, Укроп, Мангольд и другие), луковицы (луковые овощные Растения – Лук Репчатый, Чеснок, Порей-Лук), утолщённые корни (корнеплоды – Морковь, Свёкла, Репа, Редис, Редька и другие) и так далее. К овощным Растениям относят также Грибы (Шампиньон). По продолжительности жизни овощные Растения делят на одно-, дву- и многолетние. Однолетние заканчивают жизненный цикл (от семени до семени) в один год и полностью отмирают (Бобовые, Тыквенные, Редис, Укроп и другие). Двулетние в 1-й год жизни образуют продуктовые органы, употребляемые в пищу, а во 2-й – семена (Лук репчатый, Чеснок, Корнеплоды, кроме Редиса, Капуста, кроме цветной и Пекинской, Артишок). Многолетние овощные Растения (Ревень, Щавель, Спаржа, Эстрагон, Батун-Лук и другие) характеризуются многократным плодоношением (образованием семян). Большинство овощных Растений происходит из тропических и субтропических поясов. Многие из них теплолюбивы, требовательны к плодородию почвы и её влажности. Некоторые виды овощных Растений холодостойки, что даёт возможность выращивать их на Севере, в ранние сроки в Центральном районе и зимой в субтропических районах. Смотрите также Овощеводство. Под Овощными Культурами понимается группа культурных Растений, возделываемых в основном для получения овощей (сочных плодов, листьев, луковиц, корнеплодов). Известно около 120 овощных культур, в бывшем Союзе Советских Социалистических Республик (СССР) – около 70. Более 600 Видов почти из 80 ботанических Семейств; в бывшем СССР насчитывалось свыше 60 Видов. В зависимости от продуктивности органов их подразделяют на:- (i) Корнеплоды (Морковь, Пастернак, Петрушка, Редис, Редька, Репа, Сельдерей, Столовая Свёкла и другие); (ii) Листовые (Капуста, Листовая Петрушка, Мангольд, Салат, Укроп, Шпинат и другие); (iii) Луковичные (Лук и Чеснок); (iv) Овощные (Горох, Фасоль и другие); и (v) Плодовые (Баклажан, Кабачок, Огурец, Патиссон, Перец, Томат, Тыква). К овощным культурам относят также ранний Картофель и Сахарную Кукурузу. Овощные культуры принадлежат к следующим ботаническим Семействам:- (i) Астровых (Салат-Латук, Эндивий); (ii) Гречишных (Ревень, Щавель); (iii) Зонтичных (Морковь, Пастернак, Петрушка, Сельдерей, Укроп и другие); (iv) Капустовых (Капуста, Редис, Редька, Репа); (v) Луковых (Лук и Чеснок); (vi) Маревых (Мангольд, Столовая Свёкла, Шпинат); (vii) Паслёновых (Баклажан, Картофель, Перец, Томат, Физалис); (viii) Тыквенных (Кабачок, Огурец, Патиссон, Тыква); и (ix) Яснотковых (Базилик, Майоран, Мята, Чабер). По типу развития и продолжительности жизни Овощные культуры делятся на:- (i) Однолетние (например, Огурец, Редис, Томат, Укроп); (ii) Двулетние (многие корнеплоды и капуста, кроме цветной); и (iii) Многолетние (Любисток, Ревень, Хрен, Щавель). Овощные культуры выращивают во всех земледельческих районах мира. Южные и Северные границы их ареала совпадают с границами земледелия. Наибольшие площади заняты Капустой, Луком, Овощным Горохом, Огурцом, Сахарной Кукурузой, Томатом. В бывшем СССР были повсеместно распространены Капуста, Лук, Морковь, Огурец, Столовая Свёкла, Томат. Основные работы (обработка почвы, посев, уход за посевами, уборка многих культур) механизированы. Внедряются в производство интенсивные технологии возделывания Овощных культур. Получила распространение Астраханская технология. Выведены высокопродуктивные сорта Овощных культур, хорошо приспособленные к условиям выращивания. Средняя урожайность Овощных культур в бывшем СССР в 1985 – 157 ц/га.

VEGETABLE FARMING = ВОЗДЕЛЫВАНИЕ ОВОЩЕЙ (или ОВОЩЕВОДСТВО) – Vegetable Farming is a growing of vegetable crops, primarily for use as human food. The term Vegetable in its broadest sense refers to any kind of plant life or plant product; in the narrower sense, as used in this article, however, it refers to the fresh, edible portion of a herbaceous plant consumed in either raw or cooked form. The edible portion may be a root, such as Rutabaga, Beet, Carrot, and Sweet Potato; a tuber or storage stem, such as Potato and Taro; the stem, as in Asparagus and Kohlrabi; a bud, such as Brussels Sprouts; a bulb, such as Onion and Garlic; a petiole or leafstalk, such as Celery and Rhubarb; a leaf, such as Cabbage, Lettuce, Parsley, Spinach, and Chive; an immature flower, such as Cauliflower, Broccoli, and Artichoke; a seed, such as Pea and Lima Bean; the immature fruit, such as Eggplant, Cucumber, and Sweet Corn (Maize); or the mature fruit, such as Tomato and Pepper. The popular distinction between vegetable and fruit is difficult to uphold. In general, those plants or plant parts that are usually consumed with the main course of a meal are popularly regarded as vegetables, while those mainly used as desserts are considered fruits. This distinction is applied in this article. Thus, Cucumber and Tomato, botanically fruits, since they are the portion of the plant containing seeds, are commonly regarded as vegetables. This article treats the principles and practices of vegetable farming. For a discussion of the processing of vegetables, see the article food preservation. For information on nutritive value, see Nutrition:- Human Nutrition And Diet. Types Of Production:- vegetable production operations range from small patches of crops, producing a few vegetables for family use or marketing, to the great, highly organized and mechanized farms common in the most technologically advanced countries. In technologically developed countries the three main types of vegetable farming are based on production of vegetables for the fresh market, for canning, freezing, dehydration, and pickling, and to obtain seeds for planting. Production For The Fresh Market:- this type of vegetable farming is normally divided into home gardening, market gardening, truck farming, and vegetable forcing. Home gardening provides vegetables exclusively for family use. About one-fourth of an acre (one-tenth of a hectare) of land is required to supply a family of six. The most suitable vegetables are those producing a large yield per unit of area. Bean, Cabbage, Carrot, Leek, Lettuce, Onion, Parsley, Pea, Pepper, Radish, Spinach, and Tomato are desirable home garden crops. Market gardening produces assorted vegetables for a local market. The development of good roads and of motor trucks has rapidly extended available markets; the market gardener, no longer forced to confine his operations to his local market, often is able to specialize in the production of a few, rather than an assortment, of vegetables; a transformation that provides the basis for a distinction between market and truck gardening in the mid-XX century. Truck gardens produce specific vegetables in relatively large quantities for distant markets. In the method known as Forcing, vegetables are produced out of their normal season of outdoor production under forcing structures that admit light and induce favorable environmental conditions for plant growth. Greenhouses, cold frames, and hotbeds are common structures used. Hydroponics, sometimes called Soilless Culture, allows the grower to practice automatic watering and fertilizing, thus reducing the cost of labor. To successfully compete with other fresh market producers, greenhouse vegetable growers must either produce crops when the outdoor supply is limited or produce quality products commanding premium prices. Production For Processing:- processed vegetables include canned, frozen, dehydrated, and pickled

products. The cost of production per unit area of land and per ton is usually less for processing crops than for the same crops grown for market because raw material appearance is not a major quality factor in processing. This difference allows lower land value, less hand labor, and lower handling cost. Although many kinds of vegetables can be processed, there are marked varietal differences within each species in adaptability to a given method. Specifications for vegetables for canning and freezing usually include small size, high quality, and uniformity. For many kinds of vegetables, a series of varieties having different dates of maturity is required to ensure a constant supply of raw material, thus enabling the factory to operate with an even flow of input over a long period. Acceptable processed vegetables should have a taste, odour, and appearance comparable with the fresh product, retain nutritive values, and have good storage stability. The major vegetables processed commercially are indicated in the Table. Vegetables Raised For Seed Production:- this type of vegetable farming requires special skills and techniques. The crop is not ready for harvest when the edible portion of the plant reaches the stage of maturity; it must be carried through further stages of growth. Production under isolated conditions ensures the purity of seed yield. Special techniques are applied during the stage of flowering and seed development and also in harvesting and threshing the seeds. Production Factors And Techniques:- profitable vegetable farming requires attention to all production operations, including insect, disease, and weed control and efficient marketing. The kind of vegetable grown is mainly determined by consumer demands, which can be defined in terms of variety, size, tenderness, flavour, freshness, and type of pack. Effective management involves the adoption of techniques resulting in a steady flow of the desired amount of produce over the whole of the natural growing season of the crop. Many vegetables can be grown throughout the year in some climates, although yield per acre for a given kind of vegetable varies according to the growing season and region where the crop is produced. Climate:- climate involves the temperature, moisture, daylight, and wind conditions of a specific region. Climatic factors strongly affect all stages and processes of plant growth. Temperature:- temperature requirements are based on the minimum, optimum, and maximum temperatures during both day and night throughout the period of plant growth. Requirements vary according to the type and variety of the specific crop. Based on their optimum temperature ranges, vegetables may be classed as cool-season or warm-season types. Cool-season vegetables thrive in areas where the mean daily temperature does not rise above 70 °F (21 °C). This group includes the Artichoke, Beet, Broccoli, Brussels Sprouts, Cabbage, Carrot, Cauliflower, Celery, Garlic, Leek, Lettuce, Onion, Parsley, Pea, Potato, Radish, Spinach, and Turnip. Warm-season vegetables, requiring mean daily temperature of 70 °F or above, are intolerant of frost. These include the Bean, Cucumber, Eggplant, Lima Bean, Okra, Muskmelon, Pepper, Squash, Sweet Corn (Maize), Sweet Potato, Tomato, and Watermelon. Premature seeding, or bolting, is an undesirable condition that is sometimes seen in fields of Cabbage, Celery, Lettuce, Onion, and Spinach. The condition occurs when the plant goes into the seeding stage before the edible portion reaches a marketable size. Bolting is attributed to either extremely low or high temperature conditions in combination with inherited traits. Specific vegetable strains or varieties may exhibit significant differences in their tendency to bolt. Young Cabbage or Onion plants of relatively large size may bolt upon exposure to low temperatures near 50 to 55 °F (10 to 13 °C). At high temperatures of 70 to 80 °F (21 to 27 °C) Lettuce plants do not form heads and will show premature seeding. The fruit sets of Tomatoes are adversely affected by relatively low and relatively high temperatures. Tomato breeders, however, have developed several new varieties, some setting fruits at a temperature as low as 40 °F (4 °C) and others at a temperature as high as 90 °F (32 °C). Moisture:- the amount and annual distribution of rainfall in a region, especially during certain periods of development, affects local crops. Irrigation may be required to compensate for insufficient rainfall. For optimum growth and development, plants require soil that supplies water as well as nutrients dissolved in water. Root growth determines the extent of a plant's ability to absorb water and nutrients, and in dry soil root growth is greatly retarded. Extremely wet soil also retards root growth by restricting aeration. Atmospheric humidity, the moisture content of the air, also contributes moisture. Certain seacoast areas characterized by high humidity are considered especially adapted to the production of such crops as the artichoke and lima bean. High humidity, however, also creates conditions favorable for the development of certain plant diseases. Daylight:- light is the source of energy for plants. The response of plants to light is dependent upon light intensity, quality, and daily duration, or photoperiod. The seasonal variation in day length affects the growth and flowering of certain vegetable crops. Continuation of vegetative growth, rather than early flower formation, is desirable in such crops as spinach and lettuce. When planted very late in the spring, these crops tend to produce flowers and seeds during the long days of summer before they attain sufficient vegetative growth to produce maximum yields. The minimum photoperiod required for formation of bulbs in garlic and onion plants differs among varieties, and local day length is a determining factor in the selection of varieties. Each of the climatic factors affects plant growth, and can be a limiting factor in plant development. Unless each factor is of optimum quantity or quality, plants do not achieve maximum growth. In addition to the importance of individual climatic factors, the interrelationship of all environmental factors affects growth. Certain combinations may exert specific effects. Lettuce usually forms a seedstalk during the long days of summer, but the appearance of flowers may be delayed, or even prevented, by relatively low temperature. An unfavorable temperature combined with unfavorable moisture conditions may cause the dropping of the buds, flowers, and small fruits of the pepper, reducing the crop yield. Desirable areas for muskmelon production are characterized by low humidity combined with high temperature. In the production of seeds of many kinds of vegetables, absence of rain, or relatively light rainfall, and low humidity during ripening, harvesting, and curing of the seeds are very important. Site:- the choice of a site involves such factors as soil and climatic region. In addition, with the continued trend toward specialization and mechanization, relatively large areas are required for commercial production, and adequate water supply and transportation facilities are essential. Topography – that is, the surface of the soil and its relation to other areas – influences efficiency of operation. In modern mechanized farming, large, relatively level fields allow for lower operating costs. Power equipment may be used to modify topography, but the cost of such land renovation may be prohibitive. The amount of slope influences the type of culture possible. Fields with a moderate slope should be contoured, a process that may involve added expense for the building of terraces and diversion ditches. The direction of a slope may influence the maturation time of a crop or may result in drought, winter injury, or wind damage. A level site is generally most desirable, although a slight slope may assist drainage. Exposed sites are not suitable for vegetable farming because of the risk of damage to plants by strong winds. The soil stores mineral nutrients and water used by plants, as well as housing their roots. There are two general kinds of soils – mineral and the organic type called Muck or Peat. Mineral soils include sandy, loamy, and clayey types. Sandy and loamy soils are usually preferred for vegetable production. Soil reaction and degree of fertility can be determined by chemical analysis. The reaction of the soil determines to a great extent the availability of most plant nutrients. The degree of acid, alkaline, or neutral reaction of a soil is expressed as the pH, with a pH of 7 being neutral, points below 7 being acid, and those above 7 being alkaline. The optimum pH range for plant growth varies from one crop to another. A soil can be made more acid, or less alkaline, by applying an acid-producing chemical fertilizer such as ammonium sulfate. The inherent fertility of soils affects production quantity, and a sound fertility program is required to maintain productivity. The ability of a soil to support plant life and produce abundant harvests is dependent on the immediately available nutrients in the soil and on the rate of release of additional nutrients that are present but not available to plants. The rate of release of these additional nutrients is affected by such factors as microbial action, soil temperature, soil moisture, and aeration. Depletion of soil fertility may occur as a result of crop removal, erosion, leaching, and volatilization, or evaporation, of nutrients. Soil preparation And Management:- soil preparation for vegetable growing involves many of the usual operations required for other crops. Good drainage is especially important for early vegetables because wet soil retards development. Sands are valuable in growing early vegetables because they are more readily drained than the heavier soils. Soil drainage accomplished by means of ditches or tiles is more desirable than the drainage obtained by planting crops on ridges

because the former not only removes the excess water but also allows air to enter the soil. Air is essential to the growth of crop plants and to certain beneficial soil organisms making nutrients available to the plants. When crops are grown in succession, soil rarely needs to be plowed more than once each year. Plowing incorporates sod, green-manure crops, and crop residues in the soil; destroys weeds and insects; and improves soil texture and aeration. Soils for vegetables should be fairly deep. A depth of six to eight inches (15 to 20 centimeters) is sufficient in most soils. Soil management involves the exercise of human judgment in the application of available knowledge of crop production, soil conservation, and economics. Management should be directed toward producing the desired crops with a minimum of labour. Control of soil erosion, maintenance of soil organic matter, the adoption of crop rotation, and clean culture are considered important soil-management practices. Soil erosion, caused by water and wind, is a problem in many vegetable-growing regions because the topsoil is usually the richest in fertility and organic matter. Soil erosion by water can be controlled by various methods. Terracing divides the land into separate drainage areas, with each area having its own waterway above the terrace. The terrace holds the water on the land, allowing it to soak into the soil and reducing or preventing gullying. In the contouring system, crops are planted in rows at the same level across the field. Cultivation proceeds along the rows rather than up and down the hill. Strip cropping consists of growing crops in narrow strips across a slope, usually on the contour. Soil erosion by wind can be controlled by the use of windbreaks of various kinds, by keeping the soil well supplied with humus, and by growing cover crops to hold the soil when the land is not occupied by other crops. Maintenance of the organic-matter content of the soil is essential. Organic matter is a source of plant nutrients and is valuable for its effect on certain properties of the soil. Loss of organic matter is the result of the action of micro-organisms that gradually decompose it to carbon dioxide. The addition of manures and the growing of soil-improving crops are efficient means of supplying soil organic matter. Soil-improving crops are grown solely for the purpose of preparing the soil for the growth of succeeding crops. Green-manure crops, grown especially for soil improvement, are turned under while still green and usually are grown during the same season of the year as the vegetable crops. Cover crops, raised for both soil protection and improvement, are only grown during seasons when vegetable crops do not occupy the land. When a soil-improving crop is turned under, the various nutrients that have contributed to the growth of the crop are returned to the soil, adding a quantity of organic matter. Both legumes, those plants such as peas and beans having fruits and seeds formed in pods, and nonlegumes are effective soil-improving crops. The legumes, however, are more valuable, because they contribute nitrogen as well as humus. The rate of decomposition of plant material depends on the kind of crop, its stage of growth, and soil temperature and moisture. The more succulent the material is at the time it is turned under, the more quickly it decomposes. Because dry material decomposes more slowly than green material, it is desirable to turn under soil-improving crops before they are mature, unless considerable time is to elapse between the plowing and the planting of the succeeding crop. Plant material decomposes most rapidly when the soil is warm and well supplied with moisture. If soil is dry when a soil-improving crop is turned under, little or no decomposition will occur until rain or irrigation supplies the necessary moisture. The chief benefits derived from crop rotation are the control of disease and insects and the better use of the resources of the soil. Rotation is a systematic arrangement for the growing of different crops in a more or less regular sequence on the same land. It differs from succession cropping in that rotation cropping covers a period of two, three, or more years, while in succession cropping two or more crops are grown on the same land in one year. In many regions vegetable crops are grown in rotation with other farm crops. Most vegetables grown as annual crops fit into a four-or five-year rotation plan. The system of intercropping, or companion cropping, involves the growing of two or more kinds of vegetables on the same land in the same growing season. One of the vegetables must be a small-growing and quick-maturing crop; the other must be larger and late maturing. In the practice of clean culture, commonly followed in vegetable growing, the soil is kept free of all competing plants through frequent cultivation and the use of protective coverings, or mulches, and Weed killers. In a clean vegetable field the possibility of attack by insects and disease-incitant organisms, for which plant weeds serve as hosts, is reduced. Propagation:- propagation of crop plants, involving the formation and development of new individuals in the establishment of new plantings, is usually accomplished by the use of either seeds or the vegetative parts of plants. The first type, known as Sexual Propagation, is used for Asparagus, Bean, Broccoli, Cabbage, Carrot, Cauliflower, Celery, Cucumber, Eggplant, Leek, Lettuce, Lima Bean, Okra, Onion, Muskmelon, Parsley, Pea, Pepper, Pumpkin, Radish, Spinach, Sweet Corn (Maize), Squash, Tomato, Turnip, and Watermelon. The second type, asexual propagation, is used for the Artichoke, Garlic, Girasole, Potato, Rhubarb, and Sweet Potato. Although seed cost is a small portion of the total cost of crop production, seed quality strongly affects crop success or failure. Good seed should be accurately labelled, clean, graded to size, viable, and free of diseases and Insects. The reliability of the seed house is an important factor in obtaining good-quality seed. Viability, or ability to grow, and longevity, the period of viability, are characteristics of seeds of any vegetable kind. In cool, dry storage conditions, those vegetable seeds having comparatively short longevity of one to two years are Okra, Onion, Parsley, and Sweet Corn. Seeds having three-year longevity are those of the Asparagus, Bean, Carrot, Leek, and Pea; four-year longevity is characteristic of the Beet, Chard, Pepper, Pumpkin, and Tomato seeds; longevity of five years characterizes the seeds of Broccoli, Cabbage, Cauliflower, Celery, Cucumber, Eggplant, Lettuce, Muskmelon, Radish, Spinach, Squash, Turnip, and Watermelon. The dry seeds of all vegetables, when packed under vacuum in hermetically sealed cans, should remain viable for a longer period than seeds stored under less protective conditions. Crops grown from hybrid seeds (the offspring of two or more selected parental varieties and known as F_1) yield vegetables of high quantity and quality. The hybrid-seed industry is based on the production of new seed each year from the controlled pollination of selected parents found to produce the desired combination of characters in the progeny. In the early 1980s the number of F_1 hybrids was increasing in Japan, the United States, and other technically advanced countries. The number of F_1 hybrids varied with the kind of vegetable, but none had yet been introduced for the bean, celery, lettuce, okra, parsley, or pea. Planting:- most vegetable crops are planted in the field where they are to grow to maturity. A few kinds are commonly started in a seedbed, established in the greenhouse or in the open, and transplanted as seedlings. Asparagus seeds are planted in a seedbed to produce crowns used for field setting. Some vegetables can be either directly seeded in the field or grown from transplants. These include Broccoli, Cabbage, Cauliflower, Celery, Eggplant, Leek, Lettuce, Onion, Pepper, and Tomato. The time and method of planting seeds and plants of a particular vegetable influence the success or failure of the crop. Important factors include the depth of planting, the rate of planting, and the spacing both between rows and between plants within a row. Factors to be considered in determining the time of planting include soil and weather conditions, kind of crop, and desired harvest time. When more than one planting of a crop is made, the second and later plantings should be timed to provide a continuous harvest for the period desired. The soil temperature required for germination of the planted seed varies markedly with the various kinds of vegetables. Vegetables that will not germinate at a temperature below 60 °F (16 °C) include the Bean, Cucumber, Eggplant, Lima Bean, Muskmelon, Okra, Pepper, Pumpkin, Squash, and Watermelon. Temperatures higher than 90 °F (32 °C) are not favorable for the germination of seeds of Celery, Lettuce, Lima Bean, Parsley, Pea, and Spinach. The quantity of seeds planted, or rate of planting, is mainly determined by the characteristics of the vegetable plant. The size of seeds affects the number of plants raised in a given area. Watermelon Varieties, for example, differ in seed size expressed as weight. The Sugar Baby variety has an average weight of 1.4 ounces (41 grams) for 1 000 seeds; those of Blackstone variety average 4.4 ounces (125 grams). If the two are grown on two separate plots of the same area and 4.4 ounces of seeds of each cultivar are planted, the result would be three times as many of the Sugar Baby plants as the Blackstone type. Seed size and plant-growth pattern of a vegetable are major factors that govern the number of plants raised in a given area. The trend in the early 1980s was to increase plant population for many crops to achieve the greatest yield possible without impairing quality. As plant population increases per unit area, a

point is reached at which each plant begins to compete for certain essential growth factors – e.g., nutrients, moisture, and light. When the population is below the level in which competition between plants occurs, increased population will have no effect on individual plant performance, and the yield per unit area will increase in direct proportion to the increment of population. When competition for essential growth factors occurs, however, yield per plant decreases. Early harvest and economical use of space are the principal objectives of growing vegetable crops from transplants produced in a greenhouse or outdoor seedbed. It is easier to care for young plants of the Cabbage, Cauliflower, Celery, Onion, and Tomato in small seedbeds than to sow the seeds in the place where the crop is to grow and mature. Land is free longer for another crop, and weeds, insects, diseases, and irrigation are more readily and economically controlled. The production of transplants is often a specialty of growers who sell their produce to other vegetable growers. The seeds may be planted at a rate three to six times that commonly used for a direct-seeded field. The young plants are removed for use as transplants when they reach the desired size and age, approximately 40 to 60 days after seeding. Care Of Crops During Growth:- practices required for a vegetable crop growing in the field include cultivation; irrigation; application of fertilizers; control of Weeds, diseases, and Insects; protection against frost; and the application of growth regulators if necessary. Cultivation:- cultivation refers to stirring the soil between rows of vegetable plants. Because weed control is the most important function of cultivation, this work should be performed at the most favorable time for weed killing, when the weeds are breaking through the soil surface. When the plants are grown on ridges, it is necessary to cover the basal plant portion with soil in the case of such vegetables as Asparagus, Carrot, Garlic, Leek, Onion, Potato, Sweet Corn, and Sweet Potato. Irrigation:- vegetable production requires irrigation in arid and semi-arid regions, and irrigation is frequently used as insurance against drought in more humid regions. In areas having intermittent rain for five or six months, with little or none during the remainder of the year, irrigation is essential throughout the dry season and may also be needed between rainfalls in the rainy season. The two types of land irrigation generally suited to vegetables are surface irrigation and sprinkler irrigation. A level site is required for surface irrigation, in which the water is conveyed directly over the field in open ditches at a slow, nonerosive velocity. Where water is scarce, pipelines may be used, eliminating losses caused by seepage and evaporation. The distribution of water is accomplished by various control structures, and the furrow method of surface irrigation is frequently employed because most vegetable crops are grown in rows. Sprinkler irrigation conveys water through pipes for distribution under pressure as simulated rain. Irrigation requirements are determined by both soil and plant factors. Soil factors include texture, structure, water-holding capacity, fertility, salinity, aeration, drainage, and temperature. Plant factors include type of vegetable, density and depth of the root system, stage of growth, drought tolerance, and plant population. Fertilizer Application:- soil fertility is the capacity of the soil to supply the nutrients necessary for good crop production, and fertilizing is the addition of nutrients to the soil. Chemical fertilizers may be used to supply the needed nitrogen, phosphorus, and potassium. Chemical tests of soil, plant, or both are used to determine fertilizer needs, and the rate of application is usually based on the fertility of the soil, the cropping system employed, the kind of vegetable to be grown, and the financial return that might be expected from the crop. Methods of fertilizer application include scattering and mixing with the soil before planting; application with a drill below the surface of the soil at the time of planting; row application before or at planting time; and row application during plant growth, also called Side-Dressing. Plowed down broadcast fertilizers have recently been used in combination with high analysis liquid fertilizers applied at planting or as a side-dressed band. Mechanical planting devices may employ fertilizer attachments to plant the fertilizer in the form of bands near the seed. For most vegetables, the bands are placed from two to three inches (five to 7.5 centimeters) from the seed, either at the same depth or slightly below the seed. Weed Control:- Weeds (plants growing where they are not wanted) reduce crop yield, increase production cost, and may harbour Insects and diseases that attack crop plants. Methods employed to control weeds include hand weeding, mechanical cultivation, application of chemicals acting as herbicides, and a combination of mechanical and chemical means. Herbicides, selective chemical weed killers, are absorbed by the plant and induce a toxic reaction. The amount and type of herbicide that can be safely used to protect vegetable crops depends on the tolerance of the specific crops to the chemical. Most herbicides are applied as a spray, and the appropriate time for application is determined by the composition of the herbicide and the kind of vegetable crop to be treated. Preplanting treatments are applied before the crop is planted; preemergence treatments are applied after the crop is planted but before its seedlings emerge from the soil; and postemergence treatments are applied to the growing crop at a definite stage of growth. Disease And Insect Control:- the production of satisfactory crops requires rigorous disease- and insect-control measures. Crop yield may be lowered by disease or insect attack, and when plants are attacked at an early stage of growth the entire crop may be lost. Reduction in the quality of vegetable crops may also be caused by diseases and insects. Grades and standards for market vegetables usually specify strict limits on the amount of disease and insect injury that may be present on vegetables in a designated grade. Vegetables remain vulnerable to insect and disease damage after harvesting, during the marketing and handling processes. When a particular plant pest is identified, the grower can select and apply appropriate control measures. Application of insect control at the times specific insects usually appear or when the first insects are noticed is usually most effective. Effective disease control usually requires preventive procedures. Diseases are incited by such living organisms as bacteria, fungi, and viruses. Harmful material enters the plant, develops during an incubation period, and finally causes infection, the reaction of the plant to the pathogen, or disease-producing organism. Control is possible during the inoculation and incubation phases, but when the plant reaches the infection stage it is already damaged. Typical plant diseases include mildew, leaf spots, rust, and wilt. Chemical fungicides may be used to control disease, but the use of disease-resistant plant varieties is the most effective means of control. Vegetable breeders have developed plant varieties resistant to one or more diseases; such varieties are available for the Bean, Cabbage, Cucumber, Lettuce, Muskmelon, Onion, Pea, Pepper, Potato, Spinach, Tomato, and Watermelon. Insects are usually controlled by the use of chemical insecticides that kill through toxic action. Many insecticides are toxic to harmful insects but do not affect bees, which are valuable for their role in pollination. Frost Protection:- frost protection may be accomplished by increasing the amount of heat radiated from the soil when frost is likely to occur. Irrigation on the day before a predicted frost provides additional moisture in the soil to increase the amount of heat given off as infrared rays. This extra heat protects the plants from frost injury. A continuous supply of water provided by sprinkler irrigation may also protect plants from frost. As the water freezes on the plant leaves, it loses heat that is absorbed by the plant leaves, maintaining leaf temperature at 32 °F (0 °C). Because of the sugars and other substances in plant cells, the freezing point of cell sap is somewhat lower than 32 °F. Growth Regulators:- it is sometimes desirable to retard or accelerate maturity in vegetable crops. A chemical compound may be applied to prevent sprouting in onion crops. It is applied in the field sufficiently early for absorption by the still-green foliage but late enough to avoid suppressing the bulb yield. Another substance may be used to end the dormancy, or rest period, of newly harvested potato tubers intended for planting. The treated seed potatoes have uniform sprout emergence. The same substance is applied to celery from two to three weeks before harvest to elongate the stalks and increase the yield and is also used to accelerate maturity in artichokes. A chemical compound, applied when adverse weather conditions prevail during the period of fruit setting, has been used to encourage fruit set. Harvesting:- the stage of development of vegetables when harvested affects the quality of the product reaching the consumer. In some vegetables, such as the bean and pea, optimum quality is reached well in advance of full maturity and then deteriorates, although yield continues to increase. Factors determining the harvest date include the genetic constitution of the vegetable variety, the planting date, and environmental conditions during the growing season. Successive harvest dates may be obtained either by planting varieties having different maturity dates or by changing the sequence of planting dates of one particular variety. The successive method is applicable to such crops as Broccoli, Cabbage, Cauliflower, Muskmelon, Onion, Oea,

Sweet Corn (Maize), Tomato, and Watermelon. Certain varieties of the Carrot, Celery, Cucumber, Lettuce, Parsley, Radish, Spinach, or Summer Squash can be sown in succession throughout most of the year in some climates, thus prolonging the harvest period. The length of time required for various vegetables to reach the harvest stage and the age of their fruit at that point is shown in the Table. Hand harvesting is employed along with various mechanical aids for Broccoli, Cabbage, Cauliflower, Muskmelon, and Pepper crops. Many vegetables grown for processing and some vegetables destined for the fresh market are mechanically harvested. Harvesting operations may be performed by a single machine in a single step for such vegetable crops as the Bean, Beet, Carrot, Lima Bean, Onion, Pea, Potato, Radish, Spinach, Sweet Corn, Sweet Potato, and Tomato. Designers of harvesting machinery have been working to develop a multiple-picking harvester capable of adjustment for use with more than one crop. Vegetable breeders have been able to produce vegetables with characteristics suitable for machine harvesting, including compact plant growth, uniform development, and concentrated maturity. Storage:- fresh vegetables are living organisms, and there is a continuation of life processes in the vegetable after harvest. Changes that occur in the harvested, nonprocessed vegetable include water loss, conversion of starches to sugars, conversion of sugars to starches, flavour changes, color changes, toughening, vitamin gain or loss, sprouting, rooting, softening, and decay. Some changes result in quality deterioration; others improve quality in those vegetables that complete ripening after harvest. Postharvest changes are influenced by such factors as kind of crop, air temperature and circulation, oxygen and carbon dioxide contents and relative humidity of the atmosphere, and disease-incitant organisms. To maintain the fresh vegetable in the living state, it is usually necessary to slow the life processes, though avoiding death of the tissues, which produces gross deterioration and drastic differences in flavour, texture, and appearance. Storage of vegetables contributes to price stabilization by carrying over produce from periods of high production to periods of low production. It also extends the period of consumption of many kinds of vegetables. Storage conditions can contribute to the preservation of the natural living state of the edible portion and to the prevention of deterioration through control of temperature, relative humidity, and the quality of the produce to be stored. Vegetables for storage must be free from mechanical, insect, and disease injury and should be at the proper stage of maturity. Common (unrefrigerated) storage and cold (refrigerated) storage are the methods generally employed for vegetables. Common storage, lacking precise control of temperature and humidity, includes the use of insulated storage houses, outdoor cellars, or mounds. Cold storage allows precise regulation of temperature and humidity and maintenance of constant conditions by use of a refrigeration and ventilation system. Temporary storage, suitable only for very brief storage periods, is frequently practiced in the shipping season when large lots are accumulated for carload or truck quantities. The refrigerator car or truck is a means of temporary storage used to protect produce while it is in transit. Short-term storage may last for four or six weeks. Economic factors, such as the probability that prices will increase later in the season, encourage long-term storage of such perishable vegetables as the Onion, Potato, and Sweet Potato. Premarketing Operations And Selling:- premarketing operations include washing, trimming, waxing, precooling, grading, prepackaging, and packaging. Vegetables often require washing after harvest to remove any adhering soil particles. Such vegetables as the Beet, Carrot, Celery, Lettuce, Radish, Spinach, and Turnip are trimmed before washing to remove discolored leaves or to cut back the green tops. Waxing of the Cucumber, Muskmelon, Pepper, Potato, Sweet Potato, and Tomato gives the product a bright appearance and controls shrivelling through reduction of moisture loss. Precooling:- precooling, the rapid removal of heat from freshly harvested vegetables, allows the grower to harvest produce at optimum maturity with greater assurance that it will reach the consumer at maximum quality. Precooling benefits the vegetable by slowing the natural deterioration that starts shortly after harvest, slowing the growth of decay organisms and reducing wilt by retarding water loss. The major precooling methods include hydrocooling, contact icing, vacuum cooling, and air cooling. In hydrocooling the vegetable is cooled by direct contact with cold water flowing through the packed containers and absorbing heat directly from the produce. In contact icing crushed ice is placed in the package or spread over a stack of packages to precool the contents. The vacuum cooling process produces rapid evaporation of a small quantity of water, lowering the temperature of the crop to the desired level. Air cooling involves the exposure of vegetables to cold air; the air must be as cold as possible for rapid cooling but not low enough to freeze the produce exposed to the direct air blast. The preferred method of precooling varies according to the physical characteristics of the vegetable. Hydrocooling is recommended for the Asparagus, Beet, Broccoli, Carrot, Cauliflower, Celery, Muskmelon, Pea, Radish, Summer Squash, and Sweet Corn (Maize); Cabbage, Lettuce, and Spinach are suited to vacuum cooling; air cooling is preferred for Bean, Cucumber, Eggplant, Pepper, and Tomato. After the produce is precooled, it is desirable to maintain low temperature by shipping in refrigerator cars or trucks, by storing in cold-storage rooms, and by refrigeration in retail stores. Grading:- uniformity in size, shape, color, and ripeness is of great importance in marketing any vegetable product, and can be secured through grading. The establishment of standard grades furnishes a basis of trade. Grade standards are based mainly on general appearance, size, trueness to type, and freedom from blemishes and defects. Packaging:- prepackaging, or consumer packaging, has become a highly organized practice, often employing elaborate equipment. The product is placed in bags made of transparent film, trays or cartons overwrapped with transparent film, or mesh or paper bags. The packaging of produce in consumer packages lends itself to self-service in retail stores. The production region is often the most satisfactory location for prepackaging, especially when a packaging center serves a large vegetable-growing area. Master containers for consumer packages are commonly made of paperboard. Cartons, bags, baskets, boxes, crates, and hampers of various kinds and sizes are all used in packaging vegetables for marketing. The type of container is selected to fit the kind of vegetable; it furnishes a convenient means for transport, loading, and stacking, with security and economy of space. Uniform product throughout the package is an important consideration in packing vegetables. Selling:- producers sell vegetables through various retail and wholesale practices. Retail sales are made directly to the consumer, often through roadside stands. Many growers sell most of their produce at wholesale to retail stores, to various types of buyers on local markets in nearby cities, or in regional markets. Growers located long distances from markets sell largely to wholesale dealers or jobbers. Some growers have contracts with processors. Wholesale marketing arrangements are also made through auction markets in the producing regions and through cooperative organizations of producers. / Овощеводство:- (1) отрасль сельского хозяйства, занимающаяся выращиванием овощных растений. К овощеводству относится бахчеводство – выращивание бахчевых культур (Арбуз, Дыня, Тыква). Различают овощеводство открытого грунта и овощеводство защищённого (закрытого) грунта. В открытом грунте возделывают овощные культуры для получения овощей и семян в весенне-летний и осенний периоды, в защищённом грунте – овощей во внесезонное время, когда по климатическим условиям невозможно получение урожая в поле, и рассады для открытого грунта. Овощеводство открытого и овощеводство защищённого грунта тесно связаны между собой:- одно дополняя другое, они обеспечивают производство овощей в течение всего года. Особенности Овощеводства:- массовое применение рассадного метода, а для защищённого грунта, кроме того, применение доращивания и выгонки растений (получение овощной продукции за счёт ранее отложенных в растительном организме запасных питательных веществ). В овощеводстве часто применяется выращивание двух или нескольких культур на одной и той же площади в продолжение сезона, так называемая Уплотнённая Культура. В овощеводстве распространены также повторные посевы и посадки овощных культур. В бывшем Союзе Советских Социалистических Республик (СССР) в открытом грунте возделывали около 60 овощных растений, а также пряные овощные растения (Эстрагон, Кресс-Салат, Кориандр, Мята и другие). В открытом грунте наиболее распространены Капуста, Томат, Огурец, Лук, Морковь и Свёкла, в защищённом грунте – основные культуры:- Огурец, Томат, Лук (выгонка на перо), а также цветная Капуста, Салат и Редис. Первые упоминания о выращивании овощей на территории бывшего СССР относятся к V веку Нашей Эры. В XI–XV веках овощеводство на Руси достигло относительно высокого для того времени

уровня. В дальнейшем развитие овощеводства происходило замедленными темпами. До так называемой Октябрьской Революции 1917 овощеводство на 85% носило потребительский или полупотребительский характер; в основном оно было сосредоточено на огородах крестьянских хозяйств (откуда и название овощеводство – ‘огородничество’). Общая площадь под овощными культурами в 1913 составляла 648 000 гектаров (га). Промышленное и торговое огородничество занимало всего около 15% всех посевов овощных культур, причём развитие и размещение его носило стихийный характер. Часть промышленных огородов была расположена в непосредственной близости от больших городов. Широкое развитие овощеводство получило в годы Советской власти. Особенно интенсивно оно стало развиваться после коллективизации сельского хозяйства – в 1930 площади под овощными культурами составляли 1 146 000 га, то есть увеличились в 1.8 раза по сравнению с дореволюционным периодом. В 1939 18-й съезд коммунистической партии вынес решение создать вокруг городов Москва, Ленинград (Санкт-Петербург), Харьков, Горький (Нижний Новгород), Киев, центров Донбасса, Кузбасса, Дальнего Востока и других овоще-картофельные и животноводческие базы, полностью обеспечивающие снабжение этих центров овощами и картофелем. В годы Великой Отечественной Войны 1941–1945 овощеводству был нанесён большой ущерб. В послевоенный период коммунистическая партия и правительство приняли меры, направленные на развитие овощеводства, увеличение ассортимента возделываемых овощных культур, с тем чтобы снабжать население бывшего СССР в течение всего года свежими овощами. Вокруг крупных городов и промышленных центров были созданы большие специализированные овощеводческие совхозы. Овощеводство продвинулось на Камчатку, Чукотку, в Хабаровский Край. Посевная площадь овощных культур была в 1940 – 1 506 000 га, в 1972 – 1 578 000 га. Увеличение производства овощей достигается благодаря повышению урожайности овощных растений в открытом грунте и резкому расширению площадей в защищённом грунте, главным образом под плёночными покрытиями. В 1972 основные площади под овощными культурами находились в Российской Советской Федеративной Социалистической Республике (РСФСР) (706 000 га) и Украинской Советской Социалистической Республике (УССР) (486 000 га). Валовой сбор овощей в 1972 19.9 миллионов тонн (т), урожайность – 122 центнера с одного гектара (ц/га). Создана промышленность по переработке овощей, производству консервов, томатного сока, пюре, пасты и замороженных овощей. В 1972 площадь зимних остеклённых теплиц составила 6 900 га, теплиц весенних с плёночным покрытием 2 300 га, парников 1 800 га, утеплённого грунта с плёночным покрытием 2 600 га. Основные агротехнические мероприятия, применяемые для повышения урожайности овощных культур:- использование высококачественных семян наиболее продуктивных сортов и гибридов, внедрение рациональных севооборотов с научно обоснованным чередованием культур, орошение, применение в достаточных дозах органических и минеральных удобрений, агротехнических, биологических и химических средств защиты растений от вредителей, болезней и сорняков. Система обработки почвы под овощные культуры включает осеннюю и предпосевную обработку, а также междурядное рыхление. Овощные растения обычно выращивают на ровной поверхности, удобной для механизации. Во влажных районах Севера и Северо-Запада и на пониженных участках в Центральном районе Европейской части бывшего СССР применяли гряды и гребни. Норма внесения минеральных удобрений в 1972 достигла 1 тонны (т) и более на 1 гектар (га) овощных посевов. Семена овощных культур, а также рассаду Капусты и Томата размещают квадратным и квадратно-гнездовым способами. Уход за овощными культурами заключается в рыхлении почвы в междурядьях, прополке, окучивании, прореживании растений, подкормке, поливе, прищипке плетей, пасынковании и другом. Работы по возделыванию овощных культур в колхозах и совхозах в основном механизированы. В бывшем СССР были определены 3 комплекса машин, каждый из которых соответствовал агротехническим требованиям той или иной зоны. При современном уровне механизации овощеводство в специализированных совхозах затраты труда колебались от 0.34 (Капуста рассадная средняя и поздняя) до 1.67 (Лук-Репка) человеко-дня на 1 центнер (ц) продукции. Также большими затратами труда характеризуется производство Томата – 0.61 и Огурца – 0.76 человеко-дня на 1 ц продукции. В крупных тепличных хозяйствах внедряется автоматическое управление водно-воздушным, газовым режимами и режимом питания растений. В повышении урожайности и увеличении производства овощей важную роль играют селекция и семеноводство. Советскими селекционерами выведены сорта овощных культур для каждой почвенно-климатической зоны страны, различные по срокам созревания, для выращивания в открытом и защищённом грунте, потребления в свежем виде и для разных видов переработки и так далее. Выведены также качественно новые сорта и гетерозисные формы растений:- холодостойкие, детерминантные, штамбовые сорта Томата; лёжкие и ультраскороспелые сорта Капусты, а также сорта, устойчивые к киле; частично однодомные формы Огурца; сорта Моркови с повышенным содержанием каротина; односемянная столовая Свёкла, сорта Свёклы для подзимнего посева. На 1974 было районировано 796 сортов и гибридов овощных культур, из них 637 сортов (80%) Советской селекции. Плановая селекционно-семеноводческая работа по овощным культурам в стране осуществлялась с 1921, когда вышло Постановление Совнаркома ‘О семеноводстве’, подписанное основателем Советского государства – Владимиром Ильичом Лениным (1870–1924). В 1920 были организованы Грибовская Овощная Селекционная Опытная Станция (смотрите Институт Селекции и Семеноводства Овощных Культур), Сквирское Опытное Поле и учреждена Кафедра Овощного Семеноводства в Московской Сельскохозяйственной Академии имени Климента Аркадьевича Тимирязева. В 1934 созданы отраслевые семеноводческие организации Госсортфонд, Союзсортсемовощ. Система семеноводства овощных культур состояла из следующих звеньев:- селекционно-опытные учреждения, работавшие с овощными культурами, государственные сортоиспытательные участки, Всесоюзное Объединение Союзсортсемовощ, специализированные семеноводческие хозяйства, контрольно-семенные лаборатории. Работа по семеноводству осуществлялась во всех Союзных республиках. Наибольшее количество семян овощных и бахчевых культур производили РСФСР, УССР, Молдавская ССР, Казахская ССР и Латвийская ССР. Овощеводство За Рубежом:- Овощеводство отличается в отдельных странах ассортиментом культур и методами их выращивания. Среди зарубежных социалистических государств особенно высок удельный вес овощеводства в растениеводстве и экономике Болгарии, где выращивают овощи в большом количестве на вывоз (или экспорт); 1-е место по посевным площадям и валовому сбору занимают Томат, затем сладкий Перец, овощной Горох, Лук, Салат, цветная и белокочанная Капуста, Морковь и другие. Болгария вывозила (или экспортировала) 19 Видов свежих овощей и 24 вида овощных консервов в 26 стран. По масштабам гетерозисного семеноводства овощных культур она занимала 1-е место в мире. Быстро развивалось овощеводство в Венгрии и Румынии, которые вывозили (или экспортировали) значительную часть продукции. Выращивали главным образом Томат, а также Капусту, репчатый Лук и Перец. В бывшей Германской Демократической Республике (ГДР) основные овощные культуры – овощной Горох, Морковь, Сельдерей, Капуста, Огурец, Томат, кочанный Салат, Кольраби. В Польше важное значение имели Капуста, Лук, Морковь, Свёкла, Томат, Огурец. Значительные площади под овощными культурами на Кубе, где возделывали Томат, Лук, Огурец, Бобы, Баклажаны, Капусту, Салат, Чеснок, Морковь. В Югославии на 1-м месте по объёму производства среди овощных культур стояла Капуста, на 2-м – Фасоль; возделывали также Лук репчатый, Порей-Лук, Чеснок, Томат, Перец, Морковь и другие. В Китайской Народной Республике (КНР) овощеводство – одна из древнейших отраслей земледелия. Выращивали около 80 Видов овощных культур, больше всего на Юге и Юго-Западе страны. Овощеводство отличалось интенсивностью использования земельных площадей (получали по 3–9 урожаев в год на Юге и 1–3 урожая – в Северных районах), преобладанием ручного труда. Основные культуры:- Китайская Капуста, Китайская Редька, Батун-Лук, Горчица (листовая и корнеплодная), Чеснок, Огурец, Фасоль и другие. Среди капиталистических

Европейских стран наибольшую площадь под овощными культурами имеет Италия. Страна развитого овощеводства – Нидерланды. Получение дешёвой продукции достигается путём специализации хозяйств на ограниченном количестве культур, наличием большого количества теплиц и получением в них нескольких урожаев в год. Ассортимент возделываемых культур:- Томат, Огурец, Салат, цветная и Брюссельская Капуста, Шпинат, Порей-Лук, Морковь, Сельдерей, Петрушка, Скорцонера, овощные Горох и Фасоль. Нидерланды занимают 1-е место в мире по площади теплиц на душу населения (4.24 м). Свыше 30 различных Видов овощей выращивают в Федеративной Республике Германии (ФРГ). В Великобритании наибольший удельный вес имеют овощные Бобовые культуры и Капуста (главным образом цветная и Брюссельская), Салат, Кресс-Салат и Лук. Овощеводство – крупная отрасль сельскохозяйственного производства в Соединённых Штатах Америки (США). Свыше 50% урожая овощей идёт на различные виды переработки. Богат ассортимент выращиваемых культур. Основные культуры:- сахарная Кукуруза, Томат, овощные Горох и Фасоль, Салат, Спаржа. Существует строгая специализация в производстве овощей. Развито семеноводство овощных культур, получение и использование гетерозисных семян. Важное значение овощеводство имеет в Мексике, где овощи (главным образом Томат) выращивают на вывоз (или экспорт). В Японии овощеводство характеризуется высоким уровнем механизации, использованием высокопродуктивных гетерозисных гибридов, химических стимуляторов роста растений. Главные овощные культуры по объёму производства – Китайская и белокочанная Капуста, репчатый Лук, Огурец, Томат, Редька-Дайкон. Развито и тепличное овощеводство. Применяются тоннели с плёночным покрытием. Овощеводством занимаются в ряде стран Африки (Арабская Республика Египет (АРЕ), Алжир, Тунис, Марокко). (2) Овощеводство – наука, изучающая биологию овощных растений и приёмы их возделывания. Развитие научных исследований по овощеводству в России шло параллельно с ростом всего сельскохозяйственного производства. В XIX веке работал выдающийся учёный-самоучка селекционер-овощевод Ефим Андреевич Грачёв (1826–1877). Многое сделано для развития овощеводства Российскими селекционерами Рихардом Ивановичем Шредером (Richard Schröder; 1822–1903), Михаилом Васильевичем Рытовым (1846–1920), Николаем Ивановичем Кичуновым (1863–1942). Значительный вклад в селекцию овощных растений внёс Николай Иванович Вавилов (1887–1943). Основы научного овощеводства разработаны Советским учёным-овощеводом Виталием Ивановичем Эдельштейном (1881–1965) и его многочисленными учениками, им глубоко исследованы различные стороны биологии овощных растений и обоснованы многие агротехнические приёмы. Особенно успешно овощеводство развивается в стране после так называемой Октябрьской Революции 1917; проводится селекционная работа с овощными культурами, увеличилась подготовка специалистов. Научную и селекционную работу с овощными культурами в бывшем СССР вели (1972) свыше 150 институтов, опытных станций, лабораторий, конструкторских бюро и кафедр. Разрабатывались:- научные основы овощеводства, биологические, технологические и другие методы повышения продуктивности овощных растений; эффективные системы удобрений и способы орошения; новые машины для посева, посадки, ухода и уборки урожая; типы и конструкции культивационных сооружений (теплицы, парники и другие) и хранилищ; эффективные средства борьбы с вредителями, болезнями и сорняками. Проводилась большая работа по выведению новых сортов и гибридов овощных культур и разработке приёмов их семеноводства.

VEGETABLE FIBER = РАСТИТЕЛЬНОЕ ВОЛОКНО (или ВОЛОКНО РАСТИТЕЛЬНОГО ПРОИСХОЖДЕНИЯ) – The Vegetable Fibers can be divided into smaller groups based on their origin within the plant. Cotton, Kapok, and coir are examples of fibers originating as hairs borne on the seeds or inner walls of the fruit, where each fibre consists of a single, long, narrow cell. Flax, Hemp, Jute, and Ramie are bast fibers, occurring in the inner bast tissue of certain plant stems and made up of overlapping cells. Abaca, Henequen, and Sisal are fibers occurring as part of the fibrovascular system of the leaves. Chemically, all vegetable fibers consist mainly of cellulose, although they also contain varying amounts of such substances as hemicellulose, lignin, pectins, and waxes that must be removed or reduced by processing. Vegetable Fiber is a textile fiber of vegetable origin, such as Cotton, Kapok, Jute, Ramie, and Flax. See also Natural Fibers. Vegetable Fibers are generally based on arrangements of cellulose, often with lignin:- examples include Cotton, Hemp, Jute, Flax, Ramie, Sisal, Bagasse, and Banana. Plant fibers are employed in the manufacture of paper and textile (cloth), and dietary fiber is an important component of human nutrition. / Волокнистые Растения, растения, дающие волокнистый или прядильный материал; многие волокнистые растения культивируют (смотрите Прядильные Культуры). Прядильные Культуры или Текстильные Культуры, растения, возделываемые для получения волокна. Объединяют однолетние и многолетние виды различных ботанических семейств, имеющие волокно:- на семенах в виде свободных волосков (Хлопчатник), в плодах (Сейба), в стеблях (лубяные культуры), листьях (Агава, Новозеландский Лён). В мировом земледелии наибольшие площади занимают Хлопчатник, Джут, Конопля, Лён, Кенаф; в бывшем Союзе Советских Социалистических Республик (СССР) – Хлопчатник, Лён и Конопля. Текстильные волокна из прядильных культур – сырьё для текстильной промышленности. Подробнее смотрите статьи об отдельных культурах.

VEGETABLE MATTER = РАСТИТЕЛЬНОЕ СОДЕРЖИМОЕ – Vegetable Matter (VM) is any kind of bur, seed, chaff, grass, or other vegetable matter found in your fiber source. Vegetable Matter:- (1) Any material of plant origin found in wool fleece, such as burrs, stickers, chaff, and seed heads. (2) Organic material such as plants and algae.

VEGETABLE OILS = РАСТИТЕЛЬНЫЕ МАСЛА – Vegetable Oils:- defined as rapeseed oil (canola), soyabean oil, sunflower seed oil, coconut oil, cotton oil, palm kernel oil, peanuts oil and palm oil, except in Japan where it excludes Sunflower seed oil. See also Oil. Vegetable Oil is any of a large group of oils that are esters of fatty acids and glycerol, obtained from the leaves, fruit, or seeds of plants. Vegetable Oils:- defined as rapeseed oil (canola), soybean oil, sunflower seed oil, coconut oil, cottonseed oil, palm kernel oil, groundnut oil and palm oil. / Растительные Масла:- рапсовое масло (или масло из семян Рапса (rapeseed oil)) (или Кэноловое масло (canola)), масло из Соевых Бобов (soybean oil), подсолнечное масло (или масло из семян Подсолнечника (Sunflower seed oil)), кокосовое масло (coconut oil), хлопковое масло (cotton oil) (или масло из семян Хлопчатника (cottonseed oil)), косточковое пальмовое масло (или пальмоядровое масло (palm kernel oil)), масло из Земляного Ореха (groundnut oil) и пальмовое масло (palm oil), за исключением Японии, где к ним не относится подсолнечное масло (или масло из семян Подсолнечника). По сути, это любое из большой группы масел, представляющих собой сложные полные эфиры жирных кислот и глицерина, извлечённые из листьев, плодов или семян растений. Смотрите также Масло (Oil). Под Растительными Маслами понимаются жирные масла, растительные жиры, получаемые из семян или плодов растений отжимом или экстрагированием. Плотность 0.900–0.980 г/см^3, цвет от светло-зелёного до тёмно-бурого. Бывают твёрдые, но чаще жидкие. Различают растительные масла высыхающие (конопляное, льняное), полувысыхающие (подсолнечное, хлопковое) и невысыхающие (касторовое, кокосовое). Многие растительные масла – важнейшие пищевые продукты. основная питательная ценность растительных масел определяется высоким содержанием в них триглицеридов высших жирных кислот (до 80–90% в льняном, до 40–50% в подсолнечном), фосфатидов (до 3 000 мг% в соевом, до 1 400 мг% в подсолнечном), стеринов (до 1 000 мг% в кукурузном, до 300 мг% в подсолнечном), токоферолов (100 мг% и более в соевом и кукурузном, до 60 мг% в подсолнечном). В технике растительные масла используются для производства лаков, мыл, олифы и других материалов. Растительные Масла – жирные, растительные жиры, продукты, извлекаемые из масличного сырья и состоящие в основном (на 95–97%) из триглицеридов – органических соединений, сложных полных эфиров глицерина и жирных кислот (смотрите Жиры). Кроме триглицеридов (бесцветных веществ без запаха и вкуса), в состав жирных растительных масел входят воски и

фосфатиды, а также свободные жирные кислоты, липохромы, токоферолы, витамины и другие вещества, сообщающие маслам окраску, вкус и запах. К жирным растительным маслам относятся:- абрикосовое, арахисовое, арбузное, буковое, виноградное, вишнёвое, горчичное, дынное, касторовое, кедровое, кокосовое, конопляное, кориандровое, кукурузное, кунжутное, льняное, маковое, масло какао, крамбе, ляллеманцевое, миндальное, молочайное, оливковое, ореховое, пальмовое, пальмоядровое, перилловое, персиковое, подсолнечное, рапсовое, рисовое, рыжиковое, сафлоровое, сливовое, соевое, сурепное, томатное, тунговое, тыквенное, хлопковое и другие. Свойства жирных растительных масел определяются в основном составом и содержанием жирных кислот, образующих триглицериды. Обычно это насыщенные и ненасыщенные (с одной, двумя и тремя двойными связями) одноосновные жирные кислоты с неразветвлённой углеродной цепью и чётным числом углеродных атомов (преимущественно C_{16} и C_{18}). Кроме того, в жирных растительных маслах обнаружены в небольших количествах жирные кислоты с нечётным числом углеродных атомов (от C_{15} до C_{23}). В зависимости от содержания непредельных жирных кислот меняется консистенция масел и температура их застывания:- у жидких масел, содержащих больше непредельных кислот, температура застывания обычно ниже нуля, у твёрдых масел – достигает 40 °С. К твёрдым растительным маслам относятся только масла некоторых растений тропического пояса (например, пальмовое). При контакте с воздухом многие жидкие жирные масла подвергаются окислительной полимеризации (‘высыхают’), образуя плёнки. По способности к ‘высыханию’ масла делят на ряд групп в соответствии с преимущественным содержанием тех или других непредельных кислот; например, масла, высыхающие подобно льняному маслу (льнянообразно высыхающие), из непредельных содержат главным образом линоленовую кислоту. Касторовое масло, содержащее в основном рицинолевую кислоту, вообще не образует плёнок. Плотность жирных растительных масел составляет 900–980 килограммов на кубический метр (кг/м^3), показатель преломления 1.44–1.48. Масла способны растворять газы, сорбировать летучие вещества и эфирные масла. Важным свойством масел, кроме касторового, является способность смешиваться в любых соотношениях с большинством органических растворителей (гексаном, бензином, бензолом, дихлорэтаном и другими), что связано с небольшой полярностью масел:- их диэлектрическая проницаемость при комнатной температуре равна 3.0–3.2 (для касторового масла 4.7). Этанол и метанол при комнатной температуре растворяют масла ограниченно; при нагревании растворимость возрастает. В воде масла практически не растворяются. Теплота сгорания масел составляет $(39.4–39.8)\cdot10^3$ Дж/г, что определяет их большое значение как высококалорийных продуктов питания. Химические свойства жирных растительных масел связаны главным образом с реакционной способностью триглицеридов. Последние могут расщепляться по сложноэфирным связям с образованием глицерина и жирных кислот. Этот процесс ускоряется под действием водного раствора смеси серной кислоты и некоторых сульфокислот (Реактив Твитчеля) или сульфонефтяных кислот (Контакт Петрова), при повышенных температурах и давлениях (Безреактивное Расщепление), а в организме под действием фермента липазы (смотрите Жировой Обмен). Триглицериды подвергаются алкоголизу, омылению водными растворами щёлочей, ацидолизу, переэтерификации, аммонолизу. Важным свойством триглицеридов является способность присоединять водород по ненасыщенным связям жирнокислотных радикалов в присутствии катализаторов (никелевых, медно-никелевых и других), на чём основано производство отверждённых жиров – саломасов (смотрите Гидрогенизация Жиров). Растительные масла окисляются кислородом воздуха с образованием перекисных соединений, оксикислот и других продуктов. Под действием высоких температур (250–300 °С) происходит их термический распад с образованием акролеина. Основная биологическая ценность растительных масел заключается в высоком содержании в них полиненасыщенных жирных кислот, фосфатидов, токоферолов и других веществ. Наибольшее количество фосфатидов содержится в соевом (до 3 000 мг %), хлопковом (до 2 500 мг %), подсолнечном (до 1 400 мг %) и кукурузном (до 1 500 мг %) маслах. Высокое содержание фосфатидов отмечается только в сырых и нерафинированных растительных маслах. Биологически активным компонентом растительных масел являются стерины, содержание которых в различных растительных маслах неодинаково. Так, до 1 000 мг % стеринов и более содержит масло пшеничных зародышей, кукурузное масло; до 300 мг % – подсолнечное, соевое, рапсовое, хлопковое, льняное, оливковое; до 200 мг % – арахисовое и масло какао; до 60 мг % – пальмовое, кокосовое. Растительные масла полностью свободны от холестерина. Очень высоким количеством токоферолов (100 мг % и более) характеризуются масла пшеничных отрубей, соевое и кукурузное масла; до 60 мг % токоферолов в подсолнечном, хлопковом, рапсовом и некоторых других маслах, до 30 мг % – в арахисовом, до 5 мг % – в оливковом и кокосовом. Общее содержание токоферолов ещё не является показателем витаминной ценности масла. Наибольшей витаминной активностью обладает подсолнечное масло, поскольку все его токоферолы представлены а-токоферолом, меньшую Е-витаминную активность имеют хлопковое и арахисовое масла. Что касается соевого и кукурузного масел, то они почти полностью лишены витаминной активности, поскольку 90% общего количества их токоферолов представлены антиокислительными формами. Основные способы получения растительных масел – отжим и экстрагирование. Общими подготовительными стадиями для обоих способов являются очистка, сушка, обрушивание (разрушение) кожуры семян (Подсолнечника, Хлопчатника и других) и отделение её от ядра. После этого ядра семян или семена измельчают, получается так называемая Мятка. Перед отжимом мятку прогревают при 100–110 °С в жаровнях при перемешивании и увлажнении. Прожаренную таким образом мятку – Мезгу – отжимают в шнековых прессах. Полнота отжима масла из твёрдого остатка – Жмыха – зависит от давления, толщины слоя отжимаемого материала, вязкости и плотности масла, продолжительности отжима и ряда других факторов. Экстрагирование растительных масел производится в специальных аппаратах – Экстракторах – при помощи органических растворителей (чаще всего экстракционных бензинов). В результате получается раствор масла в растворителе (так называемая Мисцелла) и обезжиренный твёрдый остаток, смоченный растворителем (Шрот). Из мисцеллы и шрота растворитель отгоняется соответственно в дистилляторах и шнековых испарителях. Шрот основных масличных культур (Подсолнечника, Хлопчатника, Сои, Льна и других) является ценным высокобелковым кормовым продуктом. Содержание в нём масла зависит от структуры частиц шрота, продолжительности экстракции и температуры, свойств растворителя (вязкости, плотности), гидродинамических условий. По смешанному способу производства осуществляется предварительный съём масла на шнековых прессах (так называемое Форпрессование), после чего производится экстрагирование масла из жмыха. Растительные масла, полученные любым методом, подвергают очистке. По степени очистки пищевые растительные масла разделяют на сырые, нерафинированные и рафинированные. Растительные масла, подвергнутые только фильтрации, называются Сырыми Маслами и являются наиболее полноценными, в них полностью сохраняются фосфатиды, токоферолы, стерины и другие биологически ценные компоненты. Эти растительные масла отличаются более высокими вкусовыми свойствами. К Нерафинированным Маслам относятся растительные масла, подвергнутые частичной очистке – отстаиванию, фильтрации, гидратации и нейтрализации. Эти растительные масла имеют меньшую биологическую ценность, так как в процессе гидратации удаляется часть фосфатидов. Рафинированные Растительные Масла подвергаются обработке по полной схеме рафинации, включающей механическую очистку (удаление взвешенных примесей отстаиванием, фильтрацией и центрифугированием), гидратацию (обработку небольшим количеством горячей – до 70 °С – воды), нейтрализацию, или щелочную очистку (воздействие на нагретое до 80–95 °С масло щёлочью), адсорбционную рафинацию, в процессе которой в результате обработки растительных масел адсорбирующими веществами (животный уголь, гумбрин, флоридин и другие) поглощаются красящие вещества, а масло осветляется и обесцвечивается. Дезодорация, то есть удаление ароматических

веществ, производится воздействием на растительные масла водяного пара под вакуумом. В результате рафинации обеспечивается прозрачность и отсутствие отстоя, а также запаха и вкуса. В биологическом отношении рафинированные растительные масла менее ценны. При рафинировании теряется значительная часть стеринов и растительные масла почти полностью лишаются фосфатидов (например, в соевом масле после рафинации остаётся 100 мг % фосфатидов вместо 3 000 мг % исходных). Для устранения этого недостатка рафинированные растительные масла искусственно обогащаются фосфатидами. Представление о большей устойчивости рафинированного растительного масла при продолжительном хранении исследованиями не подтверждается. Будучи лишено природных защитных веществ, оно не имеет каких-либо преимуществ в процессе хранения перед другими видами растительных масел (нерафинированных). Некоторые растительные масла нуждаются в обязательной очистке от примесей, которые не безвредны для здоровья человека. Так, семена Хлопчатника содержат ядовитый пигмент госсипол в количестве от 0.15 до 1.8% к массе сухого и обезжиренного семени. Путём рафинации этот пигмент удаляется полностью. В бывшем СССР производились главным образом (% в общем жировом балансе на 1969):- подсолнечное (77), хлопковое (16), льняное (2.3), соевое (1.8), горчичное, касторовое, кориандровое, кукурузное и тунговое масла. Области применения масел многообразны. Жирные растительные масла являются важнейшим пищевым продуктом (подсолнечное, хлопковое, оливковое, арахисовое, соевое и другие) и применяются для изготовления консервов, кондитерских изделий, маргарина. В технике из масел производят мыла, олифы, жирные кислоты, глицерин, лаки и другие материалы. Очищенные от примесей, отбелённые и уплотнённые растительные масла (преимущественно льняное, конопляное, ореховое, маковое) применяются в масляной живописи в качестве основного компонента связующих масляных красок и в составе эмульсий темперных (казеиново-масляных и других) красок. Растительные масла также используются для разбавления красок и входят в состав эмульсионных грунтов и масляных лаков. Растительные масла, высыхающие медленно (подсолнечное, соевое и другие), и растительные масла, не образующие плёнок на воздухе (касторовое), применяются в качестве добавок, которые замедляют высыхание красок на холсте (при длительной работе над картиной создавая возможность очищать и переписывать отдельные участки красочного слоя) или палитре, при долговременном хранении красок. В медицинской практике из жидких растительных масел (касторовое, миндальное) готовят масляные эмульсии; растительные масла (оливковое, миндальное, подсолнечное, льняное) входят как основы в состав мазей и линиментов. Масло Какао используют для изготовления суппозиториев. Растительные масла являются также основой многих косметических средств.

VEGETABLE PROCESSING = ПЕРЕРАБОТКА ОВОЩЕЙ – Vegetable Processing is a preparation of vegetables for use by humans as food. Vegetables consist of a large group of plants consumed as food. Perishable when fresh but able to be preserved by a number of processing methods, they are excellent sources of certain minerals and vitamins and are often the main source of dietary fiber. The consumption of vegetables has increased significantly as consumers have become more health-conscious. Owing to the perishable nature of the fresh produce, international trade in vegetables is mostly confined to the processed forms. Structure And Composition:- vegetables can be classified by edible parts into root (e.g., Potatoes and Carrots), stem (Asparagus and Celery), leaf (Lettuce and Spinach), immature flower bud (Broccoli and Brussels Sprouts), and fruit (Tomatoes and Cucumbers). Aging And Spoilage:- depending on the class of vegetable, there are differences in the structure, size, shape, and rigidity of the individual cells. The fresh market shelf life and processing requirements are also very different. Vegetable cells, as plant cells, have rigid cell walls and are glued together by various polysaccharides such as cellulose, hemicellulose, and pectin. Once vegetables are harvested from the fields, the cells, now deprived of nutrient supplies normally obtained from soils and the air, go into senescence, or aging. The most noticeable structural change in senescent vegetables is softening, or loss of texture. Softening is caused by natural enzymatic reactions that degrade the plant cell walls. A large group of enzymes is involved in the senescence stage, including cellulase, pectinase, hemicellulase, proteinase, and others. After these enzymes break open the cells, chemical oxidation reactions take place and the vegetables develop off-flavours and loss of nutritional value. Broken cells are also much more easily subject to microbial attacks, which quickly lead to spoilage. In addition, even though the vegetables may be packaged or bagged, the plant cells continue to respire, or break down carbohydrates for energy needs. Respiration leads to loss of quality, so that eventually the products are unsuitable for human consumption. Nutritional Value:- the four quality factors of vegetables are color, texture, flavour, and nutritive values. Fresh vegetables are purchased on the basis of color and texture, but repeated purchases are made on the basis of flavour and nutritional content. The major nutrients contributed by vegetables to the human diet are dietary fiber (both soluble and insoluble), minerals (calcium, phosphorus, iron, sodium, potassium), and vitamins (vitamin C, vitamin A, thiamine, niacin, folic acid). The nutrient composition of selected vegetables is shown in the Table. Certain vegetables contribute lipids to the diet, mostly in the form of unsaturated oils. Roots and legumes can be important contributors of dietary proteins – especially in developing countries, where animal proteins are scarce. One potential nutritional problem of obtaining proteins from a single vegetable source is the low concentration of essential amino acids in vegetables. Twenty common amino acids are considered to be building blocks of proteins for the body. Of these 20, the body cannot synthesize eight; these eight must be obtained from foods. Most vegetable proteins are low in one of the eight essential amino acids; for example, corn is low in lysine, and soybeans are low in methionine. However, if proteins are obtained from a proper mixture of vegetables, there will not be a nutritional problem. It is a common misconception that fresh vegetables are always superior in nutritional value to processed vegetables. Several investigations have shown frozen or canned vegetables can actually have higher nutritional value than fresh products. Fresh vegetables are subject to quality and vitamin losses during transportation and storage, whereas processing before these losses occur can yield a nutritionally superior product. Research has shown that a major cause of nutrient loss in vegetables is in the draining of cooking or processing liquids. Fresh And Minimally Processed Vegetables:- Harvesting And Storing:- most leafy vegetables that do not require harvesting by mechanical device are cooled immediately after harvest to remove field heat, sorted to remove debris, washed to remove dirt, and bundled or packed for shipping and retail. In most cases vegetables are bundled as whole plants, since cutting will injure the cells and liberate ethylene, which promotes senescence and shortens shelf life. Low-temperature storage is essential in the handling of quality leafy vegetables. On the other hand, storing below refrigerated temperature may lead to chilling injury of certain vegetables and to rapid loss of quality. In developing countries where refrigeration is not available, postharvest losses of fresh vegetables can be as much as half the total harvest. For roots and legumes, the harvesting of which is normally done by machines, some sorting and grading are performed either in the field or at collection stations. Bulk handling of these vegetables is common, and few additional steps of preparation are performed before distribution. For vegetables that need to be stored for long periods of time, treatments to avoid microbial spoilage, insects, and small-animal invasion may be necessary. For some vegetables such as cucumbers, a washing and waxing step may be taken to improve the shelf life and the attractiveness of the produce. Packaging:- provided in response to demands for convenient foods, minimally processed fresh produce has gained popularity in the marketplace. These vegetables go through additional preparation steps of washing, sorting, grading, cutting, and packaging into retail-size containers. In order to extend the shelf life of these products, vacuum packing and modified-atmosphere (MA) packaging are practiced. In most cases air is replaced by an atmosphere high in carbon dioxide and low in oxygen. This modified atmosphere can slow the respiration rate and therefore the senescence of cut vegetables. The most common products in American and European markets are various types of cut lettuces with shredded Carrots, Cabbages, and other vegetables. Modern packaging techniques employing ‘clean room’ concepts make it possible for such vegetable products as salad mix and stir-fry mix to have shelf lives

approaching those of the whole plants. The products can be shipped by refrigerated containers to overseas locations and still have a shelf life long enough to reach consumers. Minimally processed vegetables normally do not contain any preservatives and have not gone through any heat or chemical treatment. The disadvantage of these products is that refrigeration storage is essential, limiting its practice to developed countries. Processing Of Vegetables:- because of the varied growing and harvesting seasons of different vegetables at different locations, the availability of fresh vegetables differs greatly in different parts of the world. Processing can transform vegetables from perishable produce into stable foods with long shelf lives and thereby aid in the global transportation and distribution of many varieties of vegetables. The goal of processing is to deter microbial spoilage and natural physiological deterioration of the plant cells. Generally, the techniques include blanching, dehydrating, canning, freezing, fermenting and pickling, and irradiating. Blanching:- after vegetables have been washed clean, they must undergo blanching (heating) in hot water at 88 °C (190 °F) for two to five minutes or with steam in a conveyor at 100 °C (212 °F) for one-half to one minute. Blanching inactivates natural enzymes that would cause discoloration and off-flavours and aromas. It also serves to reduce the number of microorganisms and to render vegetables limp for easy packing into containers. For some vegetables, such as spinach, snap beans, and collards, the blanching step also serves to remove harsh flavours. After blanching the vegetables must go through rapid cooling in either cold water or cold air for better quality retention. The vegetables are then ready for the various food-processing methods described below. Dehydration:- drying is probably the oldest method of preserving foods. The removal of water from vegetables is accomplished primarily by applying heat, whether it be through the radiant energy of the sun or through air heated by electrical energy. A major advantage of removing water is a reduction in volume and weight, which aids in storage and transportation of the dried products. Modern drying techniques are very sophisticated. Many machines are available to perform tunnel drying, vacuum drying, drum drying, spray drying, and freeze-drying. Although freeze-drying produces a food of outstanding quality, the cost is high, and it has not been used widely in vegetable products. One of the most familiar dehydrated products is instant potatoes. Almost all the mashed potato dishes served in restaurants and institutions are rehydrated instant potatoes. In restaurants and institutions dehydrated potato granules are used, while dehydrated flakes are preferred for home cooking. Potato granules have high bulk density and are easy to handle in large quantity. However, they produce mashed potatoes with a pasty texture – an effect caused by the rupture of cells during processing, so that starch is released from the cells. Mashed potatoes made from flakes, on the other hand, have a mealy texture comparable to that of freshly prepared mashed potatoes. The major difference in the processing of these two dehydrated products is in the drying steps. For granules, air-lift drying is used to bring the product to 10–13 percent moisture. After screening to proper granule size, the product is dried to 6 percent moisture in a fluidized-bed drier. In the making of flakes, a steam-heated drum drier is used to bring a flattened sheet of potato solids to final moisture content before it is broken into a suitable size for packaging. Although a considerable quantity of the potato cells are ruptured during the breaking of the dried sheet, the reconstituted product has an acceptably mealy texture because the potatoes are subjected to a precooking and cooling treatment as well as the addition of a monoglyceride emulsifier. A small amount of sulfite may be used in producing certain dried vegetables. The sulfite serves as an antimicrobial agent, aids in heat transfer, and (in the case of potatoes) acts as a blanching agent. A small percentage of the consumer population is allergic to sulfite. Although the rehydrated product contains little or no sulfite, consumer concerns are forcing the industry to search for economically feasible sulfite replacements. Canning:- putting foods into metal cans or glass jars is the major food-processing method of the world. It is particularly useful in developing countries where refrigeration is limited or nonexistent. In the canning process, vegetables are often cut into pieces, packed in cans, and put through severe heat treatment to ensure the destruction of bacteria spores. The containers are sealed while hot so as to create a vacuum inside when they are cooled to room temperature. Properly processed canned vegetables can be stored at room temperature for years. Minor defects of the process, however, will result in bulged cans after long periods of storage. For safety reasons, the contents of these cans should not be consumed. Although in most cases bulged cans are caused by the formation of gas from chemical reactions between the metal cans and their acidic contents, there is a remote possibility that inadequate heat processing did not destroy all bacteria spores. And, even though most heat-resistant spores are nonpathogenic, spores of Clostridium botulinum can survive underprocessing and produce deadly toxins that cause botulism. Unfortunately, because of the severe heat treatment, some canned vegetables can have inferior quality and less nutritive value than fresh and frozen products. The nutrient most susceptible to destruction in canning is vitamin C. For high-quality products, aseptic canning is practiced. Also known as High-Temperature-Short-Time (HTST) processing, aseptic canning is a process whereby presterilized containers are filled with a sterilized and cooled product and sealed in a sterile atmosphere with a sterile cover. The process avoids the slow heat penetration inherent in the traditional in-container heating process, thus creating products of superior quality. The canning process can be illustrated by the example of green beans (Phaseolus Vulgaris L.). After arrival at the processing plant, the beans are conveyed to size graders. Graders consist of revolving cylinders with slots of various diameters through which the beans fall onto conveyers. The conveyers carry them to snipping machines, where their tips and stems are cut off. The snipped beans then pass over inspection belts, where defective beans are removed. Smaller beans are canned as whole beans, while larger beans are cut crosswise by machine into various lengths. Some smaller beans are cut lengthwise and marketed as French-cut beans. Both the small whole and cut beans are blanched for 1 1/2 to 2 minutes in 82 °C (150 °F) water and mechanically packed in cans. The cans are then filled with hot water and dry salt or with brine, steam-exhausted for approximately five minutes, and sealed while hot or with steam flow. Depending on the size of the can, they are heat-processed for various periods of time – from 12 minutes at 120 °C (250 °F) to 36 minutes at 115 °C (240 °F). The cans are cooled to room temperature, labeled, and packaged for storage or immediate distribution. Freezing:- frozen foods have outstanding quality and nutritive value. Indeed, some frozen vegetables, such as green peas and sweet corn, may be superior in flavour to fresh produce. The high quality of frozen foods is mainly due to the development of a technology known as the Individually Quick-Frozen (IQF) Method. IQF is a method that does not allow large ice crystals to form in vegetable cells. Also, since each piece is individually frozen, particles do not cohere, and the final product is not frozen into a solid block. Various freezing techniques are commonly used in the preservation of vegetables. These include blast freezing, plate freezing, belt-tunnel freezing, fluidized-bed freezing, cryogenic freezing, and dehydrofreezing. The choice of method depends on the quality of end product desired, the kind of vegetable to be frozen, capital limitations, and whether or not the products are to be stored as bulk or as individual retail packages. Most vegetables frozen commercially are intended for direct consumer use or for further processing into soups, prepared meals, or specialty items. Advances in packaging materials and techniques have led to bulk frozen products being stored in large retortable pouches. Many restaurants and institutions prefer bulk frozen soups packaged in these pouches because of their quality and convenience. One of the most important vegetable crops preserved by freezing is Sweet Corn (Zea Mays L.). Both corn on the cob and cut corn are frozen. Sweet Corn must be harvested while still young and tender and while the kernels are full of ‘milk’. After the ears are mechanically harvested, they are promptly hauled to the processing plant, where they are automatically dehusked and desilked. Probably more than any other vegetable, Sweet Corn loses its quality rapidly after harvest. Frozen Corn maintains high quality by being processed within a few hours of picking. Corn on the cob is a particularly difficult vegetable to freeze. The dehusked and desilked ears are thoroughly washed and blanched in steam for 6 to 11 minutes and then promptly cooled. However, even an 11-minute blanch in steam does not completely inactivate all the enzymes in the cob portion. It is believed that the off-flavour frequently found in home-frozen corn on the cob comes from off-flavours produced in the cob that migrate out to the kernels. Blanched and cooled Corn is quickly frozen by the fluidized-bed freezing process before packing. Blanched whole-kernel Corn is produced either by blanching the Corn on the cob before cutting; by

partially blanching on the cob to set the milk, then cutting and blanching again; or by cutting before blanching. The 'split' method of blanching twice produces the highest-quality product. After the corn is cut, impurities such as husk, silk, and imperfect kernels must be removed by either brine flotation or froth washing. In both methods the sound corn stays at the bottom while the impurities float off the tank. Whole-kernel corn can be frozen quickly using the individually quick-frozen method. Frozen corn can be packaged into polyethylene bags or cardboard cartons and labeled for retail, or it can be bulk-stored for further processing into components of value-added products such as frozen dinners. Fermentation And Pickling:- in both fermented and pickled vegetables, acid is used to preserve the products. Pickled vegetables include cucumbers, green tomatoes, onions, radishes, and cabbages. The variety of vegetables used for fermentation or pickling may not be the same as fresh market vegetables. Owing to the acid environment, fermented or pickled vegetables need less heat treatment before being placed in containers. Irradiation:- ionizing radiation, mostly gamma-ray, has been used in several countries to preserve vegetables. The practice is quite common in preventing potatoes from sprouting during long-term storage. Despite studies showing that products treated with low-dose ionizing radiation are safe, consumers are still concerned about this processing technology and have not accepted it.

VEGETABLE SEED = СЕМЯ ОВОЩНОЙ КУЛЬТУРЫ – Vegetable Seed is a specific seed of the kinds and varieties that are or may be grown in gardens or on truck farms and are or may be generally known and sold under the name of vegetable seed. See also Seed. / В ботанике под Семенем понимается орган воспроизведения, расселения и переживания неблагоприятных условий у семенных растений. Семя развивается из особого образования – семяпочки (семязачатка), обычно после оплодотворения. В семени различают зародыш, кожуру (оболочку) и у многочисленных растений ткани с запасными питательными веществами (эндосперм, перисперм); при отсутствии этих тканей, например, у бобовых, запасные питательные вещества откладываются в семядолях зародыша. У покрытосеменных растений семя заключено в плоде, у голосеменных – формируется открыто на семенных чешуях в мегастробилах (шишках). Вес семени может варьироваться от 0.002 мг (у некоторых Орхидей) до 9 кг (у некоторых Пальм). Признаки внешнего и внутреннего строения семени используются в систематике растений. Семя может быть сырьём для изготовления продуктов питания, технических масел, красок, лекарственных и других веществ. Семена – средство размножения большинства овощных культур. Важнейшим условием повышения урожайности и улучшения качества получаемой продукции является высокое качество семян, используемых при выращивании овощных культур. Качество семян определяется двумя показателями:- сортовой чистотой и посевными качествами.

VEGETATIVE = ВЕГЕТАТИВНОЕ (или РАСТИТЕЛЬНОЕ) – Vegetative:- growth of leaves and stems as opposed to flowers. A method of non-sexual reproduction by means of offsets, cuttings. Vegetative:- referring to asexual (stem, leaf, root) development in plants in contrast to sexual (flower, seed) development. Vegetative:- (1) of, or relating to, the non-flowering parts of a plant; (2) producing new plants asexually by the spread or fragmentation of sterile (non-reproductive) tissue, without the formation of seeds. / (стебель, лист, корень) . Под Вегетативным от позднелатинского слова Vegetativus, от Латинского слова Vegeto, означающее Возбуждаю или Оживляю, в дальнейшем – Расту), или Растительным, понимается биологический термин, имеющий ряд значений в морфологии и физиологии растений и животных. Например, вегетативные функции (питание, рост) свойственны не только растениям, но и животным. Соответственно вегетативные органы (органы растительной жизни) выделяют как у растений (корень, стебель, лист, грибница – смотрите Вегетативные Органы), так и у животных (органы пищеварения, выделения и другие). В яйцах животных вегетативный полюс – область яйца, наиболее богатая питательными веществами (желтком). При откладке яиц в воду вегетативный полюс оплодотворённого яйца, как более тяжёлый, обычно обращён вниз, реже, когда желток содержит много жира (у многих морских Рыб), вегетативный полюс находится наверху. Для вегетативной области яйца, в отличие от анимальной, характерны меньшее содержание протоплазмы и меньшая интенсивность обмена веществ. Вегетативный период у Растений – время от начала развития особи до её половой зрелости. Под Вегетацией, от Латинского слова Vegeto, означающее Возбуждаю или Оживляю, или Vegetatio, означающее Возбуждение или Оживление, понимается произрастание, активная (в отличие от состояния покоя) жизнедеятельность растительных организмов. Под Вегетативным Размножением понимается образование нового многоклеточного организма из части материнского путём почкования, деления (у низших Животных и Растений), а также при помощи клубней, корневищ, луковиц, отпрысков и других (у высших растений). Используется в плодоводстве, овощеводстве и других отраслях сельского хозяйства. Иногда вегетативное размножение относят к бесполому размножению.

VEGETATIVE BRANCH = ВЕГЕТАТИВНАЯ ВЕТВЬ (или РОСТОВАЯ ВЕТВЬ) – Vegetative Branch is a lateral branch on a Cotton Plant that does not have a fruit at each node; fruiting branches, however, can develop from vegetative branches. Vegetative branches have a terminal and often develop fruiting branches, especially under low plant populations. See also Monopodium.

VEGETATIVE CELL = ВЕГЕТАТИВНАЯ КЛЕТКА – Vegetative Cell:- a cell of a bacterium or unicellular Alga that is actively growing rather than forming spores. Vegetative Cell is:- any of the cells of a plant or animal except the reproductive cells; a cell that does not participate in the production of gametes. / Вегетативная Клетка:- любая клетка растительного организма, за исключением клеток участвующих в половом размножении.

VEGETATIVE COMPATIBILITY GROUP = ГРУППА ВЕГЕТАТИВНОЙ СОВМЕСТИМОСТИ – Vegetative Compatibility Group:- a sub-grouping of a fungal species based on the ability of closely related isolates to exchange nuclear material via the fusion of fungal strands (hyphae). / Подгруппирование Видов Грибов, основанное на способности тесно связанных отдельных к обмену содержащего ядровещества посредством слияния тяжей грибницы (гиф).

VEGETATIVE CONTROLS = ВЕГЕТАТИВНЫЕ КОНТРОЛИ (или ХХ) – Vegetative Controls:- nonpoint source pollution control practices that involve plants (vegetative cover) to reduce erosion and minimize the loss of pollutants.

VEGETATIVE COVER = ВЕГЕТАТИВНЫЙ ПОКРОВ (или РАСТИТЕЛЬНЫЙ ПОКРОВ) – Vegetative Cover:- trees, perennial grasses, legumes, or shrubs with an expected life span of five years or more. See also Permanent Vegetative Cover.

VEGETATIVE GROWTH = ВЕГЕТАТИВНЫЙ РОСТ – Vegetative Growth is a general term for undesirable Cotton plant growth, typified by lack of fruit; often tall and rank. The roots, stems and leaves as distinct from the reproductive growth of flowers and bolls. Vegetative Growth is the period of growth between germination and flowering is known as the Vegetative Phase of plant development. During the vegetative phase, plants are busy carrying out photosynthesis and accumulating resources that will be needed for flowering and reproduction. Different types of plants show different growth habits. The movies in this section will document various growth processes that occur during the vegetative phase of development. / Корни, стебли и листья в отличие от репродуктивного роста цветков и коробочек.

VEGETATIVE PHASE/STAGE = ВЕГЕТАТИВНАЯ ФАЗА/СТАДИЯ – Vegetative Phase/Stage is the period from seed germination to the panicle initiation stage. Vegetative Phase:- Growth vs. Development:- It is helpful to differentiate between growth and development. Growth is an increase in biomass, whether for a leaf, plant, or grassland. Growth rate varies over time and depends on the life cycle of the plant, its environment, and the management imposed. Development, in contrast, is the passage through life cycle phases. For

forage grasses, the life cycle is divided into developmental phases:- vegetative, transition, and reproductive. The vegetative phase is characterized by meristems producing leaves. The transition phase produces an elevation of the apical meristem, while the reproductive phase centers around meristems producing flowers. In the vegetative phase, which begins at germination and continues through tillering, the tissues of growth (meristems) are busy producing leaves. This is important because sufficient leaf surface area is needed to capture sunlight and continue photosynthesis. Good leaf development eventually implies roots are being established. When a plant has enough leaves for photosynthesis and roots for anchoring, storage, and uptake of minerals then grazing and mowing management can be considered. The late vegetative stage is a valuable phase for harvesting forage. Management Implications:- (i) Seedlings:- grazing of new seedings must be deferred until plants have become well anchored in the soil. This usually requires that seedling have 3–4 leaves. (ii) Established Stands:- shoots in the vegetative stage are relatively insensitive to mismanagement as long as there is no sheath elongation or culm internode development. As long as the collar zone of the leaf blades, and the apical meristem zone of the shoots remain safely nested below the normal grazing height, the grass should continue vegetative development when grazed during this growth phase. Nevertheless, sufficient leaf blade tissue should remain on the shoots to ensure normal growth and root development. The rule of thumb is:- 'take half-leave half' meaning allow enough leaf blades to work as sites of photosynthesis. Practical Applications:- Farmers in the Plains states commonly graze wheat during the vegetative stage. However, they closely monitor shoot development by splitting a shoot longitudinally to locate the growing point and determine the onset of internode elongation. Livestock are removed at the first sign of culm development.

VEGETATIVE PRACTICE = ВЕГЕТАТИВНАЯ ПРАКТИКА – Vegetative Practice is a conservation practice that primarily involves the establishment or planting of a site-specific vegetative cover to conserve, protect from degradation, or improve soil, water, or related natural resources in the most cost-effective manner. Vegetative Practices:- Turf uses the natural processes of infiltration, filtration, and biological uptake to reduce flows and pollutant loadings. A number of vegetative practices can be used to incorporate these processes in golf course design. Vegetative Filtration:- Common examples of vegetative filters that can be used throughout the golf course are conservation areas or buffers, land absorption areas (vegetated filter strips) and swales (diversions, berms). Vegetative filters act as natural biofilters to reduce storm water flow and pollutant load, and turf areas are effective filters. Vegetated filter strips remove sediment and attached chemicals, organic material, trace metals, and nutrients (nitrogen and phosphorus). Sediment removal rates are generally greater than 70% and nutrient removal is typically greater than 50%. Vegetative filters require management to achieve dense, hearty vegetation. Where changes in vegetative cover must be made, these changes are normally established in low maintenance ground covers. This practice may include the use of native or naturalized plants, including low maintenance turfgrasses. When turf is used as the filtration medium, cultural activities should focus on producing healthy turf with a minimum of maintenance activities. Turf should be allowed to grow to the highest end of the optimum range for more effective filtration. Fertilizers and pesticides are usually not applied in these areas except sparingly (sometimes during establishment to reduce erosion and runoff problems much faster) or after a risk assessment has determined that application of certain materials will have no impact in adjacent areas. Establishing these buffers reduces erosion and sediment loss decreases. Buffers also protect surface waters by attenuating pollutants in surface runoff. Soil surface runoff may also be moderated, reducing the impact on receiving water bodies and streams. The greatest benefit is the protection of adjacent ecologically sensitive areas – potential pollutants are simply not introduced, or are introduced on a limited basis compared to more highly maintained turf areas. Figure 4–1 shows several examples of vegetated buffers. Conservation Areas or Buffers:- These are areas where it is critical to establish and maintain perennial vegetative cover to protect resources. The most sensitive portions of watercourses are the areas immediately adjacent to the water. Disturbance within and adjacent to watercourses can degrade water quality by increasing the availability and transport of pollutants. Therefore, retaining vegetated buffers along watercourses is one of the most effective practices used to protect water quality and should be designed to handle the anticipated runoff. If the area is a state or locally designated wetland, a buffer may be required and the width of the buffer specified by the regulating authority. Critical Area Planting:- Planting vegetation on highly erodible or critically eroding areas also protects water quality. The greatest amount of soil erosion and sediment delivery to surface waters occurs when large areas are graded during the construction phase, which requires phased construction to minimize the amount of bare land. Quickly establishing vegetation reduces the movement of materials in runoff, as plants take nutrients in the soil and reduce the amount that can be washed into surface waters or leach into groundwater, as well as trap particulates. Sodding is an important consideration in these areas since it provides instant ground cover and rooting can occur rapidly for permanent establishment. In certain instances, strip sodding rather than solid sodding can be used if the slopes are not too steep and the strips are wide enough to adequately handle the sediment carried in the runoff. However, sod production systems that use inputs can potentially contribute to water quality issues after installation; pesticides have been found in groundwater monitoring wells on very sandy sites following sodding. Grassed Swales Or Berms Or Diversions. Channels constructed across a slope with a supporting ridge on the lower side are another effective control. These channels stabilize a runoff area and reduce sheet and rill erosion by reducing the length of slope. These measures also eliminate vertical channeling and large gullies, which reduces the amount of sediment and related pollutants delivered to the surface waters. Berms direct water into specific areas to allow vertical filtration rather than allowing surface runoff. Vegetated swales are used to permit filtering and infiltration of storm water. The grasses for these swales should be water tolerant and erosion resistant (rapid germination and establishment to form dense sod). These types of swales are used on gentle slopes where slower velocities enhance the filtering and infiltration processes. Swales are also effective in routing water to maximize contact time of water and vegetation. An example in which swales are helpful is the routing of water from the underdrains of greens. Filtration can be greatly increased by carefully choosing the route of water from the underdrain. If space is limited, drainage water could be directed to flow along a path that maximizes the distance of contact with vegetation, rather than choosing the shortest route to the lowest elevation. The effectiveness of swales in reducing flows and pollutants is similar to that of filter strips. Vegetated Filter Strips:- Filter strips are manmade or naturally occurring flat areas established at the perimeter of disturbed or impervious areas to intercept runoff as sheet flow and remove particulate matter and contaminants. Either grassed or wooded areas can function as filter strips. Grassed Waterways:- These natural or constructed channels are shaped, graded, and planted to ensure the stable flow of runoff. This practice reduces erosion in a concentrated flow area, such as in a gully or in ephemeral gullies, and reduces sediment and substances delivered to receiving waters. Vegetation may also filter some of the sediment delivered to the waterway; however, filtration is a secondary function of a grassed waterway. Any chemicals applied to the waterway in treating the adjacent areas may wash directly into the surface waters when runoff occurs shortly after spraying. If standing water is present, applications of fertilizer or pesticides should also be avoided. Turfgrass Used As A Vegetative Filter:- One of the most effective BMPs for protection of surface water is use of turf as a vegetative filter in swales and filter strips. Turfgrass areas are extremely effective in reducing soil losses compared to other cropping systems. In a comparison of soil loss from conventional agriculture with soil loss from turf, measured soil loss from tobacco production (4 210 lbs/acre) was 842 times higher than from turf areas (5 lbs/acre), even with a slope of 16% on a silt loam soil. Where polluted runoff from agricultural areas has occurred, establishment of turf buffer strips of only 15 feet have been shown to improve water quality. Studies at Oklahoma State University have shown that turfgrass buffers of 16 ft effectively reduce concentrations of chemicals in runoff (Cole et al 1997). Other studies noted that in cases where water quality has declined due to agricultural practices that lead to loss of nutrients and erosion, grass buffer strips placed between treated fields and surface waters significantly reduce the problem. This result is related to the architecture of the turf

canopy, the fibrous turf root system, and the development of a vast macropore soil structural system that encourages infiltration rather than runoff. Turf density, leaf texture, rooting strength, and canopy height physically restrain soil erosion and sediment loss by dissipating impact energy from rain and irrigation water droplets. These turf features also provide resistance to surface movement of water over turf. Additionally, turfgrasses have an extensive fibrous root system, with 80% of the root mass found in the upper 4 inches of the soil profile. The combination of turf canopy and root mass has a strong soil stabilizing effect.

VEGETATIVE PROPAGATION = ВЕГЕТАТИВНОЕ РАЗВЕДЕНИЕ (или ВЕГЕТАТИВНОЕ КУЛЬТИВИРОВАНИЕ, или ВЕГЕТАТИВНОЕ РАСПРОСТРАНЕНИЕ, или ВЕГЕТАТИВНОЕ РАЗМНОЖЕНИЕ, или ВЕГЕТАТИВНОЕ ВОСПРОИЗВОДСТВО, или или ВЕГЕТАТИВНОЕ СБЛИЖЕНИЕ) – Vegetative Propagation is a form of asexual reproduction of a plant. Only one plant is involved and the offspring is the result of one parent. The new plant is genetically identical to the parent. (1) Natural Vegetative Propogation:- new plants grow from parts of the parent plant. They include:- (i) Stems:- runners are stems that grow horizontally above the ground. They have nodes where buds are formed. These buds grow into a new plant. (ii) Roots:- new plants will grow out of swollen, modified roots called Tubers. Buds develop at the base of the stem and then grow into new plants. (iii) Leaves:- leaves of some plants will grow into a new plant if they become detached from the parent plant. Other plants grow small plants called plantlets on the edge of their leaves. (iv) Bulbs:- a bulb contains an underground stem. Leaves are attached to the stem. These leaves contain much stored food. At the centre of the bulb is an apical bud. Also attached are lateral buds. The apical bud will produce leaves and a flower while the lateral buds will produce new shoots. As the plant grows and develops it will form a new bulb underground. (2) Artificial Vegetative Reproduction:- Horticulturists and farmers use artificial means to produce plants that are identical to the parent plant. Some of the methods used are:- (i) Cuttings:- cuttings are part of the plant that is cut off of the parent plant. Shoots with leaves attached are usually used. New roots and leaves will grow from the cutting. The shoot is cut at an angle. A growth promoter may be used to help with the growth of the roots. (ii) Grafting:- in grafting 2 plants are used to develop a new plant with combined traits from the 2 parent plants. In grafting the scion is the above ground part of one plant. The scion is attached to the stock which is the rooted part of the second plant. (iii) Layering:- in layering a shoot of a parent plant is bent until it can be covered by soil. The tip of the shoot remains above ground. New roots and eventually a new plant will grow. These plants can then be separated. See also Propagation, and Vegetative Reproduction. / Вегетативное Сближение, метод преодоления нескрещиваемости растений при отдалённой гибридизации. Вегетативное сближение заключается в том, что черенок одного растения (привой) прививают в крону другого (подвой), через несколько лет пыльца, развивающаяся в цветках привоя, приобретает способность прорастать в завязь цветков подвоя. Термин ‘Вегетативное Сближение’ был введён Русским селекционером, садоводом-генетиком Иваном Владимировичем Мичуриным (1855–1935), который, применяя вегетативное сближение, получил более ста новых сортов растений.

VEGETATIVE REPRODUCTION = ВЕГЕТАТИВНАЯ РЕПРОДУКЦИЯ (или ВЕГЕТАТИВНОЕ РАЗМНОЖЕНИЕ) – Vegetative Reproduction is a form of asexual reproduction in plants, in which multicellular structures become detached from the parent plant and develop into new individuals that are genetically identical to the parent plant. For example, liverworts and mosses form small clumps of tissue (called Gemmae) that are dispersed by splashing raindrops to form new plants. Bulbs, corms, offsets, rhizomes, runners, suckers, and tubers are all important means of vegetative reproduction and propagation in cultivated plants. Vegetative Reproduction is the reproduction of a plant via stems, leaves and rhizomes. Vegetative Reproduction, any form of asexual reproduction occurring in plants in which a new plant grows from a fragment of the parent plant or grows from a specialized reproductive structure (such as a stolon, rhizome, tuber, corm, or bulb). For a general discussion of plant reproduction, see Reproductive System, Plant. For an overview of the cultivation of plants for food and ornament, see Horticulture. / Под Репродукцией (биологической), от Латинских слов Re – приставка, означающая возобновляемое, воспроизводимое, повторное действие или действие, противоположное (обратное) выраженному корнем слова, или противодействие, и Produco, означающее Произвожу, понимается воспроизведение организмами себе подобных; то же, что Размножение. Под Вегетативным Размножением понимается образование нового многоклеточного организма из части материнского путём почкования, деления (у низших Животных и Растений), а также при помощи клубней, корневищ, луковиц, отпрысков и других (у высших Растений). Используется в плодоводстве, овощеводстве и других отраслях сельского хозяйства. Иногда вегетативное размножение относят к бесполому размножению. Под Вегетативным Размножением понимается образование нового организма из части материнского; один из способов бесполого размножения, свойственный многоклеточным организмам. Вегетативное размножение у животных организмов осуществляется путём деления (простейшие) или почкования (губки, кишечнополостные, мшанки); у низших Растений (например, Водоросли) – чаще путём деления, реже почкования (некоторые сумчатые грибы, например, Дрожжи, некоторые базидиальные Грибы); у низших многоклеточных Растений наблюдается также распадение тела на отдельные участки, способные к регенерации. Высшие Растения могут размножаться корневищами (Свинорой, Пырей Ползучий, Ландыш, Ирисы, Канны, многолетние Астры и другие), луковицами (Гиацинты, Крокусы, Лилии, Лук, Тюльпаны, Чеснок, и другие), клубнями (метаморфизированными стеблями – Картофель, Топинамбур; метаморфизированными корнями – Багат, Маниок). Среди естественных способов вегетативного размножения применительно к плодовым и ягодным культурам различают размножение специализированными и неспециализированными органами. Вегетативное Размножение Специализированными Органами включает:- размножение усами (Земляника, Клубника), плетями (Клюква, Костяника, Морошка и другие), верхушечными отводками (Ежевика). Вегетативное Размножение Неспециализированными Органами включает размножение корневыми отпрысками (многие Виды Ивы, Осины; из плодовых – дикие Среднеазиатские Виды Яблони, Малина, многие Сорта Вишни, Сливы и другие). Многие Кустарники (например, Крыжовник, Смородина) и Травянистые Многолетники (некоторые Мятликовые) возобновляются от почек у основания побегов. Партикуляция встречается у Земляники, Крыжовника, Малины, Смородины и других. Среди искусственных способов вегетативного размножения плодовых Растений различают размножение черенками, отводками и прививкой. Зимними черенками размножают Виноград, Смородину, многие сорта Крыжовника, подвои некоторых типов для Яблони и Сливы, Айву, Инжир; из лесных и декоративных пород – Жасмин, Иву, Тополь и другие. Летними (зелёными) черенками размножают Айву, Вишню, Крыжовник, Лимон, Облепиху, Сливу, Смородину, многие декоративные Кустарники и травянистые цветочные Растения (Герань, Хризантемы и другие). Листовыми черенками разводят Бегонию, Узамбарскую Фиалку (Сенполия) и другие; корневыми черенками – Ежевику, Красную Малину, Яблоню, некоторые Сорта Вишни, Сливы и другие. Вегетативное размножение вертикальными отводками наиболее распространено в питомниках для получения клоновых подвоев Груши и Яблони; горизонтальные отводки применяются при размножении ягодных культур, Айвы, Шелковицы, клоновых подвоев Яблони и другие. Внедряется в производство метод ускоренного микроразмножения Растений (Абрикоса, Вишни, Груши, Земляники, Картофеля, Крыжовника, Малины, Розы, Сирени, Сливы, Яблони и других), основанной на получении посадочного материала из изолированных апексов (верхушек побегов). Этот метод даёт возможность из одного Растения в течение года вырастить несколько тысяч вегетативных потомков, обладающих всеми признаками исходной формы; получать посадочный материал, не заражённый вирусными, грибными и нематодными болезнями; быстро размножать ценные клоны; планировать выпуск посадочного материала к определённому сроку и другое. Вегетативное Размножение, образование нового организма из части материнского. Способы вегетативного размножения,

наблюдаемые в природе, разнообразны. Простейший из них – восстановление организма из одной вегетативной клетки в результате её последовательного деления и дифференциации образующихся клеток. Вегетативное размножение свойственно микроорганизмам, низкоорганизованным животным, почти всем растениям. У животных вегетативное размножение осуществляется путём почкования (например, у Губок, Кишечнополостных, Мшанок) или деления (например, у простейших); у одноклеточных растений (Водоросли, Грибы и другие) – чаще путём деления, реже почкования, у низших многоклеточных растений распадением тела на отдельные участки, способные к регенерации (восстановлению). Высшие растения могут размножаться корневищами, отпрысками, луковицами, клубнями и другими вегетативными органами. У многих культурных растений вегетативное размножение – единственно возможный путь сохранения ценных сортовых признаков и свойств. У высших растений существует размножение отводками (Пихта, Рододендроны, дикие формы Винограда и так далее), то есть частями органов, связь которых с материнским растением поддерживается до тех пор, пока они не начинают питаться самостоятельно; плетями или усами (Земляника, Ежевика, Батат, Лютик ползучий, Будра и другие); корневыми отпрысками (многие лиственные и хвойные деревья и травы – Рябина, Роза, Ольха, Таусагыз, Осот полевой и другие). Луковицами, клубнями размножаются многие овощные и декоративные растения (Лук, Тюльпан, Лилия, Картофель, Батат и многие другие), корневищами, как правило, – многолетние растения (Ландыш, Мята, Спаржа, Бамбук и многие сорные Растения). В растениеводстве широко распространено размножение черенками (стеблевыми, корневыми и листовыми). Естественное размножение листьями свойственно Бриофиллуму, у которого образовавшиеся на листовых пластинках побеги опадают и укореняются в почве. В плодоводстве применяют корнесобственные способы вегетативного размножения (размножение отводками и черенкование) и прививку (смотрите Прививки В Растениеводстве). Отводок – часть наземного стебля с почками, не отделяемая на период укоренения от материнского растения. Стебли, подлежащие укоренению, окучивают. Укоренившиеся стебли отделяют от материнского растения, разрезают на части (имеющие корни) и сразу высаживают на плантации или доращивают в питомнике (1–2 года). Многие виды сельскохозяйственных и декоративных Растений (Ежевика, Плющ, Сумах, Скумпия, Рододендрон и другие) размножаются естественными отводками. В плодоводстве чаще всего применяют размножение вертикальными и горизонтальными отводками; так размножают многие сорта Крыжовника, некоторые подвои Яблони, в декоративном садоводстве – Сирень, Калину, Жимолость и другие. Многие сорта Ежевики и ежевикообразной Малины размножают верхушечными отводками. При черенковании используются части растения (черенки), способные при определённых условиях восстанавливать корни (на стеблях), или почки (на корнях), или почки и корни (на листьях). Различают черенки стеблевые, листовые и корневые. Стеблевые черенки могут быть без листьев (зимние), с листьями (летние, или зелёные), травянистые и деревянистые. Безлистные черенки обычно заготавливают осенью, чаще из однолетних побегов, которые разрезают на части длиной 20–30 сантиметров (см), высаживают осенью или весной, сохраняя их прикопанными в подвале, в снегу. Зимними черенками размножают виноград, некоторые сорта Крыжовника, некоторые типы подвоев Яблони и Сливы, Айву, Инжир, Гранат, Спирею, Жасмин, Тополь, Иву и другие. Для зелёных черенков используют облиственные побеги, разрезая их на части длиной 5–10 см, иногда срезают со стебля часть коры с древесиной и одной почкой (листопочковые черенки). Зелёными черенками размножают Крыжовник, Вишню, Сливу, Айву, Облепиху, Маслину, многие декоративные кустарники и травянистые цветочные растения – Хризантему, Герань, Гвоздику, Георгину, Флокс и другие. Процесс корнеобразования у зелёных черенков многих растений стимулируют с помощью ростовых веществ. У Вишни, Сливы, Сирени и других зелёные черенки легче укореняются в период, когда черенкуемые побеги находятся в фазе интенсивного роста в длину; у Яблони, Крыжовника и других – в конце этой фазы, а у чёрной Смородины и некоторых сортов Крыжовника – в течение всей фазы роста. Большое значение при размножении зелёными черенками имеют температура (оптимальная 20–25 °С), влажность воздуха и субстрата, световой режим. При зелёном черенковании применяют искусственный туман, создаваемый автоматизированными системами над местом укоренения черенков. В атмосфере тумана резко возрастает укореняемость черенков, в 2–3 раза сокращаются затраты труда. Листовой черенок – это лист или его часть. Лист сажают в среду укоренения (чаще в песок) черешком или укладывают нижней стороной, слегка надрезая выпуклые жилки листа. Затем слегка присыпают песком, поливают. Листовыми черенками размножают Бегонию, Седум, Узамбарскую (Африканскую) Фиалку и другие. Корневые черенки – части корня; заготавливают их обычно осенью, длиной 10–15 см, хранят прикопанными в песке и торфе, весной высаживают в плодородную почву. Корневыми черенками размножают Малину (красную), Ежевику, молодые сеянцы Яблони, некоторые сорта Вишни, Сливы и другие. Вегетативное Размножение – один из видов бесполого размножения. Оно свойственно почти всем представителям Царства Растений. В природе нередко наблюдается такая картина:- одно растение, например Земляника, разрастаясь своими ползучими побегами – усами, занимает большую территорию. При этом некоторые побеги могут оторваться от материнского организма и продолжать жизнь самостоятельно. Та же отломившаяся ветка Ивы, попав в благоприятные условия, укореняется. Вскоре из ветки вырастает новое растение, иногда на достаточно далеком расстоянии от материнского. Это примеры вегетативного размножения растений с помощью стебля. Растения в природе нередко размножаются листьями. Так, в сыроватых местах луга встречается растение Сердечник Луговой. Его сложные листья, соприкасаясь с влажной поверхностью почвы, образуют придаточные корни и почки. Отделившись после этого от материнской особи, они образуют из почек свои побеги и живут как новое растение. Листьями в природе размножаются, например, Бегония, Сансевьера, Каланхоэ, Сенполия. Начало развитию новых растений при вегетативном размножении всегда дают почки (пазушные или придаточные). Вегетативное Размножение – это воспроизведение Растений из вегетативных частей тела:- корня и побега. Вегетативное размножение свойственно Высшим и Низшим Растениям. У Низших Растений (Водорослей) вегетативное размножение могут осуществлять отделившиеся кусочки слоевища или отдельные его клетки. Высшие растения (споровые и семенные) размножаются всеми вегетативными органами – корнями, побегом, а также его частями:- стеблем, листьями, почками. У высших растений, особенно у цветковых, вегетативное размножение может сочетаться и чередоваться с половым размножением. Растения, возникшие вегетативным путём, обладают такими же свойствами, какие были у материнского растения. Лишь в новых условиях окружающей среды у них могут проявиться иные свойства, например, измениться размеры растения. При вегетативном размножении отделившиеся дочерние растения полностью воспроизводят наследственные свойства материнского организма. Совокупность новых растений (особей), возникших вегетативным путём от одного материнского растения, называется Клоном (от Греческого слова Клон, означающее Ветвь или Отпрыск). Образование клонов позволяет каждому растению иметь однородное потомство, повторять себя в своих потомках без изменения наследственных качеств. Клонированием создаётся возможность сохранить исходные свойства материнских растений в течение достаточно длительного времени. Только таким способом удаётся сохранить своеобразные особенности какого-либо сорта у культурных растений. В этом проявляется уникальность вегетативного размножения, а также его существенное отличие от полового. Растения, появившиеся путём вегетативного размножения, обычно развиваются значительно быстрее, чем особи, появившиеся из семян, то есть половым путём. Они могут раньше перейти к плодоношению, значительно быстрее захватить необходимую им площадь, быстрее расселиться на большой территории. Вегетативное размножение позволяет сохранить неизменными свойства вида. В этом заключается его большое биологическое значение. Если прорастание семян почему-либо у вида затруднено и подавлено, растение переходит на вегетативное размножение. Вегетативное размножение у растений может осуществляться случайно отделившимися

частями тела растения. Укоренение частей побегов, отдельных листьев, почек, кусочков корней и корневищ – это явление широко представлено в природе. Но у многих растений в процессе эволюции сформировались особые, специализированные части. К ним относятся:- клубни, луковицы, столоны, усы, клубнелуковицы, корневища. Тому же служат и особые вегетативные части растения, называемые выводковыми почками. Выводковые почки возникают у растений на листьях (Бриофиллюм, Папоротник-Асплениум) или в соцветии. Там они прорастают, образуя маленькую розеточку листьев с корнями, маленькую луковичку в пазухах листьев (Лилии, Лук, Чеснок) или крохотный клубень в соцветии (Горец Живородящий, Мятлик Бульбоносный). Люди с давних пор очень широко используют вегетативное размножение растений в своём хозяйстве.

VEGF = VASCULAR ENDOTHELIAL GROWTH FACTOR

VEHCAR = CARGO LOADED ON VEHICLES

VEHICLE = ТРАНСПОРТНОЕ СРЕДСТВО – (1) Vehicle means a road vehicle or railway freight wagon (railroad freight car), permanently attached to an underframe and wheels or to a chassis and wheels, which is loaded and unloaded as a unit. This term also includes a trailer, semitrailer or similar mobile unit except those used solely for the purposes of loading and unloading. See also Motor Vehicles. Vehicle is any vehicle, truck, tractor, trailer or combination of these hauled by a single power unit.

(2) Vehicle:- motorized vehicles used by US households for personal transportation. Excluded are motorcycles, mopeds, large trucks, and buses. Included are automobiles, station wagons, passenger vans, cargo vans, motor homes, pickup trucks, and jeeps or similar vehicles. To be included, vehicles must be:- (1) owned by members of the household; or (2) company cars not owned by household members but regularly available to household members for their personal use and ordinarily kept at home; or (3) rented or leased for 1 month or more. See also Automobile, Bus, Car, Minivan, Moped, Motorcycle, Motor Vehicle, Semi, Semitrailer, Taxi, Tractor-Semitrailer, Tractor Trailer, Truck, Truck Tractor, and Van. In the United States, Vehicle:- as the term is applied to private entities, does not include a rail passenger car, railroad locomotive, railroad freight car, or railroad caboose, or other rail rolling stock described in Section 242 of Title III of the Act.

VEHICLE ACQUISITION = ПРИОБРЕТЕНИЕ ТРАНСПОРТНЫХ СРЕДСТВ – Vehicle Acquisition:- the number of vehicles a household acquires or obtains during the year. The average number of vehicles in the stock is computed using these data. See also Vehicle Disposition.

VEHICLE CLASS = КЛАСС ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Class:- a term that includes sedans, station wagons, ambulances, buses and trucks, or different categories of vehicles according to Federal Standards for fiscal year 1992. Vehicle Class:- the first three characters of the vehicle license number on a government vehicle. The first character will always be 'G'.

VEHICLE COMPANIES = ТРАНСПОРТНЫЕ КОМПАНИИ (или КОМПАНИИ С ТРАНСПОРТНЫМИ СРЕДСТВАМИ) – Vehicle Companies are financial entities created to be holders of securitized assets or assets that have been removed from the balance sheets of corporations or government units as part of the restructuring of these units. Many are organized as trusts or special purpose vehicles created solely to hold specific portfolios of assets or liabilities.

VEHICLE CONFIGURATION = КОНФИГУРАЦИЯ ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Configuration:- the combination of vehicular units comprising a commercial motor vehicle.

VEHICLE DISPOSITION = ОТЧУЖДЕНИЕ ТРАНСПОРТНЫХ СРЕДСТВ – Vehicle Disposition:- the number of vehicles a household disposes of during the survey year. Disposed vehicles include those sold, traded, or the owner moved out of the household. The average number of vehicles in the stock is computed using these data. See also Vehicle Acquisition.

VEHICLE FUEL = ТОПЛИВО ДЛЯ ТРАНСПОРТНЫХ СРЕДСТВ – Vehicle Fuel is the predominant type of fuel purchased during 1991. Data categories are leaded and unleaded gasoline, diesel motor fuel and 'other' which includes propane and gasohol. See also Fuel, Gasohol, Gasoline, and Kerosene.

VEHICLE FUEL CONSUMPTION = ПОТРЕБЛЕНИЕ ТОПЛИВА ТРАНСПОРТНЫМ СРЕДСТВОМ – Vehicle Fuel Consumption is computed as the vehicle miles traveled divided by the fuel efficiency reported in miles per gallon (MPGs). Vehicle fuel consumption is derived from the actual vehicle mileage collected and the assigned MPGs obtained from the US EPA (short for the Environmental Protection Agency) certification files adjusted for on-road driving. The quantity of fuel used by vehicles.

VEHICLE FUEL EFFICIENCY = ТОПЛИВНАЯ ЭФФЕКТИВНОСТЬ ТРАНСПОРТНЫХ СРЕДСТВ (или ТОПЛИВНЫЙ КОЭФФИЦИЕНТ ПОЛЕЗНОГО ДЕЙСТВИЯ ТРАНСПОРТНЫХ СРЕДСТВ) – Vehicle Fuel Efficiency is a form of thermal efficiency, meaning the ratio from effort to result of a process that converts chemical potential energy contained in a carrier (fuel) into kinetic energy or work. Overall fuel efficiency may vary per device, which in turn may vary per application fuel efficiency, especially fossil fuel power plants or industries dealing with combustion, such as ammonia production during the Haber process (also called Haber-Bosch process; it is named after its inventors, the German chemists Frits Haber (1868–1934) and Carl Bosch (1874–1940)). In the context of transport, fuel economy is the energy efficiency of a particular vehicle, given as a ratio of distance traveled per unit of fuel consumed. It is dependent on engine efficiency, transmission design, and tire design. Fuel economy is expressed in miles per gallon (mpg) in the USA and usually also in the UK (imperial gallon); there is sometimes confusion as the imperial gallon is 20% larger than the US gallon so that mpg values are not directly comparable. In countries using the Metric system fuel economy is stated as 'Fuel Consumption' in liters per 100 kilometers (L/100 km). Litres per mil are used in Norway and Sweden. Fuel consumption is a more accurate measure of a vehicle's performance because it is a linear relationship while fuel economy leads to distortions in efficiency improvements. Weight-specific efficiency (efficiency per unit weight) may be stated for freight, and passenger-specific efficiency (vehicle efficiency per passenger). Fuel Efficiency Of Motor Vehicles:- The fuel efficiency of motor vehicles can be expressed in more ways:- (i) Fuel Consumption is the amount of fuel used per unit distance; for example, litres per 100 kilometres (L/100 km). In this case, the lower the value, the more economic a vehicle is (the less fuel it needs to travel a certain distance); this is the measure generally used across Europe (except the UK, Denmark and The Netherlands – see below), New Zealand, Australia and Canada. Also in Uruguay, Paraguay, Guatemala, Colombia, China, and Madagascar, as also in post-Soviet space. (ii) Fuel Economy is the distance travelled per unit volume of fuel used; for example, kilometres per litre (km/L) or miles per gallon (MPG), where 1 MPG (imperial) ≈ 0.354 006 km/L. In this case, the higher the value, the more economic a vehicle is (the more distance it can travel with a certain volume of fuel). This measure is popular in the USA and the UK (mpg), but in Europe, India, Japan, South Korea and Latin America the metric unit km/L is used instead. Converting from mpg or to L/100 km (or vice versa) involves the use of the reciprocal function, which is not distributive. Therefore, the average of two fuel economy numbers gives different values if those units are used, because one of the functions is reciprocal, thus not linear. If two people calculate the fuel economy average of two groups of cars with different units, the group with better fuel economy may be one or the other. However, from the point of energy used as a shared method of measure, the result shall be the same in both the cases. The formula for converting to miles per US gallon (exactly 3.785 411 784 litres (L)) from L/100 km is 235.215 / x, where x is value of L/100 km. For miles per Imperial gallon (exactly 4.54609 L) the formula is 282.481 / x. In parts of

Europe, the two standard measuring cycles for 'litre/100 km' value are 'urban' traffic with speeds up to 50 km/h from a cold start, and then 'extra urban' travel at various speeds up to 120 km/h which follows the urban test. A combined figure is also quoted showing the total fuel consumed in divided by the total distance traveled in both tests. A reasonably modern European supermini and many mid-size cars, including station wagons, may manage motorway travel at 5 L/100 km (47 mpg US/56 mpg imp) or 6.5 L/100 km in city traffic (36 mpg US/43 mpg imp), with carbon dioxide emissions of around 140 g/km. An average North American mid-size car travels 21 mpg (US) (11 L/100 km) city, 27 mpg (US) (9 L/100 km) highway; a full-size SUV (short for the sport-utility vehicle) usually travels 13 mpg (US) (18 L/100 km) city and 16 mpg (US) (15 L/100 km) highway. Pickup trucks vary considerably; whereas a 4 cylinder-engined light pickup can achieve 28 mpg (8 L/100 km), a V8 full-size pickup with extended cabin only travels 13 mpg (US) (18 L/100 km) city and 15 mpg (US) (15 L/100 km) highway. The average fuel economy is higher in Europe due to the higher cost of fuel. In the UK, a gallon of gas without tax would cost USD1.97, but with taxes cost USD6.06 in 2005. The average cost in the United States was USD2.61. Consumers prefer 'muscle cars' but choose more fuel efficient ones when gas prices increase. European-built cars are generally more fuel-efficient than US vehicles. While Europe has many higher efficiency diesel cars, European gasoline vehicles are on average also more efficient than gasoline-powered vehicles in the USA. Most European vehicles cited in the CSI study run on diesel engines, which tend to achieve greater fuel efficiency than gas engines. Selling those cars in the United States is difficult because of emission standards, notes Walter McManus, a fuel economy expert at the University of Michigan Transportation Research Institute. 'For the most part, European diesels don't meet US emission standards', McManus said in 2007. Another reason why many European models are not marketed in the United States is that labor unions object to having the big 3 import any new foreign built models regardless of fuel economy while laying off workers at home. An example of European cars' capabilities of fuel economy is the microcar Smart Fortwo cdi, which can achieve up to 3.4 L/100 km (69.2 mpg_{-US}) using a turbocharged three-cylinder 41 bhp (30 kW) Diesel engine. The Fortwo is produced by Daimler AG and is currently only sold by one company in the United States. Furthermore, the current (and to date already 10-year-old) world record in fuel economy of production cars is held by the Volkswagen Group, with special production models (labeled '3L') of the Volkswagen Lupo and the Audi A2, consuming as little as 3 L/100 km (94 mpg_{-imp}; 78 mpg_{-US}). Diesel engines generally achieve greater fuel efficiency than petrol (gasoline) engines. Passenger car diesel engines have energy efficiency of up to 41% but more typically 30%, and petrol engines of up to 37.3%, but more typically 20%. That is one of the reasons why diesels have better fuel efficiency than equivalent petrol cars. A common margin is 25% more miles per gallon for an efficient turbodiesel. For example, the current model Skoda Octavia, using Volkswagen engines, has a combined European fuel efficiency of 41.3 mpg for the 105 bhp (78 kW) petrol engine and 52.3 mpg for the 105 bhp (78 kW) – and heavier – diesel engine. The higher compression ratio is helpful in raising the energy efficiency, but diesel fuel also contains approximately 10% more energy per unit volume than gasoline which contributes to the reduced fuel consumption for a given power output. In 2002, the United States had 85 174 776 trucks, and averaged 13.5 miles per US gallon (17.4 L/100 km; 16.2 mpg_{-imp}). Large trucks, over 33 000 pounds (15 000 kg), averaged 5.7 miles per US gallon (41 L/100 km; 6.8 mpg_{-imp}). The average economy of automobiles in the United States in 2002 was 22.0 miles per US gallon (10.7 L/100 km; 26.4 mpg_{-imp}). By 2010 this had increased to 23.0 miles per US gallon (10.2 L/100 km; 27.6 mpg_{-imp}). Average fuel economy in the United States gradually declined until 1973, when it reached a low of 13.4 miles per US gallon (17.6 L/100 km; 16.1 mpg_{-imp}) and gradually has increased since, as a result of higher fuel cost. A study indicates that a 10% increase in gas prices will eventually produce a 2.04% increase in fuel economy. One method by car makers to increase fuel efficiency is lightweighting in which lighter-weight materials are substituted in for improved engine performance and handling. Fuel Efficiency In Microgravity:- How fuel combusts affects how much energy is produced. The National Aeronautics and Space Administration (NASA) has investigated fuel consumption in microgravity. The common distribution of a flame under normal gravity conditions depends on convection, because soot tends to rise to the top of a flame, such as in a candle, making the flame yellow. In microgravity or zero gravity, such as an environment in outer space, convection no longer occurs, and the flame becomes spherical, with a tendency to become more blue and more efficient. There are several possible explanations for this difference, of which the most likely one given is the hypothesis that the temperature is evenly distributed enough that soot is not formed and complete combustion occurs, National Aeronautics and Space Administration, April 2005. Experiments by NASA in microgravity reveal that diffusion flames in microgravity allow more soot to be completely oxidised after they are produced than diffusion flames on Earth, because of a series of mechanisms that behaved differently in microgravity when compared to normal gravity conditions. LSP-1 experiment results, National Aeronautics and Space Administration, April 2005. Premixed flames in microgravity burn at a much slower rate and more efficiently than even a candle on Earth, and last much longer. Vehicle Efficiency And Transportation Pollution:- Fuel efficiency directly affects emissions causing pollution by affecting the amount of fuel used. However, it also depends on the fuel source used to drive the vehicle concerned. Cars for example, can run on a number of fuel types other than gasoline, such as natural gas, LPG or biofuel or electricity which creates various quantities of atmospheric pollution. A kilogram of carbon, whether contained in petrol, diesel, kerosene, or any other hydrocarbon fuel in a vehicle, leads to approximately 3.6 kg of CO_2 emissions. Due to the carbon content of gasoline, its combustion emits 2.3 kg/l (19.4 lb/US gal) of CO_2; since diesel fuel is more energy dense per unit volume, diesel emits 2.6 kg/l (22.2 lb/US gal). This figure is only the CO_2 emissions of the final fuel product and does not include additional CO_2 emissions created during the drilling, pumping, transportation and refining steps required to produce the fuel. Additional measures to reduce overall emission includes improvements to the efficiency of air conditioners, lights and tires. See also Miles Per Gallon. / процесса Хаба (Haber), называемого также процессом Хаба-Боша (Haber-Bosch process; в честь его изобретателей – Немецких химиков Фритца Хаба (Frits Haber; 1868–1934) и Карля Боша (Carl Bosch; 1874–1940)). Волтё МэкМэнас (Walter McManus). Смат Фотво (Smart Fortwo). Даймля А.Ге. (Daimler AG). Фольксвагэн Груп (Volkswagen Group), со специальными производственными моделями (этикетированными '3L') Фольксвагэн Люпо (Volkswagen Lupo) и Ауди А2 (Audi A2). Например, текущая модель Щкода Октавиа или Актэйвиа (Škoda Octavia), использующая двигатели Фольксвагэн (Volkswagen), имеет .

VEHICLE FUEL EXPENDITURES = ИЗДЕРЖКИ НА ТОПЛИВО ДЛЯ ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Fuel Expenditures:- the cost, including taxes, of the gasoline, gasohol, or diesel fuel added to the vehicle's tank. Expenditures do not include the cost of oil or other items that may have been purchased at the same time as the vehicle fuel.

VEHICLE FUEL TANK CAPACITY = ЁМКОСТЬ ТОПЛИВНОГО БАКА ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Fuel Tank Capacity:- the tank's unusable capacity (i.e. the volume of fuel left at the bottom of the tank when the vehicle's fuel pump can no longer draw fuel from the tank) plus its usable capacity (i.e. the volume of fuel that can be pumped into the tank through the filler pipe with the vehicle on a level surface and with the unusable capacity already in the tank). The term does not include the vapor volume of the tank (i.e. the space above the fuel tank filler neck) nor the volume of the fuel tank filler neck.

VEHICLE IDENTIFICATION NUMBER = ИДЕНТИФИКАЦИОННЫЙ НОМЕР ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Identification Number (VIN):- a set of codes, usually alphanumeric characters, assigned to a vehicle at the factory and inscribed on the vehicle. When decoded, the VIN provides vehicle characteristics. The VIN is used to help match vehicles to the US EPA (short for the Environmental Protection Agency) certification file for calculating MPGs (short for the miles per gallon). Vehicle Identification Number (VIN):- assigned by the manufacturer, this number is unique to each vehicle and appears on the vehicle's registration and title. Vehicle Identification Number (VIN) is a set of about 17 codes, combining letters and numbers, assigned to a vehicle at the factory and

inscribed on a small metal label attached to the dashboard and visible through the windshield. The VIN is a unique identifier for the vehicle and therefore is often found on insurance cards, vehicle registrations, vehicle titles, safety or emission certificates, insurance policies, and bills of sale. The coded information in the VIN describes characteristics of the vehicle such as engine size and weight.

VEHICLE IMPORTER = ИМПОРТЁР ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Importer is an original vehicle manufacturer (of foreign or domestic ownership) that imports vehicles as finished products into the United States.

VEHICLE IN USE = ТРАНСПОРТНОЕ СРЕДСТВО В ИСПОЛЬЗОВАНИИ (или XX) – Vehicle In Use:- all vehicles in the inventory that are permanently assigned to an agency or in paid seasonal storage.

VEHICLE–KILOMETER = ТРАНСПОРТНОЕ СРЕДСТВО–КИЛОМЕТР – (1) Vehicle-Kilometer is the unit of measurement representing the movement of a road motor vehicle over one kilometer. Context:- the distance to be considered is the distance actually run. It includes movements of empty road motor vehicles. Units made up of a tractor and a semi-trailer or a lorry and a trailer are counted as one vehicle.

(2) Vehicle-Kilometer (for inland waterways transport) is the unit of measurement of traffic representing the movement of an individual inland waterways transport (IWT) vessel or convoy over one kilometer. Context:- the distance taken into account is the distance actually run. Movements of unladen individual vessels or convoys are included. Vehicle Kilometer:- unit of measurement of traffic representing the movement of an individual Inland Waterways Transport (IWT) vessel or convoy over one kilometer.

VEHICLE MAINTENANCE = ТЕХНИЧЕСКОЕ ОБСЛУЖИВАНИЕ ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Maintenance:- all activities associated with revenue and non-revenue (service) vehicle maintenance, including administration, inspection and maintenance, and servicing (cleaning, fueling, etc) vehicles. In addition, it includes repairs due to vandalism, and accident repairs of revenue vehicles.

VEHICLE MAINTENANCE REPORTING STANDARDS = СТАНДАРТЫ ОТЧЁТНОСТИ ТЕХНИЧЕСКОГО ОБСЛУЖИВАНИЯ ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Maintenance Reporting Standards (VMRS) is a set of codes developed to facilitate computerized tracking of parts and labor used in equipment repair. Established and maintained by the American Trucking Associations.

VEHICLE MANEUVER = МАНЕВР ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Maneuver:- last action (maneuver) this vehicle's driver engaged in either (1) just prior to the impact or (2) just before the driver realized the impending danger. See also Crash, and Vehicle Role.

VEHICLE MILE OF TRAVEL = МИЛЯ ПРОБЕГА ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Mile Of Travel (VMT):- a unit to measure vehicle travel made by a private vehicle, such as an automobile, van, pickup truck, or motorcycle. Each mile traveled is counted as one vehicle mile regardless of the number of persons in the vehicle.

VEHICLE MILES = МИЛИ ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Miles are the miles of travel by all types of motor vehicles as determined by the States on the basis of actual traffic counts and established estimating procedures. Vehicle Miles:- the total number of miles traveled by transit vehicles. Commuter rail, heavy rail, and light rail report individual car miles rather than train miles for vehicle miles.

VEHICLE MILES OF TRAVEL = МИЛИ ПРОБЕГА ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Miles Of Travel (VMT):- the number of miles traveled nationally by vehicles for a period of 1 year. VMT is either calculated using 2 odometer readings or, for vehicles with less than 2 odometer readings, imputed using a regression estimate.

VEHICLE MILES OPERATED = МИЛИ ЭКСПЛУАТАЦИИ ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Miles Operated:- sum of all miles operated by passenger vehicles, including mileage when no passengers are carried. When vehicles are operated in trains, each vehicle is counted separately, e.g., an eight-vehicle train operating for one mile equals eight vehicle miles.

VEHICLE MILES TRAVELED = МИЛИ, ПРОЙДЕННЫЕ ТРАНСПОРТНЫМ СРЕДСТВОМ (или XX) – Vehicle Miles Traveled (VMT):- the number of miles traveled nationally by vehicles for a period of 1 year. VMT is either calculated using two odometer readings or, for vehicles with less than two odometer readings, imputed using a regression estimate. Vehicle-Miles Traveled (VMT):- one vehicle traveling the distance of one mile. Total vehicle miles, thus, is the total mileage traveled by all vehicles.

VEHICLE OCCUPANCY = ВМЕСТИМОСТЬ ПАССАЖИРОВ В ТРАНСПОРТНОМ СРЕДСТВЕ (или XX) – Vehicle Occupancy:- the number of persons, including driver and passenger(s) in a vehicle; also includes persons who did not complete a whole trip. Nationwide Personal Transportation Survey (NPTS) occupancy rates are generally calculated as person miles divided by vehicle miles. Vehicle Occupancy:- the number of people aboard a vehicle at a given time; also known as auto or automobile occupancy when the reference is to automobile travel only.

VEHICLE ON HAND = ТРАНСПОРТНОЕ СРЕДСТВО НА РУКАХ (или XX) – Vehicle On Hand:- all vehicles for which General Services Administration (GSA) has accountability.

VEHICLE OPERATIONS = ОПЕРАЦИИ ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Operations:- all activities associated with the subcategories of the vehicle operations function: transportation administration and support; revenue vehicle operation; ticketing and fare collection; and system security.

VEHICLE/PEDESTRIAN DEVIATION = ОТКЛОНЕНИЕ ТРАНСПОРТНОЕ СРЕДСТВО/ПЕШЕХОД (или XX) – Vehicle/Pedestrian Deviation (VPD):- an entry or movement on an airport movement area by a vehicle operator or pedestrian that has not been authorized by air traffic control (includes aircraft operated by a non-pilot). See also Operational Deviation, Operational Error, Pilot Deviation, and Runway Incursion.

VEHICLE REVENUE MILES/HOURS = ВЫРУЧКА МИЛИ/ЧАС ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Revenue Miles/Hours are the miles/hours a vehicle travels while in revenue service. A transit vehicle is in revenue service only when the vehicle is available to the public and there is a reasonable expectation of carrying passengers that either directly pay fares, are subsidized by public policy, or provide payment through some contractual arrangement. This does not imply that a cash fare must be paid. Vehicles operated in free fare service are considered in revenue service. Vehicle revenue miles/hours exclude travel to and from storage facilities, training operators prior to revenue service, road tests and deadhead travel, as well as school bus and charter services.

VEHICLE ROLE = РОЛЬ ТРАНСПОРТНОГО СРЕДСТВА (или XX) – Vehicle Role is a role of vehicle in single or multi-vehicle crashes, i.e. non-collision, striking, and struck. See also Crash, and Vehicle Maneuver.

VEHICLES AVAILABLE FOR MAXIMUM SERVICE = ТРАНСПОРТНЫЕ СРЕДСТВА ДОСТУПНЫЕ ДЛЯ МАКСИМАЛЬНОГО ОБСЛУЖИВАНИЯ (или XX) – Vehicles Available For Maximum Service:- the number of revenue vehicles available to meet the

annual maximum service requirements. This includes spares, out-of-service vehicles, and vehicles in or awaiting maintenance, but excludes vehicles awaiting sale and emergency contingency vehicles.

VEHICLES CURRENCY = ВАЛЮТА РАСЧЁТОВ (или СВЯЗУЮЩАЯ ВАЛЮТА, или ВАЛЮТА СРЕДСТВ, или КЛЮЧЕВАЯ ВАЛЮТА) – Vehicle Currency is a form of legal tender used in a cross border import or export. Transaction that is not the domestic money of the importer or the exporter. Many international transactions for goods and services use the US Dollar as the invoicing currency even if neither party is based in the United States, since most national currencies trade actively against the Dollar in the Forex market. Vehicles Currency is the currency used to invoice an international trade transaction, especially when it is not the national currency of either the importer or the exporter. / Ведущая Валюта:- валюта, используемая в международных операциях для котировок и платежей. В настоящее время чаще всего используют Доллар США.

VEHICLES IN TOTAL FLEET = ТРАНСПОРТНЫХ СРЕДСТВ ВО ВСЁМ ПАРКЕ (или XX) – Vehicles in Total Fleet:- all revenue vehicles held at the end of the fiscal year, including those in storage, emergency contingency and awaiting sale.

VEHICLES OPERATED IN MAXIMUM SERVICE = ТРАНСПОРТНЫЕ СРЕДСТВА ЭКСПЛУАТИРУЕМЫЕ В МАКСИМАЛЬНОМ ОБСЛУЖИВАНИИ (или XX) – Vehicles Operated In Maximum Service:- the number of revenue vehicles operated to meet annual maximum service requirements. This is the revenue vehicle count during the peak season of the year, on the week and day that maximum service is provided. Vehicles operated in maximum service exclude atypical days or one-time special events.

VEHICLE STOCK = ЗАПАС ТРАНСПОРТНЫХ СРЕДСТВ (или XX) – Vehicle Stock is the number of vehicles owned or used by a household for personal transportation. A vehicle is defined in terms of a 'Vehicle Year'. If a vehicle is present in a household for the entire year, it counted as one vehicle. If a vehicle is present in a household for one-half of the year, it is counted as only one-half of a vehicle. Therefore, the number of vehicles a sample household was considered as having during the year was computed as the days of possession summed over all vehicles in the household, divided by days in a year.

VEHICLE SYSTEMS INSTALLATION BOARD = ПАЛАТА ПО УСТАНОВКЕ СИСТЕМ ТРАНСПОРТНЫХ СРЕДСТВ (или XX) – Vehicle Systems Installation Board (VSIB) is a national (in the United Kingdom) regulatory and accreditation body for vehicle systems installers and their installations.

VEHICLE TRIP = ПОЕЗДКА ТРАНСПОРТНОГО СРЕДСТВА (или РЕЙС ТРАНСПОРТНОГО СРЕДСТВА) – Vehicle Trip is a trip by a single vehicle regardless of the number of persons in the vehicle.

VEHICLE TYPE = ТИП ТРАНСПОРТНОГО СРЕДСТВА – Vehicle Type:- a series of motor vehicle body types that have been grouped together because of their design similarities.

VEHICLE USED ON THE JOB = ТРАНСПОРТНОЕ СРЕДСТВО, ИСПОЛЬЗУЕМОЕ НА РАБОТЕ – Vehicle Used On The Job:- a vehicle used by anyone in the household for job-related activities, excluding commuting to and from work.

VEHICULAR SAFETY DEVICES = УСТРОЙСТВА БЕЗОПАСНОСТИ ТРАНСПОРТНОГО СРЕДСТВА – Vehicular Safety Devices are the seat belts, harnesses, inflatable cushions, and other devices designed to protect occupants of vehicles from injury in case of accident. A seat belt is a strap that fastens a rider to a moving vehicle and prevents him from being thrown out or against the interior of the vehicle during sudden stops. The first patent for a restraining belt designed to protect passengers in road vehicles was granted to Edward J. Claghorn (of New York, State of New York, the United States) in 1885. The first lap-type belt resembling the modern seat belt was a leather strap used on a United States Army airplane in 1910, and for the next 25 years seat belts were used primarily on aircraft. In the 1940s tests demonstrated that the severity of head injuries could be substantially reduced by holding the body in place with a seat belt, and some seat belts for automobiles were manufactured in the early 1950s. Common automobile restraint systems developed by the early 1970s were lap belts, anchored to the car underbody, to keep the rider from sliding forward; and shoulder harnesses, anchored to the car underbody and the roof rail, to keep the rider from jackknifing into the instrument panel. These fabric belts were provided with quick attach-and-release buckles and were able to withstand loads of 6 000 pounds (2 700 kilograms). Despite convincing evidence of the value of seat belts, however, motorists in all countries were apathetic, and only the passage of legislation caused seat belts to appear universally in automobiles. Even then, widespread failure by drivers and passengers to make use of the belts led to developmental work on passive-restraint systems. Passive-restraint devices protect drivers and passengers without any action on their part. Among those tested was the air bag, an inflatable pillow-like cushion stored in the instrument panel and triggered to inflate in a fraction of a second by the force of impact, cushioning and absorbing the energy of the rider and then deflating. Other important safety devices used on automobiles and other vehicles include safety glass, the newer types of which deflect without breaking under severe stress; improved door locks that keep doors closed under severe conditions; and collapsible steering columns that telescope under impact, absorbing energy. / Эдвод Дьжей. Клэгхон (Edward J. Claghorn).

VEIL = ВУАЛЬ – Veil is a length of cloth worn by women as a covering for the head and shoulders and often for the face; specifically, the outer covering of a nun's headdress; a length of veiling or netting worn over the head or face or attached for protection or ornament to a hat or headdress. Traditionally worn by brides at weddings. Example of veil used in conversation; 'By the way, my wife Bridget Marie, looked beautiful at our wedding. This was before and after she lifted her veil'. See also Voile. / Бридьжит Мори (Bridget Marie). Под Вуалью, от Французского слова Voile, означающее Завеса или Покрывало, понимается:- (1) гладкая тонкая прозрачная, вырабатываемая из шерстяной, хлопчатобумажной или шёлковой пряж, шерстяная, хлопчатобумажная или шёлковая ткань, из которой изготовляют платья, шарфы. Вуаль бывает белёная, крашеная и набивная, лицевая сторона ткани часто украшается вышитыми рисунками. Применяется главным образом для шитья дамских платьев. (2) прозрачная тонкая сетка, прикреплённая к женской шляпке и иногда закрывающая лицо.

VEILED WOOL = СМЫТАЯ (или СКРЫТАЯ, или ЗАМАСКИРОВАННАЯ) ШЕРСТЬ – Veiled Wool is the wool where the staple lengths have become disorganized and intermixed with each other. Veiled Wool has the fibers of the various staples stuck to each other.

VEILING = ВУАЛЬ (или ВЭЙЛИН, или ФАТИН, или ПРОЗРАЧНАЯ ЛЁГКАЯ ТКАНЬ ВУАЛЬ, или ЛЬНЯНАЯ ВУАЛЬ) – Veiling:- any of various light sheer fabrics. Veiling is a light gauzy fabric used for veils. / Прозрачная лёгкая ткань Вуаль полотняного или перевивочного переплетения. Под Вуалью, от Французского слова Voile, означающее Завеса или Покрывало, понимается:- (1) гладкая тонкая прозрачная, вырабатываемая из шерстяной, хлопчатобумажной или шёлковой пряж, шерстяная, хлопчатобумажная или шёлковая ткань, из которой изготовляют платья, шарфы. Вуаль бывает белёная, крашеная и набивная, лицевая сторона ткани часто украшается вышитыми рисунками. Применяется главным образом для шитья дамских платьев. (2) прозрачная тонкая сетка, прикреплённая к женской шляпке и иногда закрывающая лицо.

VEIN = ВЕНА – Vein:- in human physiology, any of the vessels that, with four exceptions, carry oxygen-depleted blood to the right upper chamber (atrium) of the heart. The four exceptions – the pulmonary veins – transport oxygenated blood from the lungs to the left

upper chamber of the heart. The oxygen-depleted blood transported by most veins is collected from the networks of microscopic vessels called Capillaries by thread-sized veins called Venules. As in the arteries, the walls of veins have three layers, or coats:- an inner layer, or tunica intima; a middle layer, or tunica media; and an outer layer, or tunica adventitia. Each coat has a number of sublayers. The tunica intima differs from the inner layer of an artery:- many veins, particularly in the arms and legs, have valves to prevent backflow of blood, and the elastic membrane lining the artery is absent in the vein, which consists primarily of endothelium and scant connective tissue. The tunica media, which in an artery is composed of muscle and elastic fibers, is thinner in a vein and contains less muscle and elastic tissue, and proportionately more collagen fibers (collagen, a fibrous protein, is the main supporting element in connective tissue). The outer layer (tunica adventitia) consists chiefly of connective tissue and is the thickest layer of the vein. As in arteries, there are tiny vessels called Vasa Vasorum that supply blood to the walls of the veins and other minute vessels that carry blood away. Veins are more numerous than arteries and have thinner walls owing to lower blood pressure. They tend to parallel the course of arteries. See also Artery; and Capillary. / Под Веной, от Латинского слова Vena, понимается кровеносный сосуд, несущий насыщенную углекислотой (венозную) кровь от органов и тканей к сердцу (исключая лёгочные и пупочную вены, которые несут артериальную кровь). Под Венами, от Латинского слова Vena, означающее Жила или Кровеносный Сосуд, понимаются сосуды, несущие кровь от органов и тканей к сердцу. Вены большого круга кровообращения (смотрите Сердце, Кровообращение) собирают кровь, насыщенную двуокисью углерода, продуктами обмена веществ, гормонами желёз внутренней секреции и другими веществами, от органов и частей тела и несут её в правое предсердие. Вены малого круга обеспечивают отток обогащённой кислородом крови из лёгких в левое предсердие. Через систему воротной вены осуществляется передача в общий кроветок пищевых веществ, всасывающихся в желудочно-кишечном тракте. Венозная система берёт начало от капиллярной сети. Здесь формируются венулы, при слиянии которых образуются вены. Стенка вен значительно тоньше и пластичнее, чем стенка артерий, мускулатура её развита относительно слабо; давление крови в венах очень мало, а в крупных венах – ниже атмосферного. На продвижение крови по венам большое влияние оказывают дыхательные движения грудной клетки (присасывающее действие), движения диафрагмы, на глубокие вены конечностей – мышечные сокращения. Клапаны вен, расположенные по току крови, пропускают кровь только к сердцу. Многочисленные нервные окончания в стенках некоторых крупных вен (верхняя и нижняя полые, воротная и другие вены) участвуют в регуляции кровообращения.

VEIN = ЖИЛА – Vein:- in geology, ore body that is disseminated within definite boundaries in unwanted rock or minerals (gangue). The term, as used by geologists, is nearly synonymous with the term lode, as used by miners. There are two distinct types:- fissure veins and ladder veins. Fissure veins, the earliest described bedrock deposits, occupy one or more fissures; they are tabular, with two dimensions much greater than the third. Fissure veins are formed in two stages, sometimes greatly separated in time; first the fissure is formed, and then it is filled with ore. There are several varieties:- simple, with relatively straight, parallel walls; chambered, with irregular, fragmented walls; dilation, or lenticular, with fat lenses in a string or roughly parallel in schists; sheeted, with several distinct, closely spaced, parallel fractures; and composite, with several roughly parallel fissures and connecting diagonals in partially replaced rock. Ladder veins are short, rather regularly spaced, roughly parallel fractures that traverse dikes (tabular bodies of igneous rocks) from wall to wall. Their width is restricted to the width of the dike, but they may extend great distances along it. Ladder veins are not as numerous or important as fissure veins. / Жила, минеральное тело, заполняющее трещину в горной породе. Простые жилы – одиночные минерализованные трещины; сложные – пучки переплетающихся трещин, зон дробления или рассланцевания. По деталям морфологии среди жил выделяются чётковидные, камерные, седловидные, лестничные и оперённые. Жилы, пересекающие слои вмещающих пород, называются секущими жилами; залегающие согласно с наслоением и падением вмещающих пород – пластовыми жилами. Длина жилы полезных ископаемых колеблется от 1 метра (м) и менее до 200 километров (км) (например, жилы золотых руд в Калифорнии). По падению некоторые жилы выклиниваются на близком расстоянии от земной поверхности, а другие, например, жила месторождения Колар в Индии, разрабатываются на глубине более 3 км. У жил различают геологическую и рабочую мощность (наименьшая величина мощности, при которой возможна эксплуатация жильного месторождения). Рабочая мощность жилы в зависимости от ценности слагающих их минералов колеблется от нескольких сантиметров до десятков метров.

VEIN = ЖИЛКА – Vein is a strand of vascular tissue in a flat organ such as a leaf. Veins are the small ribs or branches of the framework of leaves. / Под Жилками понимается:- (i) система проводящих пучков в листьях и других органах высших растений, исключая мхи; и (ii) у насекомых – полые трубчатые утолщения пластинки крыла, в которых расположены ответвления трахей и нервов; образуют каркас крыла. Расположение жилок (жилкование) – важный систематический признак. Жилки (‘нервы’) у Растений, сосудисто-волокнистые пучки в листовых пластинках, выполняющие проводящие и механические функции. Крупные жилки образованы несколькими сосудисто-волокнистыми пучками и нередко включают тяжи механических тканей и паренхиму; такие жилки обычно выступают в виде рёбер на нижней, а иногда и на верхней стороне листовой пластинки. Жилки видны также в лепестках и чашелистиках цветков, в плодах и в стеблях растений (смотрите Жилкование). У Насекомых – полые трубчатые склеротизованные утолщения пластинки крыла. После выхода взрослого насекомого из куколки или нимфы жилки наполняются гемолимфой, давление которой расправляет крыло. Различают продольные и поперечные жилки; система их обеспечивает прочность и аэродинамические свойства крыла.

VELCRO® = ЛИПУЧКА (или ВЭЛЬКРО®, или ВЭЛКРОУ®, или КОНТАКТНАЯ ЗАСТЁЖКА) – Velcro® is a trademark for a fastening tape consisting of a strip of nylon with a surface of minute hooks that fasten to a corresponding strip with a surface of uncut pile. Velcro® is the brand name of a type of fastening tape consisting of opposing pieces of fabric, one piece with a dense arrangement of tiny nylon hooks and the other with a dense nylon pile, that interlock when pressed together, used as a closure on garments, luggage, etc, in place of buttons, zippers, and the like. Velcro® is a burr-like fastening device with one side made of a velvet-like material and the other of small stiff hooks. This fastening can be used for clothing and home furnishing items. Velcro® is a Nylon material made with both a surface of tiny hooks and a complementary surface of an adhesive pile, used in matching strips that can be pressed together or pulled apart for easy fastening and unfastening. / Найлан™ (Nylon™). Под Вэлькро®, от Французских слов Велюр (Velour), означающее Бархат, и Крошэ (Crochet), означающее Крючок, понимается . Во всем мире застёжка липучка известна как Вэлькро. У нас застёжку де Местраля называют липучкой, а официальное Русское название – Тканевая Застёжка. Липучка или Вэлькро® – застёжка, действующая по принципу репейника. Изобретена в 1948 Швейцарским инженером по имени Жёрж дё Местраль (George de Mestral). Является удачным примером биомиметики. Другие названия:- ворсистая молния, ворсовка, текстильная застёжка, лента вэлкроу®, лента вэлькро®, контактная лента, липучка. Англоязычный вариант – Hook & Loop. Разновидность застёжки, представляет собой пару текстильных лент, на одной из которых размещены микрокрючки, на другой – войлок. При соприкосновении двух лент микрокрючки зацепляются за войлок, и одна лента ‘прилипает’ к другой, за что застёжка и получила название ‘липучки’. Застёжка широко применяемая в швейной и обувной промышленности, и для специальных изделий. Velcro® – зарегистрированный товарный знак во многих странах. Интересные Факты:- на Международной Космической Станции вэлкро используется для крепления предметов к стенам. В Российском

сегменте ворсистой частью липучки оклеены все стены. А на инструменты, карандаши, прочие предметы лепится крючковатая часть со специальной липкой подложкой. Велкро – контактная тесьма-застёжка ‘репейник’.

VELDA SUE = VENTURE ENHANCEMENT & LOAN DEVELOPMENT ADMINISTRATION FOR SMALLER UNDERCAPITALIZED ENTERPRISES

VELIGER = ВЕЛИГЕР (или ПАРУСНИК) – Veliger:- larva typical of certain mollusks such as marine snails and bivalves. The veliger develops from trochophore larva and has large, ciliated lobes (velum) that form from the ciliary ring (prototroch) characteristic of the trochophore stage. The velum, used in swimming and feeding, generally disappears in the adult. During the veliger stage, the mollusk begins to develop a foot and shell. / Под Велигером, от Латинских слов Velum, означающее Парус, и Gero, означающее Несу, понимается подобная трохофоре (смотрите Трохофора) личинка многих морских моллюсков (из пресноводных – только Дрейссены). Велигер имеет ‘ногу’, кишечник, глаза, органы равновесия (статоцисты), а также эмбриональную раковину (протоконх), в которую в случае опасности втягивается передняя часть тела, и Велум (Velum) – одну, две или несколько сложно рассечённых лопастей, покрытых ресничками и служащих для движения и захвата пищи. Некоторые Велигеры долго удерживаются в толще воды и за несколько недель преодолевают с течением Атлантический Океан. После оседания Велигера на дно происходит превращение его во взрослого моллюска. Велигер или Парусник, пелагическая личинка многих морских брюхоногих и двустворчатых моллюсков (из пресноводных – лишь у Дрейсен). У одних видов моллюсков Велигер выходит из яйца, у других проходит стадию трохофоры. Имеет велум, ногу, кишечник, глаза, органы равновесия (статоцисты), раковинную железу, выделяющую вещество личиночной раковины (протоконха), в которую может втягиваться передняя часть тела и другие органы и их системы. Некоторые Велигеры долго плавают в толще воды, часто переносятся течением на большие расстояния. После оседания на дно Велигер превращается во взрослого моллюска.

VELOCITY = СКОРОСТЬ – (1) Velocity:- quantity that designates how fast and in what direction a point is moving. Because it has direction as well as magnitude, velocity is known as a Vector Quantity and cannot be specified completely by a number, as can be done with time or length, which are scalar quantities. Like all vectors, velocity is represented graphically by a directed line segment (arrow) the length of which is proportional to its magnitude. A point always moves in a direction that is tangent to its path; for a circular path, for example, its direction at any instant is perpendicular to a line from the point to the center of the circle (a radius). The magnitude of the velocity (i.e. the speed) is the time rate at which the point is moving along its path. If a point moves a certain distance along its path in a given time interval, its average speed during the interval is equal to the distance moved divided by the time taken. A train that travels 100 km in 2 hours, for example, has an average speed of 50 km per hour. During the two-hour interval, the speed of the train in the previous example may have varied considerably around the average. The speed of a point at any instant may be approximated by finding the average speed for a short time interval including the instant in question. The differential calculus, which was invented by Isaac Newton for this specific purpose, provides means for determining exact values of the instantaneous velocity. / Айзэком Ньютчэном (или Исааком Ньютоном; Isaac Newton) . Скорость в механике, одна из основных кинематических характеристик движения точки, равная численно при равномерном движении отношению пройденного пути s к промежутку времени t, за который этот путь пройден, то есть $v = s / t$. В общем случае $v = ds / dt$, а как вектор $v = dr / dt$, где r – радиус-вектор точки. Направлен вектор скорости по касательной к траектории точки. Если движение точки задано уравнениями, выражающими зависимость её декартовых координат x, y, z от времени t, то:- $v = \sqrt{(v^2_x + v^2_y + v^2_z)}$, где $v_x = dx / dt$, $v_y = dy / dt$, $v_z = dz / dt$, а косинусы углов, которые вектор скорости образует с координатными осями, равны соответственно v_x / v, v_y / v, v_z / v.

(2) Velocity is the rate at which money balances turn over in a period for expenditures on goods and services (often measured as the ratio of gross national product (GNP) to the money stock). A larger velocity means that a given quantity of money is associated with a greater Dollar volume of transactions. Velocity (of money) is the average number of times a measure of money (as captured, for instance, by a monetary aggregate) turns over within a specified period of time. The income velocity of circulation is typically calculated as the ratio of a monetary aggregate to nominal gross domestic product (GDP). / Скорость (Обращения):- среднее число оборотов, совершаемое денежной единицей (включённой, например, в денежный агрегат) в течение определённого периода времени. Скорость обращения денежной массы обычно рассчитывается как отношение номинального ВВП к денежному агрегату.

VELOCITY LOGIC = СКОРОСТНАЯ ЛОГИКА (или ЛОГИКА СКОРОСТИ) – Velocity Logic (at CME GROUP) monitors potential significant price movements in extremely small time increments on CME Globex. It works in conjunction with price banding to preserve the integrity of our markets. Whereas price banding monitors futures price movements that would go too far, velocity logic monitors futures price movements that would go too far, too fast. It’s calculated using the highest and lowest prices within a predetermined lookback window. If a velocity logic violation occurs, the futures market is temporarily suspended, as are all associated options markets. See also Circuit Breaker, Price Banding, and Price Limits.

VELOCITY OF CIRCULATION = СКОРОСТЬ ОБРАЩЕНИЯ – Velocity Of Circulation is the number of times a Dollar is spent, or turns over, in a specific period of time. Velocity affects the amount of economic activity generated by a given money supply. Velocity Of Circulation is a rate at which money and money substitutes, such as checks, are transferred from one holder to the next. Velocity Of Circulation is the average number of times a unit of money is used in a given time, esp calculated as the ratio of the total money spent in that time to the total amount of money in circulation. Velocity Of Circulation is the average number of times a unit of money changes hands in an economy during a given period – normally measured by dividing the total amount spent (GDP) by the amount of money available (money supply). Velocity Of Circulation is the amount of units of money circulated in the economy during a given period of time. Velocity of circulation is measured by dividing Gross Domestic Product (GDP) by the country’s total money supply. A high velocity of circulation in a country indicates a high degree of inflation. It helps in determining how vigorous a country’s economy is. / Скорость, с которой деньги и заменители денег, такие как чеки, переходят от одного держателя другому. Скорость Обращения:- средний показатель использования денежной единицы за определённый период, приблизительно равный всей сумме денег, потраченных за этот период, делённой на величину денежной массы в обращении. Скорость Обращения Денег В Кругообороте Доходов (Income Velocity Of Circulation) показывает, сколько раз определённая единица денег составляет часть личного дохода в течение определённого периода. Она вычисляется отношением валового национального продукта (ВВП; gross national product (GNP)) к денежной массе в обращении. Понятие Скорость Заключения Сделок (Transactions Velocity Of Circulation) обозначает, сколько раз определённая денежная единица используется в передаче денег за определённый период, то есть отношение всей суммы денег, потраченных в процессе продажи товаров и услуг, к денежной массе в обращении. Скорость Обращения:- темп, которым денежная масса расходуется на потребление в течение определённого периода времени, обычно года. Скорость Обращения (Velocity) денег – скорость расходования денежной массы, означающая сколько раз один Доллар расходуется за данный период времени. Понятие ‘доходной скорости обращения денег’ (income velocity of money) было впервые объяснено Американским экономистом Овином Фишёром (Irving Fisher) в 1920-х. Он считал, что скорость обращения денег имеет прямое отношение к валовому национальному продукту (ВНП; gross domestic product (GDP)). ВНП является результатом роста денежной массы (money supply) и зависит от скорости обращения денег. Скорость

обращения денег влияет на уровень экономической активности, порождаемой ростом денежной массы. Денежная масса состоит из банковских вкладов и наличных средств, находящихся в обращении. Скорость обращения денег является одним из факторов кредитно-финансовой политики (monetary policy), Совета Управляющих Федеральной Резервной Системы США, поскольку увеличение скорости обращения денег может исключить необходимость стимулирующего увеличения денежной массы. И наоборот, снижение скорости обращения денег отражает замедление экономического роста, даже если объём денежной массы остаётся постоянным. Смотрите также Фискальная Политика (Fiscal Policy).

VELOCITY OF MONEY = СКОРОСТЬ ДЕНЕГ – Velocity Of Money:- Simply defined the velocity of money is the turnover in the money supply. A shop owner can measure how fast his inventory is selling by calculating 'inventory turnover'. To do that he simply calculates Total Sales ÷ Average Inventory for the period in question. But if you expand the idea of turnover to the entire country you get the 'Velocity of Money'. 'Strictly speaking all the velocity of money tells us is how long people hold onto their money. But from that we can infer their motives and perceptions of the economy in general ....' Velocity of Money Calculation:- To Calculate the Velocity of Money you simply divide Gross Domestic Product (GDP) which is the total of everything sold in the country by the Money Supply. Thus Velocity of Money = GDP ÷ Money Supply. Now there is some debate about the proper measurement of the money supply. The most most restrictive measure of money supply is M1 which basically includes short term money, i.e. money that is available immediately. So that would be cash and checking accounts, NOW accounts and demand deposits, i.e. money you can get your hands on immediately. There is a good argument that this is the best measure of velocity of money because you want to look for an increase in the cash people are looking to hold. If people are fearful of the economy they want to hold Cash or cash equivalents. They aren't going to put money in a CD or long term holding. They want it readily available. So that if they lose their job or run into a credit crunch they will have the cash they need to continue living their lives. In the chart below we see the velocity of money using the M1 money supply. The grey shaded areas are official recessions and you can see that during these periods the velocity of money is shrinking. Interestingly during those periods GDP and the money supply itself can also be shrinking. The GDP of course might shrink because demand for goods decreases due to people holding onto their money longer. But as people default on their debts or pay them off the money supply itself might shrink but that would probably be longer term money rather than M1 so that is another reason why using M1 might be the best indicator. Back in April of 2010, I wrote Velocity of Money and Money Multiplier – Why Deflation Is Possible? During that time we were at the bottom of the slide in the velocity of money chart and leaving the official recession and entering into a slight increase in the velocity of money. But as you can see from the chart from the St. Louis Federal Reserve Bank the velocity of money has been falling again, indicating that we may never have left the recession or if we did, it is possibly resuming again. What Does the Velocity of Money Tell Us? Strictly speaking all the velocity of money tells us is how long people actually hold onto their money. But from that we can infer their motives and perceptions of their personal finances and on a broader scale the economy in general. If people are fearful for their jobs they will want to hold more cash and thus the velocity of money will fall. If on the other hand, they feel 'flush with cash' they will spend it faster. But there are other reasons people spend cash quickly. The primary one is that they fear inflation. So rather than feeling rich, a high velocity may also indicate a fear of the value of their money depreciating quickly. A perfect example of this would be during the Hyperinflation in Weimar Germany between 1921 and 1923. During this time inflation got so bad that people would pay for their meal before the meal because if they waited until the end it would cost more. This is the ultimate in money velocity where people rush out to spend the money because holding it for a few minutes longer might cause it to lose additional value. What Can We Tell From the Current Falling Velocity of Money? First of all, we can tell that the economy is not rebounding. In 2009 the velocity of money picked up a little bit. People were convinced that the recession was over and the economy would improve and so they began to spend a little bit more. This could have been the result of the QE1 stimulus. Not much in exchange for a Trillion Dollars worth of debt. But the current fall indicates that people are not convinced that the recession is over and that they would once again rather hold cash than spend it. It also indicates that people are not afraid of inflation, at least in the short term they still want to hold onto their cash. A similar idea in business is called Inventory Turnover Ratio.

VELOCITY PRESSURE = СКОРОСТНОЙ НАПОР (или ДАВЛЕНИЕ СКОРОСТИ, или ДИНАМИЧЕСКОЕ ДАВЛЕНИЕ) – Velocity Pressure is the measure of the kinetic energy of a fluid. In a moving fluid, Velocity Pressure (VP) is the pressure that would induce an equivalent velocity if applied to move the same fluid through an orifice, so that all pressure energy is converted into kinetic energy. It is used in air conditioning, heating and ventilating work to determine air velocity. / Под Напором в гидравлике, понимается линейная величина, выражающая удельную (отнесённую к единице веса) энергию потока жидкости в данной точке. Полный запас удельной энергии потока H (полный напор) определяется Уравнением Бернулли (выведено в 1738):- $H = z + (p_v / \gamma) + (v^2 / 2g)$, где z – высота рассматриваемой точки над плоскостью отсчёта, pv – давление жидкости, текущей со скоростью v, γ – удельный вес жидкости, g – ускорение силы тяжести. Два первых слагаемых трёхчлена определяют собой сумму удельных потенциальных энергий положения (z) и давления (pv / γ), то есть полный запас удельной потенциальной энергии, называется Гидростатическим Напором, а третье слагаемое – удельную кинетическую энергию (Скоростной Напор). Вдоль потока напор уменьшается. Разность напора в двух поперечных сечениях потока реальной жидкости H1 - H2 = hv называется Потерянным Напором. При движении вязкой жидкости по трубам потерянный напор вычисляется по формуле Дарси (смотрите Гидродинамическое Сопротивление). При проектировании гидротехнических сооружений расчётный напор выбирается в соответствии с поставленной задачей. Например, для плотин напором, действующим со стороны верхнего бьефа, будет глубина воды в верхнем бьефе. В задачах по истечению жидкости или газов из отверстий за действующий напор принимают глубину погружения так называемого центра тяжести площади отверстия (при истечении жидкости) или перепад давлений (при истечении газа). В гидроэлектростанциях (ГЭС) различают напор брутто (разность отметок верхнего и нижнего бьефов) и напор нетто, равный напору брутто за вычетом потерь напора на гидравлическое сопротивление.

VELOCITY RATIO = СООТНОШЕНИЕ СО СКОРОСТЬЮ (или СКОРОСТНОЕ СООТНОШЕНИЕ) – The Velocity Ratio is the ratio of the volume of the transactions to the number of shares of the stock. It is measured daily and averaged over a 12-month period preceding the review of the Conseil Scientifique. See also CAC 40®.

VELOCITY SHOP = МАГАЗИН СКОРОСТИ (или МАГАЗИН ОБОРАЧИВАЕМОСТИ) – Velocity Shop:- xxxxx. / Магазин Для Ускорения:- техника ипотечного кредитора, предусматривающая продажу большинства своих закладных на рынки вторичного кредитования таким образом, чтобы он мог быстро обернуть средства и использовать их для создания новых закладных.

VELOUR = ВЕЛЮР – Velour is:- (1) generally, a soft, closely woven fabric with a short, thick pile, weighting about 10 to 20 ounces per yard and made in a plain or satin weave. Velour is usually made of cotton or wool, or with a cotton warp in wool, silk, or mohair velour. It is also made in blends of spun manufactured fiber and wool. Velours are used for coats, draperies, upholstery, powder puffs, and other pile items. (2) A felt with velvet-like texture used for men's and women's hats. Velour is a medium weight, closely woven fabric with a thick pile. It can be made using either a plain weave or a satin weave construction. It resembles velvet, but has a lower cut pile. End uses include apparel, upholstery, and drapes. Velour is a knit fabric, allowing it to stretch. It combines the stretchy properties of knits, such as spandex, with the rich appearance and feel of velvet. It is used in dancewear for the ease of movement it affords, and is also popular for warm, colorful, casual clothing. When used as an upholstery, velour often is substituted for velvet. Plush velour seats

are an option on many luxury vehicles. Velour is also widely used in the manufacture of theater drapes and stage curtains. See also Velure. Velour is a knit or woven fabric with a thick, short pile. Every velour cloth has cut loops to produce the velour effect. [t also has a rich look, but is not as effective in drying as conventional terry cloth. It may also be spelled velours. Velour is an article of clothing made of velour, namely a fabric with a pile or napped surface resembling velvet. Any of various fabrics with a pile or napped surface resembling velvet used in heavy weights for upholstery and curtains and in lighter weights for clothing. The pile is characterized by uneven lengths (usually two) which gives it a rough look. The two lengths of pile create light and shaded areas on the surface. A rather pebbled effect. This type of velour was invented and made in Lyons, France, in 1844. 'Velours' is the French term for velvet. 'Cotton velour' is simply cotton velvet. / плотнотканая ткань с коротким, . Puff = Буф или Вставка или Клин. Велюр – тяжёлый бархат. Под Велюром, от Французского слова Velours, означающее Бархат, понимается название тканей, кожи и других материалов, имеющих мягкую ворсовую бархатистую лицевую поверхность, например, велюр-бархат, велюр-драп и тому подобное. Применяют для изготовления верхней одежды, головных уборов и другого. Под Велюром, от Французского слова Velours, означающее Бархат, от Латинского слова Villosus, означающее Волосатый или Мохнатый, понимается:- (1) чистошерстяная ворсованная ткань из пряжи суконного прядения или фетр с низким, очень густым и мягким ворсом, придающим красивый вид изделиям (верхняя одежда, головные уборы). Одна из самых ценных велюровых тканей – драп-велюр, для изготовления которого используют лучшие сорта мериносовой шерсти. (2) Велюр (или Хромовая Замша) – кожа хромового дубления, выработанная из плотных мелких шкур рогатого скота или свиней с повреждённой лицевой поверхностью и отделанная со стороны бахтармы под бархат. При изготовлении велюра для дубления или поддубливания применяют циркониевые или титановые соли, благодаря воздействию которых кожа при шлифовании после дубления приобретает хорошую ворсистость (смотрите Выделанная Кожа). При производстве велюра используют также наполнители:- альбумины, крахмалы, растительные клеи. Для придания велюру водостойкости его обрабатывают алюминиевыми или хромовыми мылами, силиконом. Используют велюр преимущественно для производства верхней одежды и обуви.

VELURE = ВЕЛЮР (или БАРХАТ, или ВЕЛЬВЕТ) – Velure:- (obsolete) velvet or a substance resembling it; a hatter's ad of velvet, plush, or the like for smoothing or dressing silk hats; also a fabric resembling velvet. Origin of Velure:- 1580–90, by alteration Middle French Velour, from Old French Velous, from Late Latin Villosus, Shaggy from Villus, Shaggy Hair. See also Velour, Velvet, and Velveteen. / Под Велюром, от Французского слова Velours, означающее Бархат, от Латинского слова Villosus, означающее Волосатый или Мохнатый, понимается:- (1) чистошерстяная ворсованная ткань из пряжи суконного прядения или фетр с низким, очень густым и мягким ворсом, придающим красивый вид изделиям (верхняя одежда, головные уборы). Одна из самых ценных велюровых тканей – драп-велюр, для изготовления которого используют лучшие сорта мериносовой шерсти. (2) Велюр (или Хромовая Замша) – кожа хромового дубления, выработанная из плотных мелких шкур рогатого скота или свиней с повреждённой лицевой поверхностью и отделанная со стороны бахтармы под бархат. При изготовлении велюра для дубления или поддубливания применяют циркониевые или титановые соли, благодаря воздействию которых кожа при шлифовании после дубления приобретает хорошую ворсистость (смотрите Выделанная Кожа). При производстве велюра используют также наполнители:- альбумины, крахмалы, растительные клеи. Для придания велюру водостойкости его обрабатывают алюминиевыми или хромовыми мылами, силиконом. Используют велюр преимущественно для производства верхней одежды и обуви.

VELUTINOUS = БАРХАТИСТОЕ (или ХХ) – Velutinous:- velvety.

VELVET = БАРХАТ (или ВЕЛЬВЕТ) – Velvet fabric is a warp-pile woven fabric with short, dense cut pile that produces a rich fabric appearance and soft texture. Two methods are used for weaving velvets. In the double-cloth method, two fabrics are woven face to face with the pile ends interlocking. A reciprocating knife cuts through these pile ends to produce two separate pieces of velvet. In the second method, pile ends are lifted over cutting wires that are inserted with the filling and that are withdrawn to cut the pile. Velvet is produced in a wide range of constructions and types. Originally made of silk, but now also of cotton or manufactured fibers giving fabrics that are sometimes washable. The fabric can be specially finished to make it crush-resistant and water-repellent or it may be embossed or patterned by burn-out printing. See also Corduroy. Velvet is a medium weight cut-pile constructed fabric in which the cut pile stands up very straight. It is woven using two sets of warp yarns; the extra set creates the pile. Velvet, a luxurious fabric, is commonly made with a filament fiber for high luster and smooth hand. Velvet is a fabric with a short and closely woven nap. The production of velvet varies between two methods. One uses a double-cloth construction in which two shifts of fabric are woven with long threads joining them together. After the double fabric is woven, the center threads are cut, producing two pieces of velvet. The second method of producing velvet uses wires. During the weaving the yarn is lifted over the wires to form the pile. After removing the wires the yarn is cut to form the velvet surface. While velvet was originally made of silk, today many other fibers are used to manufacure velvet, e.g., rayon or nylon. Velvet is a type of tufted fabric in which the cut threads are very evenly distributed, with a short dense pile, giving it a distinct feel. Velvet can be made from many different kinds of fibers, however, it is ideally made from silk. It is woven on a special loom that weaves two pieces of velvet at the same time; it is difficult to clean and usually has to be dry-cleaned. Velvet:- silk, rayon, cotton, synthetics, and a little wool and worsted. Pile, made with an extra warp yarn. Mostly made with a plain back but some with a twill. Some are made with a silk pile and a rayon or cotton back. Terms comes from the Latin 'Vellus', meaning a fleece or tufted hair. Comes in many types, qualities, and weights. Good velvet wears fairly well and is inexpensive. The cheaper cloths give little service and look well only a few times before beginning to deteriorate. Better velvet may be crush resistant, water resistant, and drapes well. Has to be handled with care, and pressed on a velvet board. Cut all one way. For the maximum amount of depth in the color, cut with the pile running up. It also wears better when cut this way. Velvet should be cut with very simple lines in the garment, so not to destroy the beauty of the fabric. It has the tendency to add weight to the figure. Velvet:- in textiles, fabric having a short, dense pile, used in clothing and upholstery. The term derives from the Middle French Velu, 'Shaggy'. Velvet is made in the pile weave, of silk, cotton, or synthetic fibers, and is characterized by a soft, downy surface formed by clipped yarns. The wrong side of the fabric is smooth and shows the weave employed. Velvets can be made water-repellent and crush-resistant. They are also occasionally patterned or embossed. / уточина. Найлан^{T3} (Nylon^{TM}). Под Бархатом понимается шёлковая или хлопчатобумажная ткань с мягким густым вертикальным ворсом (1.5–2 миллиметров (мм)) на лицевой стороне. Применяется для пошива женского платья, отделки, декоративных целей. Бархат, ткань с плотным вертикальным коротким (1–2 мм) ворсом на лицевой стороне, образованным дополнительной основой из натурального шёлка или химического волокна. Грунтовые нити основы или утка обычно хлопчатобумажные, реже – из пряденого шёлка. Основный бархат с высоким ворсом называется Плюшем. Вырабатывается также уточный бархат, называемый Полубархатом, Плисом или Вельветом. Бархат выпускается разнообразных расцветок. Применяется для пошивки платьев, детских костюмов, отделки, декоративных целей. Бархат – ворсовая ткань с мягкой пушистой лицевой поверхностью, полученной введением кроме основы и утка специальной ворсовой ткани (ворсовой основы). Основой для ворса, определяющей сорт бархата, могут служить шёлк, хлопок (полубархат) и шерсть. Ворсовую нить при прядении вытягивают при помощи специальных металлических прутков так, чтобы она образовывала на лицевой стороне петли. Если эти петли разрезались, бархат получал название разрезного, если нет – неразрезного, или петельчатого. Техника изготовления бархата была изобретена в Китае, в Европе стала известна в конце XIII

века. В России первая шёлковая мануфактура, изготавливавшая и бархат, была организована в 1717. Наиболее дорогими считались сорта шёлкового бархата, отличавшиеся от других низким ворсом. Бархат на шерстяной и хлопковой основе появился в XVII веке. Название сорта бархата определяет место или технологию изготовления. Под Вельветом или Вельветином понимается плотная хлопчатобумажная или синтетическая ткань, имеющая на лицевой поверхности продольные рубчики из уточного ворса (вельвет-корд – широкие, вельвет-рубчик – узкие). Из вельвета шьют костюмы, куртки и тому подобное. Под Вельветом или Вельветином, от Английского слова Velvet, означающее Бархат, понимается плотная ворсовая ткань с хлопчатобумажным ворсом (уточным), вырабатываемая из сравнительно тонкой пряжи. Лучшим сортом вельвета является вельвет-корд, имеющий на лицевой стороне вдоль основы ворсовые рубчики. Обычно вельвет выпускается однотонным или набивным с рисунком в виде клеток, полосок и тому подобного. Из вельвета шьют костюмы, зимние платья, куртки и другое; иногда вельвет заменяет шерстяную ткань.

VELVET CARPET = БАРХАТНЫЙ КОВЁР – Velvet Carpet is a woven carpet in which the pile ends are lifted over wires that are inserted in the same manner as the filling and that cut the pile as they are withdrawn. / уточина.

VELVETEEN = ВЕЛЬВЕТИН – Velveteen:- in textiles, fabric with a short, dense pile surface and a smooth back, usually made of cotton and resembling velvet. It is made by the filling-pile method, in which the plain or twill weave is used as a base and extra fillings are floated over four or five warps. After weaving, the floats are cut, and their ends are brushed up to form a smooth pile about one-eighth inch long. The fabric back is smooth and shows the basic weave. Velveteen has more body and is less easily draped than velvet. It imparts warmth and is used for women's and children's garments and also for draperies and bedspreads. See also Velvet. Velveteen is a fabric with a low filling pile made by cutting an extra set of filling yarns woven in a float formation and bound to the back of the material at intervals by weaving over and under one or more warp ends. Velveteen is a clothing fabric usually of cotton in twill or plain weaves made a short close weft pile in imitation of velvet. Woven with a extra filling yarn with either a plain or a twill back (twill back is the best). Warp yarns 80/inch – weft ranges from 175 to 600 depending on the desired density of the pile. Mercerized with a durable finish. Strong and takes hard wear. Poor quality rubs off. Some of it can be laundered. It is warm. Comes in all colors, gradually piece dyed or may be printed. Has to be cut all one way. Press carefully, preferably on a velvet board, or tumble dry after laundering (no pressing needed). Velveteens:- clothing made of velveteen, namely a clothing fabric usually of cotton in twill or plain weaves made a short close weft pile in imitation of velvet. Velveteens, also termed Fustians and Velverets are cotton cloth made in imitation of velvet. They are heavy cotton fabrics in which the distinguishing effect is formed by the points of the fibers in the filling yarns, termed the pile, being presented to the vision, and not the sides of the yarns as in the majority of fabrics. They are principally used for dress and hat trimmings, suitings, and upholstery, having exceptional wearing qualities and showing a full, deep color. Corduroys are sometimes termed velveteens, the same principle of construction being adopted in both fabrics, but a corduroy is distinguished by having a corded stripe effect running lengthways of the piece, the dividing line between each stripe showing both warp and filling. In the simplest type of velveteens the pile filling, after being cut, hides the warp entirely from the face. To accomplish this the goods are made with a comparatively small number of ends and large number of picks per inch. A fairly heavy loom is necessary. Figures 1 and 2 illustrate two methods of arranging the whip rolls and yarn when weaving some of the heavier picked goods. In each figure A represents the warp beam and B the whip rolls. The dotted line indicates the direction of the yarn. The goods are usually woven two or more widths in the loom, with split selvedges. In order that the fabric may remain firm after the pile picks are cut, ground or binder picks are inserted regularly, working either plain or twill as may be desired. The filling for these picks is similar to that used for the pile, only one shuttle being used. Purposes:- for dress and trimming purposes velveteens are usually of a solid color, being piece dyed. For upholstery purposes the goods are dyed, printed, embossed or stamped. Panel and stripe patterns are also made by cutting a raised figure on an uncut ground, or vice versa, by painting or by the pyrogravure process, burning. When stamping velveteens the goods are passed between two cylinders. The upper cylinder is of iron and is heated from the inside. The pattern is engraved or sunk into this. The lower cylinder is of hard wood. The pile is compressed by the projecting part of the upper cylinder, causing the pattern to stand out in relief from a dull ground, of vice versa. Velveteen is a cotton cut-pile weave fabric, utilizing extra fill yarn construction, with either a twill or a plain weave back. The fabric is woven with two sets of filling yarns; the extra set creates the pile. Velveteen is a cotton cloth made in imitation of velvet. The term is sometimes applied to a mixture of silk and cotton. Some velveteens are a kind of fustian, having a rib of velvet pile alternating with a plain depression. It is lightweight and does not have the sheen and drape of velvet. It is not appropriate for upholstery, but can be used to make skirts, tops and fuller pants. / уточина. Fustians = Бумазеи; Фланели; С Уточным Ворсом. Под Вельветом или Вельветином понимается плотная хлопчатобумажная или синтетическая ткань, имеющая на лицевой поверхности продольные рубчики из уточного ворса (вельвет-корд – широкие, вельвет-рубчик – узкие). Из вельвета шьют костюмы, куртки и тому подобное. Под Вельветоном понимается гладкокрашеная плотная ткань с мягким густым начёсанным ворсом на лицевой стороне. Применяют главным образом для пошива спортивных костюмов. Вельветон или 'обезьянья кожа' – прочная, ветронепроницаемая хлопчатобумажная ткань, из которой обычно шьют спортивную одежду. Имеет бархатистую поверхность, с лицевой стороны начёсанный, заглаженный ворс. Напоминает замшу.

VELVET GRASS = БУХАРНИК (или БУХАРНИК ШЕРСТИСТЫЙ) – Velvet Grass:- also called Yorkshire Fog (Species Holcus Lanatus) one of eight perennial grasses constituting the Genus Holcus (Family Poaceae), native to Europe and Africa. It has tufted flower clusters that may be white, green, pink, or purple. Velvet grass, so called because the entire plant has a velvety feel when touched, was introduced into Australia and North America as a forage species. It now grows as a weed in damp places such as ditches, stream banks, and drainage areas. / Бухарник (Holcus), Род Растений Семейства Злаков. Двуцветковые колоски собраны в большие или малые густые метельчатые соцветия; один цветок обоеполый, безостый, второй – тычиночный, с остью. 8 Видов произрастает в Евразии и Северной Африке (включая Канарские Острова) и 1 Вид – в Южной Африке (Капская область). В бывшем Союзе Советских Социалистических Республик (СССР) – 3 Вида. Наиболее часто встречается по сухим лугам и склонам Бухарник Шерстистый (Holcus Lanatus) – в центральной, Западной и Южной областях Европейской части и на Кавказе. По сухим лугам и кустарникам растёт Бухарник Мягкий (Holcus Molfis), главным образом, в Западных областях Европейской части. Оба вида – многолетники. На прибрежных песках Талыша (Кавказ) встречается однолетний Бухарник Щетинистый (Holcus Setosus). Бухарник даёт много зелёной массы, но при поедании в большом количестве причиняет вред скоту из-за сильной опушённости. Бухарник содержит гликозид, при разложении которого образуются ядовитые вещества.

VELVETLEAF = БАРХАТОЛИСТНИК (или ЛИМНОХАРИС) – Velvetleaf:- any of various plants with soft, velvety leaves, particularly Abutilon Theophrasti (sometimes Abutilon Avicennae), commonly known as Indian Mallow, an annual, hairy plant of the Mallow Family (Malvaceae). Native to southern Asia, Abutilon Theophrasti is cultivated in northern China for its fiber and is widely naturalized in warmer regions of North America, where it is often a weed. It grows 0.6–2.4 meters (2–8 feet) tall and has heart-shaped leaves and beaked seed pods. Velvetleaf is a Eurasian plant of the Mallow Family, with large heart-shaped velvety leaves and yellow flowers. It is naturalized in North America, where it has become a serious weed of farmland. / Канатник (или Абутилон) Теофраста (Abutilon Theophrasti).

VELVET RUG = БАРХАТНЫЙ КОВРИК – Velvet Rug is a floor covering woven on a plain harness loom with cut pile. It has solid color or printed pile.

VELVET SATIN = БАРХАТНЫЙ АТЛАС – Velvet Satin:- a satin weave is used as the base for this luxurious figured silk, made with a cut pile effect. See also Satin.

VEN = VENEZUELA

VENATION = ЖИЛКОВАНИЕ (или 'НЕРВАЦИЯ') – Venation is:- (i) the arrangement of veins in a leaf; or (ii) in an insect's wing; the system of venous blood vessels in an animal. Venation is the arrangement of veins within a structure. Venation is the distribution or arrangement of a system of veins, as in an insect's wing or a leaf blade. Patterns of venation in insect wings are often used to identify and differentiate species. In angiosperm plants, the venation of eudicot and magnoliid leaves is generally netted or reticulate, with smaller veins branching out from larger ones in a pinnate or palmate pattern, while that of monocots is parallel, with many veins of similar size running parallel to each other along the length of the plant part. These parallel veins are connected to each other by much smaller cross veins. / Жилкование – это расположение жилок внутри структуры – важный систематический признак. Жилкование листьев:- (1) дихотомическое, (2) дугонервное, (3) пальчатонервное, (4) параллельнонервное, (5) перистонервное, и (6) перистопараллельное. Жилкование или 'Нервация' Листьев, характер распределения жилок в листовых пластинках. Различают 4 основных типа:- (1) одна или несколько продольных жилок не ветвятся и не соединяются перемычками (у многих Хвойных); (2) ответвления жилок, не соединяясь перемычками, достигают краёв листа (у большинства Папоротников); жилкование нередко вильчатое (смотрите Дихотомия); (3) жилки идут вдоль листа почти параллельно (у многих Злаков с линейными листьями) или в виде дуг, сближенных у основания и у верхушки пластинки (у Ландыша), и соединены тонкими поперечными перемычками; жилкование этого типа (параллельно-нервное и дугонервное) характерно для большинства Однодольных, но имеется и у некоторых Двудольных с линейными листьями; (4) от одной или нескольких крупных продольных жилок 1-го порядка отходят более мелкие жилки 2-го порядка, дающие ещё более мелкие ответвления 3-го порядка и так далее. Жилки соединяются перемычками в разных направлениях. Вся основная ткань листа разделена на участки, окружённые мелкими жилками; внутрь этих участков проникают мельчайшие ответвления проводящей системы, заканчивающиеся слепо (перистое, или сетчатонервное, жилкование). Этот тип жилкования характерен для большинства Двудольных, но встречается и у некоторых Однодольных (у Канн, Арендных и других). Жилкование называется пальчатонервным, если несколько жилок (одна главная более толстая) лучеобразно расходятся от основания пластинки. Наиболее древнее и примитивное – дихотомическое жилкование. Изучение и описание жилкования имеет большое значение при определении по листьям как современных, так и ископаемых растений (в виде отпечатков и тому подобноrь). У Насекомых – тип расположения жилок в крыле. Число и расположение жилок – важный систематический признак, характеризующий отряды, семейства и другой систематической категории Насекомых. Особенно велико значение жилкования в систематике ископаемых форм.

VENDEE = ВЭНДИ (или ПРИОБРЕТАТЕЛЬ) – Vendee is a buyer or purchaser; an individual to whom anything is transferred by a sale. The term Vendee is ordinarily used in reference to a buyer of real property. Vendee is a buyer, particularly of real property. Vendee is one who purchases something. See also Purchaser, and Vendor. Vendee is the person to whom a thing is sold. Vendee is a purchaser or buyer; one to whom anything is sold. Generally used of the transferee of real property, one who acquires chattels by sale being called a Buyer. Vendens eandem rem duobus falsarius est. He is fraudulent who sells the same thing twice. / Покупатель.

VENDING MACHINE = ПРОДАЮЩАЯ МАШИНА (или ПРОДАЮЩИЙ АВТОМАТ) – Vending Machine:- coin-actuated machine through which various goods may be retailed. Vending machines should not be confused with coin-operated amusement games or music machines. The first known commercial use of vending machines came early in the XVIII century in England, where coin-actuated 'honour boxes' were used to sell snuff and tobacco. These devices were also in use in the British-American colonies later in the century. The first practical, commercial use of vending machines took place in the United States in 1888, when machines were used to expand the sales of chewing gum into places where gum sales otherwise could not be made, specifically the platforms of the New York City elevated railway. The American industry was limited mainly to penny-candy vending until 1926, when the modern era of automatic selling opened with the appearance of cigarette vending machines. The first soft-drink machine followed in 1937. As the United States began its defense buildup prior to its entry into World War II, plant managements estimated that people could not work efficiently for 10, 12, or more hours without a refreshment break, and vending machines proved the most practical way of providing refreshments. During the 1940s and '50s the vending machine business was concentrated in plants and factories, and by the end of that period, machines were being used to sell a wide variety of freshly prepared as well as prepackaged foods to replace or supplement traditional in-plant food service facilities. Refrigeration was added to vending machines to sell bottled soft drinks. The ability of vending machines to sell products at competitive prices around the clock without regard to holidays is now widely recognized. The business has grown beyond plants and factories, and machines are commonly used in schools, colleges and universities, recreation centers, health care facilities, offices, and the like. Typically, vending service is provided by companies (operators) who own and place machines on premises owned by others. These companies provide complete maintenance and service, as well as products, usually without any cost to the owners of the premises other than perhaps a servicing charge. Vending machines have been used in Great Britain, continental Europe, and Scandinavia since the 1880s, when they were employed to sell confectionery and tobacco products. In recent years, the vending machine business in those countries has closely paralleled the expansion of vending in the United States. Vending in Japan began in earnest in the 1960s and developed rapidly into a major factor in that country's distribution system.

VENDOR = ВЭНДО (или РАЗРАБОТЧИК, или ПОСТАВЩИК, или ПРОДАВЕЦ) – Vendor is a legal entity that promotes or exchanges goods or services for money. Vendor is a person selling goods. Vendor is a purveyor of goods or services. All of the entities in a supply chain that leads up to the final delivery of goods or services to a customer are considered vendors. Also known as Seller or Supplier. Vendor is the external supplier of merchandise. A Vendor, or a supplier, is a supply chain management term meaning anyone who provides goods or services to a company. A vendor often manufactures inventoriable items, and sells those items to a customer. The term Vendor originally represented property vendors. However, today it means a supplier of any good or service. A vendor, or a supplier, is a supply chain management term that means anyone who provides goods or services to a company or individuals. A vendor often manufactures inventoriable items, and sells those items to a customer. Typically vendors are tracked in either a finance system or a warehouse management system. Vendors are often managed with a vendor compliance checklist or vendor quality audits. Purchase orders are usually used as a contractual agreement with vendors to buy goods or services. Vendors may or may not function as distributors of goods. They may or may not function as manufacturers of goods. If vendors are also manufacturers, they may either build to stock or build to order. 'Vendor' is often a generic term, used for suppliers of industries from retail sales to manufacturers to city organizations. 'Vendor' generally applies only to the immediate vendor, or the organization that is paid for the goods, rather than to the original manufacturer or the organization performing the service if it is different from the immediate supplier. Vendor is the seller. Vendor:- (1) A seller or supplier of goods or services. (2) In the State's (Florida) Project Aspire, a Vendor is what many State Agencies

currently call a payee. Vendor is a firm or individual that supplies goods or services. / Поставщик или Продавец:- лицо, которое продаёт товары или услуги. Продавец или Поставщик или Уличный Торговец:- (1) Торговый посредник – поставщик товаров и услуг; им может быть производитель, импортёр или оптовый распространитель. Например, одним из компонентов индекса ведущих показателей (leading indicators) является объём торговли посредников, под которым понимается скорость поставки товаров коммерческим клиентам. (2) Розничный торговец – продавец, торгующий в розницу, в частности продавец, не имеющий постоянного места торговли, как уличный торговец (sidewalk vendor).

VENDOR CHARGE BACK = ВОЗВРАТ СБОРА РАЗРАБОТЧИКУ (или ВОЗВРАТ СБОРА ПОСТАВЩИКУ) – Vendor Charge Back is an amount charged back to the vendor for repair fees incurred while servicing products under warranty. Vendor Charge Backs are either deducted as an accounts payable credit or applied as an accounts receivable debit to be paid by factory check.

VENDOR FINANCING = ФИНАНСИРОВАНИЕ РАЗРАБОТЧИКОМ (или ФИНАНСИРОВАНИЕ ПОСТАВЩИКОМ) – Vendor Financing is the lending of money by a company to its customers so that the customers can in turn purchase products from the company. The company is basically increasing its sales by basically buying its own products.

VENDOR INVOICE = СЧЁТ–ФАКТУРА РАЗРАБОТЧИКА (или СЧЁТ–ФАКТУРА ПОСТАВЩИКА) – Vendor Invoice is a document listing the amounts owed to a supplier by the recipient. When a customer orders goods and services on credit, the supplier prepares an invoice and issues it to the customer. This vendor invoice contains not only a listing of the amounts owed, but also any sales taxes and freight charges, as well as the date by which payment should be made, and where to send payment. Upon receipt, the customer enters the invoice into its accounting software, and schedules it for payment. No vendor invoice is issued if a customer pays in cash; in this case, a receipt is prepared for the customer, or an invoice that is stamped 'paid'.

VENDOR–MANAGED INVENTORY = УПРАВЛЯЕМЫЕ РАЗРАБОТЧИКОМ ЗАПАСЫ – Vendor-Managed Inventory:- in a 3PL, this describes the instance of a client (vendor) controlling the inventory at the 3PL warehouse. This type of inventory control can be managed in multiple ways including a periodic physical check of inventory by the vendor in order to determine what needs to be supplied to the warehouse. The vendor can also have remote access to the warehouse's inventory control system (MRP) and order based on the levels of supply and demand visible electronically. Vendor Managed Inventories (VMI):- a customer service strategy used to manage inventory of customers to lower cost and improve service. Vendor Managed Inventory (VMI) is a process in which a supplier generates orders for its distributor based on demand information sent by the distributor. Vendor Managed Inventory was first applied to the grocery industry, between companies like Procter & Gamble (supplier) and Wal-Mart (distributor). But increasingly, Vendor Managed Inventory is providing the benefits of smoother demand, increased sales, lower inventories and reduced costs to other industries. / Xxxxx (Procter & Gamble) (поставщик) и Xxxxx (Wal-Mart).

VENDOR PLACING = РАЗМЕЩЕНИЕ РАЗРАБОТЧИКА (или РАЗМЕЩЕНИЕ ПОСТАВЩИКА) – In the United Kingdom, Vendor Placing is a method of using shares to fund an acquisition by allotting shares in the purchaser to the vendors in exchange for shares in the target (or other assets) so falling within the exemption to the Companies Act 2006 pre-emption rights requirements for issues other than cash (section 565). The consideration shares are then placed on behalf of the vendors by the purchaser's bank so that the vendors will receive cash (the proceeds of sale of shares by the purchaser's bank). A clawback (normally by open offer although it can theoretically be done by a vendor rights issue) is usually offered to the purchaser's shareholders if the new shares represent more than 10% of the company's existing issued share capital or are issued at more than a 5% discount. Vendor Placing is a situation in which a company buys a business by making shares available to raise money to pay for the business:- The group is raising £5.3m through a vendor placing of shares at 174p. Vendor Placing is a type of placing used as a means of acquiring another company or business. For example, if company X wishes to buy a business from company Y, it issues company X shares to company Y as payment with the prearranged agreement that these shares are then placed with investors in exchange for cash. Vendor placings have been popular with some companies as a cheaper alternative to a rights issue. See also Bought Deal. Vendor Placing is a sale of shares by a company, done in order to provide the finance which will allow it to buy all or part of another company. / Размещение Поставщика:- выпуск новых акций для финансирования поглощения. Разновидность размещения новых ценных бумаг, выпущенных для финансирования поглощения компании или предприятия. Например, если компания X намерена купить предприятие, принадлежащее компании Y, она выпускает новые акции и передаёт их компании Y в качестве платы за предприятие с условием, что впоследствии компания X разместит эти акции среди инвесторов за наличные деньги. Выпуск новых акций для финансирования поглощения был до недавнего времени весьма популярен среди компаний, так как он является более дешёвой альтернативой выпуску обыкновенных акций для размещения среди уже существующих акционеров (rights issue). Смотрите также Купленная Сделка (Bought Deal).

VENDOR STATEMENT = ЗАЯВЛЕНИЕ РАЗРАБОТЧИКА (или ЗАЯВЛЕНИЕ ПОСТАВЩИКА) – Vendor Statement is a statement by the seller to the buyer detailing material particulars regarding the property in question (suitability for intended use).

VENEER = ШПОН – Veneer is the extremely thin sheet of rich-colored wood (such as Mahogany, Ebony, or Rosewood) or precious materials (such as ivory or tortoiseshell) cut in decorative patterns and applied to the surface area of a piece of furniture. It is to be distinguished from two allied processes:- inlay, in which cutout pieces of decorative wood or other materials – such as metal, leather, or mother-of-pearl – are inset into cavities cut into the main structure of the piece being decorated; and marquetry, or boulle work, which is a more elaborate kind of complex veneering. There are two main types of veneering, the simplest being that in which a single sheet, chosen for its interesting grain (yew or purple wood, for example), is applied to a whole surface of inferior wood in one unit. In the more complex variation called Crossbanding, small pieces of veneer wood are fitted together within a surrounding framework in such a way that the grain changes pattern, thus altering the tone according to the light. This process can produce complex fan shapes, sunbursts, and floral patterns. When the veneers are made up of small pieces cut from the same larger piece of wood and affixed so that their grain runs in opposite directions in accordance with a formal geometric pattern, the process is known as Parquetry. Veneering allows the use of beautiful woods that because of limited availability, small size, or difficulty in working cannot be used in solid form for making furniture. In addition, it significantly increases the strength of the wood by backing it with a sturdier wood and, through the process of laminating veneers at right angles in successive layers, offsets the cross-grain weakness of the wood. Modern veneering, which uses special glues and drying and testing equipment, produces a strong and beautiful product. Basically, the process involved in making all veneers is the same. First, the decorative wood is sawn, sliced, shaved, or peeled, sometimes by a rotary machine, into pieces between 1/16 and 1/32 inch in thickness. Then the veneer is glued to a prepared, coarser wood and secured by the application of mahogany, zinc, or cardboard presses; for curved and intricately shaped surfaces, molded sandbags are used. Early hand-cut veneers were thicker than the later machine-sawn product; although they were seldom less than 1/8 inch in thickness, they were cut by hand to 1/10 inch in XVI-century southern Europe. Although the craft of veneering was practiced in classical antiquity, its use lapsed during the Middle Ages. It was revived in the XVII century, reaching its apogee in France and spreading from there to other European countries. Because of their preference for ebony, the French masters of the craft of veneering were known as Ébénistes, although they later combined veneering with technical variations such as marquetry. By the end of the XVII century, woods such as almondwood,

boxwood, cherry wood, and pearwood were used. The considerable craftsmanship involved in the artistic use of veneers is most evident in the XVIII and early XIX centuries, when Chippendale, Hepplewhite, and Sheraton used mahogany and satinwood veneers. Later, exotic woods, various metals, and animal materials such as tortoiseshell – which was also popular with XVII-century Flemish craftsmen – were in vogue. By the mid-XIX century, with the introduction of mechanical saws, the veneering process was sometimes used in mass production to cover defects in cheap pine or poplar furniture. / Эбениста (Ébénistes). Под Шпоном, от Немецкого слова Span или Spon, означающее Подкладка или Щепка, понимается древесный материал в виде тонких листов древесины, получаемый лущением коротких брёвен (чураков) на лущильных станках (лущёный шпон), строганием брусков на шпонострогальных станках (строганый шпон), пилением на фанеропильных станках или горизонтальных лесопильных рамах (пилёный шпон). Пилёный Шпон (толщина 1–10 миллиметров (мм)), вырабатываемый из древесины Ели, Кавказской Пихты и Сибирского Кедра, отличается наиболее высоким качеством и используется для изготовления дек струнных музыкальных инструментов. Производство пилёного шпона связано с большими потерями древесины на опилки (полезный выход шпона из сырья не превышает 40%). Лущёный Шпон (0.1–10 мм) вырабатывают из древесины Берёзы, Бука, Дуба, Ели, Ольхи, Осины, Сосны и других пород; это наиболее массовая разновидность шпона, широко используемая для изготовления фанеры, фанерных плит, древеснослоистых пластиков и других видов слоистой клеёной древесины, для фанерования деталей и узлов столярных изделий, в спичечном производстве (спички, спичечные коробки), для изготовления сепараторов свинцовых электрических аккумуляторов и прочего. Строганый Шпон (0.2–5 мм) вырабатывают из древесины Акации, Бука, Дуба, Ильма, Каштана, Ореха, Тисса, Ясеня, Карельской Берёзы, красного Дерева и других ценных пород, обладающих красивой текстурой древесины. Декоративный эффект текстуры, получаемый на разных разрезах древесины, определяет выбор направления строгания при изготовлении шпона; различают радиальный, радиально-тангентальный, тангентальный и тангентально-торцовый строганый шпон. Для обеспечения подбора шпона по цвету и текстуре последовательно состроганные с одного бруса листы укладывают и упаковывают в пачки (кноли) в порядке строгания. Строганый шпон применяют для фанерования столярных изделий. Возрастающая дефицитность ценных пород древесины и трудность искусственного воспроизведения их текстуры, равноценной по декоративному эффекту натуральной древесине, делают особенно перспективными развитие производства тонкого и ультратонкого (0.08–0.15 мм) шпона ценных пород и облагораживание природной текстуры древесины рядовых пород специальными видами обработки (наклонное к продольной оси ствола строгание, волнистое строгание и лущение, коническое лущение и другие).

VENETIAN = ВЕНЕЦИАНСКОЕ – Venetian:- worsted, wool worsted and wool, cotton. 5 shaft satin, some in small repeat twill weaves, in cotton, 8 shaft satin (warp face). 2 ply warp and single filling. Clear finish. Has a very good luster finish which resembles satin. Some has a slight nap. Wears well – similar cloth has worsted warp and woolen filling. In a good quality used for expensive suits for women and sports jackets for men. Also used for fine coatings for both men and women. In cotton, it resembles very heavy sateen and is used mostly for lining. / основа и уточина.

VENETIAN BLINDS = ВЕНЕЦИАНСКИЕ ШТОРЫ – Venetian Blinds:- one of the most popular window coverings to control light and privacy. Venetian blinds are made of strips of fabric, metal, or plastic. These strips can be tipped to shut out light completely or opened to varying degrees to filter light to the desired intensity. They can also be raised to the top of the window to bare it completely. Conventional Venetians hang with the slats or strips horizontal to the windowsill, but vertical Venetians are also available and often are used as room dividers as well as window coverings. Venetians are available in various colors and widths.

VENETIAN LACE = ВЕНЕЦИАНСКОЕ КРУЖЕВО – Venetian Lace is an ancient tradition especially in the small lagoon island of Burano and is recognized as an art. There are two different lace-making techniques:- (i) the needle technique, which has only survived in the lagoon area on the island of Burano producing top quality artistic lace, and (ii) the bobbin technique that developed in the city of Venice and other islands in the lagoon. The first technique has its roots in embroidery and involves just a needle and thread without any fabric, hence its evocative name 'Punto In Aria' (literally, Air Stitching), while the second uses a 'Tombolo', a cylindrical cloth-stuffed cushion. Venetian lace was appeared in XVI century in the middle of the Italian Rinascimento, a period of artistic and cultural awakening. It was immediately highly appreciated in Europe to the point that it became as important an export as Murano glass, contributing significantly to the Republic's economy. Even during the XVII and XVIII centuries Venetian lace creations continued to much sought after. Chronicles of the time illustrate how successful and popular Venetian lace was, especially among aristocrats who could afford it:- an English nobleman paid 250 Hungarian Denars in 1638 for a Venetian lace collar to be worn at the coronation of the Sun King Louis XIV of France, while the Emperor Joseph II of Austria spent 3 000 Florins for Venetian needle-lace to decorate his wedding bed. During the 1700s, foreign competition (especially cheap French lace) led to a sharp fall in output and the decline of the lace industry on Burano. This became a major crisis after the French Revolution, when the wearing of lace was banned in the name of equality and the monasteries and convents (places of production par excellence), were abolished. Then, in the 1800s machinery industrialised lace production. The art of lace-making in Venice only picked up again in 1872 when a professional school was set up by the Countess Adriana Marcello in order to revive the great traditions of Venice. The Burano school was finally closed in 1973, but the building now houses a museum (established 1981) with displays of the old tools and equipment used for sewing and lace-making, plus various examples of lace through the ages. Today original Venetian lace (especially that of Burano) is still made by hand, much appreciated and demands a high price. In order to preserve the perfection with which some masterpieces are still made and counter the perennial crisis in the lace industry, the Region of Veneto has decided to open a professional college on Burano, 130 years after the first school was established there. The aim is protect a tradition and an art that form an important part of Venice's rich cultural heritage. See also Venice Lace, and Venise Lace. / Ёзэф (Joseph). Адриана Марчэлло (Adriana Marcello).

VENEZUELAN BOLIVAR = ВЕНЕСУЭЛЬСКИЙ БОЛИВАР – Venezuelan Bolivar (VEF) is the three-letter currency ISO code representing the currency of Venezuela which is commonly known as the Bolivar.

VENICE LACE = ВЕНЕЦИАНСКОЕ КРУЖЕВО – Venice Lace:- Venice was the center of fashion for the courts of Europe in the middle ages. Not only did Venice supply silks, satins and laces together with many other luxury articles, but it also decreed their mode of use. France and England were the largest markets. Catherine de Medici took with her to France collars of rich point lace. Their popularity was immediate. There is little doubt that to Venice belongs the honour of introducing the invention of needle-made laces into Europe, and it is likely that the Italians learned the rudiments of the art from the Saracens who had settled in Sicily. At the coronation of Richard III, in England, 'fringe of Venice and mantle laces of white silk and Venice gold' appear; and later Elizabeth of York pays sundry sums of money for 'gold of Venice, and other necessaries'. Varieties of Venitian Lace:- the point-laces (punti di merletti) to which all authors give the name of Venetian are the following:- (i) Punto a Reticello:- net lace or Greek lace; (ii) Punto Tagliato:- cut lace; (iii) Punto Tagliato a Fogliami:- executed like Punto in Aria, but enriched by the outlines being in relief by means of padding threads. Sometimes this most complicated of all point laces is worked in double and triple relief, and exquisite stitches in infinite variety are introduced into the flowers:- this is the Rose or Raised Venice Point, the Gros Point de Venise, the Punto a Rilievo so much sought after, so highly prized. This lace is sometimes made in silk, such as purple, yellow, or cream; the designs are conventionalised scrolls and flowers. Though the Punto Tagliato a. Fogliami is more celebrated than any other lace made in Venice, it did not appear until all

the arts of Venice were on the decline, at the end of the XVII century. (iv) Punto in Aria:- open lace or guipure, worked on a parchment pattern without mesh net-work ground, the sections of the design connected by bridges or bars. (v) Punto di Venetia:- Venice Point. Venetian Needlepoint and Burano Lace:- according to Molmenti, lace-making was always at Venice a private enterprise, unlike the great State-protected industries, such as the glass manufactures at Murano. A great quantity of cutwork was made in the houses of the nobility for their own use, and in the convents. Viena Vendramin Nani, to whom Vecellio dedicated his book in 1591, was accustomed to make lace, and to employ the young women of her household in this 'virtuous exercise'. Cutwork, as in France and England, was originally 'greatly accepted of by ladies and gentlemen', and 'consequently of the common people'. The art spread downwards geometrical-patterned lace continued to be freely made for ornamenting linen for household purposes until the XVIII century, but in the 'La Vie Privee a Venise'. The 'Corona delle nobili et virtuose donne' (1592). I Morosini Grimani, wife of the Doge Marino Grimani, set up at her own expense a workshop, in which were employed 130 workwomen under the direction of a mistra (maestra), Cattarina Gardin, who worked exclusively for the Dogaressa. Pattern and Ornament:- in the last years of the sixteenth curved forms were introduced, and a new type of lace developed. In the early XVII century floral and human forms were often treated. The specimens with figures and animals are curious rather than beautiful. A type of lace of scroll design in flat needlepoint, recalling by its lightness very fine metal work or the arabesques of Persian ornament, is very interesting and well designed. In this type is a rosette-like or many-lobed flower, and the interlacing ribbon-like scrolls which show the influence of Oriental art. The solid part of the pattern is, in many cases, outlined by a slightly raised rib or edge, which also models portions of the ornament. The edge is also enriched by short picots, and the design is frequently united by short brides, either ornamented or varied by a single picot. Punto in Aria:- there is no distinguishing name for this rare and beautiful type of lace. It is, strictly speaking, lace punto in aria, but the needle-point laces which were produced in the XVII and XVIII centuries were virtually all comprised under the general name of punto in aria, for in 1616, 1633, and 1634, the Proveditori alle Pompe forbade the wearing of 'punto in aere da Venezia', under penalty of a fine of two hundred ducats for each offence. The term is an unfortunate one, as it was also applied to a stitch in embroidery, 'the high raised stitch', and continued to be applied to every kind of Venetian needlepoint lace, Marini quotes from a document of the XVII century, in which punti in aria appears to have been an alternative name for Burano lace. Rose Point:- Rose point differs from punto in aria in three important details: in the highly conventional character of its design, its relief, and the elaboration of its brides. The design of the heavier rose points is almost invariably a foliated scroll, with an ornamental flower based upon the pomegranate, but much conventionalised. A natural pomegranate appears in many specimens of late punto in aria, but the fruit, as it appears in rose point, is hardly recognisable. This conventional treatment of natural forms is a prominent feature of Italian design, as compared with the more naturalistic art of France, Flanders, and England. Figures and natural objects are rarely introduced even in ecclesiastical lace. A specimen of rose point, however, illustrated in Elise Ricci's 'Antiche trine Italiane', shows a ship in sail containing three figures; and in a piece belonging to Mr John Hungerford Pollen is represented the Madonna crowned and seated on clouds, with her foot on the neck of a cherub, and attired in a robe sprinkled with stars. Above are the Three Persons of the Trinity. Part of the robes are worked in open stitch, small black beads are added to the eyes. Mr Samuel Chick, again, has an altar border, the central portion of which contains emblems of the Passion. In the middle is our Lord's face upon a cushion wearing the crown of thorns, and surmounted by a halo; underneath are the dice, pincers, flagellum, and hammer, to the right the flogging-post and ladder, to the left the cross, spear, and sponge on a reed. At the top are the crown of thorns and nails. This piece was at one time the property of Mary of Orleans, Queen of Saxony, grand-daughter of Charles I. of England. In one unique collar mythological subjects are either outlined by pin-holes or distinguished from the background by a closer stitch upon the flat toile in irregular-shaped compartments. In a triangular piece in the possession of Mr Sydney Vacher stags and other conventionalised animals are introduced. Such specimens, however, were no doubt experimental in design, and are not often met with. The second point in which rose point differs from punto in aria is in its relief. In rose point, besides the raised edge which it has in common with some specimens of flat Venetian, higher relief is given by laying down a pad of coarse threads, varying according to the amount of relief it was desired to obtain, and covering this layer of thread by close button-hole stitches. This thick sheaf of threads takes naturally an unbroken curve, and to this may be attributed the almost invariably rounded and lobed forms of the ornament. This pad is often ornamented with a close fringe of picots, or by an ornament of free loops tier upon tier – ornamented with picots. No open spaces or jours are introduced into the toile, which is of an even and close button-hole stitch, varied by very small pin-holes arranged in lines or veins, or in simple chequer, chevron, or diamond diaper patterns, subordinated to the general effect of the design. In a specimen in the possession of Mr. Sydney Vacher the pin-holes form a date. The design is connected by a groundwork of brides, which have been already noticed in flat Venetian. The brides, simple in the heavy points, become highly ornamented in the finest specimens, and in point de neige are ornamented not only with picots, but with picoted circles and semicircles, and S-shapes, and star devices. Sometimes the brides are single – sometimes two or three meet together. In some specimens of rose point, however, the pattern is not strengthened on the edge by outer cordonnets of button-hole stitched work. In three square inches of a very fine specimen of rose point the following varieties of brides are to be found. The foot of this bride Occasionally there is a ground of cross-barring or trellis-pattern, the effect of which is a very open square mesh, ornamented at the points of section and in the center of each side with an ornamented device or loop. In certain late specimens the brides form a slightly irregular hexagonal mesh, richly picote. This mesh is never, as in Argentan, a perfect hexagon, but is richer in effect, owing to this slight irregularity and to the enrichment of the picots, than the plain Argentan mesh. The raised points are divided into gros point de Venise, punto neve (point de neige) with its ground of ornamented starred brides resembling snowflakes, and coraline point. Gros point de Venise, which was elaborated from 1620–50, and which was designed to lie flat and ungathered, is distinguished by the continuity of its designs, which are mostly horizontal; its scrolls are heavier than in point de neige, the brides simpler and less ornamental, the border or edge is usually straight – a single line of button-hole stitched thread enriched here and there with semicircles picote. In point de neige, which was to hang fully or to be gathered, and which was in vogue from circa 1650–1720, the style is modified; the designs are composed on a smaller scale, and the groundwork of brides becomes a more important element, the scrolls are no longer continuous; detached sprays, consisting of slender leaves and minute renderings of the flowers of gros point, covered with a profusion of flying loops which almost hide the form it enriches, spring from a vase-like ornament and are arranged in many specimens symmetrically on either side of a vertical line. This change was probably owing to French influence. is also ornamented with a small circle picote. Coraline point is a very attenuated variety of rose point in which relief is almost entirely absent, the leaves of the scroll have entirely disappeared, leaving a winding tangle of narrow coral-like ramifications ending in a small unimportant flower. The ground is of brides picotees arranged in hexagonal meshes. Point plat de Venise is similar in design to rose point, but, as its name implies, is entirely without relief. The diaper and chequer pin-hole patterns are more freely used than in rose point, but the general appearance is that of unfinished rose point. It is to be borne in mind that much of this lace was the produce of private individuals, or of convents outside Italy, and similar designs were often interchanged; but with the exception of such private or conventual manufactures of lace, it is highly improbable that point d'Espagne or Spanish joint, a term applied to a heavier make of Venetian rose joint, was ever made in Spain. The heavy and valuable point laces which unexpectedly came out of Spain after the dissolution of the monasteries in 1830, were in no way distinguishable from similar pieces known to be of Venetian workmanship, and it was no doubt from the great lace-making countries of Flanders and Italy that these valuable laces were brought. From the unfinished piece of lace, made in the XVIII century, at Freiburg, it will be seen that elaborate needle-point of typically Italian design was occasionally made outside Venice by private workers. In point de Venise a reseau, a delicate type of Venetian needle-point, the design,

unlike that of rose point which rarely varies from its variations on its highly ornamental flower, shows conventional tulips and pomegranates. This type of lace is chiefly distinguished by the conventional treatment and arrangement of the ornament, and by the general flat look of the work, by the outlining thicker thread or cordonnet stitched to the edges of the pattern and worked in flatly, by a minute border to the cordonnet of small meshes which intervenes between it and the reseau, and by the horizontal appearance of the reseau, which is of square meshes composed of double-twisted threads throughout, and very fine. The pomegranate motif, so frequent in heavy rose point, reappears; but the crest of the fruit is elaborated into a scrolling leaf. In other specimens a French influence is apparent in the larger number of open modes, in the ribbon motif crossing the design, the spacing of the ornament, and the cordonnet which is worked around certain flowers, and the more broken outlines of the ornament. The work of these grounded laces is always flat; but in some pieces minute raised button-hole stitched rings are added. Compared with this type, Brussels could not reach the high standard of Venetian workmanship, being forced to content herself with a frequent use of modes more open than the fine close modes belonging to the Venetian point a reseau, which are in general bar, chevron, trellis, and chequer pin-hole patterns, such as are found in the raised points. Variety of effect is obtained by the use of barring (or honey-comb grounding) inserted amongst the stems and leaves of the sprays; but very open modes, as a general rule, are used sparingly, like 'high lights' upon a picture. The style of Venetian a reseau is less floral and more conventional than in Brussels; and the cordonnet of Brussels straggles. Alencon Point and Venice Point:- from this grounded point certain details of fine Alencon appear to have been borrowed. Alencon differs from grounded Venetian point in design. Whatever France touched became French. Naturalistic imitations of flowers, birds, vases, and other material objects are freely interspersed in the more ornamental portions of Alencon, while in Venetian lace there is rarely any change from purely conventional treatment. Alencon also differs in workmanship from Venetian point in the raised and continuous outlines to the ornament. Lighter and more open decorative modes are introduced in Alencon; the reseau rosace is more freely used as a groundwork; the reseau of grounded Venetian point is square; that of Alencon is hexagonal and in some specimens certain details are outlined with a thick thread stitched along the stems, leaves, and flowers. The introduction of the thick thread, to give stronger definition to some of the forms, is, however, unusual in this make of lace less fine; the horizontal waved lines of the reseau are more irregular and marked in Alencon; the foliations in point de Venise a reseau are marked by minute regular open-worked fibres or veinings. In general appearance, according to Mr Cole, the designs would seem to give a date somewhere about 1650, that is, at the time when the raised points were largely in circulation. Upon the establishment of the Points de France, in 1665, the French were diligent under the tuition of their Venetian workers in their attempts to imitate. Upon this the skill and invention of the Venetians perfected the point a reseau – an attempt to win back the custom the French manufacturers were taking away from them. Here their labours culminated. As Alencon rose this type of lace declined. 'Hence it is that point de Venise a reseau, having probably had but a short existence, died out soon; comparatively few specimens of it are to be seen'. At the beginning of the XVIII century the lace industry was already declining. In 1734, French, Flemish, and English laces were sold at cheaper rates in the Venetian lace shops than the local production. In 1750, Benedetto Ranieri and Pietro Gabriele attempted to 'improve' the lace industry by imitating Flemish and French laces, especially blonde. They were exempted from taxation for years by the Senate, and their enterprise succeeded from the commercial, if not from the artistic, standpoint, as is proved by their prosperity in 1758. Burano:- the old Burano laces are a coarser outcome of the point de Venise a reseau, and alone of all the Venetian needle laces survived the dark days of the close of the XVIII century. Marini quotes from a document of the XVII century in which, speaking of merletti, it is said that 'these laces, styled 'punti in aria', or di Burano, because the greater part of them were made in the country so called, are considered by Lannoni as more noble and of greater whiteness, and for excellency of design and perfect workmanship equal to those of Flanders, and in solidity superior'. Very little is known of the early history of Burano lace. Peuchet writes that a great number of fisherfolk in the island of Burano, as well as people in Venice itself and in the convents, were employed in lace-making ; but that their profits were small. The thread, he adds, comes from Flanders, as the local flax thread was not so strong when equally fine. In 1793 the Gasetta Veneta refers to Burano Lace, 'del quale si exercitava largo commercio anche nei vecchi tempi'. The designs of old Burano, like those of Venise a reseau, are distinguished by a conventional treatment of the flowers and ornament; but the designs are somewhat thinner, there is more reseau in proportion to the pattern, and in some specimens there are semes upon the ground, as in French laces of the Louis XVI period. In a description in a letter written in 1875, of certain Burano laces in the possession of Sir Henry Layard, specimens were described as 'exactly like Alencon', the only difference perceptible being that 'the flowers are matted and thick, and very clumsily put into the ground'. In an account of Venetian lace-making, written by Urbani de Gheltof, published in Venice, and translated into English by Lady Layard, a very detailed description, accompanied by diagrams, is given of the mode of execution of Burano point. From this it appears that it is usually worked on a pillow, not, however, of course with bobbins, as for bobbin lace, the object of the pillow or bolster is merely to raise the work to a suitable height on the lap of the lace-maker, and to diminish the necessity of much handling. On the middle of the upper side of the pillow there rests a small wooden cylinder across which the parchment pattern is stretched, leaving an open space under it for the convenience of the worker; thus the strip of lace is kept smooth and flat. In working the reseau ground, a thread is fixed straight across the whole width of the lace as a foundation of each row of meshes, being passed through and fastened to any sprig or part of the pattern which may intervene, and on this thread the looped meshes are worked. The result is the formation of a remarkably square-shaped mesh, and by this and also by the streaky and cloudy appearance of the reseau (owing to the bad quality and unevenness of the thread), Burano point may be recognised. The cordonnet is, like the Brussels needlepoint, of thread stitched round the outline, instead of the Alençon button-hole stitch over horsehair. In 1866 the industry was extinct ...'. VENISE LACE = ВЕНЕЦИАНСКОЕ КРУЖЕВО – Venise Lace is a needlepoint lace usually in a floral pattern connected by picot edgings. It is also called Venetian Lace, and Venice Lace. See also Picot. / Venise на Французском языке – Венеция. Пико или Зубчик (Picot).

VENOM = ЯД – Venom:- The Difference Between Venomous and Poisonous Animals:- Both types of animals produce a toxin that is injurious or lethal to another organism, but the difference lies in how that toxin is delivered. Venomous organisms inject their toxin, whereas poisonous organisms do not deliver the toxins directly. A venomous organism will use some type of apparatus that houses the gland of the venom (for example, fangs or a stinger) to inject the toxin directly into the victim. A poisonous organism is only poisonous when its toxin is inhaled, ingested, or possibly touched. So rather than having an apparatus with a venom inside, all or part of the animal's body is poisonous to other species. What is the Difference Between Venom and Poison? In addition to how the animals deliver each toxin, the toxins themselves are slightly different. Poison will hurt or kill the affected organism however it is received. Venom usually isn't poisonous, so if it is not injected it will not hurt or kill you. Venom that is poisonous can kill however it is received by the victim. Venom:- the poisonous secretion of an animal, produced by specialized glands that are often associated with spines, teeth, stings, or other piercing devices. The venom apparatus may be primarily for killing or paralyzing prey or may be a purely defensive adaptation. Some venoms also function as digestive fluids. The venom poisoning of humans is primarily a problem of rural tropical

regions, though it occurs worldwide. Many thousands of human deaths due to venom poisoning occur each year. Most venoms injure humans only when introduced into the skin or deeper tissues, usually through a sting or bite. Venoms are mixtures of toxic enzymes and various other proteins that act on the body in different ways. Neurotoxin venoms act on the brain and nervous system and can cause either nervous excitation (characterized by such symptoms as muscle cramps, twitching, vomiting, and convulsions) or nervous depression (with such symptoms as paralysis and weakening or arrest of respiration and heartbeat). Hemotoxins affect the blood or blood vessels:- some destroy the lining of the smaller blood vessels and allow blood to seep into the tissues, producing local or widespread hemorrhages, while others render the blood less coagulable or cause abnormally rapid clotting, leading to circulatory collapse that can be fatal. Still other venoms produce the symptoms of an allergic reaction, resulting in wheals, blisters, and violent inflammation, often followed by death of tissue and muscle spasms. Most major animal phyla contain venomous species, but relatively few come into harmful contact with humans. These few include certain Snakes (e.g., Cobras, Mambas, Vipers, Pit Vipers, Coral Snakes, and Rattlesnakes); certain Fishes (e.g., Stingrays, Weevers, spiny Sharks, scorpion Fish, Ratfish, and certain Catfish); a few lizards (Gila monster); some Scorpions and several Spiders (e.g., the Black Widow and Brown Recluse); some social insects (e.g., the Bee, Wasp, and certain Ants); and various marine invertebrates, including some sea anemones, fire corals, jellyfish, cone shells, and sea urchins. Snakes and spiders inject venom into their victims with their fangs; fishes use venomous spines and scorpions and many insects use stings. Venom attacks can range in severity from a simple localized inflammation of the skin to almost immediate death, depending on the animal involved and the potency and mode of action of its venom. An attack’s severity also depends on the victim’s age (children are more severely affected than are adults) and the location of the injury (a venom wound on an arm or leg is usually less serious than a similar one on the head or trunk). See also Poison. / Смотрите также Отрава или Яд (Poison). Змеиный Яд, ядовитые выделения слюнных желёз некоторых Видов Змей. Змеиный яд – негустая бесцветная, соломенно-жёлтая или зеленоватая жидкость; состоит из альбуминов, глобулинов, ферментов, воды, солей и другого. В сухом виде сохраняется до 23 лет. Свойства яда различных Змей неодинаковы:- яд Гадюки содержит геморрагин, вызывающий кровоизлияния, яд Кобры богат нейротоксином, поражающим нервную систему. Поэтому и последствия укуса различных Змей проявляются по-разному. При укусе Гадюки – боль, отёк в области укуса, геморрагии кожи с образованием пузырей (иногда с омертвением тканей); укус Кобры вызывает одышку, сердцебиение, головокружение, тошноту, иногда – рвоту, гибель происходит от паралича дыхательного центра. Яд Кобры, Щитомордника и гремучей Змеи оказывает антикоагулирующее действие на кровь, яд Гадюки – коагулирующее. В бывшем Союзе Советских Социалистических Республик (СССР) встречалось 14 Видов ядовитых Змей:- Кобра, Гюрза, песчаная Эфа, Щитомордник, Гадюки – обыкновенная, песчаная, Казнакова, Армянская и другие. Профилактика укусов:- ношение высокой обуви, соблюдение осторожности в походах, при полевых работах и тому подобном. Змеиный яд чрезвычайно быстро распространяется в организме пострадавшего, поэтому наложение тугой перетяжки выше места укуса, разрезы, прижигания не только бесцельны, но и вредны. Первая помощь:- полная неподвижность укушенной конечности, наложение шин на неё, обильное питье (чай, кофе, вода). Наиболее эффективное средство – специфическая противозмеиная сыворотка, которую готовят из змеиного яда. Малые дозы змеиного яда применяют для лечебных целей:- яд Гадюки Рассела – для тампонирования кровоточащих дёсен у больных гемофилией после удаления зубов; яд Кобры – как болеутоляющее средство; яд гремучей Змеи и Кобры – для лечения эпилепсии, бронхиальной астмы и других. Из змеиного яда готовят лечебные препараты, оказывающие болеутоляющее и противовоспалительное действие; применяют для лечения невралгий, мышечных болей, хронических заболеваний суставов и другого. Препараты змеиного яда выпускают в виде мазей (випросал, випратокс), реже – раствора для подкожного и внутримышечного введения (випраксин, виперактин и другие). Противопоказано лечение змеиным ядом при туберкулёзе, лихорадочных состояниях, общем истощении, нарушениях кровообращения, тяжёлых заболеваниях печени и почек. Под Пчелиным Ядом или Апитоксином, от Латинского слова Apis, означающее Пчела, и Греческого слова Toxikón, означающее Яд, понимается секрет, выделяемый нитевидной железой жалящего аппарата рабочей Пчелы. Густая бесцветная жидкость с характерным запахом и горьким вкусом. Химический состав точно не установлен. Пчелиный яд содержит биологически активный белок (мелиттин), ферменты (гиалуронидазу, лецитиназу А), свободные аминокислоты, гистамин, муравьиную и другие кислоты, жиры, стероидоподобные вещества, летучие масла, некоторые микроэлементы. К действующим веществам пчелиного яда относят гликозид гистамина, липиды и вещества, близкие к сапонинам животного происхождения. Плотность пчелиного яда 1.131. На воздухе быстро твердеет. Легко растворяется в воде, труднее в муравьиной кислоте и 60°-ном спирте. Термоустойчив (замораживание и температура до 115 °С не изменяет его свойств). При ужалении Пчела выделяет 0.2–0.3 миллиграмма (мг) яда; смертельная доза – 500–1 000 ужалении (около 0.2 грамма (г)). Пчелиный яд оказывает противовоспалительное и холинолитическое действие. Препараты пчелиного яда (венапиолин, токсапин, апизартрон, вирапин) применяют в растворах, мазях, путём электрофореза при заболеваниях суставов, миозитах, радикулитах, невралгии, крапивнице, мигрени, трофических язвах, тромбофлебите и других. Применение пчелиного яда противопоказано при инфекционных заболеваниях, болезнях печени, почек, крови, диабете, сердечно-сосудистых, психических заболеваниях и особенно при индивидуальной повышенной чувствительности к пчелиному яду. Яды, вещества, способные при воздействии на живой организм вызвать резкое нарушение нормальной его жизнедеятельности – отравление или смерть. Отнесение тех или иных веществ к ядам условно, так как токсичность многих из них определяется обстоятельствами или способом введения в организм. Действие ядов обусловлено их химическими реакциями с веществами, входящими в состав клеток и тканей организма, а также принимающими участие в тканевом обмене (например, при отравлении синильной кислотой). Сила и характер действия ядов зависят от их химической структуры, физико-химических свойств, структурных и функциональных особенностей организма, что обусловливает избирательную токсичность ядов по отношению к отдельным видам животных или растений, а также ‘сродство’ (‘тропность’) к определённым системам или органам (например, нейротронные яды, поражающие преимущественно нервную систему). По происхождению яды делят на растительные (смотрите Ядовитые Растения), животные (смотрите Ядовитые Животные), минеральные и продукты химического синтеза (Промышленные Яды, Пестициды). Яды проникают в организм человека главным образом через пищеварительные (смотрите Пищевые Отравления) и дыхательные органы; из организма выделяются почками, кишечником, лёгкими и другими. Изучением действия ядов занимается токсикология. Смотрите также Антидоты. Яды Промышленные или Яды Профессиональные или Яды Производственные, химические соединения, используемые в промышленности и оказывающие вредное действие на организм человека. При несоблюдении правил техники безопасности и гигиены труда ядовитыми могут быть различные виды сырья, а также промежуточные, побочные или конечные продукты производства:- чаще возникают хронические отравления. Некоторые промышленные яды вызывают поражения плода, оказывают вредное влияние на потомство (смотрите Тератогенез, Мутагенез), являются канцерогенными веществами. Профилактика отравлений промышленными ядами:- исключение из производственного процесса высокотоксичных промышленных ядов, замена их менее токсичными; обеспечение непрерывности технологического процесса, герметичности аппаратов и коммуникаций; рациональная планировка рабочих мест (‘чистые’ и ‘грязные’ зоны); эффективная вентиляция; уменьшение длительности контакта с промышленными ядами; индивидуальные средства защиты (одежда, противогазы, респираторы, защитные пасты и другие); периодические медицинские осмотры; профилактическое питание и медикаментозная профилактика (ингалятории и другое); установление предельно-допустимых концентраций (ПДК) вредных газов, паров и аэрозолей в воздухе рабочей зоны.

Смотрите также Отравление, Профессиональные Болезни, Профессиональные Вредности. Ядовитые Животные (Venomous Animals), содержат в организме постоянно или периодически вещества, токсичные для особей других видов. Введённый даже в малых дозах в организм другого животного яд вызывает болезненные расстройства, а иногда – смерть. Всего существует около 5 000 видов ядовитых животных:- простейших – около 20, кишечнополостных – около 100, червей – около 70, членистоногих – около 4 000, моллюсков – около 90, иглокожих – около 25, рыб – около 500, земноводных – около 40, пресмыкающихся – около 100, млекопитающих – 1 вид. В бывшем Союзе Советских Социалистических Республик (СССР) – около 1 500 видов. Из ядовитых животных наиболее изучены Змеи, Скорпионы, Пауки, Жуки-Нарывники и некоторые другие; наименее – Земноводные, Рыбы, Моллюски и Кишечнополостные. Одни из ядовитых животных имеют особые железы, вырабатывающие яд, другие содержат токсические вещества в тех или иных тканях тела. У части животных имеется ранящий аппарат (так называемые вооружённые ядовитые животные), способствующий введению яда в тело врага или жертвы. У простейших (например, Инфузорий) это трихоцисты, у кишечнополостных (Гидры, Актинии, Медузы) – стрекательные клетки, у ‘жгучих’ гусениц – на теле одноклеточные кожные железы с колющими хрупкими волосками, у ряда членистоногих (Скорпионов, Пчёл, Ос) – многоклеточные кожные железы, связанные с жалом, а у Рыб – такие же железы, соединённые с шипами на плавниках (например, Скорпеновые) и жаберных крышках (морские Дракончики). У многих животных (Многоножки, Пауки, некоторые Двукрылые, Клопы, а также Змеи) ядовитые железы связаны с ротовыми органами, и яд вводится в тело жертвы при укусе или уколе. Вооружённым ядовитым животным яд служит для защиты и для нападения. У ядовитых животных, имеющих ядовитые железы, но не имеющих специального аппарата для введения яда в тело жертвы, например, у Земноводных (Саламандр, Тритонов, Жаб и других), железы расположены в различных участках кожи; при раздражении животного яд выделяется на поверхность кожи и действует на слизистые оболочки хищника. У ядовитых животных, не имеющих специальных ядовитых желёз, ядовитость вызвана свойствами тех или иных тканей. Она оказывает влияние только при поедании этих животных другими. Ядовиты могут быть половые железы (у некоторых Жуков и кольчатых Червей), а также икра ряда Рыб (Усачей, Маринок), сыворотка крови (например, Угря, Мурены, Скатов). Многие внутренние паразиты животных также являются ядовитыми животными. Например, паразитические круглые Черви анкилостомиды выделяют токсические вещества, растворяющие эритроциты. Яд при поступлении в организм прежде всего оказывает местное действие, а по мере всасывания сказывается и общее его влияние на организм. В одних случаях местное действие очень сильное, а общее – слабое (ужаливание Пчелы), в других – наоборот (укус Кобры). Местное действие проявляется в отёке в области укуса, сильной боли, образовании пузырей, разрушении ткани (некроз) и прочем. Общее действие обычно сказывается на нервной системе, сердечно-сосудистой и других и проявляется в параличе сердца, дыхательного центра, в воспалении почек, свёртывании крови и прочем, что иногда приводит к смертельному исходу. Например, укус самки Каракурта вызывает тяжёлую, местную и общую реакции; последняя проявляется в возбуждении, судорогах, частичном параличе и иногда кончается гибелью пострадавшего. Действие некоторых ядов буквально молниеносно. Так, у гусеницы сразу наступает паралич, как только жало ядовитой Осы аммофилы проколет узел нервной цепочки; мышь погибает через 3–4 секунды (сек) после укуса Гюрзы. Сила действия яда зависит от его природы, дозы, а также от пути его поступления в организм; яд, попавший в кровь, обычно действует гораздо быстрее, чем при попадании в ткани, бедные кровеносными сосудами (всасывание яда при этом происходит очень медленно). Чувствительность разных животных к одному и тому же яду различна (одно и то же количество яда гремучей Змеи смертельно для 24 Собак, 60 Лошадей, 600 Кроликов, 800 Крыс, 2 000 морских Свинок, 300 000 Голубей). Степень отравления зависит также от величины тела животного и его возраста. Некоторые животные малочувствительны к тем или иным ядам, например, Свиньи – к яду гремучей Змеи, Ежи – к яду Гадюки, Грызуны, обитающие в пустынях, – к яду Скорпионов. Некоторые Птицы (Аисты, Вороны, Кондоры, Птицы-Секретари) поедают ядовитых Змей; ядовитые Змеи (например, Лахезис) – других ядовитых Змей (коралловую Змею), неядовитая Змея Муссурана – ядовитых Змей. Некоторые Птицы могут поедать жгучих гусениц; Куры – Каракурта, а сам Каракурт может поедать шпанских Мушек, кантаридин которых для него не опасен. Таким образом, не существует ядовитых животных, опасных для всех остальных животных; их ядовитость относительна. Человек и животные могут стать невосприимчивы к яду, который длительное время в небольших дозах вводился в их организм. Так, иногда пчеловоды становятся нечувствительны к яду Пчёл. Малые дозы змеиного яда, пчелиного яда и некоторых других используются для лечебных целей. Смотрите также Токсины. Ядовитые Растения, Растения, вырабатывающие и накапливающие в процессе жизнедеятельности яды. Вызывают отравления животных и человека. В мировой флоре известно более 10 000 Видов Ядовитых Растений, главным образом в тропиках и субтропиках, много их и в странах умеренного и холодного климатов; в бывшем Союзе Советских Социалистических Республик (СССР) около 400 Видов. Ядовитые Растения встречаются среди Грибов, Хвощей, Плаунов, Папоротников, Голосеменных и Покрытосеменных Растений. В странах умеренного климата наиболее широко они представлены в Семействе Лютиковых, Маковых, Молочайных, Ластовневых, Кутровых, Паслёновых, Норичниковых, Ароидных. Многие растительные яды в небольших дозах – ценные лечебные средства (морфин, стрихнин, атропин, физостигмин и другие). Основные действующие вещества ядовитых растений – алкалоиды, гликозиды (в том числе сапонины), эфирные масла, органические кислоты и другие. Они содержатся обычно во всех частях растений, но часто в неодинаковых количествах, и при общей токсичности всего растения одни части бывают более ядовиты, чем другие. Например, у Веха ядовитого, Видов Аконита, Чемерицы особенно ядовито корневище, у Картофеля – цветки, Болиголова – плоды, у Софоры, Куколя, Гелиотропа – семена, у Наперстянки – листья. Некоторые растительные яды накапливаются и образуются только в одном органе растения (например, гликозид амигдалин – в семенах горького Миндаля, Вишни, Сливы). Бывает, что некоторые части ядовитых растений неядовиты (например, клубни Картофеля, кровелька семян Тисса, семена Мака снотворного). Содержание ядовитых веществ в растениях зависит от условий произрастания и фазы развития растения. Как правило, ядовитые растения, растущие на Юге, накапливают действующих веществ больше, чем произрастающие на Севере. Одни растения более токсичны перед зацветанием, другие – в период цветения, третьи – при плодоношении. Наиболее ядовиты растения в свежем виде. При высушивании, отваривании, силосовании токсичность может снижаться, а иногда утрачивается совсем. Однако у большинства ядовитых растений токсичность сохраняется и после переработки, поэтому примесь их в фураже нередко бывает источником сильных отравлений сельскохозяйственных животных (при силосовании трав с примесью Чемерицы алкалоиды из последней выщелачиваются, пропитывают силосную массу и делают её ядовитой). Животные, как правило, не поедают ядовитые растения, однако при бескормице и весной после длительного стойлового содержания они с жадностью поедают свежую зелень, в том числе и ядовитые растения (часты отравления животных, перевезённых в районы, где встречаются незнакомые для них ядовитые растения). Растений, обладающих абсолютной ядовитостью, в природе, по-видимому, не существует. Например, Белладонна и Дурман ядовиты для человека, но безвредны для Грызунов, Кур, Дроздов и других Птиц, морской Лук, ядовитый для Грызунов, безвреден для других животных, Пиретрум ядовит для Насекомых, но безвреден для Позвоночных и так далее. Обычно отравление ядовитыми растениями происходит при попадании растений через рот, органы дыхания (при вдыхании пылевидных частиц ядовитых растений или выделяемых ими летучих веществ), а также через кожу в результате соприкосновения с ядовитыми растениями, их соками. Отравления людей через дыхательные пути обычно относят к профессиональным; наблюдаются у сборщиков Хмеля, столяров при работе с некоторыми видами

древесины (например, древесиной Бересклета), людей, имеющих дело с лекарственными растениями (например, с Белладонной, Секуринегой, Лимонником и тому подобными). Реже наблюдаются бытовые отравления летучими веществами, выделяемыми ядовитыми растениями. Большие букеты Магнолий, Лилий, Черёмухи, Мака, Тубероз могут вызвать недомогание, головокружение, головную боль. Нередки отравления детей соблазнительными на вид ядовитыми плодами. Отравление после поедания ядовитых растений может проявиться через несколько минут, например, после употребления хвои Тисса, в других случаях – через несколько дней и даже недель. Некоторые ядовитые растения (например, Хвойник) могут быть ядовиты лишь при длительном их употреблении, так как действующие начала их в организме не разрушаются и не выводятся, а накапливаются. Большинство ядовитых растений одновременно действуют на различные органы, однако какой-то орган или центр обычно бывает поражён сильнее. По действию на организм животных различают ядовитые растения, вызывающие поражение:- центральной нервной системы (Виды Аконита, Безвременника, Белены, Болиголова, Ветренницы, Веха и других), сердца (Виды Ландыша, Наперстянки, Обвойника и других), печени (Виды Гелиотропа, Крестовника, Люпина и других), одновременно органов дыхания и пищеварения (Горчица полевая, Желтушник левкойный, Триходесма седая) и так далее. В профилактике отравлений ядовитыми растениями человека важное значение имеет санитарное просвещение населения; животных – уничтожение ядовитых растений на пастбищах. Многие растительные яды в небольших (так называемых терапевтических) дозах применяются как лекарственные средства (например, сердечные гликозиды, получаемые из Наперстянки и Ландыша, атропин – из Белены). Из некоторых ядовитых растений получают инсектициды (например, пиретрум – 113 Ромашки Далматской).

VENT = СПУСКНОЙ КЛАПАН (или ДЫМОХОД) – Vent is an opening in a vessel or other enclosed space for the removal of gas or vapor. / Дымоход или Дымовой Канал, канал для отвода дымовых газов отопительных печей, плит, водогрейных колонок и тому подобного. В кирпичных зданиях дымоходы устраиваются обычно во внутренних капитальных стенах (толщина стенки дымохода должна быть не менее 1/2 кирпича); нередко дымоходы выполняются из асбестоцементных труб, керамических или бетонных блоков. Сечение дымоходов может быть прямоугольным, круглым или овальным. Дымоход выводится над крышей здания для выпуска дыма в атмосферу и заканчивается оголовком в виде дымовой трубы, часто объединяющей несколько дымоходов. Рядом с дымоходом рекомендуется устраивать каналы вытяжной вентиляции, работающей с естественным побуждением.

VENT BOX = ВЕНТ СУНДУК (или ПРОВЕТРИВАЕМЫЙ СУНДУК) – Vent Box is a container designed to carry commodities requiring air circulation or ventilation during transit. / Контейнер, предназначенный для перевозки различных видов сырья, требующего циркуляции воздуха или вентиляции в процессе транзита.

VENTILATED/COFFEE = ВЕНТИЛИРУЕМЫЙ/КОФЕ – Ventilated/Coffee:- identical to the general purpose container (GP container), except for the inclusion of full length ventilation galleries sited along the top and bottom side rails, and thus ideal for the carriage of Coffee, as condesation is prevented from accumulating. 20’ only.

VENTILATED CONTAINER = ВЕНТИЛИРУЕМЫЙ КОНТЕЙНЕР (или ПРОВЕТРИВАЕМЫЙ КОНТЕЙНЕР) – Ventilated Container is a container designed with openings in the side and/or end walls to permit the ingress of outside air when the doors are closed.

VENTED DECORATIVE APPLIANCES = ПРОДУВАЕМЫЕ ДЕКОРАТИВНЫЕ УСТРОЙСТВА – Vented Decorative Appliances:- a vented appliance whose only function lies in the aesthetic effect of the flames. Gas hearth appliances tested to the American National Standards Institute (ANSI) Standard Z.21.50 include gas fireplaces, fireplace inserts, and freestanding appliances.

VENTED GAS = ПРОДУВОЧНЫЙ ГАЗ – Vented Gas is a gas released into the air on the production site or at processing plants.

VENTED/FLARED GAS = ПРОДУВОЧНЫЙ/ВЫЖИГАЕМЫЙ ГАЗ – Vented/Flared Gas is a gas that is disposed of by releasing (venting) or burning (flaring).

VENTED NATURAL GAS = ПРОДУВОЧНЫЙ ПРИРОДНЫЙ ГАЗ – Vented Natural Gas is a gas released into the air on the base site (production site) or at processing plants. See also Vented Gas. / Газ, выпускаемый (сбрасываемый) в атмосферу на месте добычи или на перерабатывающих заводах.

VENTILATED CONTAINER = ВЕНТИЛИРУЕМЫЙ КОНТЕЙНЕР – Ventilated Container is a container used for transporting cargo requiring ventilation. Ventilated Container is a container designed with openings in the side and/or end walls to permit the ingress of outside air when the doors are closed. / вентиляция.

VENTILATING = ВЕНТИЛЯЦИЯ (или ПРОВЕТРИВАНИЕ) – Ventilating is the natural or mechanically induced movement of fresh air into or through an enclosed space. The supply of air to an enclosed space involves the removal of a corresponding volume of expired air, which may be laden with odours, heat, noxious gases, or dust resulting from industrial processes. The hazards of poor ventilation were not clearly understood until the early XX century. Carbon dioxide accumulation, once thought to be the major cause of illness resulting from poor ventilation, has since been revealed to have a minimal effect under most circumstances. A more immediate problem is posed by the increased temperatures and humidity generated by the bodily warmth and exhalations of human occupants. Natural ventilation results from thermal effects, such as those from a flue, or may be caused by wind, or both. These forces are small and often variable. Their effectiveness is aided by opening or closing windows. Much greater control can be achieved with mechanical ventilation systems. They typically include a fan (from the standard propeller or disk type to the quieter centrifugal type), a heater, and a filter to remove particulate matter. A mechanically powered inlet of air, when combined with a natural exhaust, tends to cause a slight positive pressure within an enclosed space, so that the air leakage is outward. If such a system is installed in a hospital or in an internal office in a factory having a dust- or fume-laden atmosphere, the office will remain essentially contamination-free. A mechanical exhaust with a natural air inlet causes a slight negative pressure, so that air leakages are inward. In many cases this type of ventilating system is used to discourage the escape of fumes or smells into surrounding areas of a building. Examples of such systems occur in laboratories forming part of a college teaching block, in a hotel kitchen adjacent to restaurant areas, and in toilet accommodations generally. In industry, compartments and areas that generate grinding dust, paint spray, fumes, and smoke are similarly treated; these undesirable contaminants are then confined to the spaces in question, leaving surrounding areas free from pollution. Ventilation is a natural or mechanically induced air movement sufficient to provide oxygen and remove excessive heat load and noxious gases. Ventilation is the process of supplying or removing air by natural or mechanical means to or from any space. Such air may or may not have been conditioned or treated. / Под Вентиляцией, от Латинского слова Ventilatio, означающее Проветривание, понимается регулируемый воздухообмен в помещении, а также устройства, которые его создают. Вентиляция предназначена для обеспечения необходимых чистоты, температуры, влажности и подвижности воздуха. Эти требования определяются гигиеническими нормативами:- наличие вредных веществ в воздухе (газы, пары, пыль) ограничивается предельно допустимыми (безвредными для здоровья людей) концентрациями, а температура, влажность и подвижность воздуха устанавливаются в зависимости от условий, необходимых для наиболее благоприятного самочувствия человека. Для многих производственных помещений (цехи сборки точных механизмов, радиоэлектроники и другого) чистота воздуха, его

температура и влажность определяются также особенностями технологического процесса. В ряде случаев температура и влажность воздуха в помещениях должны отвечать условиям наилучшей сохранности находящихся в них предметов и материалов (фондохранилища музеев, архивы, склады), оборудования, а также строительных конструкций. Основной источник выделения вредных веществ, тепла и влаги в производственных помещениях – происходящий в них технологический процесс. В жилых домах эти выделения имеют место, главным образом, в санитарных узлах и кухнях, особенно во время пользования газовыми плитами. Жизнедеятельность человеческого организма также сопровождается выделением вредных веществ (углекислый газ), запахов, тепла и влаги. Приготовление пищи, стирка, купание, чистка одежды повышают температуру и влажность воздуха помещений, увеличивают его запылённость и бактериальную загрязнённость (особенно при наличии больных). Все эти вещества подлежат удалению посредством вентиляции. При загрязнении воздушного бассейна (например, выхлопными газами автомобильного транспорта, промышленными выбросами и другим) вредные вещества могут попадать в помещения с наружным воздухом. Источниками дополнительных теплопоступлений в помещения являются Солнечная радиация (в основном через окна), а также искусственное освещение. Уменьшение выделения вредных веществ, избытков тепла и влаги – существенный фактор улучшения состояния воздушной среды в производственных помещениях, оно создаёт также более благоприятные условия для действия вентиляции. В этих целях в производственных процессах применяют нетоксичные или малотоксичные вещества, герметизируют технологическое оборудование и коммуникации, покрывают тепловой изоляцией поверхности, выделяющие тепло. Снижение избыточных теплопоступлений достигается применением Солнцезащитных устройств на окнах, теплопоглощающих стекол, использованием для освещения светильников с принудительным отводом тепла и другими мероприятиями. Гигиенические нормы, действовавшие в бывшем Союзе Советских Социалистических Республик (СССР), предусматривали, что воздух жилых помещений должен иметь (в зимний период):- температуру 18–22 °С, относительную влажность 40–60%, подвижность 0.1–0.2 метра в секунду (м/сек), содержание CO_2 не более 0.1%; в воздухе не должно быть примесей вредных газов. Различают вентиляцию:- приточную, вытяжную, приточно-вытяжную, общеобменную, местную, естественную и механическую. Приточная Вентиляция обеспечивает только подачу чистого воздуха в помещение; удаление воздуха из него происходит в основном через неплотности в ограждающих конструкциях и открывающиеся двери, за счёт возникающего избыточного давления. Вытяжная Вентиляция предназначена для удаления воздуха из вентилируемого помещения и создания в нём разрежения, за счёт которого в это помещение через неплотности в ограждениях и двери может поступать воздух снаружи и из соседних помещений. Приточно-Вытяжная Вентиляция обеспечивает одновременно подачу воздуха в помещение и организованное удаление его; при этом в зависимости от соотношения количества подаваемого и извлекаемого воздуха в помещении может быть избыточное давление или разрежение. В смежных помещениях избыточное давление и разрежение препятствуют проникновению загрязнённого воздуха из одного помещения в другое (например, из курительной в фойе, из кухни в обеденный зал, из гальванического отделения в сборочный цех и так далее). Для эффективности этого приёма необходимо, чтобы избыточное давление или разрежение в вентилируемых помещениях создавалось устойчиво интенсивным воздухообменом. Показателем интенсивности воздухообмена, который может происходить без вентиляционного устройства (через неплотности в ограждениях, под действием ветра и разности температур внутреннего и наружного воздуха), является кратность воздухообмена, то есть отношение объёма поступающего или удаляемого в течение 1 часа (ч) воздуха к внутреннему объёму помещения. При Общеобменной Вентиляция, применяемой во всех жилых и общественных зданиях, выделяющиеся в помещении вредные вещества разбавляются подаваемым в него чистым воздухом до предельно допустимых концентраций; избытки тепла и влаги ассимилируются приточным воздухом, который должен иметь при этом более низкие температуру и влажность. Местная Приточная Вентиляция создаёт требуемые условия воздушной среды на ограниченном пространстве производственных помещений при помощи воздушных душей, воздушных оазисов и тому подобного. При местной вытяжной вентиляции вредные включения улавливаются и удаляются от мест их возникновения посредством местных отсосов:- вытяжных шкафов, зонтов, бортовых отсосов и другого. При выделении вредных веществ от технологического оборудования последнее снабжается встроенными местными отсосами и укрытиями, представляющими собой его неотъемлемую часть. При Естественной Вентиляции воздух поступает в помещение и удаляется из него вследствие разности температур (а, следовательно, и плотностей наружного и внутреннего воздуха), а также под воздействием ветра. Неорганизованная естественная вентиляция осуществляется инфильтрацией и эксфильтрацией воздуха через неплотности в ограждающих конструкциях здания, в окнах, дверях и так далее, а организованная естественная вентиляция – путём подачи и удаления воздуха, перемещаемого по воздуховодам, а также через открываемые в определённом порядке отверстия в стенах, окнах и фонарях (смотрите Аэрация Зданий). Механическая Вентиляция осуществляется преимущественно вентиляторами с электрическим приводом. В приточных системах производится воздухоподготовка наружного воздуха, оборудование для которой обычно располагают в приточной вентиляционной камере, вблизи воздухозабора. От камеры воздух распределяется приточными воздуховодами по вентилируемым помещениям и подаётся в них через жалюзи, перфорированные потолки, декоративные решётки и другие приточные вентиляционные насадки. При общеобменной вентиляции воздух удаляется через сеть вытяжных воздуховодов, снабжённых вентиляционными решётками, а при местной вентиляции – через местные отсосы, присоединяемые обычно к отдельным вытяжным системам. Воздух, загрязнённый особо токсичными веществами или местными отсосами, подвергают очистке. С этой целью перед выбросом загрязнённого воздуха в атмосферу устанавливают очистные устройства, пылеулавливатели, фильтры и тому подобное. Оборудование вытяжных вентиляционных систем располагают в вытяжных камерах; на промышленных предприятиях (при благоприятных климатических условиях) возможно открытое расположение. Если шум от вентиляционного оборудования не создаёт существенных помех для работы, выполняемой в цехе, на складе или в каком-либо другом производственном помещении, это оборудование допускается размещать непосредственно в вентилируемом помещении. В таких случаях применяют также приточные, отопительные и вытяжные вентиляционные агрегаты, устанавливаемые на полу или на колоннах и стенах. В жилых домах наиболее распространена вытяжная вентиляция с естественным побуждением из кухонь и санитарных узлов, с поступлением наружного воздуха через открываемые в окнах створки, форточки, неплотности в стенах. В современных промышленных и общественных зданиях широко применяется приточно-вытяжная вентиляция с механическим побуждением. В ряде случаев приточную вентиляцию совмещают с воздушным отоплением, для чего снабжают её более мощным воздухоподогревателем, обеспечивающим подогрев подаваемого воздуха до температуры более высокой, чем температура в помещении. При этом избыточное тепло, которое несёт с собой приточный воздух, идёт на возмещение теплопотерь помещения. Если параметры воздуха в помещении должны постоянно отвечать строго определённым условиям (кондициям), применяют кондиционирование воздуха. При этом заданные параметры воздуха в помещениях поддерживаются посредством автоматического регулирования процессов обработки воздуха в кондиционерах в зависимости от состояния наружного воздуха, выделения тепла и влаги в помещениях. Развитие и расширение применения кондиционирования воздуха и совершенствование способов его подачи в помещения способствуют дальнейшему повышению эффективности действия вентиляции. О вентиляции горных выработок смотрите Проветривание Шахты, Проветривание Карьера.

VENTILATION/SUCTION = ВЕНТИЛЯЦИЯ/ВСАСЫВАНИЕ – Ventilation/Suction:- the act of admitting fresh air into a space in order to replace stale or contaminated air, achieved by blowing air into the space. Similarly, suction represents the admission of fresh air into an interior space by lowering the pressure outside of the space, thereby drawing the contaminated air outward. See also Suction, and Ventilating.

VENTILATION SYSTEM = СИСТЕМА ВЕНТИЛЯЦИИ – Ventilation System is a method for reducing methane concentrations in coal mines to non-explosive levels by blowing air across the mine face and using large exhaust fans to remove methane while mining operations proceed.

VENTILATOR = ВЕНТИЛЯТОР – Ventilator is a wooden or metal pipe used to supply or to exhaust air. See also Fan. Ventilator (in the US) is a thing that ventilates; esp., any device used to bring in fresh air and drive out foul air. Ventilator is a device that lets fresh air into a room or building and lets old or dirty air out. Ventilator (in the UK) is a device that lets fresh air into a room or building and lets old or dirty air out. / Под Вентилятором, от Латинского слова Ventilo, означающее Вею или Махаю, понимается машина для подачи воздуха или другого газа при давлении не выше 12–15 килоНьютонов на квадратный метр (кН/м^2) (0.12–0.15 килограмм силы на квадратный сантиметр (кгс/см^2)). Вентиляторы служат для вентиляции зданий и рудников, для подачи воздуха в котельные и печные агрегаты и удаления из них дымовых газов, сушки материалов, охлаждения деталей машин и механизмов, создания воздушных завес, пневматического транспортирования сыпучих и волокнистых материалов, обеспечения некоторых технологических процессов, для охлаждения радиаторов, конденсаторов, подачи воздуха. Кроме промышленных вентиляторов, широкое распространение получили настольные и подвесные вентиляторы различных типов. Центробежный, или радиальный, вентилятор имеет расположенное в спиральном кожухе лопаточное колесо, при вращении которого газ, поступающий через входное отверстие, попадает в каналы между лопатками и под действием возникающей центробежной силы перемещается в спиральный кожух и направляется в выпускное отверстие. Осевой вентилятор имеет расположенное в цилиндрическом кожухе лопаточное колесо, при вращении которого поступающий газ перемещается в осевом направлении. Осевые вентиляторы по сравнению с центробежными проще, имеют больший коэффициент полезного действия (кпд), реверсивны (при изменении направления вращения колеса изменяется направление движения газа), но не обеспечивают больших давлений. Диаметральный, или поперечно-проточный, вентилятор имеет центробежное колесо с загнутыми лопатками, частично заключённое в кожух. При вращении колеса создаётся несимметричное вихревое поле, вызывающее течение воздуха в диаметральном направлении. При этом поток двукратно проходит через вращающуюся решётку лопаток колеса. Диаметральные вентиляторы по сравнению с центробежными и осевыми могут создавать большие давления и более производительны. Вентиляторы для перемещения дымовых газов называются дымососами, а для воздуха, засорённого механическими примесями, – пылевыми вентиляторами; вентиляторы, встраиваемые в кровлю, – крышными вентиляторами. В специальном исполнении выпускаются взрывобезопасные и кислотоупорные вентиляторы. Вентилятор приводится в действие двигателем через ремённую передачу или непосредственно с помощью упругой муфты. Колёса малых вентиляторов могут укрепляться на валу двигателя. Крупные вентиляторы имеют также регулировочные и виброизоляционные устройства. Для классификации вентиляторов пользуются понятиями:- критерий быстроходности n_y, выражающий связь между производительностью, давлением, угловой скоростью, и критерий давления Y, зависящий от формы и числа лопаток колеса. Их значения входят в маркировку вентиляторов. Среди центробежных вентиляторов общего назначения имеют применение Ц4-70, ЦП7-40, П8-18 и другие. Буква Ц означает ‘Центробежный’, П – ‘Пылевой’, следующая цифра или число – Y, умноженное на 10, и далее – n_y. Для увеличения производительности и развиваемого давления вентиляторы соединяют соответственно параллельно и последовательно, например, осевые вентиляторы для рудников и метрополитена. Совершенствование вентиляторов идёт по пути улучшения аэродинамической схемы и конструктивного исполнения с целью обеспечения большей экономичности и производительности в прежних габаритах. Вентиляторы выбирают по характеристикам, построенным для наиболее выгодных условий работы. На графике для различных типоразмеров в системе координат p-L (p – давление в Ньютонах на квадратный метр (н/м2), L – производительность в кубических метрах в секунду (м3/сек)) нанесены линии неизменных угловых скоростей w и кпд h). В соответствии с L и p на характеристике находят точку, определяющую искомые угловую скорость и кпд, после чего подсчитывается мощность.

VENTILATOR COWL = РАСТРУБ ВЕНТИЛЯТОРА (или ЗОНТ ВЕНТИЛЯТОРА, или ВЫТЯЖНОЙ ЗОНТ) – Ventilator Cowl:- the swiveled opening at the top of a ventilator.

VENTING SYSTEM = СИСТЕМА ВЕНТИЛЯЦИИ (или ДРЕНАЖНАЯ СИСТЕМА) – Venting System:- a continuous open passageway from the flue collar or draft hood of the appliance to the outside atmosphere for the purpose of removing flue gases.

VENT ORIFICE = ПРОДУВОЧНЫЙ ЖИКЛЁР (или ПРОДУВОЧНЫЙ ШТУЦЕР, или ХХ) – Vent Orifice is a part of a pressure regulator, located in the chamber above the diaphragm. An opening which allows for the free flow of air in and out in the area above the diaphragm. Also provides for the escape of fuel gas in the event of a diaphragm rupture. See also Orifice. / Под Жиклёром, от Французского слова Gicleur, от Gicler, означающее Брызнуть, понимается калиброванное отверстие для дозирования подачи жидкого топлива или воздуха. В технической литературе жиклёрами называют детали карбюратора (пробки, форсунки) с калиброванными отверстиями. По выполняемым функциям и в зависимости от того, в какой системе карбюратора он установлен, различают жиклёр топливный, воздушный, главный, компенсационный, холостого хода и другие. Жиклёры оценивают их пропускной способностью (производительностью), то есть количеством жидкости (обычно воды), которое может пройти через калиброванное отверстие в единицу времени; пропускная способность жиклёров выражается в кубических сантиметров в минуту (см^3/мин)). Штуцер, деталь трубопровода или его соединительного узла, представляющая собой втулку, один из концов которой имеет внутреннюю или наружную резьбу для крепления к различным ёмкостям или трубопроводам. Форма другого конца штуцера зависит от способа присоединения к последующим деталям. Штуцером называют также отрезок трубы небольшого диаметра (10–20 миллиметров (мм)) для выпуска воды или воздуха, отбора жидкости из трубопровода с целью измерения её давления.

VENTRAL = ВЕНТРАЛЬНОЕ (или БРЮШНОЕ) – Ventral:- pertaining to the under surface of the abdomen. On the anterior or inner surface of an organ. See also Dorsal. Ventral:- relating to the inner surface or part of an organ; the part nearer the axis. / В анатомии под Вентральным, от Латинского слова Ventralis от Venter, означающее Брюхо или Живот, понимается брюшной, например, вентральный корешок спинномозгового нерва. Смотрите также Дорзальное (или Дорсальное (Dorsal)). Вентральный или Брюшной, термин, применяемый в анатомии животных и человека к органу (или его части), расположенному на брюшной стороне (вентральный плавник у Ланцетника), ближе к ней по сравнению с лежащим ближе к спинной стороне (вентральный корешок спинномозгового нерва) или обращённому к брюшной стороне (вентральный край или поверхность тела или органа). Средний спинной, или дорзальный.

VENTRICOSE = ВЗДУТОЕ (или ИМЕЮЩЕЕ ВЫПУКЛОСТЬ С ОДНОЙ СТОРОНЫ) – Ventricose:- distended or inflated. Ventricose:- swelling unequally, or inflated on one side.

VENTURE = ВЕНЧУР (или ХХ, или НАУДАЧУ) – (1) Venture is an investment that is very risky but could yield great profits.

(2) Venture is an undertaking, such as one voyage of a vessel.

VENTURE CAPITAL = ВЕНЧУРНЫЙ КАПИТАЛ – Venture Capital (VC) is an equity capital provided by venture capital companies to young, innovative companies from growth sectors with uncertain prospects. Management consultancy services are also offered to start-up companies. Venture capital companies usually raise capital by launching venture capital funds. Private investors, pension funds and other investors who want to invest part of their assets in high-risk assets acquire fund shares and leave the choice of investment up to the VC company. Venture capital companies usually invest in young companies for a period of five to eight years. After that period, the VC company finds an exit strategy to realize its gain from the investment. Also known as Risk Capital. Venture Capital:- investment company whose primary objective is capital growth. New assets invested largely in companies that are developing new ideas, products, or processes. Venture Capital:- funds used to start a new business or enterprise. Because new ventures entail high risks, investors often choose to provide this capital in return for part ownership of the enterprise rather than a loan. If the enterprise is successful, the return to an equity investor will likely exceed the return to a lender, given the same amount of capital provided. In corporate finance, funds invested in an enterprise that involves substantial risks for its owners or shareholders. Venture Capital is capital committed to an unproven venture. The initial, start-up money is referred to as 'Seed Money' and entails the greatest risk. If the project gets off the ground it may require additional financing at additional 'rounds' or the 'mezzanine level' before the company is finally brought to the market and the venture capitalist can enjoy handsome rewards. Experienced investors in venture capital situations typically plan on turning away a minimum of 9 out of every 10 proposals which are brought to them, and then they expect as many failures as successes from their selected investments. Venture Capital:- corporate financing, in particular for new or small and medium-sized private companies with advanced technology and high growth potential. To raise the capital for such companies, many banks and specialized financial institutions offer venture (or risk) capital at special terms, often involving some form of participation. Venture Capital:- The Difference Between Private Equity and Venture Capital:- there are significant differences between the ways in which private equity entities and venture capital firms do business. These differences are as follows:- (i) Maturity Level:- a venture capital firm invests in start-up or growth-stage businesses, with the intent of increasing their initial value. A private equity firm is more likely to invest in a more established business, and then improve its operations in order to increase the value of its investment. (ii) Investment Trigger:- a venture capital firm is looking for a high-grade management team, which it can rely upon to create a high-value business. A private equity firm looks for undervalued assets, which it can use its expertise to enhance. (iii) Investment Level:- a venture capital firm usually takes a relatively small, non-controlling interest in a company, and relies upon the existing management team to enact the changes needed to increase the value of the business. A private equity firm is more likely to buy all of a target company, so that it has complete control over the operations and financing of the entity. (iv) Investment Scale:- a venture capital firm likes to limit the amount of its investments, since each start-up in which it invests is at high risk of failure. Conversely, a private equity firm may plow large amounts into its investees, on the grounds that these more established firms are unlikely to go bankrupt, which reduces the risk of loss. (v) Investment Type:- a venture capital firm is more likely to buy an equity position in its target companies, while a private equity firm could also loan funds, or provide a mix of equity and debt to its investees. (vi) Diversification:- a venture capital firm likes to spread its investments among many investees, so that a few losses on some investments are offset by gains elsewhere. A private equity firm tends to concentrate its funds with a smaller number of companies. (vii) Expected Growth:- a venture capital firm needs one or two businesses in its investment portfolio to be a clear winner, which funds its flat or losing investments. A private equity firm targets a reasonable return on all of its investments. In short, the only things that these types of investors have in common is that they have money to spend – in all other respects, their paths to earning a return are entirely different. See also Capital; Merger; and Risk Capital. Venture Capital is an investment in a start-up business that is perceived to have excellent growth prospects but does not have access to capital markets. Type of financing sought by early-stage companies seeking to grow rapidly. / Известен также как Рисковый Капитал (Risk Capital). Смотрите также Капитал (Capital); Слияние (Merger); и Рисковый Капитал (Risk Capital). Венчурный Капитал:- (1) средства, инвестированные в предприятия, которые обычно не имеют доступа к традиционным источникам капитала (банкам, рынку акций и так далее); (2) средства, полученные в результате эмиссии новых акций; (3) реинвестированные денежные суммы владельцев акций. Венчурный Капитал (Venture Capital):- важный источник финансирования для начинающих (start-up) компаний или других предприятий, предпринимающих новые (turnaround) инициативы, влекущие за собой некоторый инвестиционный риск, но предлагающие потенциальную возможность будущих доходов на уровне выше среднего. Источники венчурного капитала включают богатых частных инвесторов; подразделения банков и других корпораций (акционерных компаний), организованных как малые деловые инвестиционные компании (small business investment companies (SBICs)), а также группы инвестиционных банков и другие финансовые источники, объединяющие инвестиции в фонды венчурного капитала или товарищества с ограниченной ответственностью по вложениям в венчурный капитал (venture capital limited partnerships). Администрация Малого Бизнеса (Small Business Administration (SBA)) предлагает программы участия во вложениях в рисковый капитал через лицензирование и финансирование мелких инвестиционных компаний (SBICs). Финансирование с помощью венчурного капитала часто дополняет личные или внешние источники, которые предприниматель (entrepreneur) в состоянии привлечь, или заменяет собой займы из других источников, которыми обычные финансовые институты не могут или не хотят рисковать. Некоторые источники венчурного капитала вкладывают средства только на определённых стадиях организации предприятия, например, в начальной стадии или в стадии первоначального вложения средств (seed money), на последующих стадиях – первый раунд (first round) или во втором раунде (second round), на 'мезонинном уровне' (mezzanine level) – стадии развития новой компании, которая непосредственно предшествует первоначальному открытому предложению (initial public offering) акций на рынке. В обмен на принятие инвестиционного риска предприниматели, предоставляющие венчурный капитал, обычно получают некоторую корзину прибыли (profits), состоящую из привилегированных акций (preferred stock), долевых отчислений (royalties) с продаж и дохода от роста капитала, приходящегося на обыкновенные акции.

VENTURE CAPITAL COMPANY = КОМПАНИЯ ВЕНЧУРНОГО КАПИТАЛА – Venture Capital Company:- government, semi-government, or private firm that provides startup or growth equity capital and/or loan capital to promising ventures for returns that are higher than market interest rates. / Компания Венчурного Капитала – компания, занимающаяся вложением капитала с риском. Смотрите также Венчурный Капиталист (Venture Capitalist).

VENTURE CAPITAL CORPORATION = КОРПОРАЦИЯ ВЕНЧУРНОГО КАПИТАЛА – Venture Capital Corporation (VCC):- in some Canadian jurisdictions such as the Province of British Columbia (BC), this term may have a very specific meaning. In BC a VCC is a specially incorporated investment company in which investors may receive a special investment incentive in the form of a refundable tax credit. For example, an investor in a VCC may receive a 30% refundable – in cash – credit from the provincial government. A VCC invests in so-called 'Eligible' small businesses that mean certain criteria, e.g., manufacturing, processing, high tech, etc.

VENTURE CAPITAL FUNDING = ФОНДИРОВАНИЕ ВЕНЧУРНОГО КАПИТАЛА – Venture Capital (VC) Funding is provided by venture capital firms. These organizations are looking for a specific set of conditions before they will invest funds in an investee.

Consequently, a company in search of cash should be aware of the needs of a venture capital firm before contacting them about a possible investment. The following issues should all be considered when pursuing venture capital funding:- (i) Relevant Investments:- each venture capital firm builds up an area of expertise. They have partners and supporting staff who are experts in certain industries, as well as deep connections within that area. For example, a firm may only investment in green technology or biotechnology, because that is their comfort zone. Consequently, research these firms in advance to see where they invest, and only contact those firms that have a history of doing so in the industry in which your company is located. (ii) Growth:- venture capital firms are deeply interested in obtaining a return on their investment of several hundred percent. This means that you must be able to present an opportunity to them that can potentially achieve a massive revenue increase within a relatively short period of time, and justify how this expansion will take place. Your argument should include a discussion of what competitors will be doing at the same time, and how your business has such a unique competitive advantage that it will rise above the competition and grab additional market share. (iii) Expertise:- a venture capitalist that is willing to invest millions of Dollars wants to put its cash in the hands of experienced business people, not raw neophytes. This means you must present a management team that has relevant expertise in expanding a business and bringing products to market. At a minimum, fill the most crucial positions with experienced personnel before approaching a venture capitalist. (iv) Loss Of Control:- venture capital firms want to take a significant stake in an investee. They will certainly want one or more board seats, and may also want some degree of control over how the business is eventually sold. Therefore, you should make it clear that you are willing to have some loss of control in exchange for an investment. The preceding points should make it clear that the typical venture capitalist is essentially searching for a needle in a haystack. Few organizations can present an opportunity that meets VC funding criteria. Consequently, it can make more sense to use every other source of funding before trying to get venture capital funding – the odds are simply not in your favor.

VENTURE CAPITAL FUNDS = ФОНДЫ ВЕНЧУРНОГО КАПИТАЛА – Venture Capital Funds are are investment funds that manage the money of investors who seek private equity stakes in startup and small- to medium-sized enterprises with strong growth potential. These investments are generally characterized as high-risk/high-return opportunities. In the past, venture capital investments were only accessible to professional venture capitalists, although now accredited investors have a greater ability to take part in venture capital investments. Venture capital is a type of equity financing that gives entrepreneurial or other small companies the ability to raise funding. Venture capital funds are private equity investment vehicles that seek to invest in firms that have high-risk/high-return profiles, based on a company's size, assets and stage of product development. Venture capital funds differ from mutual funds and hedge funds in that they focus on a very specific type of early-stage investment. All firms that receive venture capital investments have high-growth potential, are risky and have a long investment horizon. Further, venture capital funds take a more active role in their investments by providing guidance and often holding a board seat. Venture capital funds have portfolio returns that resemble a barbell approach to investing. Many of these funds make small bets on a wide variety of young startups, believing that at least one will achieve high growth and reward the fund with a comparatively large payout at the end. This allows the fund to mitigate the risk that some investments will fold. The Operation of a Venture Capital Fund:- venture capital investments are considered either seed capital, early-stage capital or expansion-stage financing depending on the maturity of the business at the time of the investment. However, regardless of the investment stage, all venture capital funds operate in much the same way. First, like all funds, venture capital funds must raise money prior to making any investments. A prospectus is given to potential investors of the fund who then commit money to that fund. All potential investors who make a commitment are called by the fund's operators and individual investment amounts are finalized. From there, the venture capital fund seeks private equity investments that have the potential of generating positive returns for its investors. This normally means the fund's manager or managers review hundreds of business plans in search of potentially high-growth companies. The fund managers make investment decisions based on the prospectus and the expectations of the fund's investors. After an investment is made, the fund charges an annual management fee of around 2%. Investors of a venture capital fund make returns when a portfolio company exits, either in an IPO or a merger and acquisition. If a profit is made off the exit, the fund also keeps a percentage of the profits in addition to the annual management fee. / Фонды Венчурного Капитала:- взаимные фонды, инвестированные в ценные бумаги фирм, которые малоизвестны и часто ещё не зарегистрированы в Комиссии по Ценным Бумагам и Биржам.

VENTURE CAPITALIST = ВЕНЧУРНЫЙ КАПИТАЛИСТ – A Venture Capitalist is an investor who either provides capital to startup ventures or supports small companies that wish to expand but do not have access to equities markets. Venture capitalists are willing to invest in such companies because they can earn a massive return on their investments if these companies are a success. Venture capitalists also experience major losses when their picks fail, but these investors are typically wealthy enough that they can afford to take the risks associated with funding young, unproven companies that appear to have a great idea and a great management team. Well-known venture capitalists include Jim Breyer, an early Facebook (FB) investor, Peter Fenton, an investor in Twitter (TWTR), Peter Theil, the co-founder of PayPal (PYPL) and Facebook's first investor, Jeremy Levine, the largest investor in Pinterest, and Chris Sacca, early investor in Twitter and ride-share company Uber. Venture capitalists look for a strong management team, a large potential market and a unique product or service with a strong competitive advantage. They also look for opportunities in industries that they are familiar with, and the chance to own a large percentage of the company so that they can influence its direction. Brief History of Venture Capital in the US:- some of the first venture capital firms in the US started in the mid to early 1900s, around the time of the second World War. Georges Doriot, a Frenchman who moved to the US to get a business degree and ended up staying to teach at Harvard's business school and work at an investment bank would go on to found what would be the first publicly owned venture capital firm, American Research and Development Corporation, or ARDC. What made ARDC remarkable was that for the first time, it was a firm that raised money from sources other than exclusively wealthy family's. For a long time in the US, wealthy family's like the Rockefellers or Vanderbilts were the ones to fund start-ups or provide capital for growth. ARDC's had millions in it's account from educational institutions and insurers. Firms like Morgan, Holland Ventures, and Greylock Ventures were founded by ARDC alums, and still other firms like J.H. Whitney & Company popped up around the mid XX century. Venture Capital began to resemble the industry it's known as today after the Investment Act of 1958 was passed. The act made it so small business investment companies could be licensed by the Small Business Association that had been established five years earlier by then President Eisenhower. Those licenses 'qualified private equity fund managers and provide(d)s them with access to low-cost, government-guaranteed capital to make investments in US small businesses'. Venture capital, by it's nature invests in new businesses with high potential for growth but also an amount of risk substantial enough to scare off banks. So it's not too surprising that Fairchild Semiconductor (FCS), one of the first and most successful semiconductor companies, was the first venture-capital backed startup, setting a pattern for venture capital's close relationship with emerging technologies in the Bay Area of San Francisco. Private equity firms in that region and time also set the standards of practiced used today, setting up limited partnerships to hold investments where professionals would act as general partners and those supplying the capital would serve as passive partners with more limited control. Numbers of independent venture capital firms increased throughout the 1960s and 1970s, prompting the founding of the National Venture Capital Association in the early 1970s. Dot-Com Bust:- venture capital firms began posting some of their first losses in the mid 1980s after the industry had become flush with competition from firms both in and outside the US looking for the next Apple (AAPL) or Genentech. As IPO's from

VC backed companies were looking increasingly unremarkable, venture capital funding of companies slowed. It wasn't until about mid 1990s that venture capital investments started back with any real vigor only to take a hit in the early 2000s when so many tech companies fell apart prompting venture capital investors to sell off what investments they had at a substantial loss. Since then, venture capital has made a substantial comeback, with USD47 billion Dollars invested into startups as of 2014. Structure:- a venture capital firm, along wealthy individuals, insurance companies, pension funds, foundations, and corporate pension funds among others pool money together into a fund to be controlled by a VC firm. All partners have part ownership over the fund, but it is the VC firm that controls where the fund is invested, usually into businesses or ventures that most banks or capital markets would consider too risky for investment. The Venture capital firm is the general partner, while the pension funds, insurance companies, etc are limited partners. Compensation:- payment is made to the venture capital fund managers in the form of management fees and carried interest. Depending on the firm, roughly 20% of the profits are paid to the company managing the private equity fund while the rest goes to the limited partners who invested into the fund. General partners are usually also due an additional 2% fee. Positions Within a VC Firm:- the general structure of the roles within Venture Capital firm vary from firm to firm, but they can be broken down to roughly three position:- (i) Associates usually come into VC firms with experience in either business consulting or finance, and sometimes a degree in business. They tend to more analytical work, analyzing business models, industry trends and subsections, while also working with companies in a firm's portfolio. Those who work as 'Junior Associate' and can move to 'Senior Associate' after a consistent couple of years. (ii) Principal is a mid level professional, usually serving on the board of portfolio companies and in charge of making sure they're operating without any big hiccups. They're also in charge of identifying investment opportunities for the firm to invest in, and negotiating terms for both acquisition and exit. (iii) Principals are on a 'partner track', and depending on the returns they can generate from the deals they make. Partners are primarily focused on identifying areas or specific businesses to invest in, approving deals whether they be investments or exits, occasionally sitting on the board of portfolio companies, and generally representing the firm. Venture Capitalist is a private investors who provide venture capital to promising business ventures. They typically invest where at least 25 percent annual returns within one to five years are feasible, and often demand 50 percent or more ownership to exercise control over the investee firm to offset their high risk. Often they also provide management and industry expertise and business connections with other firms and venture capitalists. Their objective usually is to bring the business to its initial public offering (IPO) stage so that they can sell their shareholdings to the public at high profit, and get out. See also Adventure Capitalist; and Angel Investor. A Venture Capitalist is a person who invests in a business venture, providing capital for start-up or expansion. The majority of venture capital (VC) comes from professionally-managed public or private firms who seek a high rate of return by (typically) investing in promising startup or young businesses that have a high potential for growth but are also high risk. VC firms typically invest in business sectors such as IT, bio-pharmaceuticals, clean technologies, semiconductors, etc. An investment from a venture capitalist is a form of equity financing – the VC investor supplies funding in exchange for taking an equity position in the company. Equity financing is normally used by non-established businesses that are unable to secure business loans from financial institutions (debt financing) due to insufficient cash flow, lack of collateral, or high risk profile. A company may also solicit the participation of venture capitalists due to the need for additional business expertise. For example, in 1981 Bill Gates decided that Microsoft needed strategic thinking and sound advice from an experienced business person and he was able to convince venture capitalist Dave Marquardt to invest in Microsoft and join the board of directors, even though Microsoft was not in need of investment capital at the time. As it turned out, Dave Marquardt was the only venture capitalist ever to invest in Microsoft and he remained on Microsoft's board for over 30 years. VC investments in businesses are typically long-term (the average is from five to eight years). This is normally how long it takes for a young business to mature to the point where its equity shares have value and the company goes public or is bought out. VC firms expect returns on investment of 25% or greater given the risk profile of the companies they invest in. VC firms obtain investment capital by pooling money from pension funds, insurance companies, and wealthy investors. The firm makes the decisions about which businesses to invest in and receives management fees and a percentage of the profits as compensation. VC firms range in size from small (capital pools of a few million Dollars, typically investing in only a few new businesses each year) to huge (billions of Dollars in assets and invested in hundreds of companies). For example, Accel Partners, a VC investor in Facebook, Etsy, and Dropbox, manages over USD6 billion in pooled funds. Who Has Control of the Company When a VC Investor is Involved? VC financing is a poor choice for entrepreneurs who wish to retain control of their business. In exchange for providing funding most VC firms obtain majority voting rights by having the majority of the shares (or a preferred class of shares that are senior to common shares), as well as special veto rights. VC investments are often structured so that in the case of a share sale the VC investors have priority rights in terms of compensation. To additionally safeguard their investments VC firms take an active role in the businesses they invest in, typically supplying a board member and involving themselves in all important management decisions, including exercising veto rights over issues such as the sale of the company, additional financing, major business expenditures, etc. How Hard is it to Get Venture Capital Funding For a Business? Unfortunately the vast majority of businesses do not qualify for venture capital funding. VC firms are very choosy about the businesses they invest in – according to the US Small Business Administration less than 0.1% of businesses are funded by venture capital. Of the few that are able to obtain VC funding, almost all are firms that are past the startup stage and can demonstrate a viable product or service. The vast majority of new business seed money still comes from the business owner themselves or from angel investors. Venture Capitalist (VC) is a professional equity-based investor. He/She manages one or more venture capital funds looking for suitable high-reward investments. VC investment are normally in riskier start-up or expansion ventures. Being high-risk investors, venture capitalists normally look for a substantially higher rate of return than might be realized in more traditional investments. (ARDC), и Дьжей.Эйч. Витни Энд Кампэни (J.H. Whitney & Company). Президент Айзенхавэ (Eisenhower). Фэачайлд Сэмикэндакто (Fairchild Semiconductor; Эф.Си.Эс. (FCS)). Дат-Кам (Dot-Com). Эпл (Apple; Эй.Эй.Пи.Эл. (AAPL)) или Дьженэнтэк (Genentech). Бил Гейтс (Bill Gates) Майкрософт (Microsoft) Дэйв Маква (Dave Marquardt). Эксэл Патнёз (Accel Partners), Фэйсбук (Facebook), Этси (Etsy), и Дропбокс (Dropbox). Венчурный Капиталист:- лицо, которое предоставляет полный набор финансовых услуг для новых или растущих коммерческих предприятий, например, таких, как капитал для создания новой компании и её расширения, изучение возможностей рынка, консультации по мэнэдьжменту, помощь при переговорах о технических соглашениях, в наборе служащих и развитии соглашений с занятыми. Венчурный Капиталист – лицо, инвестирующее деньги в новые предприятия.

VENTURE CAPITAL LIMITED PARTNERSHIP = ТОВАРИЩЕСТВО ВЕНЧУРНОГО КАПИТАЛА С ОГРАНИЧЕННОЙ ОТВЕТСТВЕННОСТЬЮ (или ХХ) – Venture Capital Limited Partnership:- an agreement between a venture capital firm and a start-up company in which the venture capital firm provides funding and, in exchange, receives a certain percentage of ownership in the company. In other words, the venture capital firm is the limited partner and the start-up is the general partner, which manages the company. This structure gives the venture capital firm limited liability; that is, if the company goes bankrupt, the venture capital company can lose no more than the amount it invested. It also provides the start-up with capital necessary to continue operations and

perhaps become profitable. In Australia the Venture Capital Limited Partnerships (VCLPs) are investment vehicles that provide tax exemptions for those investing in innovative companies at the early and growth stages of a startup. At these stages of development, companies will typically have received one or more rounds of initial funding but not yet have the scale and track-record needed to go public or attract buy-in from institutional investors. Reforming VCLPs will make them more internationally competitive and will attract greater levels of venture capital investment. What is new? Under the new arrangements:- (i) a new 10 per cent non-refundable carry-forward tax offset is available to partners in new Early Stage Venture Capital Limited Partnerships (ESVCLPs) for capital invested during the year; (ii) the maximum fund size for new and existing ESVCLPs has been increased from AUD100 million to AUD200 million; and (iii) ESVCLPs are no longer needed to divest a company when its value exceeds AUD250 million. Changes to both the VCLP and ESVCLP regimes relax eligibility and investment requirements to allow managers to undertake a broader range of investment activities and greater diversity of investors. When is it happening? The enabling legislation, the Tax Laws Amendment (Tax Incentives for Innovation) Bill 2016, received Royal Assent on 05 May 2016, as announced by the Minister for Industry, Innovation and Science. The new arrangements came into effect on 01 July 2016, with the new tax offset available for eligible investments made on or after this date. Venture Capital Limited Partnership is a partnership between a startup company and a brokerage firm or entrepreneurial company that provides capital for the new business in return for stock in the company and a share of the profit. The Venture Capital Limited Partnership (VCLP) program is designed to increase the amount of foreign investment in the Australian venture capital sector by providing tax incentives to certain foreign VCLP investors (eligible venture capital partners). Innovation Australia administers the program and maintains the register of applications. Benefits:- key benefits of the program include:- (i) flow-through tax treatment for a VCLP; and (ii) an exemption for eligible foreign venture capital partners from income tax on profits (capital or revenue) from the disposal by the VCLP of eligible venture capital investments. Eligibility:- for the tax benefits to apply, the VCLP must be registered and remained registered under the provisions of the Venture Capital Act 2002. If you're a fund manager, you can apply to Innovation Australia for registration as a VCLP if you meet all the following conditions:- (i) you seek to raise a new venture capital fund to make investments in Australian businesses with total assets of not more than AUD250 million; (ii) the fund is structured as a limited partnership; (iii) the fund has committed capital of at least AUD10 million; and (iv) committed capital is the sum of the amounts that the partner may, under the partnership agreement, become obliged to contribute to the partnership. Innovation Australia will grant registration if it is satisfied that the application meets the requirements. A VCLP can only make eligible investments and carry on the business of a VCLP. An eligible venture capital investment is an investment that:- (i) does not represent more than 30% of the VCLP's committed capital; (ii) is an acquisition of new shares or units; (iii) is an Australian business in its early stage of development; (iv) has total assets of no more than AUD250 million; (v) does not have property development, land ownership, certain finance activities, insurance, construction or the making of passive investments as its primary activity; and (vi) is not listed on the stock exchange. / Товарищество Венчурного Капитала С Ограниченной Ответственностью (вкладывающее средства в рисковый капитал). Инвестиционное предприятие, организованное брокерскими или предпринимательскими компаниями с целью привлечения капитала для организуемых (start-up) компаний или компаний, находящихся на ранних стадиях разработки продуктов или услуг. Товарищество обычно приобретает часть акций компании в обмен на предоставляемый капитал. Участники товарищества с ограниченной ответственностью получают доход от прибылей, которые может получить компания. Если компания действует успешно и реализует свои акции в открытой продаже, то участники товарищества с ограниченной ответственностью могут получить средства в результате продажи своих ранее частных акций в открытой продаже. Товарищество такого типа отличается от товарищества с ограниченной ответственностью по вложениям в исследования и разработки (research and development limited partnership) тем, что в товариществах с ограниченной ответственностью по вложениям в исследования и разработки (R&D) доходы получаются только от реализации определённой продукции, продажу которой они гарантируют (underwrite), в то время как товарищество с ограниченной ответственностью, вкладывающее средства в рисковый капитал, участвует в прибылях компании вне зависимости от того, какая продукция или услуги реализуются. Смотрите также (Entrepreneur); и (Limited Partnership). Партнёрство Венчурного Капитала С Ограниченной Ответственностью:- инвестиционный проект брокерской или предпринимательской фирмы, предназначенный для привлечения капитала с целью создания новых компаний или для поддержки фирм, находящихся на ранней стадии процесса разработки товаров или услуг. Обычно партнёрство принимает пакет акций компании в обмен на предоставленный капитал.

VENTURE CAPITAL POOL = ПУЛ ВЕНЧУРНОГО КАПИТАЛА – Venture Capital Pool (VCP) company is a small public capital pool company set up under the rules of the former Vancouver Stock Exchange. Now called a Capital Pool Corp. under the rules of the Canadian Venture Exchange (CDNX).

VENTURE CAPITAL TRUST = ТРАСТ ВЕНЧУРНОГО КАПИТАЛА – A Venture Capital Trust (VCT) is a quoted company which invests in unquoted trading companies. You can buy shares in VCT rather than in the underlying companies, thereby spreading your risk. To encourage investment of this type, various tax reliefs are given by the Inland Revenue (UK) if you invest in an approved VCT.

VENTURE ENHANCEMENT & LOAN DEVELOPMENT ADMINISTRATION FOR SMALLER UNDERCAPITALIZED ENTERPRISES = АДМИНИСТРАЦИЯ ПО СОВЕРШЕНСТВОВАНИЮ ВЫСОКОРИСКОВЫХ ПРЕДПРИЯТИЙ И РАЗВИТИЮ ЗАЙМОВ ДЛЯ МАЛЫХ НЕДОКАПИТАЛИЗИРОВАННЫХ ПРЕДПРИЯТИЙ – Venture Enhancement & Loan Development Administration for Smaller Undercapitalized Enterprises (VELDA SUE):- is a federal agency that buys and pools small business loans made by banks, and then issues securities that are bought by large institutional investors. Duties of the administration shall:- (i) in consultation with originators, develop uniform underwriting, security appraisal, and repayment standards for qualified loans; (ii) determine the eligibility of certified poolers to contract with the Administration for the provision of guarantees for specific mortgage pools; and (iii) provide guarantees for the timely repayment of principal and interest on qualified loans and securities representing interest in, or obligations backed by, pools of qualified loans. Venture Enhancement and Loan Development Administration for Smaller Undercapitalized Enterprises (VELDA SUE) is a federal agency that buys and pools small business loans made by banks, and then issues securities that are bought by large institutional investors. / Администрация роста венчурного капитала и организации кредитования Для Малых Недокапитализированных Предприятий – федеральное агентство, которое покупает небольшие производственные банковские кредиты, а затем выпускает ценные бумаги на основе пула таких кредитов и продаёт их крупным институциональным инвесторам.

VENTURER = АВАНТЮРИСТ (или ИСКАТЕЛЬ ПРИКЛЮЧЕНИЙ, или ПРЕДПРИНИМАТЕЛЬ, или УЧАСТНИК СОВМЕСТНОЙ ДЕЯТЕЛЬНОСТИ, или ПРЕДПРИНИМАТЕЛЬ, ИДУЩИЙ НА РИСК) – Venturer is a business enterprise involving some risk in expectation of gain. Venturer is a person who undertakes or shares in a trading venture. Venturer is a merchant who undertakes a trading venture (especially a venture that sends goods overseas). / Предприниматель:- сторона в совместной деятельности, участвующая в совместном контроле над этой деятельностью.

VENTURI TUBE = ТРУБА ВЕНТУРИ (или РАСХОДОМЕР ВЕНТУРИ) – Venturi Tube is a short pipe with a constricted inner surface, used to measure fluid flows and as a pump. The XVIII–XIX-century Italian physicist Giovanni Battista Venturi (1746–1822), observing the effects of constricted channels on fluid flow, designed an instrument with a narrow throat in the middle; fluid passing

through the tube speeds up as it enters the throat, and the pressure drops. There are countless applications for the principle – e.g., an automobile carburetor, in which air flows through a venturi channel at whose throat gasoline vapor enters through an opening, drawn in by the low pressure. The pressure differential can also be used to measure fluid flow. See also Bernoulli's Theorem. / Итальянский физик Дьжованни Баттиста Вентури (Giovanni Battista Venturi). Смотрите также Теорема Бэрнуйи (или Теорема Бэрнолли; Bernoulli's Theorem). Труба Вентури или Расходомер Вентури, устройство, обеспечивающее местное сужение потока жидкости, газа или пара; применяется для измерения расхода или скорости потока. Названо по имени Итальянского учёного Дьжованни Баттиста Вентури. В трубе Вентури скорость потока изменяется, вызывая изменение давления; в результате возникает перепад давления ($P_2 - P_1$), который однозначно связан с расходом и скоростью потока. Давление измеряется с помощью дифференциального манометра. Погрешность измерения трубы Вентури составляет 2–10%. Труба Вентури состоит из сопла и диффузора.

VENUE = (ТЕРРИТОРИАЛЬНАЯ) ПОДСУДНОСТЬ (или МЕСТО СУДЕБНОГО РАЗБИРАТЕЛЬСТВА) – In Law, a Venue is:- (i) the locality where a crime is committed or a cause of action occurs; (ii) the locality or political division from which a jury is called and in which a trial is held; (iii) the clause within a declaration naming the locality in which a trial will be held; and (iv) the clause in an affidavit naming the place where it was sworn to. The particular jurisdiction where a legal dispute is tried. Venue:- in law, locality in which a criminal offense or civil litigation is to be conducted. The concept of venue involves important issues of public policy in the adjudication of crimes. Local and general statutes specify the court in which a criminal offense or civil claim must be tried. If the case is brought before an improper official, either the accused in a criminal case, a defendant in a civil case, or the court itself may move for a change of court, or a change of venue. The grounds for a change of venue are specified in statutes, though there is considerable discretion left to the court. Grounds for a change have included newspaper reporting considered to have biased all potential jurors, the danger of violence, racial prejudice, and the convenience of jurors or witnesses. In criminal cases the right to request a change of venue generally must be exercised by the accused, but the prosecution also may seek a change. The judge may disqualify himself and request a change to another court in another jurisdiction. A codefendant has the right to request a change even if it requires splitting the trial into two or more separate cases. Venue statutes usually specify that a trial must occur in the district that has subject-matter jurisdiction over the offense. Often this is the district in which the crime was committed or in which a Corpus Delicti (Latin:- 'Body Of The Crime') was discovered. If a trial is held in an improper court, the defendant cannot later complain if he has failed to request a change. If he makes such a request and it is wrongfully denied, an appeals court can require a new trial. / Территориальная Подсудность – отнесение дел к ведению различных судов одного и того же звена судебной системы в зависимости от места совершения преступления (по уголовному делу), места жительства ответчика – физического лица, места нахождения органа или имущества ответчика – юридического лица (по гражданскому делу). Если место совершения преступления определить невозможно, подсудность устанавливается по месту окончания предварительного следствия или дознания. Территориальная подсудность гражданских дел может определяться также:- (i) при неизвестности места жительства ответчика местом нахождения его имущества или его последним известным местом жительства; (ii) в предусмотренных законом случаях по выбору истца (альтернативная подсудность); (iii) соглашением сторон (договорная подсудность); и (iv) указанным в законе местом рассмотрения исков по определённым категориям дел (исключительная подсудность). Территориальная Подсудность:- смотрите в статье Подсудность. Подсудность, разграничение между судами дел, подлежащих рассмотрению по первой инстанции. По Советскому праву различали 3 вида подсудности:- (i) предметную (родовую), (ii) территориальную (местную), и (iii) по связи дел. Предметная Подсудность – отнесение дел к ведению того или иного звена судебной системы в зависимости от вида преступления или предмета и характера гражданского дела. Территориальная Подсудность – отнесение дел к ведению различных судов одного и того же звена судебной системы в зависимости от места совершения преступления (по уголовному делу), места жительства ответчика – физического лица, места нахождения органа или имущества ответчика – юридического лица (по гражданскому делу). Если место совершения преступления определить невозможно, подсудность устанавливается по месту окончания предварительного следствия или дознания. Территориальная подсудность гражданских дел может определяться также:- при неизвестности места жительства ответчика местом нахождения его имущества или его последним известным местом жительства; в предусмотренных законом случаях по выбору истца (альтернативная подсудность); соглашением сторон (договорная подсудность); указанным в законе местом рассмотрения исков по определённым категориям дел (исключительная подсудность). Подсудность По Связи Дел – отнесение к ведению одного и того же суда связанных между собой дел (например, встречный иск подсуден тому же суду, который рассматривает первоначальный иск). Для дел, рассматриваемых военными трибуналами, различают ещё и персональную подсудность – отнесение дел к ведению того или иного звена системы трибуналов в зависимости от воинского звания и должностного положения обвиняемого. Вышестоящий суд вправе принять к производству любое дело, подсудное нижестоящему суду. Споры о территориальной подсудности не допускаются. При поступлении в суд дела, превышающего его предметную подсудность, дело направляется для определения подсудности в вышестоящий суд. Конкретная юрисдикция, где будет рассматриваться правовой спор. Подсудность, разграничение компетенции между судами по рассмотрению дел по первой инстанции. Территориальная подсудность по месту совершения преступления или месту жительства ответчика.

VEO = VISIBLE EMISSION OBSERVATION

VERs = VOLUNTARY EXPORT RESTRAINTS

VERBAND DEUTSCHER VERSICHERUNGS–MAKLER E.V. = ФАБАНД ДОЙЧА ФАЗЫХЯРУНГС–МАКЛЯ Э.ФАУ. (или СОЮЗ НЕМЕЦКИХ СТРАХОВЫХ МАКЛЕРОВ Э.ФАУ.) – Verband Deutscher Versicherungs-Makler E.V. (VDVM) is the German insurance brokers' association. Headquartered in Hamburg, Germany. Verband Deutscher Versicherungsmakler E.V. is a trade association that represents insurance brokers in Germany. Verband Deutscher Versicherungsmakler e.V. was founded in 1918. VDVM represents more than 600 insurance broker companies with more than 12 000 employees. As traditional and also forward-looking professional association the aim of VDVM is to consistently represent the professional interests of its members and to support their commercial interests. Another concern is to promote general acceptance of the profession as qualified insurance broker. VDVM works in different ways on a national and international level to represent and support the professional interests of its members. Furthermore, the association offers a variety of different services for its members. The activities of the association for the profession:- It works on a federal and state level for a legislation that safeguards the interests of the insurance broker, e.g., in case of hearings and by comments. It exchanges information and ideas with federal ministries, the Federal Supervisory Authority for Financial Services as well as central associations and organisations of the insurance business such as GDV (short for the Gesamtverband der Deutschen Versicherungswirtschaft E.V. or, in English, German Insurance Federation) IHKs (short for the Industrie- und Handelskammertag or, in English, Chamber of Industry and Commerce)/DIHKs (short for the Deutscher Industrie- und Handelskammertag E.V. or, in English, German Chamber of Industry and Commerce). It is represented in the insurance council of the Federal Supervisory Authority for Financial Services and in the so-called Committee of Assignment of Tasks in accordance with the Insurance Broking Act (VersVermV). It networks with other associations of intermediaries such as BVK (short for the Bundesverband Deutscher Versicherungskaufleute e.V.

or, in English, the Federal Association of German Insurance Representatives) and VGA (short for the Verband der Geschäftsstellenleiter der Assekuranz, now the Bundesverband der Assekuranzführungskräfte E.V. or, in English, the Federal Association of German Insurance Executives) in respect of all important questions relating to insurance intermediaries The association is in close contact to representatives of insurance companies thus contributing to a better mutual understanding. Furthermore, VDVM works in many national and international panels and institutions to enforce the interests of the insurance brokers:- In Germany these are for example the community committee for the insurance field force of the GDV discussing legal questions in respect of sales and insurance with insurers and other associations of intermediaries which have a direct impact on intermediaries and their customers. VDVM works on an international level together with BIPAR, the Bureau International des Producteurs d'Assurances & de Réassurances and is represented in the so-called steering committee. This especially applies to the European Regulation of Intermediaries as well as to questions relating to professional practices and taxes. As a member of the Federal Association of the Economy of Services, VDVM has got various possibilities of lobbying activities to support the interests of the small and medium-sized businesses. By means of public relation and advertisement VDVM promotes the reputation of the professional insurance broker as highly qualified profession in the service sector. VDVM advocates an education which assures quality and which is specific to brokers. For this reason VDVM has developed the education 'certified insurance broker'. Furthermore the association is connected in many aspects with BWV (short for the Berufsbildungswerk der Deutschen Versicherungswirtschaft E.V. or, in English, the German Insurance Association for Vocational Training or the Professional Association of the German Insurance Business) and DMA (short for the Deutsche Makler Akademie E.V. or, in English, the German Broker Academy). Once a year VDVM invites specialised journalists of all important newspapers and magazines to attend a press conference for exchanging ideas and information about today's chances and challenges in the insurance business. / Фабанд Дойча Фазыхярунгс-Макля Э.Фау. (Verband Deutscher Versicherungs-Makler E.V.; Фау.Дэ.Фау.Эм. (VDVM)). Гезамтфабанд дэа Дойчэн Фазихерунгзвиртшафт Э.Фау. (Gesamtverband der Deutschen Versicherungswirtschaft E.V.). Дэ.И.Ха.Ка. (DMA) (обозначение для Дойчэ Макля Акадэми Э.Фау. (Deutsche Makler Akademie E.V.)).

VERDANT = ИЗУМРУДНОЕ (или ЗЕЛЕНЕЮЩЕЕ, или ОБЛИСТВЕННОЕ) – Verdant:- green in tint or color; green with grass or other rich vegetation; of the bright green color of lush grass.

VERIFIABILITY = ВЕРИФИЦИРУЕМОСТЬ (или ПОВЕРЯЕМОСТЬ, или ПРОВЕРЯЕМОСТЬ, или СВЕРЯЕМОСТЬ, или ДОКАЗЫВАЕМОСТЬ) – Verifiability:- the accounting rules that apply to US companies are designed to produce accounting information that investors, regulators and the public can understand and trust as truthful representations of a company's financial condition. One of the key principles behind those accounting rules is verifiability:- the ability to see how a company arrives at a certain result from the data it provides. A company's accounting results are verifiable when they're reproducible, so that, given the same data and assumptions, an independent accountant can produce the same result the company did. Say your business lists a piece of equipment as an asset worth USD10 000. If you told an outside accountant how much the equipment originally cost, how old it is, and what schedule you used to depreciate the equipment, that accountant should come up with the same figure. If not, the result isn't verifiable. Assumptions:- assumptions play a huge role in accounting. Forecasting such complexities as sales revenue, warranty costs, productivity or product returns all involves making assumptions about customers, competitors, the economy, even your own employees. Verifiability isn't about determining whether the assumptions a company makes are correct. Rather, it's about determining whether the accounting result the company reaches is appropriate for the data, given the assumptions that have been made. Importance:- major accounting scandals sometimes hinge on verifiability. The financial results of Enron – one of the largest corporations in the country before it collapsed into scandal and bankruptcy in 2002 – were shot through with unverifiability. Its accounting was a black box, with outsiders unable to figure out how the company arrived at the astounding revenue and profit figures it reported. The Financial Accounting Standards Board, which writes the rules for the US accounting profession, says that verifiability provides assurance that 'accounting measures represent what they purport to represent'. It's not enough for a company to say the answer is '2'. It also has to show you the '1 + 1' on the other side of the equation. Limitations:- verifiability doesn't have to do with determining the truthfulness of the data a company provides, but rather with making sure its results logically flow from the data. If a company tells you that total revenue is USD200 000, total costs are USD125 000 and profit is USD75 000, the math is verifiable – but if the revenue and cost figures are incorrect, the profit figure is not accurate. As mentioned, verifiability also doesn't pass judgment on whether the assumptions made are correct or even appropriate, just whether the result matches the assumptions. Finally, verifiability is silent on the interpretation of accounting results. A company may tell shareholders that it's strong because revenue rose 25 percent last year. The claim about revenue increasing can be tested for verifiability; what the increase says about the company's prospects cannot. Other accounting principles – representational faithfulness, reliability – cover these matters. Verifiability is where the fact is capable of being tested (verified or falsified) by experiment or observation. Verifiability means that the accounting information presented in financial statements must be verifiable by independent accountants. Accounting information presented in the financial statements is considered verifiable if two independent accountants (e.g., auditors) can reasonably conclude on the basis of their verification that it is a fair reflection of the underlying transactions and circumstances. Verification of accounting information can be either direct or in-direct. Importance:- verifiability helps to assure users that the financial statements are a true and fair representation of the underlying transactions. If the information contained in the financial statements is not verifiable, the users would have no sound basis to place trust in the information. In some cases it is necessary to disclose forward-looking information in the financial statements that is not currently verifiable but is of relevance to users. An example of such information is the accounting and disclosure of a pending legal dispute. It is important in such instances to disclose all necessary assumptions, methods and context relating to such information in order to facilitate the users in their assessment of its reliability. Verifiability is not a fundamental qualitative characteristic but is a highly desirable one. Verify:- to prove the truth of, as by evidence or testimony; confirm; substantiate:- Events verified his prediction. / Энрон (Enron). Проверяемость:- качественная характеристика финансовой информации, означающая, что данные финансовых отчётов могут быть проверены или воспроизведены независимыми лицами с использованием одинаковых средств измерения.

VERIFIABLE = ВЕРИФИЦИРУЕМОЕ (или ПОВЕРЯЕМОЕ, или ПРОВЕРЯЕМОЕ, или СВЕРЯЕМОЕ, или ДОКАЗЫВАЕМОЕ) – A transaction is Verifiable when it can be substantiated. The concept is important in accounting, where auditors are called upon to verify account balances by comparing them to source documents or calling upon third parties for substantiation. In order to be verifiable, there must be an accounting system in place that clearly shows how information was derived. Thus, a verifiable system would allow two people to arrive at the same result by accessing the system's data and recorded assumptions.

VERIFICATION = ВЕРИФИКАЦИЯ (или ПОВЕРКА, или ПРОВЕРКА, или СВЕРКА) – Verification is the use of various procedures to ensure the accuracy or truth of information. For example, auditors may compare source documents to a balance recorded in a company's general ledger to verify that the balance is correct and recorded within the correct date range. Similarly, an auditor can send a confirmation to a company's customer to verify that a receivable balance is correct. Verification is the process whereby those responsible for a prospectus ensure that every statement in it is supported by evidence. A term Verification refers to the principal methods to review, audit, or verify the accuracy of the disseminated data, e.g., internal review, statistical confidence tests, internal audit, audit by outside accountants, cross-checks with other macroeconomic accounts, etc. Context:- under the Special Data Dissemination Standard (SDDS), this may entail, according to the data category under consideration, the reconciliation of stocks and transactions data; reconciliation of reported data with money and banking statistics, custodian data; differences with partner data or preshipment inspection data; the treatment of differences between gross domestic product (GDP) compiled for the production approach and GDP compiled from the expenditure approach. See also Compilation Practices, and Special Data Dissemination Standard (SDDS). / Под Верификацией, от Латинского слова Verificare, означающее Доказывать Истину, понимается . Под Верификацией, от позднелатинского слова Verificatio, означающее Доказательство или Подтверждение, от Латинских слов Verus, означающее Истинный, и Facio, означающее Делаю, понимается эмпирическое подтверждение теоретических положений науки путём 'возвращения' к наглядному уровню познания, когда идеальный характер абстракций игнорируется и они 'отождествляются' с наблюдаемыми объектами. Например, идеальные геометрические объекты – 'точки', 'прямые' и прочие – 'отождествляются' с их чувственными 'образами'. В общем случае верификация – это построение наглядной модели для любой теории. Идея верификации вызревала постепенно, по мере усиления роли логической дедукции в выработке научных понятий. Осознание, главным образом, в математике и теоретической физике, возможного несоответствия между логическим (абстрактным) мышлением и интуитивным мышлением, связанным с наглядностью (пример:- открытие непрерывных функций, не имеющих производных), породило потребность в обосновании связи между абстракцией и реальностью. Известным выражением этой потребности и одновременно выражением позиции эмпирической философии явилось выдвинутое ещё Немецким философом Иммануэлем Кантом (Immanuel Kant; 1724–1804) требование 'наглядного исключения' любой абстракции:- '... необходимо сделать чувственным (sinnlich) всякое абстрактное понятие, то есть показать соответствующий ему объект в созерцании, так как без этого понятие (как говорится) было бы бессмысленным (ohne Sinn), то есть лишённым значения' (Соч., Т. 3, М., 1964, Стр. 302). В философии неопозитивизма это требование получило статус методологического принципа возможности опытной проверки, или принципа верификации. В известном смысле оно аналогично требованию практической применимости абстракций, заключающейся в удалении абстракций, в замене их 'конкретными' объектами, от которых они (могут быть) абстрагированы. Однако, поскольку не всякую применяемую абстракцию можно верифицировать, то есть исключить 'наглядным' способом (ибо не всякая реальность, отражением которой является абстракция, наглядна), критерий верификации не тождествен критерию практики.

VERIFICATION FACTOR = ФАКТОР ВЕРИФИКАЦИИ – Verification Factor:- the verification – factor, as numerically defined, can be calculated from the net mass and the oven dry mass plus the conventional allowance.

VERIFICATION OF DEPOSIT = ВЕРИФИКАЦИЯ ДЕПОЗИТА (или ВЕРИФИКАЦИЯ ВКЛАДА) – Verification of Deposit (VOD) is a document signed by the borrower's financial institution verifying the status and balance of his/her financial accounts.

VERIFICATION OF EMPLOYMENT = ВЕРИФИКАЦИЯ ЗАНЯТОСТИ (или ВЕРИФИКАЦИЯ ТРУДОУСТРОЙСТВА) – Verification of Employment (VOE) is a document signed by the borrower's employer verifying his/her position and salary.

VERIFICATION PHASE = ФАЗА ВЕРИФИКАЦИИ – Verification Phase is the step of the California Energy Contingency Plan and Nebraska Energy Emergency Plan to determine the existence and scope of an energy shortage and report to Energy Commission executives, the Governor, the Legislature where required under the plan, and other policymakers as appropriate.

VERIFICATION STANDARD = СТАНДАРТ ВЕРИФИКАЦИИ (или СТАНДАРТ ПОВЕРКИ) – Verification Standard is the calibrated physical standard used to verify the accuracy of calibration of measurement scales, operating characteristics, or system responses of color-measuring instruments.

VERIFICATION TRIAL = ИСПЫТАНИЕ ВЕРИФИКАЦИЕЙ (или ХХ) – Verification Trial:- a public exhibition of the implementation of research-based Extension recommendations in an actual field-scale farming environment for crops. Program goals are:- (a) to optimize potential for profits, (b) to develop an on-farm database for use in economic analyses and computer-assisted management programs, (c) to aid researchers in identifying areas of production that require further study, (d) to improve or refine existing recommendations, (e) to increase the expertise of County Extension Agents in the specified commodity, and (f) to utilize and incorporate data and findings from the program into Extension educational programs at the county and state levels.

VERIFIED GROSS MASS = ВЕРИФИЦИРОВАННАЯ БРУТТО МАССА (или ПОВЕРЕННАЯ БРУТТО МАССА) – Verified Gross Mass (VGM):- Since 01 July 2016, Regulation 2 under the International Convention for the Safety of Life at Sea (SOLAS) imposed on shippers in the case of the shipment of containers the obligation either to weight the packed container using calibrated and certified equipment, or to weigh the contents of the container and add the weight of the container when empty. In either case, the VGM is to be recorded with the carrier. A failure to comply bears the sanction under the SOLAS Convention that the container 'should not be loaded onto a ship':- see paragraph 4/2, MSC1/Circ.1475, 09 June 2014. These weighing operations obviously incur expense and failure may lead to delay in loading. As this happened after 2010, it unsurprising that there was some pressure in the consultations leading to Incoterms® 2020 for a clear indication to be given as to who, as between seller and buyer, should bear such obligations. Verified Gross Mass:- The shipper is obliged to verify the gross mass of the containers carrying their cargo by either of two permissible weighing methods before these containers can be loaded on a vessel. What is Verified Gross Mass (VGM)? Effective from 01 July 2016, with the SOLAS (Safety of Life at Sea) amendment covering container weighing regulations, a packed container will no longer be allowed to be loaded on board vessels unless its Verified Gross Mass (VGM) has been provided by the shipper to the ocean carriers and/or port terminal representatives prior to the load list cut-off date. The new regulation was adopted by the IMO (International Maritime Organization) to increase maritime safety and reduce the dangers to cargo, containers, and all those involved in container transport throughout the supply chain. Calculating Verified Gross Mass:- The Verified Gross Mass (VGM) is the weight of the cargo including dunnage and bracing plus the tare weight of the container carrying this cargo. SOLAS requires the shipper to provide VGM in a 'shipping document', either as part of the shipping instruction or in a separate communication, before vessel loading. Methods Of Verifying Gross Mass:- The shipper is obliged to verify the gross mass of the containers carrying their cargo by either of two permissible weighing methods before these containers can be loaded on a vessel. Method 1:- Requires weighing the container after it has been packed. Method 2:- Requires weighing all the cargo and contents of the container and adding those weights to the container's tare weight as indicated on the door end of the container. This method will not be practical for shippers of bulk commodities like scrap, grain, etc, and it will be up to local authorities to grant permission to use this method. How VGM Can Impact You? (1) Impact On The Shipper:- With the new regulation, the shipper will be the responsible party for providing the verified gross mass of every

container to the ocean carrier and the terminal representative before vessel loading. But who is the shipper in the context of this new regulation? The shipper is the legal entity:- (i) Named on the ocean bill of lading or sea way bill or equivalent multimodal transport document as shipper; and (ii) With whom (or in whose name or on whose behalf) a contract of carriage has been concluded with a shipping company. Thus, irrespective if delegated to a 3rd party or similar, the shipper will always be the responsible party for providing VGM information so they should be aware of the impact of this new procedure:- (i) Shipper will need to provide VGM information of their containers on shipping instructions no matter whether they send this documentation manually via maersk.com or via electronic data interchange (EDI); (ii) Shipper will need to plan for VGM in the shipment cycle; (iii) They need to establish a process between supply chain members (forwarders, truckers, terminals and shipping line) integrating weighing service; (iv) Shippers need to calculate the potential cost impact for arranging this service as they are legally responsible to obtain and provide VGM; (v) They need to be aware of possible local legislation regarding government imposed penalties/fines; (vi) If a shipper does not comply and provide the VGM information in time the carrier and the terminal representative will not load the containers on the vessel; (vii) Maersk will assess impact of VGM regulations issued by governments. Our aim is to ensure an easy submission of VGM for our customers and easy information; and (viii) exchange with terminals. Shippers will need to share VGM information of their containers on shipping instructions, no matter whether they send this document manually, via maersk.com, or via EDI. (2) Impact On The Vendor (Terminal Operators):- The IMO regulation is clear that no container shall be loaded on a vessel unless a VGM is provided- with no exceptions. It is, therefore, the terminal operator's obligation that a VGM exists before including containers in the final stowage plan. Maersk will ensure that the final load list only includes containers with a VGM. Local and national legislation will dictate the consequences of loading a container without a VGM, and terminal operators naturally need to be aware of this. Terminal operators will be receiving the VGM information either from the shipper or from the ocean carrier, and will need to have EDI or other processes in place to receive and process this information. If the VGM is obtained by weighing at the terminal operator's premises, the terminal operator needs a process to send this VGM information back to the carrier. Maersk will be liaising with all terminal operators to ensure that a process is in place. In rare cases, terminals may weigh a packed container for which a VGM has already been communicated. Where different, the VGM arrived at by the terminal will be used. Other vendors that are not part of the SOLAS Amendment – providing services such as barge, rail, depot, trucking, etc at origin – may be included in the delivery of information relevant for the SOLAS Amendment where this is practical.

VERIFY = ВЕРИФИЦИРОВАТЬ (или ПОВЕРЯТЬ, или ВЫВЕРЯТЬ, или УДОСТОВЕРЯТЬ) – Verify:- to assess the overall reliability and accuracy of an instrument or method of measurement by use of material standards for which the measurable quantities have accepted values. / Поверка Первичная и Периодическая; Поверено; Свидетельство о Поверке; Поверитель; Поверительное Клеймо.

VERMICULATE = ЧЕРВЕОБРАЗНОЕ – Vermiculate:- worm-shaped.

VERMICULITE = ВЕРМИКУЛИТ – Vermiculite:- clay mineral similar to montmorillonite in structure and, in some cases, composition. Vermiculite is typically formed by the alteration of biotite, and it occurs both as large pseudomorphs replacing biotite and as small particles in soils and ancient sediments. It is also formed at the interface between acidic intrusive rocks and basic rocks such as pyroxenites and dunites. Large deposits occur in South Africa, Australia, Russia, and Brazil. In the United States, it is found in Montana and the Carolinas. For chemical formula and detailed physical properties, see Clay Mineral (table). When rapidly heated to about 300 °C (570 °F), vermiculite can expand to 20 times its original thickness; its name, from the Latin word meaning 'To Breed Worms', alludes to this property. In its natural state the mineral has little commercial use, but exfoliated vermiculite is extremely light (specific gravity as low as 0.09) and is used in lightweight concrete or plaster, for thermal and acoustic insulation, or as a packing medium, a soil conditioner, a starting medium for seeds, and a filler or extender in paper, paint, or plastics. / Вермикулит:- инертная среда для выращивания растений, иногда используемая как добавка в почву или для укоренения черенков. Под Вермикулитом, от Латинского слова Vermiculus, означающее Червячок, понимается минерал из группы гидрослюдяных имеющих слоистую структуру с добавочной молекулярной межслоевой водой. При нагревании из пластинок вермикулита образуются червеобразные столбики. Химический состав отвечает приблизительной формуле $Mg_x\ (Mg,\ Fe)_{3-x}\ (AlSi_3O_{10})\cdot(OH)_2\cdot 4H_2O$. Кристаллизуется в моноклинной системе. Образует листоватые агрегаты или крупные пластинчатые кристаллы золотисто-жёлтого или бурого цвета. Твёрдость по минералогической шкале 1–1.5; плотность 2 400–2 700 кг/м^3; не поддаётся истиранию и по смазочным свойствам подобен графиту. При нагревании до температуры 900–1 000 °C вермикулит вспучивается (в результате расщепления частиц под действием расщепляющейся межслоевой воды) с увеличением объёма в 15–20 раз. Возникшие между чешуйками прослойки воздуха обусловливают низкую плотность и высокие тепло- и звукоизоляционные свойства вспученного вермикулита. Вермикулит – продукт вторичного изменения тёмных слюд (биотита и флогопита). Промышленные месторождения вермикулита в бывшем Союзе Советских Социалистических Республик (СССР) известны на Кольском Полуострове (Мурманская Область) и на Урале (Челябинская Область); за рубежом – в Соединённых Штатах Америки (США) (штаты Монтана, Колорадо, Вайоминг, Северная Каролина, Джорджия), в Западной Австралии. Применяется вермикулит в строительстве при изготовлении теплоизоляционных изделий, звукопоглощающих материалов (смотрите Акустические Материалы), лёгких бетонов (смотрите Вермикулитобетон), штукатурных растворов; кроме того, вермикулит применяется в качестве наполнителя резин, пластмасс, красок, ядохимикатов, в производстве антифрикционных материалов; в сельском хозяйстве – для улучшения структуры почв.

VERMILION = ПУНЦОВОЕ (или ЯРКО–КРАСНОЕ, или БАГРЯНОЕ, или АЛОЕ, или КИНОВАРЬ) – Vermilion (sometimes spelled Vermillion):- a variable color averaging a vivid red or slightly orange color. Borrowed from Old French Vermeillon ('Vermilion'), from Vermeil, from Latin Vermiculus ('Little Worm'), from Vermis ('Worm'), ultimately in reference to Kermes Vermilio, a type of scale insect used to make a crimson dye. / Под Киноварью, от Греческого слова Kinnábari, понимается минерал, относящийся к классу сульфидов; химический состав HgS; содержит 86.2% Hg. Кристаллизуется в тригональной системе, образуя кристаллы ромбоэдрического облика и кристаллически зернистые или порошковатые массы. Цвет красный, иногда наблюдается тёмная синевато-серая побежалость. В тонких осколках киноварь прозрачна, обладает ярким 'алмазным' блеском. Твёрдость по минералогической шкале 2–2.5; плотность 8 090–8 200 кг/м^3. Киноварь – наиболее распространённый минерал ртути. Образуется в гидротермальных близповерхностных месторождениях вместе с кварцем, кальцитом, баритом, антимонитом, пиритом, марказитом, реже реальгаром, самородным золотом. В бывшем Союзе Советских Социалистических Республик (СССР) месторождения киновари известны на Украине (Никитовка), в Киргизии (Хайдаркен, Чаувай), на Алтае (Акташ, Чаган-Узун) и другие; за рубежом – в Испании (Альмаден), Югославии (Авала), Италии (Идрия), США (Нью-Альмаден). Природная киноварь служит исходным сырьём для получения ртути, а также для приготовления красок, главным образом художественных (акварельных и масляных). Как художественную краску киноварь применяли уже в Древнем Египте.

VERNALIZATION = ЯРОВИЗАЦИЯ – Vernalization:- the artificial exposure of plants (or seeds) to low temperatures in order to stimulate flowering or to enhance seed production. By satisfying the cold requirement of many temperate-zone plants, flowering can be induced to occur earlier than normal or in warm climates lacking the requisite seasonal chilling. Knowledge of this process has been

used to eliminate the normal two-year growth cycle required of winter Wheat. By partially germinating the seed and then chilling it to 0 °C (32 °F) until spring, it is possible to cause winter wheat to produce a crop in the same year. Devernalization can be brought about by exposing previously vernalized plants or seeds to high temperatures, causing a reversion to the original nonflowering condition. Onion sets that are commercially stored at near freezing temperatures to retard spoilage are thereby automatically vernalized and ready to flower as soon as they are planted. Exposure to temperatures above 26.7 °C (80 °F) for two to three weeks before planting, however, shifts the sets to the desired bulb-forming phase. Vernalization is an exposure of germinated seedlings to low temperatures to promote flowering. A term Vernalization refers to the process via which plants 'sense' the cold of winter, and activate the plant's innate defense response to cold stress, i.e. thereby waiting for spring to begin their flowering. For example, in the Wheat plant (Triticum Aestivum), a gene known as VRN2 represses flowering. However, exposure of that plant to prolonged cold will down-regulate that gene (thereby enabling flowering to begin when spring's warm weather arrives). / Вернализация (Vernalization) или Яровизация (Jarovization), от Латинского слова Vernus, означающее Весенний, – индукция под действием ряда факторов (в основном низкой температуры) ускоренного перехода растений от вегетативного развития к генеративному (цветению и плодоношению). Процесс вернализации имеет генетическую основу. Например, у Arabidopsis Thaliana ген FLC супрессирует формирование цветков в холодный период времени, а ген VRN2 выключает эту супрессию. Явление вернализации было открыто в 1918 Немецким Профессором ботаники Йоханом Густафом Гасна (Johann Gustav Gassner; 1881–1918). В 1929 Советский учёный Трофим Денисович Лысенко (1898–1976) предложил для обозначения наблюдаемого явления термин 'Яровизация'. Термин 'Вернализация' был предложен в 1933 Робэтом О Вайтом (Robert Orr Whyte; 1903–1986) и Пи.Эс. Хадсэном (P.S. Hudson). Яровизация (Vernalization):- реакция растения, находящегося в вегетативном состоянии, на воздействие в определённый период низких положительных температур. Яровизация (стимуляция цветения) – реакция растения, находящегося в вегетативном состоянии, на воздействие в определённый период низких положительных температур (2–10 °C). Свойственна озимым, некоторым двулетним и многолетним растениям. Яровизация – результат адаптации растений к сезонным климатическим изменениям. Обеспечивает переход растений от вегетативного роста к генеративному развитию, то есть цветению. При яровизации происходит подготовка растения к формированию зачатков цветков в конусе нарастания. Впервые начал изучение яровизации Немецкий Профессор ботаники Йохан Густаф Гасна (Johann Gustav Gassner; 1881–1918) в 1918. Способность к яровизации проявляется у некоторых растений в раннем возрасте, например, у озимых зерновых – в фазе прорастания семян. Физиологические механизмы яровизации связаны, вероятно, с образованием в растении фитогормонов, входящих в комплекс гормонов цветения. Яровизацией также называется приём, заключающийся в предпосевном воздействии низкой положительной температуры на семена озимых культур, вследствие чего растения зацветают и при весеннем посеве. Используют в селекции растений для получения нескольких урожаев озимых культур в год или для получения урожая семян при весеннем высеве озимых, для сближения сроков цветения яровых и озимых, для ускорения получения семян овощных культур и тому подобного. Из овощных культур яровизация необходима всем двулетним овощным культурам, если нужно получить семена. Наиболее активны для прохождения яровизации температуры 4–10 °C. Длительность прохождения яровизации зависит от культуры и величины растения. Продолжительность воздействия на маточники овощных культур положительными низкими температурами у различных культур различна. Например, у плотнокочанных лежких сортов Капусты белокочанной – около 4–5 месяцев, у Свёклы – более 50 дней, у Моркови и Пастернака – более 60, Сельдерея 40–50, у Редьки, Репы, Брюквы 30–40, Редиса – 15–30 дней. Чем крупнее продуктивный орган (кочан, корнеплод), чем ближе температура к 4–5 °C, тем быстрее проходит яровизация. Яровизация, реакция растения, находящегося в вегетативном состоянии, на воздействие в определённый период низких положительных температур (2–10 °C). Выражается эта реакция в своеобразной подготовке растения к формированию зачатков цветков в конусе нарастания. Изучение явления яровизации впервые начал Немецкий ботаник Йохан Густаф Гасна (Johann Gustav Gassner; 1881–1918) в 1918. Яровизация свойственна озимым, некоторым двулетним и многолетним растениям. У некоторых образование зачатков цветков может быть непосредственным результатом яровизации. Однако у многих из этих растений (озимые Злаки, двулетняя Белена, озимый Рапс и другие) цветение после яровизации наступает только в условиях длинного дня (смотрите Фотопериодизм). Способность к яровизации проявляется у некоторых растений в раннем возрасте; так, у озимых Злаков – в фазе прорастания семян, у двулетней Белены – в месячном возрасте. Яровизация – результат адаптации растений к сезонным изменениям климата. Физиологические механизмы яровизации связаны, по всей вероятности, с образованием в растении фитогормонов, входящих в комплекс гормонов цветения (смотрите также Цветение Растений). Яровизацией называют также агротехнический приём, заключающийся в предпосевном воздействии низкой положительной температуры на семена озимых культур, которые в результате этого могут зацвести при весеннем посеве. Используется в селекции растений.

VERNAL POOLS = ДЕМИСЕЗОННЫЕ ПУЛЫ (или ВЕШНИЕ ПУЛЫ, или ХХ) – Vernal Pools:- typically, very small ephemeral water bodies (no inlets and outlets), usually forming in shallow depressions, that exist in the spring and fall and are home to small insect, plant, and animal life. Vernal Pools are seasonal depressional wetlands that occur under the Mediterranean climate conditions of the West Coast and in glaciated areas of northeastern and midwestern states. They are covered by shallow water for variable periods from winter to spring, but may be completely dry for most of the summer and fall. These wetlands range in size from small puddles to shallow lakes and are usually found in a gently sloping plain of grassland. Western vernal pools are sometimes connected to each other by small drainages known as Vernal Swales, forming complexes. Beneath vernal pools lies either bedrock or a hard clay layer in the soil that helps keep water in the pool. Climatic changes associated with each season cause dramatic changes in the appearance of vernal pools. The pools collect water during winter and spring rains, changing in volume in response to varying weather patterns. During a single season, pools may fill and dry several times. In years of drought, some pools may not fill at all. In the spring, wildflowers often bloom in brilliant circles of color that follow the receding shoreline of the pools. By early summer, the water has evaporated, and the clay pools appear brown, barren, and cracked. Functions & Values:- However, appearances may be deceiving. The unique environment of vernal pools provides habitat for numerous rare plants and animals that are able to survive and thrive in these harsh conditions. Many of these plants and animals spend the dry season as seeds, eggs, or cysts, and then grow and reproduce when the ponds are again filled with water. In addition, birds such as egrets, ducks, and hawks use vernal pools as a seasonal source of food and water. Status:- Vernal pools are a valuable and increasingly threatened ecosystem, often smaller than the bulldozer that threatens to destroy them. More than 90% of California's vernal pools have already been lost. Great efforts are being made to protect the remaining vernal pools, as their disappearance marks the loss of rare and important habitat and some of the associated plant and animal species as well.

VERNATION = ЛИСТОРАСПОЛОЖЕНИЕ (или ЛИСТОСЛОЖЕНИЕ) – Vernation is the arrangement of bud scales or young leaves in a leaf bud before it opens. Vernation:- the arrangement of leaves in the bud. Vernation is the arrangement of bud scales or young leaves in a shoot bud. They may be rolled lengthwise (circinate); pleated lengthwise (plicate); rolled from the sides to the centre of the underside (involute); rolled from the sides to the centre of the upper side (revolute); rolled from the sides with one side folded around the other (convolute); or folded so that each leaf clasps those next to it inside the fold (conduplicate). / размещение листьев в почке. Листорасположение, порядок размещения листьев на стебле, отражающий симметрию в структуре побега.

Листорасположение зависит в первую очередь от порядка заложения листовых зачатков на конусе нарастания и обычно является систематическим признаком. Различают 3 основных типа листорасположения:- спиральное, или очередное, – от каждого узла стебля отходит 1 лист (Дуб, Берёза, Злаки, Зонтичные); супротивное – на каждом узле сидят друг против друга 2 листа (Клён, Сирень, Губоцветные); мутовчатое – каждый узел несёт 3 и более листьев (Олеандр, Элодея, Уруть). Общая закономерность всех типов листорасположения – равное угловое расстояние между листьями, сидящими на одном узле или на последовательных узлах спирали, называемой Основной Генетической Спиралью. Для супротивного и мутовчатого листорасположения характерно чередование листьев соседних пар или мутовок; при этом на стебле образуются вертикальные ряды листьев (ортостихи), в числе, вдвое большем, чем число листьев на одном узле. Спиральное листорасположение по числу ортостих и величине углов дивергенции (расхождения) между последовательными листьями может быть разнообразным и выражается формулой листорасположения, которая представляет дробь, соответствующую значению угла дивергенции в долях окружности. Наиболее часто встречаются 1/2 (двурядное листорасположение), 1/3 (трёхрядное листорасположение), 2/5, реже – 3/8, 5/13 и так далее. Знаменатель дроби показывает число ортостих; чем он больше, тем меньше листья затеняют друг друга. Причины правильности листорасположения связаны с размерами конуса нарастания и листовых зачатков и их взаимовлиянием. По одной из гипотез, каждый листовой зачаток образует вокруг себя физиологическое поле, тормозящее заложение новых зачатков в непосредственной близости к нему, по другой, – заложение каждого последующего листового зачатка не тормозится, а стимулируется предыдущим.

VERNEUIL PROCESS = ПРОЦЕСС ВЕРНОЙА (или ПРОЦЕСС ВЕРНЕЙЛЯ) – Verneuil Process:- also called Flame-Fusion Process method for producing synthetic rubies and sapphires. Originally developed (1902) by a French chemist, Auguste Verneuil, the process produces a boule (a mass of alumina with the same physical and chemical characteristics as corundum) from finely ground alumina (Al_2O_3) by means of an inverted oxyhydrogen torch that opens into a ceramic muffle. With slight modifications, this method is used to produce spinel, rutile, and strontium titanate. Highly purified alumina is placed in a container with a fine sieve at its base. When the container is tapped by a mechanically-activated hammer, the alumina sifts down into the enclosed chamber. Oxygen passes into this chamber and carries the fine alumina particles into the intense heat of the central part of an oxyhydrogen flame, where they fuse and fall on the molten upper surface of the boule as droplets. Flame characteristics and the rate of powder feed and boule lowering are adjusted to produce a boule of uniform diameter. The temperature of the upper surface of the boule is held just above the melting point, which for colorless sapphire is 2 030 °C (about 3 690 °F). When a boule reaches the desired size, normally 150 to 200 carats, the furnace is shut down, and the boule is cooled. Strain develops during cooling, because the outer surface cools faster than the interior; this phenomenon causes considerable loss from cracking during the manufacturing process. The strain is relieved by splitting the boule longitudinally, which is induced by snapping off its elongated stem. Some residual strain not disadvantageous for gem and most industrial uses is left in the half-boule developed by splitting. Strain-free, whole boules may be produced by annealing at 1 950 °C. Synthetic Corundum:- before 1940 all synthetic corundum was made in Switzerland, Germany, and France. For several years after the discovery of the process of manufacture, all of the production was used for gemstones. Synthetic ruby was the chief product and was produced by using an intimate mixture of aluminum and chromium oxides; 5 percent chromium oxide (Cr_2O_3) yields a pale-pink boule and 6 percent a deep-red one. The higher the percentage of chromium oxide, the more difficult it is to control boule growth and the greater the loss from cracking on cooling. Blue sapphire is produced by adding iron and titanium, green by cobalt, and yellow by nickel and magnesium oxides. Star rubies and sapphires, first developed in 1947 in the United States, are made by adding one percent rutile (titanium oxide, TiO_2) to the starting powder, forming the boules in the usual manner, and then heat treating them at temperatures between 1 100 °C and 1 500 °C. The rutile forms small needlelike crystals that are oriented along the hexagonal crystal planes within the boule; these are similar to the same crystals in natural star sapphire. The synthetic gems have sharper and more distinctly developed stars than the natural crystals. It is very difficult to distinguish between natural and synthetic colorless sapphires. The natural crystals have microscopic irregularly-shaped gas and liquid inclusions, whereas the synthetic gems usually show microscopic cracks along and normal to the intersection of facets. Under the microscope, colored synthetic stones show curved lines parallel to the upper growth surface of the boule. They represent uneven distribution of pigmentation. Occasionally, especially in blue sapphire, they are visible to the unaided eye. Synthetic Spinel:- spinel boules have a square cross section with round corners but otherwise are like corundum boules in manufacture, size, and appearance, although they do not develop internal stresses during cooling. They are made in all colors by adding appropriate pigments. Synthetic Rutile:- synthetic rutile, first produced in 1948 by the Verneuil process, is far superior to the natural material as a gemstone, because natural rutile is dark in color and the pure synthetic boules may be produced in nearly any shade by the addition of appropriate pigments. Rutile boules have a square cross section similar to spinel boules but rarely exceed 100 carats in weight. When removed from the furnace they are black in color, because some titanium is still unoxidized; on heating in an oxygen atmosphere, however, the oxygen is slowly absorbed and the color fades until only a faint yellow tinge remains in unpigmented boules. / Французским химиком Огюстом Вернойем (Auguste Verneuil).

VERNOLIC ACID = ВЕРНОЛИЧЕСКАЯ КИСЛОТА – Vernolic Acid (Leukotoxin) is a Δ12-epoxy fatty acid (i.e. a fatty acid molecule which contains an epoxy ring molecular sub-structure), which is naturally produced in small amounts in the seeds of the wild plants Crepis Palaestina, Vernonia Galamensis, and Euphorbia Lagascae.

VERONICA = VERY EASY RODENT–ORIENTED NETWIDE INDEX TO COMPUTERIZED ARCHIVES

VERRUCOSE = БОРОДАВЧАТОЕ – Verrucose:- of a surface covered with warty protrusions. Verrucose:- covered with wart-like protrusions (or elevations). / Бородавчатое – о поверхности, покрытой бородавками (бородавчатыми выступами). :- покрытое бородавчатыми выступами.

VERSATILE = РАЗНОСТОРОННЕЕ (или МНОГОСТОРОННЕЕ, или УНИВЕРСАЛЬНОЕ) – Versatile:- relating to an anther attached near the middle and moving freely on its support.

VERSICOLOR = ВЭРСИКОЛОР (или РАЗНОЦВЕТНОЕ) – Versicolor:- variable in color. / , от Латинского слова Versus, означающее Стих, и .

VERSION = ВЕРСИЯ – A Version is the identification of an issue of a data element specification in a series of evolving data element specifications within a registration authority. Version is a particular form of something differing in certain respects from an earlier form or other forms of the same type of thing. / Под Версией, от позднелатинского слова Versio, означающее Видоизменение или Поворот, понимается:- (1) одно или несколько отличных друг от друга изложений или объяснений какого-либо факта, события. (2) В следственной и судебной деятельности предположение следователя или суда о наличии или отсутствии событий и фактов из числа имеющих значение для правильного разрешения дела, основанное на доказательствах и других фактических материалах конкретного уголовного дела и построенное с учётом опыта расследования аналогичных дел, а также возможное объяснение их возникновения и характера. Версия является разновидностью гипотезы. Специфика версии состоит в форме её проверки, осуществляемой процессуальным путём, то есть путём проверки, оценки доказательств в формах, установленных уголовно-процессуальным законом. Следственные и судебные версии делятся на общие и частные. Общая версия относится

к предмету доказывания по уголовному делу в целом, в частности содержит предположение о наличии (отсутствии) события преступления и о виновных в нём лицах. Частная версия относится к отдельным сторонам и элементам предмета доказывания, содержит предположение об отдельных сторонах исследуемого события (например, о мотиве преступления, его месте, времени, орудии и так далее). Соотношение между общей и частной версиями по уголовному делу отражает объективно существующую связь между целым, которое призвана объяснить общая версия, и частью этого целого, которое призвана объяснить частная версия. В процессе расследования либо судебного разбирательства уголовного дела по каждому из элементов (или фактов) предмета доказывания, а равно по всей их совокупности могут быть выдвинуты версии противоположного характера (например, о наличии или об отсутствии события преступления; о наличии или об отсутствии отягчающих вину обстоятельств и так далее). Они могут быть выдвинуты любым участником производства по уголовному делу и в случае обоснованности включаются следователем и судом в круг версий, подлежащих проверке. Все имеющиеся по делу версии, независимо от того, кто их выдвинул, должны проверяться полно, всесторонне, объективно. Версии, выдвигаемые в процессе предварительного и судебного следствия, позволяют определить, какие следственные либо судебные действия и в каком порядке целесообразно проводить, то есть позволяют определить общее направление производства по делу. Судебные версии органически связаны со следственными, но имеют свою специфику. С точки зрения суда вывод следователя о виновности обвиняемого составляет лишь версию обвинения, которая подлежит проверке судом в условиях судебного разбирательства. Специфика судебной версии в том и состоит, что суд не ограничивается этой версией, а наряду с ней обязательно проверяет и контрверсию – то есть версию, прямо противоположную версии, выдвинутой обвинением. Суд проверяет также, были ли исследованы до конца все вытекающие из обстоятельств дела версии, противоречащие выводам следствия, в частности версии, выдвинутые обвиняемым или вытекающие из его показаний, содержащиеся в ходатайствах и заявлениях участников производства по делу и так далее. Кроме того, суд проверяет подтверждённость доказательствами версии, положенной в основу обвинения. Характер достоверного объяснения фактов, составляющих предмет доказывания, приобретает лишь та версия, которая объективно подтверждена в ходе следственной и судебной проверки и полностью исключает все другие объяснения.

VERSION IDENTIFIER = ИДЕНТИФИКАТОР ВЕРСИИ – A Version Identifier is an identifier assigned to a version under which a data element registration is submitted or updated.

VERSUS = ВЭРСУС (или ПРОТИВ) – (1) Versus (Latin:- Against, and often written in Italics) is used in legal and general language to mean 'Against' or 'Opposed To', as in 'John Doe versus Richard Roe', and is often abbreviated to v. (with the punctuation point) or vs (without the point). / На Латинском языке, Против или В Отличии От, или В Сравнении С. Дьжон Доу против Ричод Роу (John Doe versus Richard Roe).

(2) Versus:- as the alternative to or in contrast with:- 'freedom of information versus invasion of privacy'.

VERSUS CASH = ПРОТИВ НАЛИЧНЫХ – Versus Cash:- a transaction generally used by two hedgers who want to exchange futures for cash positions. Also referred to as Against Actuals or Exchange for Physicals. See also Against Actuals, and Exchange For Physicals.

VERT = ЗЕЛЁНОЕ (или ПОДЛЕСОК) – Vert:- the heraldic color green.

VERTICAL ACQUISITION = ВЕРТИКАЛЬНОЕ ПОГЛОЩЕНИЕ (или ВЕРТИКАЛЬНАЯ АКВИЗИЦИЯ) – Vertical Acquisition is the buying or taking over a firm in the same industry in which the acquired firm and the acquiring firm represent different steps in the production process.

VERTICAL ANALYSIS = ВЕРТИКАЛЬНЫЙ АНАЛИЗ – Vertical Analysis is the proportional analysis of a financial statement, where each line item on a financial statement is listed as a percentage of another item. Typically, this means that every line item on an income statement is stated as a percentage of gross sales, while every line item on a balance sheet is stated as a percentage of total assets. The most common use of vertical analysis is within a financial statement for a single time period, so that one can see the relative proportions of account balances. Vertical analysis is also useful for timeline analysis, to see relative changes in accounts over time, such as on a comparative basis over a five-year period. For example, if the cost of goods sold has a history of being 40% of sales in each of the past four years, then a new percentage of 48% would be a cause for alarm. Vertical Analysis of the Income Statement:- the most common use of vertical analysis in an income statement is to show the various expense line items as a percentage of sales, though it can also be used to show the percentage of different revenue line items that make up total sales. Vertical Analysis of the Balance Sheet:- the central issue when creating a vertical analysis of a balance sheet is what to use as the denominator in the percentage calculation. The usual denominator is the asset total, but one can also use the total of all liabilities when calculating all liability line item percentages, and the total of all equity accounts when calculating all equity line item percentages. Vertical Analysis is the process of dividing each expense item in the income statement of a given year by net sales to identify expense items that rise more quickly or more slowly than a change in sales. See also Vertical Financial Analysis. Vertical Analysis of financial statements is a technique in which the relationship between items in the same financial statement is identified by expressing all amounts as a percentage a total amount. This method compares different items to a single item in the same accounting period. The financial statements prepared by using this technique are known as Common Size Financial Statements. This analysis is performed on the income statement as well as the balance sheet. (1) Balance Sheet:- When applying this method on the balance sheet, all of the three major categories accounts (i.e. assets, liabilities, and equity) are compared to the total assets. All of the balance sheet items are presented as a proportion of the total assets. These percentages are shown along with the absolute currency amounts. For example, suppose a company has three assets; cash worth USD4 million, inventory worth USD7 million and fixed assets worth USD9million. The vertical analysis method will show these as:- (i) Cash:- 20%; (ii) Inventories:- 35%; and (iii) Fixed Assets:- 45%. (2) Income Statement:- And when applying this technique to the income statement, each of the expense is compared to the total sales revenue. The expenses are presented as a proportion of total sales revenue along with the absolute amounts. For example, if the sales revenue of a company is USD10 million and the cost of sales is USD6 million, the cost of sales will be reported as 60% of the sales revenue. The main advantage of using vertical analysis of financial statements is that income statements and balance sheets of companies of different sizes can be compared. Comparison of absolute amounts of companies of different sizes does not provide useful conclusions about their financial performance and financial position. Usually the vertical analysis is performed for a single accounting period to see the relative proportions of different account balances. But it is also useful to perform vertical analysis over a number of periods to identify changes in accounts over time. It can help to identify unusual changes in the behavior of accounts. For example, if the cost of sales has been consistently 45% in the history, then a sudden new percentage of 60% should catch the attention of analysts. Reasons behind this change should be investigated and then measures should be taken to bring this percentage back to its normal level. Vertical Analysis is a type of financial analysis involving income statements and balance sheets. All income statement amounts are divided by the amount of net sales so that the income statement figures will become percentages of net sales. All balance sheet amounts are divided by total assets so that the balance sheet figures will become percentages of total assets. Vertical Analysis (also

known as Common-Size Analysis) is a popular method of financial statement analysis that shows each item on a statement as a percentage of a base figure within the statement. To conduct a vertical analysis of balance sheet, the total of assets and the total of liabilities and stockholders' equity are generally used as base figures. All individual assets (or groups of assets if condensed form balance sheet is used) are shown as a percentage of total assets. The current liabilities, long term debts and equities are shown as a percentage of the total liabilities and stockholders' equity. To conduct a vertical analysis of income statement, sales figure is generally used as the base and all other components of income statement like cost of sales, gross profit, operating expenses, income tax, and net income etc are shown as a percentage of sales. In a vertical analysis the percentage is computed by using the following formula:- Percantage Of Base = (Amount Of Individual Item / Amount Of Base) x 100. A basic vertical analysis needs an individual statement for a reporting period but comparative statements may be prepared to increase the usefulness of the analysis. Vertical analysis states financial statements in a comparable common-size format (percentage form). One of the advantages of common-size analysis is that it can be used for inter-company comparison of enterprises with different sizes because all items are expressed as a percentage of some common number. Vertical Analysis is a technique for identifying relationship between items in the same financial statement by expressing all amounts as the percentage of the total amount taken as 100. In a balance sheet, for example, cash and other assets are shown as a percentage of the total assets and, in an income statement, each expense is shown as a percentage of the sales revenue. Financial statements using this technique are called common size financial statements. See also Horizontal Analysis. Vertical Analysis is a method of financial statement analysis in which each entry for each of the three major categories of accounts, or assets, liabilities and equities, in a balance sheet is represented as a proportion of the total account. Vertical analysis is also used across other financial statements as a percentage measure. The main advantage of vertical analysis is the balance sheets, income statements and other financial reports of businesses of all sizes can easily be compared. It also makes it easy to see relative annual changes within one business. Vertical analysis reports each line item of a financial statement as a representation of the percentage of the statement's main focus. For an income statement, each line item can be representative of gross sales. On the balance sheet, each line item can be representative of total assets. In a cash flow statement, each line item can be expressed as a percentage of the firm's total cash and cash equivalents. Vertical analysis allows for a company's financial statement to be represented within a standard process across all industries. A snapshot can be taken of a company's financial position by line item. It also allows for easy comparison to previous periods for timeline analysis, including annual quarter and sequential quarter analysis, and analysis of longer time periods such as five years or three years. Financial statements including vertical analysis clearly show line item percentages in a separate column. These types of financial statements, including detailed vertical analysis, are also known as Common-Size Financial Statements and are used by many companies to provide greater detail on a company's financial position. Often, common-size financial statements also incorporate comparative financial statements that include columns comparing each line item to a previously measured period. Vertical Analysis Example:- For example, suppose XYZ Corporation has three assets:- cash and cash equivalents worth USD3 million, inventory worth USD8 million and property worth USD9 million. If vertical analysis is used, the asset column looks like:- (i) Cash and cash equivalents:- 15%; (ii) Inventory:- 40%; and (iii) Property:- 45%. If comparative financial statements are also used, then additional detail from previous periods is also included and an additional comparative column for the percentages of a previous period is added. The method of vertical analysis can also be contrasted with horizontal analysis, which uses one year's worth of entries as a baseline while every other year represents percentage differences in terms of changes to that baseline. A Vertical Analysis is used to show the relative sizes of the different accounts on a financial statement. For example, when a vertical analysis is done on an income statement, it will show the top-line sales number as 100%, and every other account will show as a percentage of the total sales number. For the balance sheet, the total assets of the company will show as 100%, with all the other accounts on both the assets and liabilities sides showing as a percentage of the total assets number. / Вертикальный Анализ:- структурный анализ, один из методов финансового анализа данных отчётности, согласно которому определяются и анализируются удельные веса или процентные соотношения отдельных элементов и статей в итоговых величинах.

VERTICAL–AXIS WIND TURBINE = ВЕТРЯНАЯ ТУРБИНА С ВЕРТИКАЛЬНОЙ ОСЬЮ – In the wind turbine business there are basically two types of turbines to choose from, Vertical Axis Wind Turbines and Horizontal Axis Wind Turbines. They both have their advantages and disadvantages and the purpose of this article is to help you choose the right system for your application. Horizontal axis wind turbine dominate the majority of the wind industry. Horizontal axis means the rotating axis of the wind turbine is horizontal, or parallel with the ground. In big wind application, horizontal axis wind turbines are almost all you will ever see. However, in small wind and residential wind applications, vertical axis turbines have their place. The advantage of horizontal wind is that it is able to produce more electricity from a given amount of wind. So if you are trying to produce as much wind as possible at all times, horizontal axis is likely the choice for you. The disadvantage of horizontal axis however is that it is generally heavier and it does not produce well in turbulent winds. In comes the vertical axis wind turbine. With vertical axis wind turbines the rotational axis of the turbine stands vertical or perpendicular to the ground. As mentioned above, vertical axis turbines are primarily used in small wind projects and residential applications. Vertical-Axis Wind Turbine:- This niche comes from the OEM's claims of a vertical axis turbines ability to produce well in tumultuous wind conditions. Vertical axis turbines are powered by wind coming from all 360 degrees, and even some turbines are powered when the wind blows from top to bottom. Because of this versatility, vertical axis wind turbines are thought to be ideal for installations where wind conditions are not consistent, or due to public ordinances the turbine cannot be placed high enough to benefit from steady wind. Xxxxx. Vertical-Axis Wind Turbine (VAWT) is a type of wind turbine in which the axis of rotation is perpendicular to the wind stream and the ground. Vertical axis wind turbines are advocated as being capable of catching the wind from all directions, and do not need yaw mechanisms, rudders or downwind coning. Their electrical generators can be positioned close to the ground, and hence easily accessible. A disadvantage is that some designs are not self-starting. There have been two distinct types of vertical axis wind turbines:- The Darrieus and the Savonius types. The Darrieus rotor was researched and developed extensively by Sandia National Laboratories in the USA in the 1980's. New concepts of vertical axis wind machines are being introduced such as the helical types particularly for use in urban environments where they would be considered safer due to their lower rotational speeds avoiding the risk of blade ejection and since they can catch the wind from all directions. Horizontal axis wind turbines are typically more efficient at converting wind energy into electricity than vertical axis wind turbines. For this reason they have become dominant in the commercial utility-scale wind power market. However, small vertical axis wind turbines are more suited to urban areas as they have a low noise level and because of the reduced risk associated with their slower rates of rotation. One can foresee some future where each human dwelling in the world is equipped with wind generators and solar collectors, as global peak petroleum is reached making them indispensable for human well being. They are well suited for green buildings architectural projects as well as futuristic aquaponics; where vertical farming in a skyscraper uses automated farming technologies converting urban sewage into agricultural products. Their cost will come down appreciably once they are mass produced on a production line scale equivalent to the automobile industry. The economic development and viable use of horizontal axis wind turbines would, in the future be limited, partly due to the high stress loads on the large blades. It is recognized that, although less efficient, vertical axis wind turbines do not suffer so much from the constantly varying gravitational loads that limit the size of horizontal axis turbines. Economies of scale dictate that if a vertical axis wind turbine with a rated power output of 10 MW could be developed, with at least the same availability as a modern horizontal axis turbine, but at a lower cost per unit of rated power, then it would not matter if its blade efficiency was slightly lower from 56 to about 19–40 percent.

Darrieus Vertical Wind Turbine:- The first aerodynamic vertical axis wind turbine was developed by aeronautical engineer Georges Jean Marie Darrieus (1888–1979) in France and first patented in 1927. Its principle of operation depends on the fact that its blade speed is a multiple of the wind speed, resulting in an apparent wind throughout the whole revolution coming in as a head wind with only a limited variation in angle. Cyclists will recognize that effect:- if they go fast enough there is always a head wind. From the perspective of the blade, the rotational movement of the blade generates a head wind that combines with the actual wind to form the apparent wind. If the angle of attack of this apparent wind on the blade is larger than zero, the lift force has a forward component that propels the turbine. The angle of attack which varies in a revolution between –20 to +20 degrees should not exceed 20 degrees since at higher angles the flow along the blade is no longer laminar, which is a condition required for the generation of a lift force, but becomes turbulent causing stall. An angle of attack between zero and 20 degrees requires a sufficiently high blade speed. A Darrieus turbine cannot be self starting; it needs to be brought to a sufficiently high blade speed by external means. However, the lack of a control system to point the turbine into the wind compensates for this shortfall. The original Darrieus turbine suffered from some negative features such as violent vibrations leading to eventual fatigue blade failure, a high noise level and a relatively low efficiency, which severely limited its success. Variable Geometry Vertical Axis Machines:- P.J. Musgrove in 1975 led a research project at Reading University in the UK whose purpose was to attempt to rationalize the geometry of the blades by straightening out the blades of a Darrieus type wind turbine. This led to the design of a straight bladed vertical axis wind turbine designated as the H rotor blade configuration. At the time it was thought that a simple H blade configuration could, at high wind speeds, overspeed and become unstable. It was thus proposed that a reefing mechanism be incorporated into the machine design thus allowing the blades to be feathered in high winds. These earlier machines with feathering blades were known as Variable Geometry Vertical Axis Wind Turbines. There were a number of these designs which had different ways of feathering their blades. During the late 1970's there was an extensive research program carried out. This included wind tunnel tests and the building of a few prototype machines in the 40–100 kW range. This work culminated in a final reefing arrowhead blade design for a large 25 meter, 130 kW rated machine, located in Carmarthen Bay in South Wales. This machine known as the VAWT 450, was built by a consortium of Sir Robert McAlpine and Northern Engineering Industries (Vertical Axis Wind Turbines Limited) in 1986. The project was funded by the UK government's Department of Trade and Industry. H Rotor Straight Bladed Vertical Machine:- From the research carried out in the UK during the 1970–80 time frame it was established that the elaborate mechanisms used to feather the blades were unnecessary. The drag/stall effect created by a blade leaving the wind flow would limit the speed that the opposing blade in the wind flow could propel the whole blade configuration forward. The fixed straight bladed or H Rotor configuration was therefore self regulating in all wind speeds reaching its optimal rotational speed, early after its cut in wind speed. There have been a few commercial companies producing H rotor wind turbines since the 1980's. However turbine designs were aimed at niche areas of the small wind turbine market. Due to the lower and more predictable stress loading on the blades of vertical axis wind turbines, they are the ideal type of machine for large scale electricity production. This potential for use for economic multi megawatt electricity production has not as yet been exploited. This is due partly due to earlier design failures and partly due to their slightly lower blade efficiency. Impulse And Aerodynamic Vertical Turbines, Tip Speed Ratio (TSR):- Aerodynamic wind turbines can be divided into two main classes:- horizontal axis wind turbines and vertical axis turbines. Large wind turbines up to a rated power of 5 MW are horizontal axis engines, much like the traditional Dutch windmills. This familiarity has given the development of horizontal turbines a higher priority than that of vertical turbines. Modern horizontal axis wind turbines have a high efficiency but their capital cost is high. They have to be directed in the direction of the wind, either manually or by the use of a sensor based yaw-control mechanism, adding to their design complexity and cost. Vertical axis turbines do not need such a control system; and can catch the wind from all directions. Vertical axis wind turbines designs can be either impulse (drag) or lift (aerodynamic) devices. According to Betz's equation, an aerodynamic turbine has a theoretical efficiency of 59 percent and an impulse type engine only 19–40 percent. Not all the energy in the wind can be extracted because if it were possible, the wind speed behind the turbine will be zero thus clogging any flow through the rotor. Part of the wind will flow through the rotor and part around it. The ratio of these two components determines the efficiency of the turbine. It might appear counter intuitive that devices covering the whole swept area have such a low efficiency. However the ancient mariners have long realized that 'Sailing before the wind' is far less energetic than 'Close hauled' or 'Half wind'. Without slip, the maximum rotor speed would be about the same speed as the wind speed. An example is the three cup anemometers commonly used for measuring wind speed. The tip speed ratio is defined as:- Tip Speed Ratio $\alpha = V_{rotor} / V_{wind}$. If the velocity of the cup is exactly the same as the wind speed, the anemometer has a tip speed ratio of unity. The ends of the cups can never go faster than the wind, thus:- $\alpha_{anemometer} \leq 1$. A way of determining whether a vertical axis turbine design is based on impulse drag or aerodynamic lift is through its tip speed ratio α. An $\alpha > 1$ implies some amount of lift, while $\alpha < 1$ means primarily drag. Aerodynamic lift based designs can usually output much more power, more efficiently. There have been multiple designs of vertical axis windmills. In fact there is evidence of the existence of vertical axis wind turbines, which can be traced back centuries before the more common horizontal axis designs. The vertical axis machines have evolved and now come in three basic types:- the Savonius, the Darrieus, and the H-Rotor concepts. The Savonius Impulse Concept:- The Savonius turbine is a vertical axis machine which uses a rotor that was introduced by Finnish engineer Sigurd Johannes Savonius (1884–1931) in 1922. In its simplest form it is essentially two cups or half drums fixed to a central shaft in opposing directions. Each cup or drum catches the wind and so turns the shaft, bringing the opposing cup or drum into the flow of the wind. This cup or drum then repeats the process, so causing the shaft to rotate further and completing a full rotation. This process continues all the time the wind blows and the turning of the shaft is used to drive a pump or a small generator. These types of windmills are also commonly used for wind speed instruments such as the anemometer. Modern Savonius machines have evolved into fluted bladed devices, which have a higher efficiency and less vibration than the older twin cup or drum machines. The Darrieus Aerodynamic Concept:- In 1931 the French engineer George J.M. Darrieus introduced the Darrieus Vertical Axis Wind Turbine. The Darrieus type of machine consists of two or more flexible airfoil blades, which are attached to both the top and the bottom of a rotating vertical shaft. The wind blowing over the airfoil contours of the blade creates an aerodynamic lift and actually pulls the blades along. Although nowhere near as much research has been carried out on these types of machine when compared with the horizontal axis machines, both the USA and Canada did have large research programs working on the Darrieus design in the 1970's and 1980's. This work culminated with the construction of a 4.2 MW machine designated as 'Eole C' at Cap Chat, Québec, Canada. There were a number of commercial wind farms built in the USA using the Darrieus design, most of which were built by The Flow Wind Corporation. The machines proved to be efficient and reliable. However there was a problem with fatigue on the blades. The airfoil blades were designed to flex, allowing for the extra centrifugal forces in high wind and blade speeds. The flexing of the blades led to premature fatigue of the blade material, leading to a number of blade failures. The vertical axis turbines built and tested in the 1970's and 1980's, used a symmetrical airfoil blade profile. Their theory was that, if the airfoil is symmetric then it will provide lift from both sides of the airfoil, therefore generating lift through more of the 360º path of the blades rotation. It was also believed at the time, that lift would only be created by the blade while traveling into the direction of the wind flow and that the drag created by the opposing blade traveling down wind was an undesirable although unavoidable effect. A symmetrical airfoil is not the most efficient approach at providing lift. A design goal was to maximize lift at the same time as utilizing the inevitable drag created by the opposing blade. There have been a number of attempts using hinged blades attached to the end of the cross arm, therefore allowing the aerofoil section of blade to maintain its optimum angle of attack through the maximum portion of its arced rotation. An

optimal blade profile and optimal fixing angle for the blade to the cross arm could achieve the same goal. The wind flowing over the high lift and low drag blade profile, coupled with the blade areas solidity, gives the machine the initial power needed to overcome its inertia. Once momentum has been established, the forward movement of the blade through the air creates its own local wind flow over its contours, creating a varying amount of lift throughout the full 360º of its rotation. In its down wind stroke, the curved underside of the blade acts like the sail of a yacht therefore creating usable torque throughout its rotation. The stalling of the blades at the top and bottom of their arc of rotation is also useful, as it regulates the speed of the blades rotation, implying that the blades accelerate up to a point of equilibrium at which they will not increase their speed no matter how hard the wind blows. The more constant and predictable loadings on a vertical axis turbine blade, coupled with there not being any need for the blades to twist or taper, not only contribute to the possibility of scale increase, but will also enables their production in sections using mechanical mass production techniques. Ropatec Vertical Wind Turbine:- Introduction:- The Ropatec wind rotors developed in Italy are neither proper Darrieus nor Savonius but a hybrid design. The wind rotors are made from airfoil sections like those of an airplane wing. A central panel between the wings referred to as the turtle back, acts as a diffuser and directs the wind flow toward the wings, turning the wind rotor at low wind speed. The Ropatec wind rotor is a vertically driven wind rotor that could be described as a hybrid building upon the Savonius and Darrieus principles. The WRE.060 model is associated with the MSP-Controller, an innovative CPU controlled charge regulator at 48 Volts with an incorporated SMD DC/AC inverter with 4 500 VA continuous output. A central pole referred to as the axis has the electrical generator bolted to the top. The axis and generator are inserted into the wind rotor assembly and the generator is bolted to the inner tube. When the wind rotor turns, it also turns the generator. The wind rotor will start to turn in a light breeze of about 7 km/hr or 4 knots. The maximum rpm is reached in winds of 50 km/hr or 27 knots. The wind rotor has a distinctive shape that creates an aerodynamic braking effect causing it to stall at high wind speeds. Winds stronger than 50 km/hr will not increase the wind rotor speed beyond its maximum rotational speed of 90 rpm. The wind rotor is rated to produce power in winds up to 230 km/hr, the central wind speeds of a Category 2 hurricane or cyclone. It is designed for a maintenance free operation of 15 years. The Ropatec design possesses the following characteristics:- (i) a low cut in wind speed at 2 m/s at every position; (ii) its operation is independent of the wind direction; (iii) it is a low maintenance system; (iv) it generates low noise even at high wind velocities; (v) it does not require a cut off wind speed; (vi) it possesses an aerodynamically auto regulated rotational speed; (vii) its nominal power output is achieved at wind speeds of 14 m/s and higher; (viii) it is not associated with an electromagnetic field built-up; (ix) it has storm suitability up to 56 m/s, with practical experience up to 75 m/s; and (x) it has a reliable, long product life time. The system can produce electricity directly or is expandable to a hybrid system including photovoltaic modules and/or diesel generator sets. Solwind Vertical Axis Wind Turbine:- Description:- The vertical axis wind turbine by Solwind in New Zealand is designed to start up at 1.5 m/s and start producing power at a wind speed of just 3.7 m/s and produce their rated output at 10 m/s. These turbines are extremely quiet in operation. This is due to their special design where the blades do not create the usual coning noise that occurs with conventional horizontal axis wind turbines when the blades pass close to the mast at each revolution. The blades are always at the same distance from the mast. The blades are made from composite fiber glass, stainless steel and lightweight aluminum, making them extremely strong yet flexible and easy to handle. A new Low Speed Magnetic Levitation Alternator (MLA), featuring only one moving part is used. This keeps the wearing components to a minimum, and so prolongs the longevity of the wind turbine. At high wind speeds the turbine will start to stall, causing the machine to slow down at around 27 m/s. In the stalling mode, the turbine will automatically maintain its output speed. This Darrieus based design lends itself to taking the wind from any direction and does not need a yawing mechanism. Generator:- The generator is a low speed Magnetic Levitation Alternator (MLA). The output is 3/6 phase up to 415 Volt AC. A 3 /6 phase rectifier pack with regulator shunt type is available to suit the end user Voltage such as 12 / 24 / 48 / 120 / 240 / 600 Volts DC or any Voltage required. The generator is base mounted at the foot of the mast, and requires no slipping assembly, no dolly bearing assembly, no brush assembly and has no power cables running up the mast. Mast Assembly:- The stayed single pole mast assemblies have been designed for erection with out the aid of any extra lifting gear for remote area operation. A complete self contained power generation system is accommodated within the base of the mast which will mean that only the 230/415 Volts AC will need to be connected to the end user via an underground or poled cable. The mast requires no guide wires and provides a smaller ground footprint than the stayed single pole mast assembly. The mast is constructed from high tensile steel, and come in standard lengths of 6.5 meters for easy handling. The maximum design wind speed is 190 km/hr. For coastal locations stainless steel fasteners are used throughout. Eurowind Wind Turbine Design:- The concept aims at utilizing an innovative and unique adaptation which allows the turbine to be mounted on industrial chimneys and other similar tall structures without inhibiting their normal use. The rotor blade design features an asymmetrical airfoil section selected for its high lift and low drag characteristics and is mounted to its supporting cross arm at a critical angle to optimize its performance. The blades are not twisted and their edges are parallel, unlike the twisted tapering blades of horizontal wind turbines. The simple, regular shape of the blade coupled with the lower blade stresses experienced by vertical axis turbines allow the blades to be produced mechanically in sections by extrusion or pultrusion. A directly coupled slow speed alternator eliminates the need for separate generator sets, gearboxes and clutches. The main features of the Eurowind turbines designs are:- (i) the turbine is self starting; (ii) Vertical axis turbines are omni directional and do not require pointing in the direction of the wind; (iii) the lower blade rotational speeds imply lower noise levels; (iv) perceived as being more aesthetically pleasing; (v) the increased blade configuration solidity and torque assists the machine in self starting; (vi) elimination the risk of the blades reaching equilibrium during start-up rotation by using 3 blades or more; (vii) reduced cyclic loading and power pulsation and fluctuation by using more than 2 blades; (viii) easy access to all mechanical and structural elements of the machine; and (ix) a direct drive, permanent magnet generator is used and there are no gear boxes with the machine having only one moving part. These machines have been adapted for use in the marine environment such as at harbors, on barges or oil rigs. Venturi Wind Turbines:- Introduction:- In horizontal axis wind turbines the blades rotate and describe a circular surface. The rotor extracts the energy from the air flowing through this rotor surface and has a theoretical maximum efficiency of 59 according to Betz's law. In the Venturi turbine concept, the rotor blades are attached to the hub at both ends. When rotating, a spherical surface is generated. Because of this aerodynamic behavior, Venturi effect turbines create a wind flow pattern that converges first, like rapids in a river. Within the sphere, a low pressure area is generated which attracts the air in front of the rotor towards the sphere. After the rotor has absorbed energy from the air, the energy poor air is swung radically outwards through the Venturi planes and is carried away by the surrounding airflow. The air flowing through the turbine and the air surrounding the rotor are used more effectively, resulting into the efficiency of the Venturi turbine being higher than the efficiency of conventional wind turbines. Description:- Venturi turbines create a wind flow pattern that converges first like rapids in a river. This is induced by the unique aerodynamic Venturi characteristics. Therefore the turbine experiences a higher wind speed than other wind turbines would observe. This enables the Venturi turbine to generate electricity at very low wind speeds. Little gusts can be utilized for electricity generation where conventional turbines would use these to start rotating. At inland locations, this characteristic enables the Venturi turbine to generate power during 80 to 90 percent of the time. Other turbines rotate just 50 percent of the time because they are designed for windy locations. Windy locations geographically cover only a small part of the land surface such as at mountain passes and sea sides. When conventional wind turbines are placed inland, energy production is low and down times are long because they will rotate only about half of the time. Also, they are too noisy when they run. At such a location, the Venturi turbine will produce 2–3 times as much energy and down times are short. Wind tunnel measurements at the Technical University of Delft have shown that a three blade Venturi Turbine has a measured efficiency of 85

percent, which is 40 percent higher than the theoretical maximum efficiency of 59 percent in Betz's law. Advantages Of Venturi Turbines:- Reduced Sound Effect:- The tips of conventional wind turbines are the main noise generators. Compared with it, the sound generated by a small Venturi turbine is virtually non existent because it does not have such a tip. Also, there is no gearbox and the number of blades reduces the speed of rotation. Low Down Time:- The six bladed rotor induces a high start up moment. This enables the turbine to run almost continuously, unless there is really no wind. The Venturi effect enables the Venturi turbine to generate a higher level of power at lower wind speeds, which is essential at an inland wind regime, where most of the applications will be found. This also minimizes the down periods to 10 to 20 percent of time where conventional turbines are known to stand still for 50 percent of the time. This results in a more constant power supply to a consuming system or a battery than conventional wind turbines would be able to deliver under the same circumstances. At lower wind speeds the Venturi turbine will potentially generate three times more energy than comparable small wind turbines simply because the Venturi turbine will run and absorb energy from gusts while other wind turbines will require these gusts for their start up. This is of crucial importance for inland locations. Attractive Design And Styling:- Rotors create visual apprehension. Because the running small wind turbine is visually associated with a transparent sphere, this unrest is reduced and is recognized as attractive and pleasing to the eye. The Venturi turbine is a fun object to be placed at locations that are meant to catch the eye, like billboards or attraction park entrances. High Reliability:- Because the blades of the Venturi turbine are attached to the hub at both ends, the feet of the blade and the flexible blade itself are subjected to non fluctuating tensile stresses only. Wind gusts and gyroscopic effects barely influence it. This way of rotor construction is so robust that it practically excludes the failure of the blades. In case a blade would fail, it is still attached to the turbine at its other end. The generator is integrated into the central hub of the Venturi turbine. The magnetic field is induced by permanent magnets. The generator dimensions are matched to the rotor characteristics thus making an expensive and problem prone gearboxes obsolete. Cost Effectiveness:- Whist the theoretical background of the blade configuration is very complex, the manufacturing is utterly simple because the blade can be laser cut from a plate. Because normally the blades constitute a large part of the cost because special tooling like a mould is required, the Venturi turbine can be economically produced at relatively low volumes. The cantilevered construction of conventional blades cause the foot of the blade to be subjected to strongly alternating bending moments caused by fluctuating wind gusts and gyroscopic effects. Additionally the unsupported tip end causes the blade as a whole to vibrate. The alternating stress loads are the main cause of blade failure. Turby Wind Turbine Design:- Description:- This design is advocated for construction in an urban environment. The vibrations, high noise levels and the low efficiency characterizing the Darrieus turbine are caused by the flow of air around the blade. The angle of attack of the apparent wind is kept below 20 degrees. The rotational speed of the turbine is for all parts of the blades is constant. In a Darrieus turbine the distance between blade and shaft varies, accordingly, the blade speed also varies. On the blade parts near the shaft the self generated head wind is low, whereas at the curve of the blade, at the greatest distance from the shaft, its reaches a maximum. The low blade speed close to the shaft results in an angle of attack of the apparent wind that over large parts of a revolution exceeds the allowable limit with stall as a consequence. There are moments of laminar flow and moments of turbulence resulting in intermittent lift power and drag on the blades and this causes vibrations. The contribution of these blade parts to the driving force of the turbine is negligible. In the curve of the blade, the speed of the headwind is high. The angle of attack of the apparent wind is small, with the consequence that the component of the lift force in the direction of the rotation also nears zero. These parts of the blades do not contribute to the driving force. However given their high speed they do generate a high level of noise. This explains why the Darrieus turbine vibrates heavily, makes a lot of noise and has a low efficiency. The blades of the Turby concept are designed with a fixed distance to the vertical shaft. To reduce the inevitable vibrations due to the change of the angle of attack between +20 and –20 degrees resulting in a change of the mechanical stress in the blade two times per revolution, its developers chose an odd number of 3 blades of a helical shape, making all changes occur gradually. Poles Designs:- Two different mast types depending on the required height can be considered. Up to 6 m height, spring supported masts. From 7.5 m and higher, freestanding tubular masts are used. Both types could be either made of stainless steel or galvanized steel. Helical Wind Turbines:- Description:- The Windside Wind Turbine developed in Finland is a vertical wind turbine whose design is based on sailing engineering principles. The turbine rotor is rotated by two spiral formed vanes. It is intended for both inland and marine environments. Designs are for use in wind speeds of up to 60 m/s. These designs for battery charging are a unique and ecological solution for energy production in harsh environments under cold or hot conditions, violent storms, as well as low wind speeds. These turbines generate almost no noise and are safe to use in population centers, public spaces, parks, wildlife parks and on top of buildings. They are also aesthetically appealing and in many cases have been used to combine art and functionality. Quietrevolution QR5 Wind Turbine:- Description:- The QR5 is a wind turbine designed in response to increasing demand for wind turbines that work well in the urban environment, where wind speeds are lower and wind directions change frequently. It possesses a sophisticated control system that takes advantage of gusty winds with a predictive controller that learns about the site's wind conditions over time to further improve the amount of energy generated. If the control system determines that sufficient wind exists for operation, the turbine is actively spun up to operating conditions at which point it enters the lift mode and starts extracting energy from the wind. It will self-maintain in a steady wind of 4.0–4.5 m/s. The turbine will brake in high wind events of speeds over 12 m/s and shut down at continuous speeds over 16 m/s. The blade tip speed is much lower than on a similarly rated horizontal axis wind turbine so less noise is produced. The helical blade design results in a smooth operation that minimizes vibration and further reduces acoustic noise. It is constructed using a light and durable carbon fiber structure and is rated at 6 kW and has an expected output of 9 600 kWhr per year at an average annual wind speed of 5.9 m/s. This would provide 10 percent of the energy for a 600 m^2 office building. Its design life is 25 years. As a safety feature, it is designed with a high tensile wire running through all its component parts, to minimize the risk of any broken parts being flung from the structure in the unlikely event of structural failure. Aerogenerator Vertical Offshore Wind Turbine Concept:- The 144 meters high and V-shaped structure would be mounted offshore and capable of generating up to 9 MW of electricity, roughly three times as much power as a conventional turbine of equivalent size. Instead of being mounted on a tower with egg whisk blades that bow outwards and meet at the top like a typical Darrieus design, it has two arms jutting out from its base to form a V-shape, with rigid sails mounted along their length at intervals. As the wind passes over these they act like airfoils, generating lift which turns the structure as a whole at roughly 3 rpm. No matter how high the two main structures are made it is relatively simple to make them with a center of gravity at its bottom. Because of this the technology lends itself to large engineering projects, which is what is needed with wind power. Windspire Wind Turbine:- The Windspire design is 30 feet tall and 2 feet in radius. It is equipped with a high efficiency generator, integrated inverter, hinged monopole, and wireless performance monitor. The slender vertical axis design allows it to operate with a low tip speed ratio, with the edges of the rotor spinning at 2–3 times the speed of the wind, making it virtually silent. Rotor:- The rotor is a low speed gyromill or a straight-bladed Darrieus design optimized for energy capture efficiency by the École Polytechique de Montréal. The rotor has modified the Darrieus high efficiency configuration into a size and form optimal for small scale power generation. The changes lowered the operating speed, making it nearly silent, while also improving its self-starting capabilities. Constructed from aircraft grade aluminum, the rotor is both high strength and low cost. At 10 mph wind, the noise level is imperceptible, and it is 8.8 dB above the ambient level in a 50 mph wind; compared with 65–100 dB of other turbine designs. The installation includes a poured concrete foundation without the need for guy wires. Generator:- Double Rotating Air Core motors and generators provide the highest achieved efficiencies ever attaining 98 percent. New manufacturing technology allows them to be produced with both the highest possible efficiency at low cost. The Windspire generator technology was

dynamometer tested and its performance verified by Oregon State University and the University of Nevada, Reno, under a program sponsored by the National Renewable Energy Laboratory (NREL). Inverter:- The design has its own integrated inverter to convert the raw electrical power from the generator into regulated electricity that ties in with the grid. The high efficiency inverter was designed to optimize operation with the rotor and generator over the encountered range of wind speeds. Wireless Monitoring:- The Windspire concept is equipped with a wireless modem that is continuously transmitting the power production information. With the Zigbee dongle modem unit, similar to a flash drive, plugged into a computer's USB drive, one can monitor the performance of the turbine. Revolution Air Wind Turbines:- Pramac, an Italian power generation equipment manufacturer offers wind turbines aimed at domestic use. A quadrangular 400 WT model with a rated power of 400 Watts, and a helical shape 1 kW WT with a rated power of 1 000 Watts are produced and offered at a price of USD3 500. Counter Rotating Turbines Arrays:- Horizontal axis wind turbines need a lot of space to operate. To avoid interference through turbulence, the spacing between the towers has to be wide. Turbines have to be made larger and taller and built in high places in order to catch more of the wind. All this adds to the cost and it impacts heavily on the visual landscape. An array of counter-rotating Vertical Axis Wind Turbines allows the use of a configuration has been identified that yields twice as much power per acre as with a Horizontal Axis Wind Turbines. Averaged over all incident wind directions, the close proximity of the turbines slightly improved their performance relative to the turbines in isolation. This is in contrast to typical performance reductions between 20–50 percent for HAWTs at a similar turbine spacing. The result is consistent with the predictions of simple numerical models which anticipated that closely-spaced VAWTs can reciprocally enhance the wind field of the adjacent turbines. The counter-rotation of the adjacent VAWTs is important because it ensures that the airflow induced by each of the turbines in the region between them is oriented in the same direction. The creation of horizontal wind shear or velocity gradient, which leads to turbulence and energy dissipation in the region between the turbines, is reduced relative to adjacent turbines that rotate in the same direction. Since the remaining wind energy between the turbines is not dissipated by turbulence, it can be subsequently extracted by VAWTs located further downwind. This process is most effective for VAWTs operating at higher tip speed ratios greater than 2, since in this regime the turbine rotation can suppress vortex shedding and turbulence in the wake in a manner similar to that observed in studies of spinning cylinders. At lower tip speed ratios, the VAWTs likely create a larger wake akin to that of a stationary cylinder with a corresponding reduced performance. This approach is different from current practices in wind energy harvesting. In this case, a large number of smaller VAWTs are implemented instead of fewer, large HAWTs. The higher levels of turbulence near the ground, both naturally occurring and induced by the VAWT configuration, enhance the vertical flux of kinetic energy delivered to the turbines, thereby facilitating their close spacing. This could alleviate many of the practical challenges associated with large HAWTs, such as the cost and logistics of their manufacture, transportation, and installation by using less expensive materials and manufacturing processes and by exploiting greater opportunities for mass production and general acceptance by local communities. The optimal configuration of the array can be determined using the analog of vortices generated in a horizontal water tank with a stream flow simulating the wind stream. Small Vertical Axis Wind Turbines Arrays:- As the wind passes around and through a wind turbine, it produces turbulence that buffets downstream turbines, reducing their power output and increasing wear and tear. Vertical-axis turbines produce a wake that can be beneficial to other turbines, if they are positioned correctly. Since the blades are arranged vertically, the wind moving around the vertical-axis turbines speeds up, and the vertical arrangement of the blades on downstream wind turbines allows them to effectively catch that wind, speed up, and generate more power. Small vertical axis wind turbines that are 10 meters tall and generate 3–5 kWs are easy to manufacture and cost less than conventional ones if produced on a large scale. The maintenance costs could be less because the generator sits on the ground, rather than at the top of a 100-meter tower, and thus is easier to access. The noise of horizontal axis wind turbines has led some communities to campaign to tear them down. These small turbines are almost inaudible and are less likely to kill birds. Their use on military bases is contemplated because they are shorter and interfere less with helicopter operations and with radar. Vertical-axis wind turbines are less efficient than horizontal axis wind turbines since half of the time the blades are actually moving against the wind, rather than generating the lift needed to spin an electrical generator. As the blades alternatively catch the wind and then move against it, they create wear and tear on the structure. Adding half a shield against the return stroke would solve the problem. Discussion:- The idea for Vertical Axis Wind Turbines (VAWTs) has been blowing around for decades, but despite many advantages the technology has so far attracted little interest. A Darrieus turbine becomes unstable above a certain height. The largest Horizontal Axis Wind Turbines (HAWTs) are capable of producing 6 MW of power and stand just short of 100 meters tall, but if made any bigger they start to become less efficient. One reason is that the weight of the turbine blades becomes prohibitive. As they turn, this places the blades under enormous stress because gravity compresses them as they rise and stretches them as they fall. The larger you make these structures, the more robust they must be in order to withstand these forces. In addition, the cost and difficulty of building the increasingly large towers needed to keep this top-heavy structure stable lead to a major engineering challenge. An advantage of VAWTs is that they can catch the wind from all directions eliminating the need for a yaw mechanism. In addition, they can be built lower, so they are less visible and can withstand much harsher environments and do not need to be shut down when wind speeds exceed 64 mph, and even then the structures are claimed to withstand speeds of up to 110 mph. / Сэндиэ Нэшинэл Лэбрэтчориз (Sandia National Laboratories). VERTICAL BALANCE SHEET = ВЕРТИКАЛЬНЫЙ БАЛАНСОВЫЙ ОТЧЁТ – A Vertical Balance Sheet is one in which the balance sheet presentation format is a single column of numbers, beginning with asset line items, followed by liability line items, and ending with shareholders' equity line items. Within each of these categories, line items are presented in decreasing order of liquidity. Thus, the presentation within the topmost block of line items (for assets) begins with cash and usually ends with fixed assets (which are much less liquid that cash) or goodwill. Similarly, the liabilities section begins with accounts payable and usually ends with long-term debt, for the same reason. The intent of a vertical balance sheet is for the reader to make comparisons between the numbers on the balance sheet for a single period. For example, someone might compare the current assets total to the current liabilities total to estimate the liquidity of a business as of the balance sheet date. The only alternative to the vertical balance sheet format is the horizontal balance sheet, where assets appear in the first column and liabilities and shareholders' equity appear in the second column. In this format, the totals of each column should always be the same. The vertical balance sheet format is much more popular than the horizontal balance sheet format, because you can use it to include the balance sheets for multiple periods on a single page, using a side-by-side presentation format that may span a large number of reporting periods.

VERTICAL BRACE = ВЕРТИКАЛЬНАЯ СВЯЗЬ (или ВЕРТИКАЛЬНАЯ СТОЙКА, или ВЕРТИКАЛЬНАЯ РАСТЯЖКА, или ВЕРТИКАЛЬНАЯ РАСПОРКА, или ВЕРТИКАЛЬНЫЙ ПОДКОС) – Vertical Brace:- cross members placed in a vertical plane between an X pattern between trusses to prevent rotation of the tops of the truss under load. / В строительных конструкциях под

Связями понимаются соединительные элементы каркаса здания (сооружения), обеспечивающие устойчивость основных (несущих) конструкций каркаса и пространственную жёсткость сооружения в целом. Связи обеспечивают также перераспределение нагрузок, приложенных к отдельным конструкциям, на соседние конструкции или на всё сооружение. Система связей обычно состоит из стержневых конструкций (порталов, ферм) и отдельных стержней (раскосов и других). Стойкой называют неподвижное звено механизма.

VERTICAL COMBINATION = ВЕРТИКАЛЬНОЕ ОБЪЕДИНЕНИЕ (или ВЕРТИКАЛЬНАЯ КОМБИНАЦИЯ) – Vertical Combination is the integration within one company of individual businesses working separately in related phases of the production and sale of a product. Also called Vertical Integration. Vertical Combination is a combining of business firms engaged in different phases of the manufacture and distribution of a product into an interacting whole. Vertical Combination is an absorption into a single firm of several firms involved in all aspects of a product's manufacture from raw materials to distribution. / Вертикальное Комбинирование.

VERTICAL COOPERATION = ВЕРТИКАЛЬНАЯ КООПЕРАЦИЯ – Vertical Cooperation is a marketing concept that theoretically allows independent producers to retain a substantial degree of ownership independence while achieving the perceived ability to meet consumer wants and needs and cost savings provided by vertical integration.

VERTICAL COORDINATION = ВЕРТИКАЛЬНАЯ КООРДИНАЦИЯ – Vertical Coordination:- the process of ensuring that each successive stage in the production, processing, and marketing of a product is appropriately managed and interrelated to the next, so that decisions about what to produce, and how much, are communicated as efficiently as possible from the consumer to the producer. Agricultural economists believe that vertical coordination of markets is particularly important in the food industry because of its complexity, the large number of firms that participate in one or more stages, and the relative perishability of the products involved. Vertical integration is a type of vertical coordination, but the latter does not necessarily require that a single organization own or control all of the stages. For example, the use of contracts and marketing agreements between buyers and sellers, and the availability of timely, accurate price and other market information are methods for achieving vertical coordination. See also Vertical Cooperation. Vertical Coordination:- where the payment of the market price for a good or service is replaced by (I) internal development within the firm, (2) acquisition, (3) merger, or (4) some type of formal (or informal) contract – has been an economic concern dating back at least to Adam Smith's (1776) The Wealth of Nations. The conversation on vertical coordination (or the more prosaic 'make or buy' decision) by (agricultural) economists, accountants, procurement specialists and marketing and management strategists has been extensive since the turn of the XX century'. Surely there must be some pearls of insight contained in this massive literature that can be of use to practitioners in the field of agriculture (and elsewhere). Indeed, important ideas on vertical coordination have been expressed by a diversity of individuals ranging from Nobel prize winners in economics (e.g., Kenneth Arrow, Ronald Coase, Douglass North and George Stigler) to the multitude of practitioners where 'make or buy' decisions are their livelihood. / Эдэм Смис (Adam Smith) (1776) (The Wealth of Nations). Лауреатов Нобелевской премии в области экономики (например, Кенэс Эроу (Kenneth Arrow), Ранэлд Кос (Ronald Coase), Даглэс Норс (Douglass North) и Дьжодьж Стиглё (George Stigler).

VERTICAL EQUITY = ВЕРТИКАЛЬНОЕ РАВЕНСТВО (или ВЕРТИКАЛЬНАЯ СПРАВЕДЛИВОСТЬ) – In the United Kingdom, an explanation of the difference between horizontal and vertical equity:- Horizontal Equity implies that we give the same treatment to people in an identical situation. E.g., if two people earn £15 000 they should both pay the same amount of income tax. Therefore, horizontal equity makes sure we don't have discrimination on the grounds such as race/gender/different types of work. Vertical Equity implies that people with higher incomes should pay more tax. Vertical equity seeks to tax in a proportional or progressive way – People with more ability to pay should pay more tax. Vertical equity is important for redistributing income within society. (See also Progressive Tax.) Horizontal equity is an important starting point for any tax system. Horizontal equity can be consistent with also achieving vertical equity. Horizontal equity is the equal treatment of equals and this is a means for achieving a distribution of tax burdens that is vertically equitable. Examples:- the Poll Tax is an example of a tax that has horizontal equity (everyone pays a lump sum of £500 a year). Mrs Thatcher's theory was that since everyone had the same access to council services everyone should pay the same tax. However, the poll tax does not meet the criteria for vertical equity. For those on low incomes, the poll tax was a high % of their disposable income. For those on high incomes and more ability to pay it was a low %. Vertical Equity is a method of collecting income tax in which the taxes paid increase with the amount of earned income. The driving principle behind vertical equity is the notion that those who are more able to pay taxes should contribute more than those who are not. The two main types of vertical equity are proportional and progressive taxation. In proportional taxation, the amount of taxes paid increases directly with income. For example, a 5% increase in earnings will cause a 5% increase in taxes. Progressive taxation includes tax brackets, where people pay taxes based on the tax bracket into which their income places them. Each tax bracket will have a different tax rate, with higher income brackets paying the highest percentages. Vertical Equity is the concept of increasing tax rates on higher incomes. Vertical equity is similar to the concept of progressive taxes. How It Works (Example):- the United States has a vertical equity tax system, which means that different portions of a person's or company's income are taxed at increasing rates (that's why the rates are often referred to as Marginal Rates). For example, the US IRS might tax a single filer's USD100 000 income as follows:- (i) the first USD8 025 is taxed at 10% = USD802.50; (ii) the next USD24 525 is taxed at 15% = USD3 678.75; (iii) the next USD49 100 is taxed at 25% = USD12 275.00; (iv) the next and final USD18 350 is taxed at 28% = USD5 138.00; and (v) total tax owed:- USD21 894.25. Because this filer's highest taxable rate is 28%, we say that he or she is in the 28% tax bracket. Note, however, that not ALL of the taxpayer's income is taxed at 28%. In fact, the taxpayer's actual total tax rate is USD21 894.25/USD100 000 = 21.89%. The highest federal tax bracket changes often, but it is usually around 35% of any income over about USD375 000 (note that this excludes state taxes and social security/Medicare, which can add as much as another 17–18% in taxes, for a total of as much as 53% in taxes on additional income). Why It Matters:- the idea behind vertical equity is that those who make more should pay more. In general discourse, however, it is important to know the difference between tax brackets and tax rates. Under a progressive tax system, many people assume that when they're in the 28% tax bracket, for example, all of their income is being taxed at 28%, which is not the case. As our example shows, you can be in the 28% tax bracket but actually have a 21.89% effective tax rate on your income. Likewise, executives and public figures are often chastised for having, say, a 15% effective tax rate, but as you now know, this does not mean that the person is not in a very high tax bracket. / Принцип Вертикальной Справедливости (Vertical Equity) гласит, что субъекты, находящиеся в неравных условиях, должны трактоваться налоговыми законами неодинаково.

VERTICAL FINANCIAL ANALYSIS = ВЕРТИКАЛЬНЫЙ ФИНАНСОВЫЙ АНАЛИЗ – Vertical Financial Analysis allows comparison of the financial ratios of a company in time – past, present and future. See also Vertical Analysis. / Вертикальный Финансовый Анализ – это одна из систем финансового анализа, базирующаяся на структурном разложении отдельных показателей финансовой отчётности предприятия. Вертикальный Анализ Отчётности – техника анализа финансовой отчётности, при которой изучается соотношение выбранного показателя с другими однородными показателями в рамках одного отчётного периода. Вертикальный Анализ (то есть анализ показателей отчётности по вертикали) направлен на изучение структуры имущества, обязательств, доходов, расходов организации. Например, вертикальный анализ актива бухгалтерского баланса даёт представление о доли основных средств, нематериальных активов, запасов, дебиторской задолженности и других видов

имущества в общих активах предприятия (вертикальный анализ актива баланса). Определив в процентах долю каждого показателя в общем итоге, у аналитика появляется возможность сравнивать предприятие по данным показателям с другими предприятиями, что невыполнимо, если оперировать абсолютными величинами. В части пассива баланса проводят структурный анализ собственных и заёмных средств, а также состав заёмных средств по срокам погашения (долгосрочные и краткосрочные обязательства). В части анализа отчёта о прибылях и убытках, вертикальный анализ используют для выявления структуры расходов и расходов, определения доли или чистой прибыли расходов в выручке от реализации. Вертикальный анализ, по определению, проводят в рамках одного отчётного периода. Однако рассчитав процентные соотношения показателей, часто прибегают к горизонтальному анализу, прослеживая изменение этих показателей в течение ряда периодов. Например, вертикальный анализ показал, что доля основных средств на 31 Декабря 2016 составила 40% от всего имущества организации; на 31 Декабря 2015 – 45%. В свою очередь, горизонтальный анализ показывает, что за год доля основных средств выросла на 5%, то есть производство стало более фондоёмким.

VERTICAL FIRING = ВЕРТИКАЛЬНОЕ ПЛАМЯ (или XX) – Vertical Firing is an arrangement of a burner such that air and fuel are discharged into the furnace in practically a vertical direction. Vertical Firing is a type of combustion furnace used in the combustion of pulverized coal. The burners are usually placed in the floor, firing vertically upward. Vertical firing is mainly used in slag-tap systems (from which ash is removed in a molten state).

VERTICAL FLAME TEST = ИСПЫТАНИЕ НА ВЕРТИКАЛЬНОЕ ПЛАМЯ – Vertical Flame Test is a test for flame resistance in which a specimen is mounted in a vertical holder and exposed to an open flame for a specific time. The open flame is then extinguished and continued flaming time and char length of the sample are measured. See also Flammability Tests. UL-94 Horizontal/Vertical Flame Test:- one flame standard often encountered in the plastics industry is the UL-94 test. Often used for classifying wire insulation and other electronic components, the UL test provides a preliminary indication of a material's acceptability for use as part of a device or appliance with respect to its flammability. It is not intended to reflect the hazards of a material under actual fire conditions. The most common flammability standards are the Horizontal Burn method, 94HB and the more stringent Vertical Burn methods, 94V and 94VTM (used for thin materials). The flammability classification considered for a material may vary, depending on the equipment or device involved. The vertical test includes three classifications – 94V-0, 94V-1 and 94V-2 – and would typically be acceptable for portable, unattended, intermittent-duty, household-use appliances (i.e. coffee makers). In the 94V classification, a 5" specimen is held vertically and a burner flame is applied to the free end of the specimen. The flame is applied for two 10 second intervals separated by the time it takes for flaming combustion to cease after the first application. A V-0 rating is assigned if burning stops within 10 seconds after two applications of the flame and no flaming drips are observed. A V-1 rating is used when burning stops within 60 seconds, again with no flaming drips. Finally the V-2 is used when the burning stops within 60 seconds, but flaming drips are observed. / Смотрите также Тесты На Воспламеняемость (Flammability Tests).

VERTICAL GENES = ВЕРТИКАЛЬНЫЕ ГЕНЫ – Vertical Gene Transfer uses reproduction as a means of gene transfer through generations, whereas horizontal gene transfer uses non-reproductive methods of gene transfer. See also Major Gene Resistance. Vertical Gene Transfer is that between parents and their offspring, while horizontal gene transfer is the movement of genes between two different organisms. Vertical Gene Transfer:- the spontaneous mutation frequency for antibiotic resistance is on the order of about of about 10^{-8}–10^{-9}. This means that one in every every 10^{8}–10^{9} bacteria in an infection will develop resistance through the process of mutation. In Escherichia coli (E. coli), it has been estimated that streptomycin resistance is acquired at a rate of approximately 10^{-9} when exposed to high concentrations of streptomycin. Although mutation is a very rare event, the very fast growth rate of bacteria and the absolute number of cells attained means that it doesn't take long before resistance is developed in a population. Once the resistance genes have developed, they are transferred directly to all the bacteria's progeny during DNA replication. This is known as Vertical Gene Transfer or Vertical Evolution. The process is strictly a matter of Darwinian evolution driven by principles of natural selection:- a spontaneous mutation in the bacterial chromosome imparts resistance to a member of the bacterial population. In the selective environment of the antibiotic, the wild type (non mutants) are killed and the resistant mutant is allowed to grow and flourish.

VERTICAL GENE TRANSFER = ВЕРТИКАЛЬНЫЙ ПЕРЕНОС ГЕНОВ – Vertical Gene Transfer:- acquisition of DNA through horizontal gene transfer is distinguished from the transmission of genetic material from parents to offspring during reproduction, which is known as Vertical Gene Transfer. See also Outcrossing. / Вертикальный Перенос Генов:- .

VERTICAL INTEGRATION = ВЕРТИКАЛЬНАЯ ИНТЕГРАЦИЯ – (1) Vertical Integration is a strategy where a company expands its business operations into different steps on the same production path, such as when a manufacturer owns its supplier and/or distributor. Vertical integration can help companies reduce costs and improve efficiencies by decreasing transportation expenses and reducing turnaround time, among other advantages. However, sometimes it is more effective for a company to rely on the established expertise and economies of scale of other vendors rather than trying to become vertically integrated. Specifically, vertical integration occurs when a company assumes control over several production or distribution steps involved in the creation of its product or service. Vertical integration can be carried out in two ways:- (i) backward integration and (ii) forward integration. A company that expands backward on the production path into manufacturing is assuming backward integration, while a company that expands forward on the production path into distribution is conducting forward integration. General Examples Of Vertical Integration:- companies from many different industries and sectors choose to vertically integrate. A mortgage company that originates and services mortgages is a vertically integrated loan-servicing firm. The company lends money to homebuyers and collects their monthly payments, rather than specializing in one service or the other. A solar power company that produces photovoltaic products and also manufactures the cells used to create those products is another example of a vertically integrated business. In this case, the company moved along the supply chain to assume the manufacturing duties, conducting a backward integration. The merger of Live Nation and Ticketmaster created a vertically integrated entertainment company that manages and represents artists, produces shows and sells event tickets. This type of integration is forward from the perspective of Ticketmaster and backward from the perspective of Live Nation. Apple as the Stalwart of Vertical Integration:- Apple Inc. is one of the best-known companies for perfecting the art of vertical integration. The company manufactures its custom A-series chips for its iPhones and iPads. It also manufactures its custom touch ID fingerprint sensor. Apple opened up a laboratory in Taiwan for developing LCD (Liquid Crystal Display) and OLED (Organic Light Emitting Diode) screen technologies in 2015. It also paid USD18.2 million for a 70 000-square-foot manufacturing facility in North San Jose in 2015. These investments allow Apple to move along the supply chain in a backward integration, giving it flexibility and freedom in its manufacturing capabilities. The company has also integrated forward as much as backward. The Apple retail model, one where the company's products are almost exclusively sold at company-owned locations, excluding Best Buy and other carefully selected retailers, allows the business to control its distribution and sale to the end consumer. Vertical Integration:- merger of companies at different stages of production and/or distribution in the same industry. When a company acquires its input supplier it is called Backward Integration. When it acquires companies in its distribution chain it is called Forward Integration. For example, a vertically integrated oil company may end up owning oilfields, refineries, tankers, trucks, and gas (petrol) filling stations. Also called Vertical Merger. See also Horizontal Integration; and Integration. Vertical Integration is the merging together of two businesses that are at different stages of production – for

example, a food manufacturer and a chain of supermarkets. Merging in this way with something further on in the production process (and thus closer to the final consumer) is known as Forward Integration. Vertical integration can be contrasted to horizontal integration, the merging together of businesses that are at the same stage of production, such as two supermarkets, or two food manufacturers. Merging with something further back in the process (if a food manufacturer were to merge with a farm, say) is known as Backward Integration. The integration of two organisations that are in completely different lines of business is sometimes referred to as Conglomerate Integration. Businesses are downstream or upstream of each other depending on whether they are nearer to or further away from the final consumer (the 'sea', as it were, to which the river of production flows). The benefits of vertical integration come from the greater capacity it gives organisations to control access to inputs (and to control the cost, quality and delivery times of those inputs). In line with the changing organisational structure of the late XX century, however, this logic became less compelling. In the late 1990s, consultants McKinsey & Company wrote:- 'Whereas historically firms have vertically integrated in order to control access to scarce physical resources, modern firms are internally and externally disaggregated, participating in a variety of alliances and joint ventures and outsourcing even those activities normally regarded as core'. Some of the best known examples of vertical integration have been in the oil industry. In the 1970s and 1980s, many companies that were primarily engaged in exploration and the extraction of crude petroleum decided to acquire downstream refineries and distribution networks. Companies such as Shell and BP came to control every step involved in bringing a drop of oil from its North Sea or Alaskan origins to a vehicle's fuel tank. The idea of vertical integration was taken a step further by Dell Computer, one of the most successful companies of the 1990s. Michael Dell, its founder, said that he combined the traditional vertical integration of the supply chain with the special characteristics of the virtual organisation to create something that he called Virtual Integration. Dell assembles computers from other firms' parts, but it has relationships with those firms that are more binding than the traditional links between buyer and supplier. It does not own them in the way of the vertically integrated firm, but through exchanges of information and a variety of loose associations it achieves much the same aim – what Michael Dell calls 'a tightly co-ordinated supply chain'. Vertical integration is a difficult strategy for companies to implement successfully. It is often expensive and hard to reverse. Upstream producers frequently integrate with downstream distributors to secure a market for their output. This is fine when times are good. But many firms have found themselves cutting prices sharply to their downstream distributors when demand has fallen just so they can maintain targeted levels of plant utilisation. The vertically integrated giants of the computer industry, firms such as IBM, Digital and Burroughs, were felled like young saplings when at the end of the 1970s Apple formed a network of independent specialists that produced machines far more efficiently than the do-it-all giant. Vertical Integration describes the ownership or control by a firm of different stages of the production process, e.g., petroleum refining firms owning 'downstream' the terminal storage and retail gasoline distribution facilities and 'upstream' the crude oil field wells and transportation pipelines. 'Forward' integration refers to the production to distribution stages whereas 'backward' integration refers to the production to raw material stages of the operations of a firm. Context:- vertical integration may be achieved through new investment and/or vertical mergers and acquisition of existing firms at different stages of production. An important motive for vertical integration is efficiencies and minimization of transaction costs. Vertical Integration describes a company's control over several or all of the production and/or distribution steps involved in the creation of its product or service. How It Works (Example):- let's assume XYZ Company, which manufactures frozen french fries, wants to vertically integrate. By purchasing a potato farm and a potato processing plant, XYZ could engage in upstream integration (also known as Backward Integration) and control the quantity, cost, and quality of the product's raw materials. Likewise, XYZ Company could engage in downstream integration (also known as Forward Integration) to control the distribution of the company's products by purchasing a packaging plant and a fleet of delivery trucks. Ultimately, XYZ could also use balanced integration, which incorporates both upstream and downstream integration, to control the cost and quality of the entire production and distribution process. Why It Matters:- one of the biggest advantages of vertical integration is that it often creates economies of scale and lowers production costs because it eliminates many of the price markups in each production step. Vertically integrated companies also achieve cost efficiencies by controlling quality at each step, which reduces repair costs, returns, and downtime. In addition, vertically-integrated companies do not have to allocate resources to pricing, contracting, paying, and coordinating with third-party vendors. Vertical integration can ultimately create barriers to entry for potential competitors, especially if the company controls access to some or all of a scare resource involved in production. This is why in some cases a company may control so much of the market or supply of raw materials that vertical integration can raise antitrust concerns. A company must have expertise in each step of the production and distribution process in order to maximize the advantages of vertical integration. Using the example above, XYZ Company must know how to farm potatoes as well as it knows how to manufacture French fries. Another considerable risk is that XYZ will need to modify its infrastructure significantly to accommodate technological changes and other industry innovations. This investment in infrastructure can be very expensive and limit the company's flexibility. By controlling the value chain, the company also becomes responsible for innovation and product variety. To simulate some aspects of vertical integration without explicitly doing so, companies may wish to sign long-term contracts with certain suppliers, co-locate facilities with suppliers or distributors, or engage in joint ventures with production partners. Vertical Integration is the extent to which a firm owns its upstream suppliers and its downstream buyers. Control upstream is referred to as Backward Integration (towards suppliers of raw material), while control of activities downstream (towards the eventual buyer) is referred to as Forward Integration. Vertical Integration:- the merger with or acquisition of a company that performs a different role in the same industry – for instance, when the producer of a good buys the distributor of the same product. This contrasts with horizontal integration, which involves combining with a company that has the same role in the same industry. Vertical integration does not necessarily require a merger or acquisition. It is often the result of internal development. The choice between outsourcing and vertical integration is a crucial decision for most companies. A company should use vertical integration when there is a threat of being unfairly exploited by its supplier. When there is a small number of suppliers, there is a possibility that these suppliers may take advantage of their clients' dependence to behave opportunistically. By using vertical integration instead of outsourcing, a firm can totally avoid this threat. Outsourcing has disadvantages that include losing control over the outsourced activity or even exposing clients to the potential opportunism of suppliers. For instance, they may charge excess fees for services that are not included in the contract. They may also make promises knowing well that they will break these in an instant, should the benefits from breaking these promises exceed the costs or disadvantages. On the other hand, outsourcing is more flexible than vertical integration because suppliers make investments. It is preferable to let suppliers make investments when the environment is uncertain because if the investments go wrong or the assets become obsolete, then the supplier will bear the cost and not the client. This makes outsourcing less risky than vertical integration. A company should use vertical integration for activities with high strategic value. These are activities based on resources and capabilities that generate a competitive advantage. For instance, product design is an activity that has high strategic value for Apple. If organisations do not possess the resources and capabilities that can provide them with a competitive advantage, there is a risk that they will become 'hollow' corporations. These are companies that have outsourced most of the resources and capabilities necessary to enjoy a competitive advantage and they generally fail. Only activities with limited strategic value can (and should) be outsourced. Example:- the Disney-Pixar relationship between 1991 and 2006 illustrates the move from outsourcing to vertical integration. Disney outsourced the production of 3D animated films to Pixar in 1991 because there was a lot of uncertainty around the potential of 3D animation. At the time it was not clear whether 3D animated films would be successful or at least as successful as 2D animated films. In addition, 2D animation capabilities were far more likely than 3D animation capabilities to

generate a competitive advantage. By 2006, vertical integration had become necessary for Disney because Pixar was taking advantage of Disney's dependence to constantly renegotiate the contract. For instance, after the success of Toy Story (1995), Steve Jobs, who was chief executive of Pixar at the time, threatened to end the relationship with Disney unless the contract terms were adjusted in Pixar's favour. Michael Eisner, chairman and chief executive of Disney, eventually agreed to renegotiate the contract in favour of Pixar in exchange for an extended duration. Moreover, the uncertainty surrounding 3D animation had disappeared and this film technique had become essential to the competitive advantage of the animation film industry. Vertical Integration:- the linking of a number of business concerns, each operating at a different stage in the same industry. This is opposed to Horizontal Integration, being the linking of a number of business concerns at the same stage. Vertical Integration is the combination within a firm or business enterprise of one or more stages of production or distribution. In the electric industry, it refers to the historical arrangement whereby a utility owns its own generating plants, transmission system, and distribution lines to provide all aspects of electric service. / Вертикальная Интеграция:- . Столвэт (Stalwart). Эпл Инк. (Apple Inc.). Смотрите также Интеграция (Integration). МэКинзи Энд Кампэни (McKinsey & Company). Щел (Shell) Би.Пи. (BP). Дэл Компьютё (Dell Computer) Майкэл Дэл (Michael Dell). Ай.Би.Эм. (IBM), Дидьжитэл (Digital) и Бэроуз (Burroughs). Эпл (Apple). Дизни-Пикса (Disney-Pixar). Той Стори (Toy Story) (1995), Стив Дьжобз (Steve Jobs). Майкэл Айзнё (Michael Eisner). Вертикальная Интеграция:- группа предприятий, осуществляющих разные стадии производства готового продукта и являющиеся собственностью одной фирмы.

(2) Vertical Integration:- an arrangement whereby the same company owns all the different aspects of making, selling and delivering a product or service. In the electric industry, it refers to the historically common arrangement whereby a utility would own its own generating plants, transmission system and distribution lines to provide all aspects of electric service. Vertical Integration is the combining of manufacturing operations with source of materials and/or channels of distribution under a single ownership or management especially to maximize profits. Vertical Integration or Vertically Integrated or Vertical:- a form of market control under which a single organization controls, via ownership or contractual agreement, two or more adjacent stages of production, processing, or marketing of a commodity. For example, the modern, vertically integrated poultry firm consists of breeder flocks, hatcheries, feed milling and delivery, grow out, assembly, processing plants, further processing plants, and delivery to buyers. Ancillary services, such as building and equipment supplies, fuel, and financing, are often affiliated with the operation. See also Factory Farm and Stable-To-Table. / Вертикальная Интеграция:- производственное и организационное объединение, слияние, кооперация, взаимодействие предприятий, связанных общим участием в производстве, продаже, потреблении единого конечного продукта:- поставщиков материалов, изготовителей узлов и деталей, сборщиков конечного изделия, продавцов и потребителей конечного продукта.

(3) Vertical Integration of a fishery (or industry) is vertically integrated when firms in the fishery engage in multiple levels of the supply chain. For example, a firm that operates and manages fishing vessels, processing plants, and a wholesale distribution operation is considered vertically integrated. See also Horizontal Integration.

VERTICAL LINE CHARTING = ПОСТРОЕНИЕ ГРАФИКА С ВЕРТИКАЛЬНЫМИ ЛИНИЯМИ – Vertical Line Charting is a technique used by technical traders and market technicians to track the price trend of a security, in order to forecast future price moves. In vertical line charting, a security's daily price action is summarized by a vertical bar. The security's daily high and low prices are denoted by the top and bottom of the bar, respectively, while its opening and closing prices are indicated by very short horizontal bars to the left and right of the vertical bar, respectively. Vertical line charting may appear simplistic, but it can convey a wealth of information to seasoned market practitioners. It generally forms the basis upon which more advanced technical analysis is carried out for a security. Vertical Line Charting is a technical analysis method that looks at the daily high, low and closing prices of a stock in order to gauge a possible pattern of price movements. Vertical Line Charting is a form of technical charting that shows the high, low, and closing prices of a stock or a market on each day on one vertical line with the closing price indicated by a short horizontal mark. Vertical Line Charting:- technical analysis tool which charts the high, low, and close of a given security each day, in an attempt to spot patterns that might help predict future price movements. Vertical Line Chart is a chart that consists of vertical bars, each representing a trading day. The top of each bar represents the highest price of the day, while the bottom represents the lowest price. The closing price is shown by a short, horizontal line to the right of the bar, while the opening price is shown by the same thing to the left of the bar. The vertical axis of the chart shows prices, while the horizontal axis shows trading days. It is also called a Bar Chart. / Вертикальный График:- вертикальное отображение в техническом анализе. Форма технического графического отображения цен. Высшая, низшая цены акций или котировок рынка, а также цены закрытия соединяются одной вертикальной линией, при этом цена закрытия изображается короткой горизонтальной отметкой. Каждая вертикальная линия отображает следующий день, а график в целом отражает тенденцию акций или рынка в течение определённого числа дней, недель, месяцев или лет. Технические аналитики определяют на основе таких графиков, закрываются ли постоянные торговые операции с акциями или рынок в целом находится на высшей или низшей границах своего потенциала. Это полезно для понимания того, является ли рынок сильным или слабым, и следовательно, понизятся или повысятся цены в ближайшем будущем. Смотрите также Технический Анализ (Technical Analysis). Построение Графика С Вертикальными Линиями:- технический график, в котором высшие, низшие цены и цены закрытия на ценную бумагу на рынке представлены на одной вертикальной линии, а цена закрытия обозначена короткой горизонтальной отметкой. Каждая вертикальная линия относится к разным дням, и график в конечном счёте показывает любые тенденции за период времени от нескольких дней до ряда лет.

VERTICAL LIP = ВЕРТИКАЛЬНАЯ КРОМКА – Vertical Lip is a vertical projection of the top deck intended for load retention purposes. See also Pallet. / Вертикальная Кромка:- вертикальный выступ верхнего настила, предназначенный для крепления ограждающих приспособлений, поддерживающих груз. Смотрите также Поддон (Pallet).

VERTICALLY INTEGRATED ENTERPRISE = ВЕРТИКАЛЬНО ИНТЕГРИРОВАННОЕ ПРЕДПРИЯТИЕ – A Vertically Integrated Enterprise is one in which different stages of production, which are usually carried out by different enterprises, are carried out in succession by different parts of the same enterprise (the output of one stage becomes an input into the next stage, only the output from the final stage being actually sold on the market. See also Horizontally Integrated Enterprise.

VERTICAL MERGER = ВЕРТИКАЛЬНОЕ СЛИЯНИЕ – Vertical Merger is an acquisition by an organization of a supplier or customer. Buying a supplier is called Backward Integration, while buying a customer is called Forward Integration. In effect, a vertical merger combines the operations in two stages of the value chain within an industry. There are several reasons for doing so, including the following:- (i) securing a source of raw materials; (ii) having an assured customer; (iii) eliminating distributors in order to get closer to the end customer; (iv) creating efficiencies by combining operations; (v) preventing competitors from using the acquired businesses; (vi) stripping profits out of the supply chain that were going to someone else. Examples of vertical mergers are:- (i) a car company acquires a car seat manufacturer in order to secure a reliable source of supplies; (ii) a gas pipeline company buys a gas exploration company in order to secure a source of gas for its pipeline; and (iii) a shoe manufacturer buys a retail shoe chain in order to have more direct access to customers. Vertical Merger:- when one firm acquires another firm that is in the same industry but at another stage in the production cycle. For example, the firm being acquired serves as a supplier to the firm doing the acquiring. A Vertical Merger is a

merger between firms operating at different stages of production, e.g., from raw materials to finished products to distribution. An example would be a steel manufacturer merging with an iron ore producer. Context:- vertical mergers usually increase economic efficiency, although they may sometimes have an anticompetitive effect. See also Conglomerate Merger, Horizontal Merger, and Merger. / Вертикальное Слияние:- слияние компаний, которые производят товары и услуги, с компаниями, которые используют эти товары и услуги. Например, если издательская фирма покупает целлюлозно-бумажную компанию, то это рассматривается как вертикальное слияние, поскольку в своей деятельности издательство использует много бумаги. В некоторых случаях правительство может воспрепятствовать вертикальным слияниям, руководствуясь при этом антитрестовскими законами (antitrust laws). Смотрите также Конгломератное Слияние (Conglomerate Merger), Горизонтальное Слияние (Horizontal Merger); и Слияние (Merger). Вертикальное Слияние:- производственное и организационное объединение, слияние, кооперация, взаимодействие предприятий, связанных общим участием в производстве, продаже, потреблении единого конечного продукта:- поставщиков материалов, изготовителей узлов и деталей, сборщиков конечного изделия, продавцов и потребителей конечного продукта. Вертикальное Слияние – слияние двух компаний, одна из которых является поставщиком другой. В США вертикальные слияния существенно ограничены актом Селлера-Кефовера и другими антитрестовскими законами.

VERTICAL MOBILITY = ВЕРТИКАЛЬНАЯ МОБИЛЬНОСТЬ – A term Vertical Mobility refers to a person or group's movement up or down a status hierarchy. This is commonly referred to as Social Mobility, yet vertical mobility can also refer to any movement up or down a hierarchy of any kind, not necessarily related to social status in the same way that social mobility is. See also Mobility Of Labour. Vertical Mobility is a type of social movement when a person or group moves up or down in status. Vertical mobility can also apply outside of social situations to any type of movement that goes up or down a hierarchy of some type. Vertical Mobility is:- (1) a movement from one social level to a higher one (Upward Mobility) or a lower one (Downward Mobility) as by changing jobs or marrying; and (2) a cultural diffusion from one social level to another, as the adoption by one economic class of the fashions current or formerly current in a higher class. / Вертикальная Мобильность:- . Смотрите также Перелив Рабочей Силы или Мобильность Рабочей Силы (Mobility Of Labour).

VERTICAL OPTION SPREAD = ВЕРТИКАЛЬНАЯ КУРСОВАЯ РАЗНИЦА ОПЦИОНОВ (или ВЕРТИКАЛЬНЫЙ СПРЭД ОПЦИОНОВ) – Vertical Option Spread:- the options vary with respect to strike price but not maturity.

VERTICAL RESISTANCE = ВЕРТИКАЛЬНАЯ РЕЗИСТЕНТНОСТЬ (или ВЕРТИКАЛЬНАЯ УСТОЙЧИВОСТЬ, или ВЕРТИКАЛЬНАЯ СОПРОТИВЛЯЕМОСТЬ, или ВЕРТИКАЛЬНАЯ СТОЙКОСТЬ) – Vertical Resistance is a resistance controlled by one or a few major genes, in which varieties with this type of resistance are usually highly resistant to one or several pathogen races or several disease races or insect biotypes of a given species but are susceptible to others. A type of resistance which is expressed against only some biotypes of a pest species and is governed by one or more genes in the host plant, each of which corresponds to a matching gene for parasitic ability in the pest species, sometimes called Gene-For-Gene Resistance. See also Horizontal Resistance. The term vertical resistance was first used by James Edward Vanderplank (August 08, 1908–1997) to describe single-gene resistance. This contrasted the term horizontal resistance which was used to describe many-gene resistance. Raoul A. Robinson (September 25, 1928 in Saint Helier, Jersey – July 25, 2014) further refined the definition of vertical resistance, emphasizing that in vertical resistance there are single genes for resistance in the host plant, and there are also single genes for parasitic ability in the parasite. This is a very important phenomenon known as the Gene-For-Gene Relationship, and it is the definitive character of vertical resistance. / Дьеймз Эдвод Вондёплэнк (James Edward Vanderplank). Раул Эй. Робинсэн (Raoul A. Robinson).

VERTICAL RESTRAINTS (OR RESTRICTIONS) = ВЕРТИКАЛЬНЫЕ СОКРАЩЕНИЯ (ИЛИ ОГРАНИЧЕНИЯ) – Vertical Restraints (Or Restrictions) refers to certain types of practices by manufacturers or suppliers relating to the resale of their products. The usual practices adopted in this regard are resale price maintenance (RPM), exclusive dealing and exclusive territory or geographic market restrictions. Under exclusive dealing and/or exclusive territory, a single distributor is the only one who obtains the rights from a manufacturer to market the product. Context:- a significant debate exists in the economic literature as to whether this confers monopoly power on the distributor. Usually, the distributor's market power is limited by inter-brand competition. The manufacturer's purpose is normally to provide incentives to the distributor to promote the product and provide better service to customers.

VERTICAL SEISMIC PROFILING = ВЕРТИКАЛЬНОЕ СЕЙСМИЧЕСКОЕ ПРОФИЛИРОВАНИЕ – Vertical Seismic Profiling (VSP) is a seismic exploration method, which details structure of the space around the well, defines the nature of geological sections, which are penetrated, and provides a speed model of the environment and level of oil saturation in strata. VSP is carried out by creation of waves on the surface, which are captured in the well by seismic receptors placed at various depths, and by subsequent study of the results. / Вертикальное Сейсмическое Профилирование (ВСП) это метод сейсмической разведки (сейсморазведки), позволяющий детализировать строение околоскважинного пространства, определять характер вскрываемых геологических разрезов, и определять скоростную модель среды и степень нефтенасыщенности пластов. ВСП осуществляется путём возбуждения волн на земной поверхности, их улавливания в скважине с помощью сейсмоприёмников, расположенных на разных глубинах, и последующего изучения результатов исследования.

VERTICAL SPREAD = ВЕРТИКАЛЬНАЯ КУРСОВАЯ РАЗНИЦА (или ВЕРТИКАЛЬНЫЙ СПРЭД) – Vertical Spread:- any of several types of option spread involving the simultaneous purchase and sale of options of the same class and expiration date but different strike prices, including Bull Vertical Spreads, Bear Vertical Spreads, Back Spreads, and Front Spreads. See also Bear Spread; Diagonal Spread; and Horizontal Spread. Vertical Spread:- any option strategy that relies on the difference in premium between two options on the same underlying with the same maturity, but different strike prices. Thus put spreads and call spreads would both be vertical spreads. Vertical Spreads:- an options spread is any combination of multiple positions. This can include buying a call and selling a call, buying a put and selling a put, or buying stock and selling the call (which would be a covered write). For our purposes, we are going to look more closely at a vertical call bull spread, which is used if we expect the price of the underlying stock to rise, although these same principles can be applied to bull put spreads, bear call spreads and bear put spreads. Fundamentally, vertical spreads are a directional play, says Joseph Burgoyne, Director of institutional and retail marketing for the Options Industry Council, which means the investor needs to have an opinion whether the underlying is going to go up or down. Additionally, while they have limited risk, they also have limited reward. Kearney explains, 'What I'm looking at is I want to control the stock, and I think we're going to a certain Dollar amount. I'm willing to give up anything above that', he says. For our example of a vertical call bull spread, he uses a stock trading at USD63 that he believes will go at least to USD70. You simply could buy either the stock or a single call, but by purchasing the bull call spread you are able to better limit your risk. In Kearney's example, we put on the 60–70 vertical call spread, which consists of buying one in-the-money 60 call and selling one out-of-the-money 70 call. Because we sold the 70 call, we limit the maximum value of our spread to USD7 (minus commissions), but we lower our breakeven for the trade because of the credit we earned selling the 70 call. Additionally, our loss is limited to the cost of the spread. Vertical Spread is the simultaneous purchase and sale of two options that differ only in their exercise price. Vertical Spread:- most commonly used to describe the purchase of one option and writing of another

where both are of the same type and of same expiration month, but have different strike prices. Example:- buying 1 XYZ May 60 call and writing 1 XYZ May 65 call. See also Bull (or Bullish) Spread and Bear (or Bearish) Spread. Vertical Spread:- buying and selling puts or calls of the same expiration month but different strike prices. Vertical Spread is an option strategy relying on the difference in premium between two options that share a common underlying and maturity, but are struck at different prices. See also Call Spread; and Put Spread. / Дьжосэф Бургойн (Joseph Burgoyne). Мати Кони (Marty Kearney). Вертикальная Курсовая Разница или Вертикальный Спрэд:- техника использования курсовой разницы в сделках с опционами на ценные бумаги, заключающаяся в одновременной покупке и продаже опционов на одни и те же лежащие в основе ценные бумаги, которые имеют одни и те же месяцы прекращения признания, но различные сходные цены. Синоним термина Ценовая Курсовая Разница или Ценовой Спрэд (Price Spread). Вертикальный Спрэд:- опционная стратегия, осуществляемая путём одновременной покупки и продажи опционов с одинаковой датой исполнения, но разными ценами исполнения. Смотрите также Bullish Credit Spread, Bearish Credit Spread, Bullish Debit Spread, Bearish Debit Spread. Вертикальный Спрэд – опционный спрэд, одновременная покупка и продажа одинакового числа опционов одного класса с разными ценами и одинаковой датой исполнения. Вертикальный спрэд применяется в расчёте на получение прибыли на разнице в премиях. К вертикальным спрэдам относятся:- бычий дебетовый колл спрэд, медвежий дебетовый пут спрэд и их разновидности. Вертикальный Спрэд:- стратегия в операциях с опционами, которая состоит в покупке опциона по одной сходной цене (strike price) и одновременной продаже другого опциона того же класса по следующей, более высокой или более низкой сходной цене. Оба опциона имеют один и тот же срок исполнения. Например, вертикальный спрэд создаётся путём покупки опциона на акции XYZ на Май с ценой исполнения 30 Долларов и продажи опциона на акции XYZ на Май с ценой исполнения 40 Долларов. Инвестор, который покупает вертикальный спрэд, надеется получить прибыль по мере роста или сокращения разницы между премиями на опцион между двух опционных позиций. Называется также Ценовой Спрэд (Price Spread). Смотрите также Option Premium.

VERTICAL SPREAD OPTIONS = ОПЦИОНЫ С ВЕРТИКАЛЬНОЙ КУРСОВОЙ РАЗНИЦЕЙ (или ОПЦИОНЫ С ВЕРТИКАЛЬНЫМ СПРЭДОМ) – Vertical Spread Options:- vertical spreads are a combination of long and short calls or long and short puts in the same expiration. To set up a long call spread, you would buy a lower strike call and sell a higher strike call against it. The main advantage of this strategy is that the sale of the upside call can significantly reduce the initial premium outlay when putting on the trade. However, the sale of this upside call also caps the profit potential of the trade. You shouldn't participate in any move above the short call strike. When using the measured move target, always be sure to sell the strike closest to the target. This is the level the market is implying the underlying can reach, thus where you would want to set up for point of maximum profit. Example:- we buy the E-mini S&P 500 August 09 weekly vertical spread of 1 715–1 720 for 0.90. The trader is buying the 1 715 calls and selling the 1 720 calls for a 0.90 net debit. The risk is USD45 per one-lot. The potential reward is USD205 per one-lot. Breakeven is 1 715.90. To take a bearish view on the market, a trader could use a vertical put spread. This involves buying a low strike put while selling a lower strike put. As with the long call vertical, a long put vertical is established for a lower initial premium outlay but has a capped profit potential. Again, look to sell the strike closest to the downside measured move target. Example:- We buy the E-mini August 09 weekly vertical spread of 1 685–1 680 for 0.85. This involves buying the 1 685 puts while selling the 1 680 puts for a 0.85 net debit. The risk is USD42.50 per one-lot. The potential reward is USD207.50 per one-lot. The breakeven is 1 684.15. Both of these strategies set up for well-defined reward-to-risk ratios and carry less risk than outright calls or puts. The muted effect that implied volatility changes have on these positions is also a factor that makes them particularly attractive around catalyst events.

VERTICAL SUPPLY LINKAGES = ВЕРТИКАЛЬНЫЕ СВЯЗИ ПРЕДЛОЖЕНИЯ – A term Vertical Supply Linkages refers to links between firms, or within a firm, up-and-down the production chain for a particular product. In recent times the production chain for a range of products and services has become more global.

VERTICAL TILLAGE = XX (или ВЕРТИКАЛЬНАЯ ОБРАБОТКА ПОЧВЫ, или ВЕРТИКАЛЬНАЯ ВСПАШКА) – Vertical Tillage is used to reduce any pushing or smearing action that may be caused by tillage tools. Many vertical tillage tools are designed to size residue into more manageable pieces and distribute crop residue, while causing some soil fracturing and mixing of soil with residue at the surface. A number of tillage tools embrace the concept of 'Vertical' Tillage, but use shallow concavity discs, low profle sweeps and extensive harrows to provide some additional soil disturbance – all the while attempting to remain true to the idea of tillage without signifcant inversion and soil smearing.

VERTICILLASTER = ПОЛУМУТОВКА (или ЛОЖНАЯ МУТОВКА, или XX) – Verticillaster (inflorescences) (type):- a pair of axillary cymes arising from opposite leaves or bracts and forming a false whorl, as in many salvias (Salvia). Verticillaster is a mixed inflorescence (as in many labiates) consisting of a pair of much-condensed nearly sessile cymes arranged around an axis like a true verticil. Verticillaster is an inflorescence in which the flowers are arranged in a seeming whorl, consisting in fact of a pair of opposite axillary, usually sessile, cymes, as in many mints. Verticillaster, a false whorl, formed of a pair of opposite cymes. Verticillaster (in botany) is an inflorescence, such as that of the dead-nettle, that resembles a whorl but consists of two crowded cymes on either side of the stem. / Мутовка, группа из трёх или более кольцеобразно расположенных листьев, ветвей, цветков, частей цветка и других органов растений, отходящих на одном уровне от осевого органа.

VERTICILLATE = МУТОВЧАТОЕ – Verticillate:- arranged in whorls. Verticillate:- disposed in a whorl.

VERTICILLIUM WILT = ВЕРТИЦИЛЛЁЗНЫЙ ВИЛТ (или ВЕРТИЦИЛЛЁЗНОЕ УВЯДАНИЕ) – Verticillium Wilt, which is caused by the fungus Verticillium Dahliae, can be found throughout the High Plains in the United States. Symptoms:- Leaf symptoms most frequently occur from the beginning of flowering to the end of the growing season. The chlorosis followed by necrosis of the leaves are similar to that found in Fusarium wilt, and may appear differently for different varieties. Usually Verticillium wilt does not cause disease symptoms in the seedling stage. Verticillium wilt has dark brown to black streaks through the center of the stem when cut diagonally. When cut longitudinally, vascular discoloration can look continuous. While these streaks may be more discontinuous than those found with Fusarium wilt, there are often exceptions to these general differences in symptoms. Therefore, disease identification should be confirmed through isolation of the causal Fungus in the laboratory. It is especially important in regions that can get both types of wilt to confirm which type is present. Verticillium Wilt is favored by cool air and soil temperatures, excessive soil moisture and higher soil nitrogen levels. Verticillium wilt is common in most cotton growing areas and the causal organism has a wide host range that includes many common weeds. Varieties with some resistance to the disease are available and should be used if the disease is present. Wilt disease can be one of the most devastating problems in cotton. Verticillium wilt is widespread and common. Plants rarely wilt but may defoliate prematurely at the end of the season. Leaves develop a characteristic yellow mottle, at the edges and between the veins. Lower leaves are usually affected first. Dead tissue develops at the leaf edges and may replace the mottled areas. The mottle can be diffuse or angular. Verticillium wilt is favored by cool seasons and early infection can lead to stunted plant growth and yield loss. Characteristic brown discoloration develops in woody tissue throughout the plant. During hot weather symptoms cease development and become less obvious. See also Bronze Wilt, Fusarium Wilt, Sudden Wilt, and Wilt. / желтая крапчатость (yellow mottle). изменение цвета сосудов . Вилт известен также как Трахеомикоз (Трахеомикозная Болезнь). Смотрите также Бронзовый Вилт

(Bronze Wilt), Молниеносный Вилт или Скоротечный Вилт (Sudden Wilt) и Фузариозный Вилт (Fusarium Wilt). . жилка (vein). Под Вилтом, от Английского слова Wilt, означающее Вянуть, понимается болезнь растений, вызываемая паразитическими грибами. Наиболее вредоносен вилт Хлопчатника. Поражается сосудистая система, растения увядают и, как правило, погибают. Под Вилтом понимается увядание растений, вызываемое разнообразными причинами. Чаще вилтом называют трахеомикозную болезнь, вызываемую несовершенными Грибами Verticillium Dahliae (Verticillium Albo-Atrum) – Вертициллиозный Вилт и Fusarium Oxysporum – Фузариозный Вилт. Первый поражает около 350 Видов Двудольных Растений. Наиболее сильно вилт поражает Хлопчатник, несколько меньше Лён, Томат, Картофель, Дыню, Арбуз, Персик, Абрикос и другие. Возбудитель развивается в почве, через корни проникает в растение и распространяется в водопроводящей системе ксилемы, вызывая увядание надземных органов. Чаще погибает всё растение, реже – отдельные его части. Болезнь передаётся через почву, с растительными остатками, посадочным материалом, поливной водой (Фузариозный Вилт) и с семенами. Поражённые растения или не дают урожая, или качество его резко снижается. Меры борьбы:- подбор устойчивых к вилту сортов; очищение почвы от возбудителей вилта путём введения рациональных севооборотов и обработки земли, внесение органических удобрений, активизирующих развитие сапрофитных микробов и Грибов-антагонистов возбудителя вилта; на сильно заражённых вилтом участках Хлопчатника внесение в почву под зяблевую вспашку фунгицидов. Вертициллёзный Вилт (или Вертициллёзное Увядание) (Verticillium Wilt):- грибная болезнь, поражающая кроме Хлопчатника ещё свыше 400 Видов растений, относящихся к различным Семействам. К примеру, от неё страдают овоще-бахчевые и многие другие сельскохозяйственные культуры, а также Сорняки (Дурнишник, Белая Марь, Портулак, Алеппское Сорго, Щирица). Но для Хлопчатника вертициллёзный вилт является наиболее распространённой и вредоносной болезнью. Возбудитель болезни – Гриб Verticillium Dahliae Klebahn. На начальной стадии развития вертициллёзный вилт проявляется в появлении желтоватых пятен на листьях нижнего яруса куста растения. Затем эти пятна буреют и подсыхают, образуя некрозы. Проявление симптомов болезни отмечено и на семядольных листьях. Заболевание начинает распространяться по кусту снизу вверх. Подверженные вертициллёзному вилту новые листья растения начинают постепенно увядать, засыхать и со временем опадать. В случае сильного поражения Хлопчатника этой болезнью с растения опадают практически все листья, а недозревшие коробочки начинают засыхать и раскрываться раньше времени. Такая длительная или хроническая форма вертициллёзного вилта ухудшает развитие растения, приводя к остановке его роста. Достаточно часто в межсезонье (mid-season) встречается молниеносный вилт (или скоротечный вилт (sudden wilt)), при котором листья Хлопчатника, не теряя зелёного окраса, очень быстро поникают, высыхают, но не опадают, а само поражённое этим видом болезни растение погибает. Характер болезни зависит от степени устойчивости разновидности Хлопчатника и фазы развития растения, в которую возникло заболевание. Наибольший урон болезнь наносит на более ранних периодах вегетации. Кроме листьев вертициллёзный вилт поражает главный стебель и нижние боковые ветви растения, на которых наблюдается побурение древесины вследствие некротизации мест поражений; эти признаки заболевания Хлопчатника ложатся в основу уточнения диагноза самой болезни вертициллёзный вилт. При срезе таких поражений предстают тёмно-бурые пятна, концентрирующиеся вокруг сосудов древесины. Ещё одним признаком этой болезни служит побурение в 3–4 миллиметрах от основания листовой пластинки тканей черешка листа. При этом на общем светло-зелёном фоне среза черешка листа заметно точечное побурение сосудистых пучков, вслед за которым происходит постепенное потемнение окружающих тканей как у листьев с явными наружными признаками заболевания, так и у внешне здоровых листьев заболевшего растения Хлопчатника. Вертициллёзный вилт наносит существенный ущерб посевным качествам семян, ухудшает их масличность, приводит к потере качества волокна и наносит значительный ущерб всему урожаю Хлопчатника. Например, на сильно заражённых плантациях Хлопчатника число коробочек снижается на 14–15%, приводя к общей потере урожая в размере 30–35%. Средний коэффициент потерь урожая Хлопчатника на 1% заболевших растений достигает диапазона 0.3–0.35, а на плантациях с 70–90% заражения – 0.5–0.6. В зонах возделывания Хлопчатника в странах бывшего Союза Советских Социалистических Республик (СССР) вертициллёзный вилт встречался повсеместно. В 1970-е потери урожая Хлопчатника в Узбекистане вследствие поражения этой болезнью достигали уровня 400 000–500 000 тонн хлопка-сырца. В качестве основной меры борьбы с вертициллёзным вилтом служат протравливание посевных семян, внесение под основную вспашку перепрелого навоза, возделывание более устойчивых к данной болезни сортов Хлопчатника, правильное использование органических и минеральных (в соотношениях 1:0.8:0.5) удобрений, внесение последней подкормки в период массовой бутонизации Хлопчатника, уборка растительных остатков с поля, внесение пентахлорнитробензола (ПХНБ) в количестве 100 килограммов на один гектар (кг/га) после сбора урожая, выращивание промежуточных и сидеральных сельскохозяйственных культур (озимый Горох, Горчица, Рапс, озимая Рожь), севооборот. С целью повышения сопротивляемости Хлопчатника к вертициллёзному вилту посевы подвергают опрыскиванию 1.5%-ным раствором карбамида (так называемой мочевиной), то есть созданным из расчёта 1.5 килограмма на 100 литров; его проводят вслед за появлением 2–5 настоящих листьев. Данное опрыскивание рекомендуется проводить, совмещая и другие препараты, которые нацелены на борьбу с сосущими насекомыми вредителями. Важное значение имеет также профилактика вертициллёзного вилта при междурядной культивации Хлопчатника; с этой целью необходимо использовать такую практику обработки растений, которая исключает повреждение его корней, в частности внесение удобрений только в середину междурядий; не допускает избыточных поливов нормально развитых растений и сбрасывания воды с заражённых участков на здоровые. Специалисты советуют к концу вегетации сохранять на одном гектаре заражённого участка на 20 000–30 000 растений больше, чем на здоровых участках с обычной густотой стояния растений; а перед переброской сельскохозяйственной техники, используемой в период вегетации Хлопчатника, с заражённых участков поля на здоровые тщательно промывать её сильной струёй воды и дезинфицировать формалином. Кроме того, в регионах, климатические условия которых позволяют выращивать длинноволокнистый Хлопчатник, в условиях сильного заражения вертициллёзным вилтом рекомендуется высевать устойчивые к нему разновидности такого Хлопчатника.

VERTICLE STRIPES = ОСЕВЫЕ ПОЛОСКИ – Verticle Stripes:- they can be observed as longitudinal gaps in the fabric. The space between adjacent wales is irregular. Causes:- (i) bent needles; (ii) heavily running needles; (iii) damaged latch needle; (iv) damaged needle hook; and (v) damaged dial or cylinder. Can be avoided by:- (i) needles and sinkers change after long time use; and (ii) use of fabric fault detector. Knitted fabric defect.

VERTISOL = ВЕРТИСОЛ (или ТЁМНАЯ СЛИТАЯ ПОЧВА, или СЛИТЫЙ ЧЕРНОЗЁМ, или ЧЕРНОЗЁМ) – (1) Vertisol is one of the 12 soil orders in the US Soil Taxonomy. Vertisols are clay-rich soils that undergo significant vertical cracking during the dry seasons. Typically forming under grassland vegetation in basin or rolling hill landscapes, they are best suited for use as pastureland and for the cultivation of plants, such as Rice, that thrive in standing surface water. Their very low water permeability when wet and unstable structure make them unsuitable for most other commercial uses. Although broadly distributed on every nonpolar continent, they occupy just over 2 percent of the land area on Earth, primarily in subtropical or tropical zones of Australia, India, and Africa and in parts of the Western United States (California and Texas) and Europe (Austria and the Balkans). Vertisols are characterized by a content of 30 percent or more by mass of clay-size particles throughout the upper half-meter (1.6 feet) of the soil profile, by centimeter-

size (0.4-inch) cracks open to the land surface during the dry season, and by distinct evidence of strong vertical mixing of the soil particles through shrinking and swelling processes accompanying drying and rewetting periods. A definite annual dry season and a parent material conducive to alkaline pH and to the formation of swelling smectite-type clay minerals are believed to be essential to the development of these soils. The topographic setting for Vertisols usually has a crumpled look created by a complex array of mounds and depressions known as Gilgai Microrelief – the direct result of shrink-swell cycles over long periods of time. Vertisol:- cracking clay (US terminology). See also Vertosol. / Вертисол:- Распространению, условиям формирования, свойствам, режимам функционирования вертисолей и вертиковых почв посвящено множество книг и статей. Эти почвы выделяют в международной классификации почв и во многих национальных классификациях почв по всему Миру с похожими названиями Vertisol, Vertosol, Vertisolic. В классификации почв России (РК) и Полевом определителе почв России выделены типы тёмных слитых почв и аллювиальных слитых почв, а также подтипы слитизированных почв в других типах. В классификации почв бывшего Союза Советских Социалистических Республик (СССР) выделялся только род слитых почв в разных типах. В соответствии с имеющимися обобщениями, вертисоли развиты на глинистых породах с высоким содержанием смектитов в условиях контрастных климатических колебаний увлажнения и иссушения почв, поэтому они имеют глинистый гранулометрический состав по всему профилю, начиная с дневной поверхности. Для вертисолей характерно сильное набухание при увлажнении, сильная усадка с образованием глубоких трещин при иссушении, в которые засыпается материал верхних горизонтов, и боковые сдвиговые деформации почвенной массы, приводящие к образованию разнонаправленных поверхностей скольжения с углом наклона от 10° до 60° к горизонтали, клиновидных структурных элементов и в особых ситуациях к деформации поверхности почвы по типу микрорельефа гильгай. Поэтому в разных классификационных системах эти почвы диагностируют, используя очень близкий комплекс признаков, немного различающийся в деталях:- глинистый гранулометрический состав, наличие сликенсайдов, клиновидной структуры, микрорельефа гильгай, трещин. В классификации почв бывшего СССР использованы иные диагностические признаки:- высокая плотность и наличие трещин в горизонте в сухом состоянии. Вертисоли и вертиковые почвы встречаются крупными массивами преимущественно в тропическом и субтропическом поясах в пределах 45° Южной широты и 45° Северной широты в Австралии, Азии, Африке, Южной части Европы, Северной и Южной Америке. В последние десятилетия появилась информация об ареалах вертисолей и вертиковых почв в более Северных районах умеренного пояса в пределах 45° Северной широты и 54° Северной широты в Канаде и в Европе. На территории России хорошо известны ареалы распространения слитых почв на Северном Кавказе, Волго-Ахтубинской пойме и в лиманах Прикаспийской Низменности. Описаны слитые почвы в долине Маныча, на Южных отрогах Донецкого кряжа. Эти ареалы расположены южнее 48° Северной широты. Советские учёные Пётр Васильевич Гришин и Е.И. Ломако отмечали слитые почвы в Поволжье (Татарстан, Чувашия, Мордовия). На основе специальных маршрутно-ключевых наблюдений недавно севернее 48° Северной широты на территории Центрально-Черноземных областей обнаружено 35 новых ареалов почв, имеющих признаки слитогенеза. Российский учёный Ирина Викторовна Ковда с соавторами выявили признаки слитогенеза в мерзлотных почвах Бурятии.

(2) Vertisol is one of the 30 soil groups in the classification system of the Food and Agriculture Organization (FAO). Vertisols are characterized by a clay-size-particle content of 30 percent or more by mass in all horizons (layers) of the upper half-meter of the soil profile, by cracks at least 1 cm (0.4 inch) wide extending downward from the land surface, and by evidence of strong vertical mixing of the soil particles over many periods of wetting and drying. They are found typically on level or mildly sloping topography in climatic zones that have distinct wet and dry seasons. Vertisols contain high levels of plant nutrients, but, owing to their high clay content, they are not well suited to cultivation without painstaking management. They are estimated to occupy about 2.7 percent of the continental land area on Earth, mainly in the Deccan Plateau of India, the Al-Jazīrah region of The Sudan, eastern Australia, Texas in the United States, and the Paraná basin of South America. Vertisols are dark-colored soils (though they have only moderate humus content) that may also be characterized by salinity and well-defined layers of calcium carbonate or gypsum. They are similar in all respects to the Vertisol order of the US Soil Taxonomy.

VERTOSOL = ВЕРТОСОЛ – Vertosol is the Australian term used to describe a soil which ‘turns’ (tills) itself (Latin Verto = To Turn). Vertosols have more than 35% clay throughout the profile, cracks greater than 5 mm at some time of the year, and the presence of slickensides. Vertosols lack distinct horizons.

VERY EASY RODENT–ORIENTED NETWIDE INDEX TO COMPUTERIZED ARCHIVES = XX УКАЗАТЕЛЬ НА КОМПЬЮТЕРИЗИРОВАННЫЕ АРХИВЫ – Very Easy Rodent-Oriented Netwide Index to Computerized Archives (VERONICA) is a search tool (like archie) that searches text that appears in Gopher menus.

VERY HIGH FREQUENCY = ОЧЕНЬ ВЫСОКАЯ ЧАСТОТА – Very High Frequency (VHF):- conventionally defined portion of the electromagnetic spectrum including any radiation with a wavelength between 1 and 10 meters and a frequency between 300 and 30 MegaHertz. VHF signals are widely employed for television and radio transmissions. In the United States and Canada, television stations that broadcast on channels 2 through 13 use VHF frequencies, as do FM radio stations. Many amateur radio operators also transmit on frequencies within the VHF band. VHF waves, unlike longer waves, are not strongly reflected from the atmosphere; therefore, they do not bend readily around the Earth’s curvature and cannot be transmitted beyond the horizon. Their range is further limited by their inability to pass through hills or large structures. Accordingly, VHF waves are limited to use in short-range, line-of-sight communications, including radio and television broadcasting, and in electronic navigation systems. They are especially suited to such applications because their reception is not impaired by random electromagnetic noise (‘static’) of longer wavelengths. Because of their limited transmission range, VHF signals of the same frequency can be used by transmitters several hundred miles apart without interfering with one another. See also UHF.

VERY HIGH FREQUENCY COMMUNICATIONS = ПЕРЕГОВОРЫ НА ОЧЕНЬ ВЫСОКОЙ ЧАСТОТЕ (или XX) – Very High Frequency (VHF) Communications:- provides radio voice communications between aircraft and ground stations, also between aircraft. Very High Frequency (VHF) is limited in angle (line of sight) and usually used for air traffic communications.

VERY HIGH FREQUENCY OMNIDIRECTIONAL RADIO RANGE = ВЫСОКОЧАСТОТНЫЙ ВСЕНАПРАВЛЕННЫЙ РАДИО ДИАПАЗОН – Radio Range, in aerial navigation, a system of radio transmitting stations, each of which transmits a signal that not only carries identification but also is of intrinsic value to a navigator in fixing his position. The older ‘A–N’ type, dating from 1927, operates at low and medium frequencies. The only equipment needed in the aircraft is an ordinary radio receiver. Each station transmits International Morse Code letters A (· –) and N (– ·) in alternate lobes of its radiation pattern. In the narrow radiants where adjacent lobes overlap, the dots and dashes of the different Morse signals blend into a continuous tone. A pilot following the steady tone knows he is flying directly toward the station or away from it; when he strays off course, he knows, by virtue of which letter he hears (A or N), which way to turn in order to get back on course. Modern Very-High-Frequency Omnidirectional Range (VOR) has been developed in various forms since about 1930. It transmits two signals simultaneously in all directions. Operating in the very high frequency (VHF) range, it is less subject than the lower-frequency radio range to disturbances by day-night alternation, weather, and

other causes. The two simultaneously emitted signals have a difference in electrical phase that varies precisely with the direction from the station. Special receiving equipment in the aircraft detects the difference and displays it to the pilot in the form of a bearing. Used with distance-measuring equipment (DME), VOR provides a basic point-to-point guidance system for airliners. Very High Frequency Omnidirectional Radio Range (VOR):- used as the basis for navigation in the US National Airspace System. Very High Frequency Omnidirectional Range (VOR) is the primary navigational aid (NAVAID) used by civil aviation in the National Airspace System (NAS). The VOR ground station is oriented to magnetic north and transmits azimuth information to the aircraft, providing 360 courses TO or FROM the VOR station. When DME is installed with the VOR, it is referred to as a VOR/DME and provides both azimuth and distance information. When military tactical air navigation (TACAN) equipment is installed with the VOR, it is known as a VORTAC and provides both azimuth and distance information. The courses oriented FROM the station are called radials. The VOR information received by an aircraft is not influenced by aircraft attitude or heading. Radials can be envisioned to be like the spokes of a wheel on which the aircraft is on one specific radial at any time. For example, aircraft A (heading 180°) is inbound on the 360° radial; after crossing the station, the aircraft is outbound on the 180° radial at A1. Aircraft B is shown crossing the 225° radial. Similarly, at any point around the station, an aircraft can be located somewhere on a specific VOR radial. Additionally, a VOR needle on an RMI will always point to the course that will take you to the VOR station where conversely the ADF needle points to the station as a RB from the aircraft. In the example above, the ADF needle at position A would be pointed straight ahead, at A1 to the aircraft's 180° position (tail) and at B, to the aircraft's right. The VOR receiver measures and presents information to indicate bearing TO or FROM the station. In addition to the navigation signals transmitted by the VOR, a Morse code signal is transmitted concurrently to identify the facility, as well as voice transmissions for communication and relay of weather and other information. VORs are classified according to their operational uses. The standard VOR facility has a power output of approximately 200 watts, with a maximum usable range depending upon the aircraft altitude, class of facility, location of the facility, terrain conditions within the usable area of the facility, and other factors. Above and beyond certain altitude and distance limits, signal interference from other VOR facilities and a weak signal make it unreliable. Coverage is typically at least 40 miles at normal minimum instrument flight rules (IFR) altitudes. VORs with accuracy problems in parts of their service volume are listed in Notices to Airmen (NOTAMs) and in the Airport/Facility Directory (A/FD) under the name of the NAVAID.

VERY LARGE CRUDE CARRIER = ОЧЕНЬ КРУПНЫЙ НЕФТЕПЕРЕВОЗЧИК (или ОЧЕНЬ КРУПНЫЙ ПЕРЕВОЗЧИК НЕФТИ) – Very Large Crude Carrier (VLCC):- super-tankers used for transporting crude oil, capable of carrying more than 200 000 Metric tons (Mt). Very Large Crude Carriers (VLCC) are crudeoil carrying ships (tankers) with a capacity between 160 001 and 320 000 deadweight tons (dwt). Very Large Crude Carrier (VLCC):- a tanker (vessel) designed for the carriage of liquid bulk cargo with a loading capacity ranging from 200 000 to 320 000 deadweight tons. It must unload petroleum products at special deep-water petroleum terminals, e.g., such as Louisiana Offshore Oil Port (LOOP). Such tankers are further divided by whether they are providing Clean or Dirty service. See also Clean Tankers, Dirty Tankers, Supertanker, Tanker, and Ultra Large Crude Carrier. Very Large Crude Carrier (VLCC) is a tanker of 200 000 to 319 000 dwt. It can carry about 2 million barrels of crude oil. Very Large Crude Carrier (VLCC) is a crude oil carrying ship of between 150 000 and 320 000 deadweight tons. They offer good flexibility for using terminals since many can accommodate their draft. They are used in ports that have depth limitations, mainly around the Mediterranean, West Africa, and the North Sea. They can be ballasted through the Suez Canal. Very Large Crude Carrier (VLCC) is a vessel designed for the carriage of liquid cargo in bulk with a loading capacity from 50 000 till 250 000 DWT. / Танкер (судно) полной грузоподъёмностью от 200 000 до 320 000 тонн дедвейт (тонн полной грузоподъёмности или т грп), разработанное для перевозки наливных грузов. Он должен сливать нефтепродукты на специальных глубоководных терминалах для нефтепродуктов, таких, например, как Шельфовый Нефтяной Порт Луизианы (ШНПЛ). Такие танкеры, в свою очередь, подразделяются на танкеры для перевозки светлых или тёмных нефтепродуктов. Смотрите также Танкер для Светлых Нефтепродуктов (Clean Tankers), Танкер для Тёмных Нефтепродуктов (Dirty Tankers), Супертанкер (Supertanker), Танкер (Tanker), и Сверх Крупный Нефтеперевозчик (Ultra Large Crude Carrier). Очень Крупный Перевозчик Нефти (ОКПН):- танкер, способный перевозить значительное количество сырой нефти.

VERY LARGE FAMILY FARMS = ОЧЕНЬ КРУПНЫЕ СЕМЕЙНЫЕ ФЕРМЫ – Very Large Family Farms are the family farms with sales of USD500 000 or more.

VERY LOW–DENSITY LIPOPROTEINS = ЛИПОПРОТЕИНЫ ОЧЕНЬ НИЗКОЙ ПЛОТНОСТИ – Very Low-Density Lipoproteins (VLDL):- VLDLs and LDLPs are the specific lipoproteins that are most likely to deposit cholesterol on artery walls inside the human body, which increases risk of coronary heart disease (CHD). / Под Липопротеинами, от Греческих слов Lípos, означающее Жир, и Protos, означающее Главный или Первый, понимаются .

VES = VERTICAL ELECTRIC SOUNDING

VES. = VESSEL

VESDEP = VESSEL DEPARTURE MESSAGE

VESICLE = ВЕЗИКУЛА (или ПУЗЫРЁК) – Vesicle is a hollow structure or cavity which may be macroscopic like a bladder or microscopic as in a sub-cellular organelle. See also Vacuole, Vesicular Transport, and Vésicule. Vesicle is a small vacuole. / Везикула – полая структура или полость, которая может быть макроскопической как пузырь или микроскопической как в субклеточной органелле. Под Везикулой, от Латинского слова Vesicula, означающее Пузырёк, понимается элемент кожной сыпи – полушаровидный пузырёк с прозрачным или мутноватым содержимым. Везикула:- маленький мембранный органоид эукариотической клетки.

VESICULAR ARBUSCULAR MYCORRHIZA = ВЕЗИКУЛЯРНО–АРБУСКУЛЯРНАЯ МИКОРИЗА (или ВЕЗИКУЛЯРНАЯ АРБУСКУЛЯРНАЯ МИКОРИЗА, или ВЕЗИКУЛЯРНЫЙ АРБУСКУЛЯРНЫЙ ГРИБОКОРЕНЬ) – Vesicular Arbuscular Mycorrhiza (VAM) is a partnership between soil borne Fungi and most crop plants, including Cotton (but not brassicas). VAM Fungi colonise the roote of the plant but without causing disease. The VAM Fungi act as an extension of the root system and transfer extra nutrients, especially phosphorus, from the soil to the plant. In return the plant provides the Fungi with sugars as a food source. VAM is a convenient abbreviation for Vesicular Arbuscular Mycorrhiza. A particular type of Mycorrhiza that is characterised by the production of vesicles and arbuscules by the Fungus in the cortex of the plant root. See also Mycorrhiza. Mycorrhiza is the product of an association between a Fungus and plant root. Vesicular-Arbuscular Mycorrhiza (VAM) is formed by the symbiotic association between certain Phycomycetous Fungi and angiosperm roots. The Fungus colonizes the root cortex forming a mycelial network and characteristic vesicles (bladder-like structures) and arbuscules (branched finger-like hyphae). The mycelia are aseptate or septate ramifying intercellularly thus causing little damage to tissues. The arbuscules are the most characteristic structures, formed intracellularly and probably having an absorptive function. The vesicles are terminal swellings of hyphae formed inter and intracellularly having a storage function. There are six Genera of Fungi belonging to Endogonaceae which have been shown to form mycorrhizal associations:- Glomus, Gigaspora, Acaulospora, Entrophospora Sclerocystis and Scutellospora. These are mainly identified by their characteristic spores and sporocarps which are formed mostly in the soil surrounding the roots and rarely inside the roots. The identification of VAM

Fungi directly from roots has been difficult. One of the striking features of VAM Fungi is their very wide host range which includes angiosperm Species belonging to almost all the Families. Even the roots of some Aquatic Plants are colonized by VAM Fungi. Vesicular Arbuscular (VA) Mycorrhiza is a common endomycorrhizal association produced by Phycomycetous Fungi of the Genus Endogone. Host range includes many agricultural and horticultural crops. / Взаимодействие между Грибом, рождённым в почве, и большинством Растений сельскохозяйственных культур, включая Хлопчатник (за исключением Капусты). Гриб Везикулярно-Арбускулярной Микоризы (ВАМ) колонизирует корни растения, не вызывая при этом заболевания. Гриб ВАМ воздействует на расширение корневой системы и передаёт из почвы растению дополнительные питательные вещества, особенно фосфор. Взамен растение обеспечивает гриб сахарозами в качестве источника питания. обозначение . в коре (cortex). Под Микоризой, от Греческих слов Мýkes, означающее Гриб, и Rhiza, означающее Корень, или Грибокорнем понимается взаимовыгодное сожительство (симбиоз) мицелия Гриба с корнем высшего растения. Различают микоризу эктотрофную (наружную), при которой Гриб оплетает покровную ткань окончаний молодых корней и проникает в межклетники самых наружных слоёв коры, и микоризу эндотрофную (внутреннюю), которая характеризуется внедрением мицелия (гиф Гриба) внутрь клеток. Эктотрофная микориза характерна для многих деревьев (Дуб, Ель, Сосна, Берёза), кустарников (Ива), некоторых кустарничков (Дриада) и травянистых растений (Гречиха живородящая). Молодые корни этих растений обычно ветвятся, окончания их утолщаются, растущая часть корней окутывается толстым плотным грибным чехлом, от которого в почву и по межклетникам в корень на глубину одного или нескольких слоёв коры отходят гифы Гриба, образуя так называемую Сеть Гартига; корневые волоски при этом отмирают (эуэктотрофный тип микоризы). У кустарничка Арктоуса арктического и травянистого растения Грушанки крупноцветковой гифы Гриба проникают не только в межклетники, но и в клетки коры (эктоэндотрофный тип микоризы). Эктотрофные микоризы образуют чаще гименомицеты (Роды Boletus, Lactarius, Russula, Amanita и другие), реже – гастеромицеты. В образовании микоризы на корнях одного растения может участвовать не один, а несколько Видов Грибов. Однако, как правило, в растительных сообществах встречаются лишь определённые рибы-микоризообразователи – симбионты данных видов растений. При развитии эндотрофной микоризы форма корней не меняется, корневые волоски обычно не отмирают, грибной чехол и ‘Сеть Гартига’ не образуются; гифы Гриба проникают внутрь клеток коровой паренхимы. У растений Семейства Вересковых, Грушанковых, Брусничных и Шикшевых гифы Гриба в клетках образуют клубки, позднее перевариваемые растением (эрикоидный тип микоризы). В образовании микоризы такого типа участвуют фикомицеты (Роды Endogone, Pythium). У растений Семейства Орхидных гифы Гриба из почвы проникают в семя, образуя клубки, перевариваемые затем клетками семени. Из Грибов такой тип микоризы свойствен несовершенным (Род Rhizoctonia) и реже – базидиальным (Род Armillaria и другие). Наиболее распространён в природе – у многих однолетних и многолетних трав, кустарников и деревьев самых различных семейств – фикомицетный тип микоризы, при котором гифы Гриба пронизывают насквозь клетки эпидермиса корня, локализуясь в межклетниках и клетках средних слоёв коровой паренхимы. Микориза оказывает на растение благоприятное воздействие:- за счёт развитого мицелия увеличивается поглощающая поверхность корня и усиливается поступление в растение воды и питательных веществ. Грибы-микоризообразователи, вероятно, способны разлагать некоторые недоступные растению органические соединения почвы, вырабатывают вещества типа витаминов и активаторы роста. Гриб же использует некоторые вещества (возможно, углеводы), извлекаемые им из корня растения. При разведении леса на почве, не содержащей Грибов-микоризообразователей, в неё вносят в небольших количествах лесную землю, например, при посеве жёлудей – землю из старой дубравы.

VESICULAR EXANTHEMA = ВЕЗИКУЛЯРНАЯ ЭКЗАНТЕМА (или ПУЗЫРЬКОВАЯ СЫПЬ) – Vesicular Exanthema:- viral disease of swine causing eruption of painful blisters on feet and snout. Blisters emerge 24 to 72 hours after exposure and are accompanied by fever, which lasts 24 to 36 hours and may occur again after two or three days. The symptoms resemble those of foot-and-mouth disease and vesicular stomatitis, thus creating a problem of diagnosis. Control programs include quarantine, elimination of infected animals, cleaning and disinfecting contaminated areas, and cooking garbage used for swine feed.

VESICULAR STOMATITIS = ВЕЗИКУЛЯРНЫЙ СТОМАТИТ – Vesicular Stomatitis is a viral disease causing blisters in the mouths of cattle, horses, and mules and on the snouts and feet of swine. Horses and cattle with vesicular stomatitis become feverish two to five days after exposure. After the blisters break, the fever subsides, and the animal usually recovers. Differential diagnosis between vesicular stomatitis, vesicular exanthema, and foot-and-mouth disease, all of which display similar symptoms, is based partly on the differing susceptibilities to the three diseases among horses, cattle, and swine. Vesicular Stomatitis is a viral disease of cattle, swine, sheep, goats, and horses, with symptoms similar to foot-and-mouth disease. Trade in infected animals is restricted. / Везикулярный Стоматит животных, острая вирусная болезнь животных, проявляющаяся лихорадкой и образованием везикул (пузырьков), главным образом в ротовой полости. Болеют крупный рогатый скот, Однокопытные и Свиньи. Регистрируется в некоторых странах Европы и Азии. Болезнь обычно наблюдается в пастбищный (особенно влажный) период, совпадая с лётом Насекомых. Источник вируса – больное животное. Факторы передачи – заражённые корма и вода, доильные установки, ухаживающий персонал. Механическими переносчиками вируса могут быть Слепни, Комары и Москиты. Болезнь протекает 1–3 недели и чаще заканчивается выздоровлением. У заболевших животных температура тела 41–42 °С, слюнотечение, отсутствие аппетита. Везикулы, кроме ротовой полости, могут возникнуть на коже других частей тела. Диагноз ставят на основании эпизоотологических и клинических данных, лабораторных исследований. С лечебной целью применяют местно противовоспалительные и противомикробные средства. Профилактика и меры борьбы:- соблюдение ветеринарно-санитарных мероприятий, изоляция больных, дезинфекция помещений, борьба с Насекомыми.

VESICULAR TRANSPORT = ПУЗЫРЬКОВЫЙ ТРАНСПОРТ – Vesicular Transport (of a protein):- one of three means for a protein molecule to pass between compartments within eucaryotic cells. The compartment ‘wall’ (membrane) possesses a ‘sensor’ (receptor) that detects the presence of correct protein (e.g., after that protein has been synthesized in the cell’s ribosomes), then bulges outward along with that protein molecule. The membrane bulge- containing protein then ‘breaks off’ and carries (transports) the protein to its destination in another compartment in the cell. / Пузырьковый Транспорт:- способ переноса белков в клетке.

VÉSICULE = ВЕЗИКУЛА – Vésicule (in French):- the same as Vesicle. / Везикула:- .

VESICULITIS = ВЕЗИКУЛИТ – Vesiculitis:- inflammation and infection of the seminal vesicles in the male reproductive tract. The seminal vesicles are ductlike glands that add fluid secretions to the seminal fluid as it passes from the body during intercourse. Infections present in the prostate or related organs usually involve the seminal vesicles also. Infections can reach the glands through the urethra or by way of the bloodstream. The symptoms of vesiculitis are similar to those in cases of prostate infection; they may include a dull aching pain in the abdomen, discomfort in the urethra, pain after sexual intercourse, the presence of blood in the seminal fluid, premature or painful ejaculation, and impotence. Treatment is usually administration of antibiotics. See also Prostatic Disorder. / Везикулит – воспаление семенных пузырьков. Боли локализуются в области паха и глубоко в тазу, отдаваясь в крестец. Боль, как правило, носит односторонний характер, так как оба семенных пузырька поражаются в разной степени. Везикулит может протекать бессимптомно. Единственной жалобой больных может быть наличие крови в сперме. Отмечается также периодическая пиурия (гной в моче) и пиоспермия (гной в сперме).

VESSEL = СОСУД (или ТРАХЕЯ) – Vessel:- also called Trachea in botany, the most specialized and efficient conducting structure of xylem (fluid-conducting tissues). Characteristic of most flowering plants and absent from most gymnosperms and ferns, vessels are thought to have evolved from tracheids (a primitive form of water-conducting cell) by loss of the end walls. A vessel consists of a vertical series of vessel members that vary from elongated to squat, drum-shaped cells the walls of which are secondarily thickened with rings, spirals, or networks of cellulose, that later become lignified. The length of vessels varies from two cells to rows several meters long. During development, the end walls, already pitted, break through and eventually disappear. The living protoplast of the cell also breaks down and disappears. See also Tracheid. Vessel or Trachea is an efficient fluid conducting structure in most angiosperm xylem, which has evolved from the primitive tracheids found in gymnosperms and ferns by loss of the end walls of the cells so that each vessel runs for several cell-lengths, reinforced by rings and spirals of cellulose fibrils thickened with lignin. / Смотрите также Трахея (Trachea). Сосуд или Трахея (Trachea) – эффективная проводящая жидкость структура в большинстве ксилем ангиоспермов (цветковых или покрытосеменных растений), которая в гимноспермах (голосеменных растениях) и папоротниках лигнином. У растений под Сосудами или Трахеями понимаются проводящие элементы ксилемы в виде длинных полых трубок, образованных одним рядом клеток (члеников) со сквозными отверстиями (перфорациями) между ними. У человека и животных под Сосудами понимаются полые трубки, по которым движется кровь (кровеносные сосуды) и лимфа (лимфатические сосуды). Сосуды или Трахеи у растений, проводящие элементы ксилемы (или древесины), представляющие собой длинные полые трубки, образованные одним рядом клеток (члеников) со сквозными отверстиями (перфорациями) на поперечных стенках. Характерны для покрытосеменных, кроме некоторых Многоплодниковых (Троходендрон, Дримис) и Лилейных (Ландыш, Драцена, Агава), встречаются у Папоротников (Орляк), Селагинелл, Хвощей, Оболочкосеменных (Эфедра, Гнетум, Вельвичия). По строению боковых стенок различают кольчатые, спиральные, лестничные и пористые сосуды. У первых двух вторичная оболочка имеет вид колец или спирально закрученных лент. Они возникают на ранних этапах развития органов растения и способны растягиваться. Остальные типы сосудов с более мощными отложениями вторичной оболочки и окаймлёнными порами в стенках формируются у органов, закончивших рост в длину. После одревеснения оболочек протопласты клеток отмирают, полость сосудов заполняется водой. Для примитивных сосудов характерны большая длина (до 1.3 миллиметра (мм)), малый диаметр, угловатое поперечное сечение члеников с лестничными перфорациями на скошенных поперечных стенках, лестничная поровость боковых стенок (Тюльпанное Дерево). Высокоспециализированные сосуды сложены короткими, в сечении округлыми широкопросветными (до 0.5 мм в диаметре) члениками с простыми перфорациями на поперечных стенках и мелкими очередными порами на боковых стенках (Ясень, Дуб). О сосудах у животных и человека смотрите в статьях Артерии, Вены, Кровеносная Система, Лимфатическая Система. Смотрите также Проводящий Пучок.

VESSEL = СУДНО – Vessel is a craft, usually bigger than a rowboat, intended for navigation on water. Vessel includes ship, lighter, barge, boat, raft, craft, hydroplane, hydrofoil, hovercraft and any floating object or apparatus, whether amphibious or not, used wholly or partly for the conveyance of persons or things by water. Vessel includes any ship or boat, or any other description of vessel used in navigation. According to Lisbon Rules, Vessel means any craft, machine, platform or rig, ship whether capable of navigation or not, which is involved in a collision. Vessel is a floating structure designed for transport. Vessel is a floating, self-propelled structure designed for the transport of cargo and/or passengers. Synonyms:- Boiler, Drum, Ship. See also Ship. Vessel:- a conveyance for the transport of goods by water. Vessel is a ship used to transport crude oil, petroleum products, or natural gas products. Vessel categories are as follows:- Ultra Large Crude Carrier (ULCC), Very Large Crude Carrier (VLCC), Other Tanker, and Specialty Ships Liquefied Petroleum Gas (LPG)/Liquefied Natural Gas (LNG). See also Barge, Boat, General Cargo Ship, Motorboat, Tanker, Towboat, and Tugboat. Vessel is every description of watercraft, used or capable of being used as a means of transportation on the water. / гребная шлюпка (rowboat), предназначенное для навигации по воде. Термин Судно включает в себя:- корабль (ship), лихтер (lighter), баржа (barge), катер (boat), плот (raft), плавучее средство (craft), гидроплан или гидросамолёт или глиссер (hydroplane), судно на подводных крыльях (hydrofoil), судно на воздушной подушке (hovercraft) и любой другой плавающий объект или аппарат, будь-то амфибийный (amphibious) или нет, используемый полностью или частично для транспортировки людей или вещей по воде. Под Кораблём, от Греческого слова Kárabos, понимается то же, что и Судно. В парусном флоте корабль – трёхмачтовое судно с полным парусным вооружением. В современном Русском языке кораблями называют военные суда. Иногда воздушным кораблём называют крупный самолёт, дирижабль. Космический корабль – пилотируемый космический аппарат. Под Судном понимается плавучее сооружение для перевозки грузов и пассажиров, для водного промысла, добычи полезных ископаемых, спортивных состязаний и прочего, а также для военных целей. Судно для военных целей принято называть Кораблём. Основные части судна:- корпус, механизмы и оборудование (судовые навигационные средства, судовые системы, судовые средства связи, судовые устройства и другие). Специфические свойства судна называют мореходными качествами и характеризуют поведение судна в плавании и его безопасность. Размеры судна определяют главные размерения (линейные размеры судна, такие как:- длина, ширина, высота борта на середине длины, осадка и так далее), водоизмещение и вместимость, а грузовых судов – также грузоподъёмность и грузовместимость. Важные характеристики судна:- автономность, дедвейт, живучесть, мореходные качества, надёжность, ремонтопригодность и другие. Наибольшие суда – танкеры (длиной более 350 метров (м), дедвейт более 500 000 тонн (т)). По характеру передвижения суда делятся на самоходные (атомоходы, газотурбоходы, пароходы, теплоходы, электроходы) и несамоходные (буксируемые, гребные, парусные); по положению относительно поверхности воды при движении – надводные (водоизмещающие, глиссирующие, на воздушной подушке и на подводных крыльях) и подводные. По типу главной энергетической установки (ЭУ) суда разделяются на атомоходы, газотурбоходы (газотурбинная ЭУ), пароходы (котломашинная или котлотурбинная ЭУ) и теплоходы (дизельная ЭУ). По назначению суда подразделяют на военные, обслуживающие, промысловые, промышленно-добывающие, спортивно-туристические, транспортные и другие. Обслуживающие суда обеспечивают работу судов другого назначения (буксирные, бункеровочные, гидрографические, дноуглубительные, спасательные суда, ледоколы, плавучие доки, плавучие маяки). Промысловые суда оборудуют для ловли рыбы, добычи морского зверя, крабов, а также для переработки добычи. К промышленно-добывающим судам относятся, например, золотодобывающие драги, кабельные, лесосплавные, нефтебуровые суда. Среди спортивно-туристических судов различают гребные, моторные и парусные суда, гоночные, прогулочные, тренировочные. На транспортных судах перевозят грузы (грузовые суда), пассажиров (пассажирские суда), иногда – одновременно грузы и пассажиров (грузопассажирские суда). Грузовые суда делят на наливные (танкеры), сухогрузные и сухогрузно-наливные. Для сухогрузных судов характерна узкая специализация по роду перевозимого груза и грузообработке:- контейнеровозы, рефрижераторы, суда с горизонтальной грузообработкой и так далее. Судно или Корабль – плавучее сооружение, предназначенное для выполнения определённых хозяйственных и военных задач, научных исследований, водного спорта и другого. Классификация Судов:- По назначению различают суда:- транспортные, промысловые, промышленно-хозяйственные, административно-служебные, военные, научно-исследовательские, судообслуживающие. Транспортные суда подразделяют на грузовые, пассажирские и грузопассажирские. Промысловые суда делятся на добывающие (рыболовные, китобойные, краболовные, водороследобывающие и другие), добывающе-перерабатывающие (например, траулеры-рыбозаводы, морозильные траулеры) и суда обслуживания промысла. Промышленно-хозяйственные суда включают:- промышленно-добывающие (рудодобывающие, нефтепромышленные, драги, соледобывающие снаряды и

другие), подъёмно-монтажные (например, портостроительные суда, плавучие краны), дноуглубительные (землечерпательные и землесосные снаряды, грунтоотвозные и другие), лесопромышленные (сплоточные, лесосплавные и другие), сельскохозяйственные (дождевальные, водоподъёмные и другие), энергоснабжающие (плавучие электростанции, компрессорные, трансформаторные), суда связи (кабелеукладочные, кабелеремонтные, радиосвязные и другие), для очистки акваторий (нефтемусоросборщики и другие). Административно-служебные суда включают инспекторские (рыбонадзорные, суда для охраны заповедников), милицейские, пограничные, таможенные суда, правительственные яхты. Военные суда подразделяются на боевые корабли (смотрите Военный Корабль), военно-транспортные и обеспечивающие (так называемые вспомогательные) суда. В число научно-исследовательских входят суда для комплексных океанических исследований и для проведения специальных исследований (геофизических, гидробиологических и других). К судообслуживающим судам относятся:- буксирные, перегрузочные (например, плавучие зерноперегружатели, нефтеперекачивающие и зачистные станции), снабженческо-приёмные (бункеровщики, суда-водолеи, суда для приёма загрязнённой воды, мусора и другого), причальные (плавучие пристани, дебаркадеры), ледоколы (линейные и портовые), навигационные (гидрографические, плавучие маяки и другие), спасательные, ремонтные (плавучие мастерские, доки, дегазационные станции и другие), посыльно-разъездные (например, лоцманские) и учебные. Отдельную группу составляют спортивные суда, медико-санитарные (госпитальные, дезинфекционные и другие), оздоровительные (плавучие дома отдыха и тому подобные), бытовые (плавучие общежития, гостиницы, склады и другие), культурно-просветительные (суда-музеи, суда-выставки, суда-клубы и другие). По району плавания суда подразделяют на морские, внутреннего и смешанного плавания. Морские суда бывают неограниченного и ограниченного плавания (с установлением района эксплуатации или допустимого расстояния от берега, порта-убежища). Категорией ледовых подкреплений определяются допустимый район и возможность плавания морских судов во льдах с ледоколом или без него. По конструктивному типу морские суда подразделяют на полнонаборные суда, допускающие приём грузов до осадки, соответствующей минимальному надводному борту, и суда с избыточным надводным бортом; разновидность последних – шельтердечные суда. Суда внутреннего плавания делят на 4 категории:- для малых рек, больших рек, водохранилищ и крупных озёр, морских заливов. Суда смешанного морского и внутреннего плавания сочетают прочность корпуса и мореходные качества, необходимые морским судам, с малой осадкой судов внутреннего плавания. Суда бывают самоходные (с механическим двигателем, парусные, гребные) и несамоходные (буксируемые). Самоходные суда по типу энергетической установки делят на атомные, дизельные (теплоходы), паротурбинные и газотурбинные (паро- и газотурбоходы), суда с паровой машиной (пароходы), суда с приводом гребного винта от электродвигателя – электроходы. По принципу движения на воде различают суда плавающие (водоизмещающие), глиссирующие, на подводных крыльях и на воздушной подушке. Суда, способные погружаться для работы под водой, называются подводными, все остальные – надводными. Историческая Справка:- В глубокой древности возникла необходимость преодолевать водные преграды и использовать реки, озёра, моря как охотничьи угодья и как удобные пути для передвижения и перевозки грузов. Вначале в качестве плавучих средств применялись древесные стволы и другие плавающие предметы. Первыми судами, по-видимому, можно считать примитивные плоты из скреплённых друг с другом стволов или обломков деревьев. Связанные деревья не переворачивались в воде, на них можно было плавать достаточно долго и безопасно; плоты-катамараны из брёвен до сих пор используются во многих странах. В течение тысячелетий на озёрах Титикака и Чад, а также в Древнем Египте применялись плоты из камыша и папируса. В Ассирии для преодоления водных преград пользовались надутыми мешками из шкур животных (бурдюками); такие средства продолжали использоваться и в XX веке, например, в Далмации (Югославия). К каменному веку восходит искусство постройки лодок из древесных стволов, которые выдалбливали или выжигали изнутри и обтёсывали снаружи (челны-однодеревки). В Северных странах издавна применяются лёгкие и манёвренные челноки, изготовляемые из коры, на каркасе (наиболее известны берестяные каноэ Индейцев Северной Америки) или из натянутых на каркас шкур (например, Алеутские каяки). В Междуречье в VIII веке до Нашей Эры были известны круглые лодки (корзины, обтянутые кожей или покрытые снаружи смолой); грузоподъёмность таких судов достигала 100 тонн (т). В Восточной Бенгалии делали круглые лодки – тигары из обожжённой глины. Развивающееся судоходство требовало увеличения размеров судов. На челны-однодеревки прилаживали по бокам один или несколько рядов досок, которые защищали от волн и увеличивали вместимость; так строились на территории Восточной Европы так называемые Набойные Лодьи (IV век), насады (XI век), казацкие чайки (XVI век), Астраханские бударки (XIX век). Однако только конструирование судов из 113 деревянных частей с отдельным каркасом (так называемом Набором) и обшивкой позволило значительно увеличить их размеры; при этом стало возможным изменять форму корпуса и соотношения главных размерений судов, улучшая их мореходность. В Древнем Египте в 3-м тысячелетии до Нашей Эры строили суда из пригнанных, проконопаченных и просмолённых по швам кусков дерева, образующих обшивку и набор. Суда Финикийцев уже в X веке до Нашей Эры имели основные элементы конструкции современных судов (киль, шпангоуты, штевни, наружную обшивку); деревянные внутренние крепления сделали ненужными обычные для Египетских судов натяжные сооружения из канатов и балок, укрепляемые над палубой и вдоль бортов. Обшивка судов выполнялась из досок, сначала тёсаных, а затем пилёных. Отдельные части обшивки и деревянного набора скреплялись деревянными гвоздями, шипами, а впоследствии – медными и железными скобами и гвоздями. Первые плавучие средства передвигались по течению или с помощью простейших судовых движителей – шестов и вёсел. Паруса были известны с 3-го тысячелетия до Нашей Эры, они изготовлялись из шкур, тростниковых циновок, деревянных планок. Долгое время паруса выполняли вспомогательную роль, их ставили только при попутном ветре, а при безветрии суда двигались и маневрировали с помощью вёсел. Вёсла на гребных судах располагали по всей длине судов в 1, 2 и 3 яруса (например, Римские униремы, биремы, триремы), каждое весло обслуживало до 10 гребцов. В VII веке появились универсальные гребные суда – галеры, а в XVI веке более крупные галеасы, на которых уже значительную роль играли паруса. Узкие и манёвренные гребные суда использовались ещё в XVIII веке, главным образом в качестве военных кораблей (смотрите Военно-Морской Флот, Гребной Флот). На широких и вместительных грузовых судах более эффективным движителем был парус. Чисто парусные суда появились в X–XIII веках в Средиземноморье, Скандинавии, Китае. С развитием техники управления парусами и лавирования суда получили возможность двигаться и против ветра, меняя галсы. Для управления гребными и парусными судами использовали широкие рулевые вёсла (с одного или обоих бортов) или одно рулевое весло в кормовой части, где впоследствии был установлен руль. С XII–XIII веков в Западной Европе строились пригодные для океанских плаваний нефы, каравеллы и другие парусные суда. Наивысшего развития парусные суда достигли во 2-й половине XIX века; длина их составляла 90 метров (м), ширина 15–17 м, грузоподъёмность 5 000 т, скорость 33 км/ч и более (смотрите также Парусный Флот). Для предохранения деревянной подводной части судна от разрушения Финикийцы обшивали её металлом (свинцовыми пластинами), с начала XVIII века нижнюю часть корпуса покрывали тонкими медными листами. Предложения применять в судостроении железо вместо дерева относятся к середине XVII века, но только 09 Июля 1787 Англичанин Дьжон ‘Чокнутый на Метале’ Вилкинсэн (John ‘Iron-Mad’ Wilkinson; 1728–1808) построил первое железное судно (iron boats) Зэ Тчрайэл (The Trial) – речную баржу длиной 21.5 м и толщиной железа 8 миллиметров (мм). Со 2-й половины XIX века железо как судостроительный материал начало уступать место более прочной стали. Изготовление корпусов судов целиком из металла позволило увеличить их прочность и уменьшило относительную массу (по отношению к водоизмещению). Корпуса

крупных стальных судов стали разделять на водонепроницаемые отсеки, устраивать двойное дно, что повысило их безопасность. Переход от клёпки к сварке ещё более повысил прочность, надёжность и долговечность судов. В XVIII веке делались попытки использовать для движения судов энергию пара. Первый речной деревянный пароход Клэмэнт (Clermont) с паровой машиной в качестве главного судового двигателя и гребными колёсами по бортам был построен в 1807 в США инженером и изобретателем Робэтом Фултчэном (Robert Fulton; 1765–1815) и адвокатом, политиком и дипломатом Робэтом Робэтом Ливиньгстэном (Robert Robert Livingston; 1746–1813). В России в 1815 регулярные рейсы между Кронштадтом и Петербургом стало совершать деревянное паровое судно Елизавета. Колёсный 20-метровый пароход из железа Вулкан (The Vulcan) был спущен со стапелей в 1818 в Великобритании. В 1-й половине XIX века на морских пароходах стали устанавливать гребные винты, которые на волнении оказались значительно эффективнее гребных колёс. На рубеже XIX и XX веков в качестве судовых двигателей начали использовать паровые турбины (02 Августа 1894 в Великобритании был построен турбоход Турбиния (Turbinia)) и двигатели внутреннего сгорания (в 1903 в России был спущен на воду дизель-электроход Вандал). К середине XX века появились суда с энергетическими установками, работающими на ядерном топливе (смотрите Атомный Флот, Атомный Ледокол Ленин). Устройство И Типы Судов:- Важнейшая характеристика судна – его эксплуатационные качества, которые численно выражают эксплуатационно-технические характеристики, или тактико-технические данные:- скорость, район и дальность плавания, автономность, энерговооружённость, уровень автоматизации производственных процессов, надёжность, ремонтопригодность, обитаемость и другие, а для транспортных – также грузоподъёмность, грузо- и пассажировместимость, регистровая вместимость и приспособленность к грузовым операциям (для грузовых судов). Специфические свойства судов как плавучих сооружений – так называемые мореходные качества (плавучесть, остойчивость, качка, ходкость, управляемость, непотопляемость). Учёт этих свойств при создании судна связан с выполнением комплекса научно-исследовательского и конструкторских работ (обоснование технико-эксплуатационных требований, проектирование, модельные испытания). При создании судна используются:- теория проектирования судна, теория корабля, строительная механика корабля, теория судовых механизмов и машин, технология постройки, экономика судостроительного производства, а также действующие правила постройки, определяемые классификационными обществами, и так далее. Обоснование и создание нового судна длится несколько лет. Важнейшие технико-эксплуатационные характеристики судна определяются основными элементами:- главными размерениями (длиной, шириной, высотой борта на середине длины судна и так далее), дедвейтом, водоизмещением, типом и мощностью главных двигателей, вместимостью. Самоходное судно состоит из корпуса с надстройками и рубками, судовых устройств и систем, энергетической установки с движителями, навигационного оборудования, средств связи. Корпус судна разделяется палубами, поперечными и продольными переборками на отсеки, в которых располагают энергетические установки, трюмы, твиндеки и так далее. На морских судах междудонное пространство в корпусе используется для хранения топлива и пресной воды, а также водяного балласта. Корпуса судов изготовляются из стали, лёгких сплавов, дерева, железобетона, пластмасс и других конструкционных материалов. Надстройки и рубки размещаются на верхней палубе и содержат каюты для экипажа и пассажиров, общественные, хозяйственные и служебные помещения. В рубках (рулевой, штурманской и радиорубке) устанавливаются навигационное оборудование и судовые средства связи, сигнализации и управления, обеспечивающие безопасное плавание судна, определение его местоположения, связь с берегом и так далее. Внешняя форма и принципиальная компоновка определяют архитектурно-конструктивный тип судна, в частности его характеризуют:- форма носовых и кормовых обводов (смотрите Корма, Нос), размеры и расположение судовых надстроек и рубок, продольная погибь верхней палубы (седловатость), место расположения энергетической установки, число палуб и трюмов, число и размеры грузовых люков, бортовых, носовых и кормовых портов. Судовые устройства и судовые системы обеспечивают безопасную эксплуатацию судна и сохранность перевозимых грузов, комфортабельные условия для экипажа и пассажиров. Энергетическая установка состоит из главных и вспомогательных механизмов и аппаратов и предназначена для обеспечения движения судна, снабжения электроэнергией, паром, водой, сжатым воздухом судовых механизмов, устройств и систем, а также средств управления. Наибольшее распространение получили дизельные энергетические установки. Автоматизированные энергетические установки работают без постоянной вахты в машинном отделении; управление и контроль за работой ведётся дистанционно, в том числе из рулевой рубки. Основной тип применяемых на судне движителей – гребные винты. Развитие судов идёт по пути их универсализации и специализации, причём специализация, например, транспортного судна, обусловливается не только видом перевозимого груза, но и технологией его перегрузки. Например, сухогрузные суда в целях сокращения времени и ликвидации ручного труда при погрузке и выгрузке, удобной укладки грузов строятся с большим раскрытием трюмов, с грузовыми устройствами или без них; судно универсального назначения – с 1–3 грузовыми люками по ширине судна, с кранами грузоподъёмностью около 25–30 т. Широкое развитие получили суда для перевозки пакетов или контейнеров с унифицированными размерами – контейнеровозы, трейлерные суда и другие. Принципиально новый вид транспортных судов – лихтеровозы, перевозящие лихтеры (плавучие контейнеры с одним трюмом грузоподъёмностью до 1 000 т). Лихтеровозы бывают одно и трёхпалубные, двухкорпусные; снабжаются мощными грузоподъёмниками. Самые крупные из сухогрузных судов – суда для перевозки навалочных и насыпных грузов. Среди них универсальные навалочники и узкоспециализированные рудовозы, цементовозы, углевозы. Жидкие грузы наливом (нефть, жидкое топливо, смазочные масла, сжиженные газы и тому подобное) перевозят в танкерах, наибольшие из которых по размерам превосходят все другие суда. Получают применение составные суда для транспортировки навалочных грузов, леса, нефти и другого в прибрежном и океанском плавании. Грузоподъёмность составных судов 5 000–50 000 т, скорость до 30 км/ч, мощность главных двигателей достигает 10 МегаВатт (МВт). Составное судно включает грузовую и энергетическую секции с жёстким или гибким счальным устройством. Грузовая секция – несамоходная баржа с якорным, швартовным, а иногда и грузовым устройством, балластно-осушительной системой; управление устройствами и системами – дистанционное (с энергетическими секциями). Современные пассажирские суда, игравшие до середины XX века большую роль в перевозке пассажиров на дальние расстояния (например, из Западной Европы в Австралию), использовались главным образом для многодневных туристических рейсов (круизов), кратковременных прогулок и местного сообщения. Туристические суда – комфортабельные и, как правило, крупные суда, рассчитанные на несколько сотен пассажиров. Суда местного сообщения отличаются быстроходностью, многие из них – суда на подводных крыльях и суда на воздушной подушке. Повышение провозоспособности судов достигается в первую очередь увеличением их грузоподъёмности и скорости, обусловливаемым интенсификацией обработки судов в портах, снижением удельных эксплуатационных расходов и прочим. Наиболее быстро растёт грузоподъёмность судов для перевозки массовых грузов (нефти, сжиженных газов, руды, удобрений и других), увеличение размеров танкеров и навалочных судов ограничивается глубинами в портах, каналах и проливах. Снижение энергозатрат обеспечивается совершенствованием обводов, движительно-рулевого комплекса и энергетической установки. Весьма интенсивный рост производительности грузовых операций обусловлен значительным повышением грузоподъёмности и скорости контейнеровозов, лихтеровозов и судов с горизонтальным способом грузовых операций. К 1970-ым для водоизмещающих судов почти достигнут рациональный предел скорости. Наибольшие перспективы роста скорости (до 100–200 километров в час (км/ч)) у судов на подводных крыльях и воздушной подушке. Посадка Судна – равновесное положение корабля на воде

при определённых, соответствующих этому положению, осадке, крене и дифференте. В эксплуатационных условиях посадка определяется по маркам углублений на судне – горизонтальным линиям, наносимым через 10 см на наружной обшивке с обоих бортов судна в районе форштевня, ахтерштевня, а на больших судах и на миделе, с числом против каждой, обозначающим углубление судна – отстояние от ватерлинии до нижней кромки горизонтального киля.

VESSEL BUNKERING = БУНКЕРОВКА СУДНА – Vessel Bunkering:- includes sales for the fueling of commercial or private boats, inclusive to oil company vessels but excluding military vessels. Vessel Bunkering includes sales for the fueling of commercial or private boats, such as pleasure craft, fishing boats, tugboats, and ocean-going vessels, including vessels operated by oil companies. Excluded are volumes sold to the US Armed Forces.

VESSEL CATCH LIMIT = ЛИМИТ ХОДА СУДНА – The Vessel Catch Limit is a limit on the quantity each individual vessel can land per trip or short period of time, e.g., day, week. / или короткий период времени, например, за сутки, за неделю.

VESSEL INSURANCE ADDITIONAL PREMIUM = ДОПОЛНИТЕЛЬНАЯ ПРЕМИЯ ЗА СТРАХОВАНИЕ СУДНА – Vessel Insurance Additional Premium (VIAP) is a charge levied when moving cargo in close proximity of war zones. / Сбор, взимаемый в тех случаях, когда перевозимый груз проходит в непосредственной близости с зонами военных конфликтов.

VESSEL–KILOMETER = СУДНО–КИЛОМЕТР – Vessel-Kilometer (for inland waterways transport) is the unit of measurement representing the movement of an inland waterways transport (IWT) vessel over one kilometer. Context:- the distance taken into account is the distance actually run. Movements of unladen vessels are included. In a convoy, each unit is counted as a vessel.

VESSEL LIST = КРЕН СУДНА – Vessel List is the amount in degrees that a vessel tilts from the vertical, along the longitudinal axis. The angle of list is the degree to which a vessel heels (leans or tilts) to either port or starboard. A listing vessel is stable and at equilibrium, but the distribution of weight aboard (often caused by uneven loading or flooding) causes it to heel to one side. By contrast roll is the dynamic movement from side to side caused by waves. If a listing ship goes beyond the point where a righting moment will keep it afloat, it will capsize and potentially sink. / Под Креном понимается отклонение вертикальной плоскости симметрии судна, летательного аппарата от вертикали к земной поверхности. Креном летательного аппарата называется также движение, при котором происходит изменение угла крена. Движение креном характеризуется скоростью крена и используется, например, при выполнении фигур пилотажа, при заходе на посадку для парирования смещения траектории летательного аппарата относительно оси взлётнопосадочной полосы (ВПП). Под Креном, от Голландского слова Krengen, означающее Класть Судно На Бок, понимается поворот судна или летательного аппарата относительно продольной оси. Под Тангажем, от Французского слова Tangage, понимается угловое движение судна или летательного аппарата, например, самолёта, относительно главной поперечной (горизонтальной) оси инерции. Угол тангажа – угол между продольной осью летательного аппарата и горизонтальной плоскостью. Под Креном, от Французского слова Caréne, означающее Киль или Подводная Часть Корабля, или от Голландского Kren-gen, означающее Класть Судно На Бок, понимается положение летательного аппарата или судна, при котором плоскость его симметрии отклонена от вертикали к земной поверхности. Крен возникает при разворотах и других манёврах летательного аппарата. У судна постоянный (статический) крен возникает при несимметричной (относительно продольной вертикальной плоскости) загрузке, приёме балласта на один борт или отрицательной начальной метацентрической высоте; переменный (динамический) крен – при воздействии переменных поперечных сил, например, от волн во время бортовой качки судна, шквала, косого рывка буксирного троса. Угол крена летательного аппарата определяется авиагоризонтом, судна – кренометром.

VESSEL LOAD FREE OUT = ЗАГРУЗКА СУДНА СВОБОДНО ОТ РАСХОДОВ ПО ВЫГРУЗКЕ (или ХХ) – Vessel Load Free Out (VLFO):- the loading and discharge terms for the cargo to be shipped, as agreed to in the chartger party. The vessel (carrier) pays for the loading of the cargo on board the ship and the receiver pays for the discharge of the cargo from the ship to the pier.

VESSEL MANIFEST = МАНИФЕСТ СУДНА (или СУДОВОЙ МАНИФЕСТ) – Vessel Manifest:- the international carrier is obligated to make declarations of the ship's crew and contents at both the port of departure and arrival. The vessel manifest lists various details about each shipment by the bill of lading (B/L) number. Obviously, the B/L serves as the core source from which the manifest is created. Vessel Manifest:- declarations made by international ocean carriers relating to the ship's crew and contents at both the port of departure and arrival. All bills of lading are registered on the manifest. / Судовой Манифест или Судовая Декларация:- декларация судового груза.

VESSEL REPAIR ENTRY = ЗАХОД СУДНА ДЛЯ РЕМОНТА – The law known as the Foreign Vessel Repair Statute provides that when any repairs in a foreign country are made on a vessel documented under the laws of the United States, an ad valorem duty of 50% is imposed on the cost of repair, including labor and labor costs, when the vessel arrives in the United States. All equipment, parts, or materials purchased, and repairs made, outside the United States must be declared on Customs Form 226 (CF-226) and filed at the port of first arrival within 5 working days. / В законодательстве известен как Статут о Ремонте Судна За Рубежом (Foreign Vessel Repair Statute), который обеспечивает возможность любых ремонтных работ в зарубежной стране, которые должны быть задокументированы в судовых бумагах в соответствии с законодательством Соединённых Штатов Америки. По прибытии судна с Соединённые Штаты Америки с него будет взыскана пошлина ад валёрэм или ценностная пошлина в размере 50% от суммы расходов на ремонтные работы, включая саму работу и понесённые в связи с ней расходы. Всё закупленное за пределами Соединённых Штатов оборудование, части или материалы должны быть задекларированы в Таможенной Форме 266 (ТФ-226) и зарегистрированы в течение 5 рабочих дней в первом же порту прибытия.

VESSELS COMMERCIAL = СУДА ТОРГОВЫЕ (или СУДА КОММЕРЧЕСКИЕ) – Vessels Commercial is the total number of commercial vessels (defined as tows, cargo, fishing, dredging, crew, non-cargo, passenger/ferry, other, and lightboats) which have passed through a lock chamber.

VESSEL SHARING AGREEMENT = СОГЛАШЕНИЕ О ДОЛЕ УЧАСТИЯ В ИСПОЛЬЗОВАНИИ СУДНА – Vessel Sharing Agreement is a term agreement between two or more carriers in which a number of container positions ('slots') equal in space are reserved on particular vessels for each of the participants. The number of slots (space) on different vessels on the same route can vary by vessel type and direction but may also be expressed as each party's capacity use of the vessels employed jointly. Vessel Sharing Agreement (VSA) is a co-operation agreement between two or more carriers, whereby liner services are provided jointly with each party contributing tonnage to the service and sharing the resulting total capacity in proportion to the tonnage provided. Vessel Sharing Agreement is an agreement between two or more ocean carriers in which a number of container slots are reserved on particular vessels for each of the participants (right to book slots and obligation of the other carrier to carry the containers). Used to create operational efficiencies across carriers, namely a higher level of slot usage, with more port calls and higher frequency of service. / Срочное соглашение между двумя или более перевозчиками, в котором количество контейнерных мест ('желобов/слотов'), равное пространству, зарезервировано за конкретными судами для каждого из участников. Количество желобов (пространства) на различных судах, обслуживающих один и тот же маршрут, может быть разным в зависимости от типа судна

и направления, но может быть выражено также в качестве использования соответствующей вместимости конкретной стороной в случае, если данные судна эксплуатируются совместно.

VESSELS OTHER = СУДА ПРОЧИЕ (или СУДА ИНЫЕ) – Vessels Other is the total number of non-commercial vessels which have passed through a lock chamber. Vessels counted in this column include Government vessels and Government-Nonfederal vessels.

VESSELS RECREATIONAL = СУДА ПРОГУЛОЧНЫЕ – Vessels Recreational is the total number of recreational vessels which have passed through a lock chamber. Recreational Vessel means:- (i) a vessel being manufactured or operated primarily for pleasure; or (ii) a vessel leased, rented, or chartered to another for the latter's pleasure.

VESSELS TOTAL = ИТОГО СУДОВ – Vessels Total is the total number of vessels which have passed through a lock chamber. Total vessels is the sum of all vessels as defined in:- tows, passenger boats/ferries, recreational vessels, cargo carrying vessels, US Government vessels, US Government contractor, commercial fishing boats, dredging vessels, crewboats, non-cargo vessels, Government-nonfederal vessels, other, and light (towboat w/o barges). Barges are counted separately.

VESSEL SUPPLIES FOR IMMEDIATE EXPORTATION = СУДОВЫЕ ПРЕДЛОЖЕНИЯ ДЛЯ НЕМЕДЛЕННОГО ВЫВОЗА (или ХХ) – Vessel Supplies for Immediate Exportation (VSIE):- allows equipment and supplies arriving at one port to be loaded on a vessel, aircraft, etc, for its exclusive use and to be exported from the same port.

VESSEL TON = СУДОВАЯ ТОННА – Vessel Ton is a unit of interior capacity of ships equal to 100 cubic feet or 2.831 685 cubic meters. Also known as Register Ton. / Судовая Тонна – единица внутренней вместимости или объёма внутренних помещений судна, равная 2.831 685 кубическим метрам или 100 кубическим футам. Известна также как Регистровая Тонна (Register Ton).

VESSEL TRAFFIC MANAGEMENT SYSTEM = СИСТЕМА УПРАВЛЕНИЯ ДВИЖЕНИЕМ СУДОВ (или ХХ) – Vessel Traffic Management System:- vessel control and management system (VTMS) usually under the authority of the harbormaster, comprising equipment (such as radars, tracking software, and radio communications), personnel (traffic operators), and regulations. Most larger maritime ports have relatively advanced vessel traffic management systems for maritime safety, protection of the environment, and coordination of marine services.

VESSEL VOYAGE AND DIRECTION = РЕЙС И НАПРАВЛЕНИЕ СУДНА – Vessel Voyage And Direction (VVD), this is used to describe the movement of the container. Example:- The SS St. Louis, sailing from Elizabeth to Rotterdam on her 13th trip, would be listed as SL 13E. / Под Рейсом, от Немецкого слова Reise, означающее Путешествие, понимается маршрут корабля, самолёта, автобуса и тому подобного в один конец.

VEST = МАЙКА (или НАТЕЛЬНАЯ РУБАШКА, или ЖИЛЕТКА, или КАМЗОЛ) – Vest is a man's sleeveless garment for the upper body usually worn under a suit coat; also, a similar garment for women; a protective usually sleeveless garment, as a life preserver, that extends to the waist; an insulated sleeveless waist-length garment often worn under or in place of a coat; (chiefly British) a sleeveless undershirt. In the US, a term Vest often denotes a waist coat. / Майка:- (1) трикотажная, обычно нижняя, рубашка без рукавов и воротника (первоначально спортивная). (2) То же, что футболка. Жилетка – то же, что жилет, то есть мужская одежда без воротника и рукавов, поверх которой надевается пиджак, сюртук, фрак, а также женская одежда такого фасона. Камзол:- старинная мужская верхняя одежда, обычно без рукавов. Под Жилетом, от Французского слова Gilet, понимается мужская или женская верхняя одежда без рукавов. В классическом варианте надевают под пиджак. Составная часть классического костюма – 'тройки'. При комбинировании разных слоёв одежды не обойтись без жилета. Как, впрочем, и в любом другом случае – на деловой презентации, на лекции в университете, на пикнике за городом, на вечеринке в дискотеке, и даже в театре. Жилет хорош сегодня везде за счёт своей универсальности. Сохранившийся во многих коллекциях классический жилет, ведущий свою историю от мужского костюма-тройки, по-прежнему особенно хорош в деловой одежде. Сегодняшнее стремление в офисной одежде к мужскому стилю (не к унисексу, а именно к весьма женственному варианту типично мужских костюмов в стиле YSL) с увлечением блузами рубашечного стиля и мужскими галстуками естественным образом воскресило и жилетки. Жилет-Корсаж (так называемый Мида (Mieder)) не стыдно надеть даже на светский приём в сочетании с бриллиантами и прочими друзьями девушек. Обычно такой жилет шьют из чёрного атласа или бархата, надевают поверх лёгкой широкой блузы, а спереди украшают 5–6 парами металлических крючков, которые сочетаются ещё и с металлическими цепочками в качестве декоративных застёжек. Актуальная тенденция Осенних и Весенних безрукавок – так называемые 'Рабочие Жилеты'. В модных безрукавках без труда можно увидеть отголоски рабочей формы Американских лесорубов или военной формы. Это очень функциональные жилеты в стиле 'сафари' или 'милитари', которые, конечно, вряд ли подойдут для гламурной вечеринки, однако прекрасно впишутся в любые другие обстоятельства – от загородного отдыха до работы в офисе. Жилеты из меха (с меховой опушкой, меховой подкладкой или просто мехом наружу) сильно напоминают некогда популярные в нашей стране тёплые практичные безрукавки, которыми с десяток лет назад была завешаны все стелажи даже в захудалых сельмагах. Сегодня жилеты из меха особенно популярны. Наверняка у каждой знаменитости найдётся в шкафу пара-тройка жилетов разных стилей. В повседневной жизни дивы большого экрана предпочитают носить классические жилеты, сочетая их с различными вещами, чаще всего не классическими. Также среди звезд очень популярны дутые жилетки, которые они одевают, когда катаются на лыжах и коньках, на прогулку при холодной погоде. Выбирая себе актуальный жилет, надо помнить несколько простых правил. Во-первых, сегодня жилеты используются совершенно в разных вариантах – и как составная часть классического костюма, и как утеплённый вариант верхней одежды, и как альтернатива свитеру. Во-вторых, они могут быть в любом стиле – от гламурного до 'милитари'. В-третьих, они могут быть из любого материала, который хорошо держит форму. А всё остальное зависит только от вашей собственной фантазии.

VEST = СРОК ДЛЯ ИСПОЛНЕНИЯ (или ПЕРИОД ПРАВА ИСПОЛЬЗОВАНИЯ) – Vest:- become applicable or exercisable. A term mainly used on the context of employee stock ownership or option programs. Employees might be given equity in a firm but they must stay with the firm for a number of years before they are entitled to the full equity. This is a vesting provision. It provides incentive for the employee to perform. Vest:- the time when all or a portion of the stock options granted are available to the optionee for exercise. / Срок, в течение которого держателю опционов на акции предоставляется возможность исполнить их целиком или частично.

VESTAL VIRGIN = ВЕСТАЛКА (или ВЕСТАЛЬСКАЯ ДЕВА) – Vestal Virgin:- the institutional favorites were variously dubbed 'the vestal virgins', 'the 70 sacred cows', 'the 50 religion stocks', or simply, 'the anointed'. In the jargon of money managers, they were 'one-decision stocks' – meaning they need never be sold:- The only decision was at what price to buy. Inevitably, the concept was for a long time self-validating, since the tremendous buying power flowing into these stocks pushed prices upward. Vestal Virgin:- by 1968, the 'go-go era' of illusory returns faded, replaced by the 'Nifty Fifty' (Nifty 50) era of buying and holding large growth stocks (often known as the 'Vestal Virgins'). That era was based on a diferent kind of foolishness:- the price of a stock was more important than its intrinsic value; and if the price were high, a firm's earnings growth would eventually justify it. The craziness of 1965–1973 ended not with a whimper but with a bang. In the Great Bear Market of 1973–74, the S&P 500 was down –50% from high to low. Ivest fell –65%, the hot Fidelity twins also tumbled – Trend Fund –62% and Capital Fund –64% – and Enterprise Fund declined 60%. Vestal Virgin:- in

Roman religion, any of the six priestesses, representing the daughters of the royal house, who tended the state cult of Vesta, the goddess of the hearth. Chosen between the ages of six and ten by the Pontifex Maximus ('Chief Priest'), they served for 30 years, during which time they had to remain virgins. Afterward they could marry, but few did, as it was considered unlucky. Those chosen as Vestal Virgins had to be of the required age, be freeborn of freeborn and respectable parents (though later the daughters of freedmen were eligible), have both parents alive, and be free from physical and mental defects. The Vestal Virgins' duties included tending the perpetual fire in the Temple of Vesta, keeping their vow of chastity, fetching water from a sacred spring (Vesta would have no water from the city water-supply system), preparing ritual food, caring for objects in the temple's inner sanctuary, and officiating at the public worship of Vesta (the Vestalia, June 07–15). Failure to attend to their duties was punished by a beating; violation of the vow of chastity, by burial alive. The Vestal Virgins enjoyed many honours and privileges, including emancipation from their fathers' rule. The Vestal Virgins were venerated priestesses of Vesta (the Roman goddess of the hearth fire; full title:- Vesta publica populi Romani Quiritium) and guardians of the luck of Rome who could intervene on behalf of those in trouble. They prepared the mola salsa that was used in all state sacrifices. Originally, there were probably 2, then 4 (in Plutarch's time), and then 6 Vestal Virgins. They were proceeded by lictors, who carried the rods and ax that could be used to inflict punishments on the people, if necessary. / Веста. Непорочная Дева – жаргонный термин 1960-х и 1970-х, относящийся к любому из 50 наиболее популярных институциональных инвесторов.

VESTED = ВОЗЛОЖЕННОЕ (или ОБЕСПЕЧЕННОЕ, или НАДЕЛЁННОЕ, или БЕЗУСЛОВНОЕ) – Vested refers to having an absolute right or title, when previously the holder of the right or title only had an expectation. Example:- after 20 years of employment Larry Loyal's pension rights are now vested. Vested:- when something is vested, the recipient obtains a guaranteed right. This right typically involves the eventual receipt of a benefit, such as a vested stock option or a vested pension plan. Vesting is usually conferred through the passage of time. For example, an employee becomes vested in the corporate pension plan after working for the company for ten years. / Лари Лойэл (Larry Loyal). Наделённое:- предоставление прав абсолютной собственности, несмотря на то, что само обладание ею может быть отложено.

VESTED BENEFIT OBLIGATION = ОБЯЗАТЕЛЬСТВО ПО ОБЯЗАТЕЛЬНОМУ ПОСОБИЮ (или ОБЯЗАТЕЛЬСТВО ПО ОБЕСПЕЧЕННОМУ ПОСОБИЮ, или XX) – A Vested Benefit Obligation (VBO) is the actuarial present value of benefits that have been earned by employees. This obligation is typically associated with multi-year cliff vesting requirements for employees, so a firm whose employees have a relatively high level of seniority will have a larger vested benefit obligation than a firm with newer employees. Vested Benefit Obligation (VBO):- the actuarial present value, using current salary levels, of vested benefits only.

VESTED BENEFIT = НАДЕЛЁННОЕ ПОСОБИЕ (или БЕЗУСЛОВНАЯ ЛЬГОТА, или ПРЕДОСТАВЛЕННАЯ ЛЬГОТА, или XX) – Vested Benefit is a financial incentive of employment that an employee is fully entitled to. Employers sometimes offer their employees benefits that they acquire full ownership of gradually or suddenly, as they accumulate more time with the company. This process is called Graduated Vesting or Cliff Vesting, and its purpose is to give employees a reason to stay with the company long term. When the employee has earned full rights to the incentive after a predetermined number of years of service, those benefits are called Fully Vested. An example of a type of benefit that might vest gradually is shares of the company's stock. An employee might be awarded 100 shares of stock as a performance bonus after year one of employment. Under a graduated vesting plan, the employee might acquire full ownership of 20% of the shares after year two, 40% after year three, 60% after year four, 80% after year five and 100% after year six. The stock bonus would be a partially vested benefit in years two to five, and a fully vested benefit after year six. See also Vested Rights.

VESTED EMPLOYEE BENEFIT = ОБЯЗАТЕЛЬНОЕ ПОСОБИЕ (или ВЫПЛАТА) РАБОТНИКА (или ОБЕСПЕЧЕННАЯ ВЫПЛАТА РАБОТНИКУ, или НАДЕЛЁННОЕ ПОСОБИЕ РАБОТНИКУ, или ГАРАНТИРОВАННАЯ ПЕНСИЯ) – Vested Employee Benefits are the employee benefits that are not conditional on future employment by the company in question, for example, a pension plan. Employee Benefits are all forms of consideration given by an entity in exchange for service rendered by employees. Employee Benefits include:- (a) short-term employee benefits, such as wages, salaries and social security contributions, paid annual leave and paid sick leave, profit-sharing and bonuses (if payable within twelve months of the end of the period) and non-monetary benefits (such as medical care, housing, cars and free or subsidized goods or services) for current employees; (b) post-employment benefits such as pensions, other retirement benefits, post-employment life insurance and post-employment medical care; (c) other long-term employee benefits, including long-service leave or sabbatical leave, jubilee or other long-service benefits, long-term disability benefits and, if they are not payable wholly within twelve months after the end of the period, profit-sharing, bonuses and deferred compensation; and (d) termination benefits. Vested Employee Benefits are employee benefits that are not conditional on future employment. / Обеспеченные Преимущества Работника или Обеспеченные Пенсии:- пенсии, право на получение которых не зависит от дальнейшей работы сотрудников.

VESTED INTEREST = ОБЕСПЕЧЕННЫЙ ИНТЕРЕС (или ШКУРНЫЙ ИНТЕРЕС, или СЛОЖИВШИЙСЯ ИНТЕРЕС, или НАДЕЛЁННЫЙ ИНТЕРЕС, или ЗАКРЕПЛЁННЫЙ ЗАКОНОМ ИНТЕРЕС) – Vested Interest:- (1) the lawful right of an individual or entity to gain access to tangible or intangible property now or in the future. A vested interest is an entitled benefit, which can be conveyed to a separate party. There is usually a vesting period before the claimant can gain access to the asset or property. Due to the right of ownership, the benefit can not be taken away, i.e. the vested funds are not contingent on any action or inaction. This can most notably be seen in employee pension plans. Contributions are made under the stipulation that retirement funds will be entitled to the participant, known as a Vested Right. The vesting period (period of time before access is granted) varies among pension plans. The withdrawal amounts can be restricted to a certain percent each year. For example, after waiting the five year vesting period, Peter was only allowed to withdraw 20% of his retirement fund each year. (2) A financial or personal stake one entity has in an action, separate entity or commitment, with the expectation of realized benefits in the present or the future. In this case, the outcome will affect the entity, thus creating a vested interest. For example, if you have a mortgage, your bank has a vested interest in your ability to make your periodic payments. Vested Interest:- a personal or private reason for wanting something to be done or to happen. Vested Interest is:- (i) an interest (as a title to an estate) carrying a legal right of present or future enjoyment; specifically:- a right vested in an employee under a pension plan; (ii) a special concern or stake in maintaining or influencing a condition, arrangement, or action especially for selfish ends; and (iii) one having a vested interest in something; specifically:- a group enjoying benefits from an existing economic or political privilege. Example:- she has a vested interest in seeing the business sold, as she'll make a profit from the sale. Vested Interest is an interest now in being, as opposed to interst anticipated. It is a term frequently used with regard to the title of goods or land. Property is said to vest when the absolute owner is finally established and that owner's interest is in no way capable of being terminated by anyone but that owner. Vested Interest is:- (1) a special interest in an existing system, arrangement, or institution for particular personal reasons; (2) a permanent right given to an employee under a pension plan; (3) vested interests, the persons, groups, etc, who benefit the most from existing business or financial systems. Examples:- (1) among other things, Egypt has a vested interest in not being sucked back into control of, and responsibility for, Gaza; (2) I am skeptical, as I have a vested interest, having dated a foreigner for many years. / Закреплённые Законом Имущественные Права, Участие:- (1) в праве – имущественные права, которые закреплены и определены, в отличие от прав, зависящих от наступления какого-либо события, которое может

и не произойти. Например, дарение чего-либо лицу А в пожизненное владение, а затем переход этого чего-либо к лицу Б означает, что права лица А являются закреплёнными в порядке непосредственного пользования (vested in possession), поскольку в данный момент он владеет имуществом. Дарение лицу Б также закреплено (однако не в порядке непосредственного пользования), так как лицо А обязательно когда-либо умрёт, и тогда лицо Б (или его наследник, если лицо Б к тому времени тоже умрёт) унаследует имущество. Дарение лицу В с условием, что оно достигнет возраста 30 лет, не является закреплённым, так как лицо В может умереть, не достигнув указанного возраста. Имущественные права или участие, не закреплённые законом, называются Условным Имущественным Правом (Contingent Interest). (2) Участие в каком-либо бизнесе, программе, операции и так далее, как правило, с надеждой получить личный доход. Закреплённое Законом Сложившееся Право:- по закону – право на что-то, что точно должно случиться, в противоположность зависимости от события, которое может и не произойти. В обычной практике – заинтересованность, имеющая элемент личного дохода. Смотрите также (Vesting). (1) Закреплённый Интерес или Закреплённые Имущественные Права:- немедленное закрепление имущественных прав на недвижимую или индивидуальную собственность, несмотря на то, что право владения и пользования может быть отложено до какой-либо даты в будущем или до свершения какого-то события. (2) Закреплённый Интерес:- при банкротстве или управлении предприятием государственным уполномоченным по решению суда; реорганизуемый согласно Акту О Банкротстве; ценные бумаги, принятые подобными компаниями (в газетных публикациях котировок облигаций и акций).

VESTED REMAINDER = НАДЕЛЁННЫЙ ОСТАТОК (или НАДЕЛЁННАЯ СОБСТВЕННОСТЬ, или ХХ) – Vested Remainder is a remainder is vested if it is given to an ascertained person, and it is not subject to a condition precedent. Of course there are three kinds of Vested Remainders:- (i) Indefeasibly Vested:- here, the remainder can not be taken away (To A for life, then to B and B's heirs). (ii) Vested, Subject to Open:- also known as Vested, subject to partial divestment:- Here at least one member of a class is known, but others could be added to that class. (To A's children and their heirs, A has one child, B. We already know that B will take a partial share, but if A has other children, B would share with those children). (iii) Vested, Subject to Divestment:- here, at least one person is known, but something could come in an divest (or take away) their taking of the property. (To A for life, then to B and her heirs, but if B does not survive A, then to C and his heirs). Note, here is where things get tricky. Note:- the only difference between a vested remainder subject to open and a contingent remainder is in the phrasing of the words. Compare:- (i) vested remainder subject to divestment:- to A for life, then to B and her heirs, but if B does not survive A, then to C and his heirs; and (ii) contingent remainder:- to A for life, then to B and her heirs if B survives A; and if B does not survive A, to C and his heirs. Vested Remainder is a remainder in the favor of an ascertained person who has a present interest and is entitled to take possession upon the termination of the prior estate. Vested Remainder:- the absolute right to receive title after a presently-existing interest in real property terminates. A 'Vested Remainder' is created by deed or by a decree of distribution of an estate given by will. Example:- 'Title to the Hard Luck Ranch to my son, Sean, subject to a life estate to my brother, Douglas'. Sean has a 'Vested Remainder' which is an absolute right Sean could sell to another person at this time, with occupancy delayed until title would pass to him. See also Vest, and Vested. Vested Remainder:- the estate that is granted to a person to be enjoyed by them at a future time when a certain event occurs. / Хад Лак Рэнч (Hard Luck Ranch) Шон (Sean), Даглэс (Douglas). Закреплённые Последующие Имущественные Права (Vested Remainder):- закреплённые имущественные права на недвижимость с отложенным правом владения и пользованием до истечения права предыдущего владельца. Следует отличать от Условных Последующих Имущественных Прав (Contingent Remainder).

VESTED RIGHTS = НАДЕЛЁННЫЕ ПРАВА (или ВОЗЛОЖЕННЫЕ ПРАВА) – Vested Rights:- deferred pensions for deferred pensioners, benefits accrued to active members and benefits of passive members. Context:- identical term, Vested Benefits. Vested Right is a right that has accrued, or is secured, to its possessor and is not contingent on any event that may or may not occur. Vested Right is a right belonging completely and unconditionally to a person as a property interest which cannot be impaired or taken away (as through retroactive legislation) without the consent of the owner.

VESTEE = МАНИШКА (или ВСТАВКА, или ХХ) – Vestee is dickey, especially one made to resemble a vest and worn under a cost; vest. Vestee is a type of blouse or top worn by women under a sweater or jacket. Vestee is a decorative piece of material showing at the neckline of a woman's dress or blouse, especially one intended to seem part of another garment worn underneath, e.g., 'an old-fashioned dress with an elaborate lace vestee. Vestee is a piece of clothing, designed to be worn under a jacket, that simulates the front of a waistcoat or similar garment. Vestee is a a decorative front piece worn under a woman's jacket or blouse so as to be visible at the neckline. / Манишка:- часть одежды, пришиваемая или пристёгиваемая на грудь мужской сорочки или женского платья. Например, крахмальная или кружевная манишка.

VESTEE = НАДЕЛЯЕМОЕ ПРАВАМИ (или ХХ) – Vestee is a person having a vested interest in something.

VESTIGIAL = ОСТАТОЧНОЕ (или РУДИМЕНТАРНОЕ) – Vestigial:- reduced to a rudimentary structure. / уменьшенное до рудиментарной структуры. Рудиментарное, от Латинского слова Rudimentum, означающее Зачаток или Первооснова, .

VESTING = НАДЕЛЕНИЕ (ПРАВАМИ) (или ВЕСТИРОВАНИЕ, или ПРИНАДЛЕЖНОСТЬ, или ПРЕДОСТАВЛЕНИЕ, или ХХ) – Vesting is the process by which an employee accrues non-forfeitable rights over employer-provided stock incentives or employer contributions made to the employee's qualified retirement plan account or pension plan. Vesting gives an employee rights to employer-provided assets over time, which gives the employee an incentive to perform well and remain with the company. The vesting schedule set up by the company determines when the employee acquires full ownership of the asset. Generally, non-forfeitable rights accrue based on how long the employee has worked there. The exact requirements for vesting are specified in the plan document, which also contains any applicable regulations. For example, an employee might receive 100 restricted stock units as part of an annual bonus. To entice this valued employee to remain with the company for the next five years, the stock vests according to the following schedule:- 25 units in the second year after the bonus, 25 units in year three, 25 units in year four and 25 units in year five. If the employee leaves the company after year three, only 50 units would be vested while the other 50 are forfeited. For some benefits, vesting is immediate. Employees are always 100% vested in their salary-deferral contributions to their retirement plans as well as SEP and SIMPLE employer contributions. Employer contributions to an employee's 401(k) plan may vest immediately. Or, they may vest after several years using either a cliff vesting schedule, which gives the employee ownership of 100% of the employer's contributions after a certain number of years, or using a graded vesting schedule, which gives the employee ownership of a percentage of the employer's contribution each year. Traditional pension plans might have a five-year cliff vesting schedule or a three- to seven-year graded vesting schedule. Just because you are fully vested in your employer's contributions to your plan doesn't mean you can withdraw that money whenever you want. You are still subject to the plan's rules, which generally require you to reach retirement age before making penalty-free withdrawals. A term Vesting refers to stock or stock options which are earned by the holder over time. For example, a company employee may be given stock options that vest over a three year period. In this case, if the employee quits after one year, only one-third of the options will have been vested and the remainder would be forfeited. Vesting occurs when you acquire ownership. Does your employer offer a retirement savings plan such as a 401(k), traditional pension, or profit-sharing plan? Did you receive a stock option grant as a year-end bonus? These employee benefits and others like them are often tied to a timeline known as a Vesting Schedule.

The vesting schedule determines when you acquire full ownership of the benefit. For example, your employer grants you 10 000 stock options as a thank-you for a job well done, but it may not be time to go mansion shopping just yet. The options may not actually be yours until you're vested. If the options are subject to a vesting schedule, you don't actually own the right to exercise your options until some time in the future. Some stock option plans allow for immediate vesting, while others may delay vesting. Consider these three alternatives for a four-year vesting schedule:- (i) 25 percent each year; (ii) 50 percent in years two and four; and (iii) 100 percent in year four. In addition, there are two permissible vesting schedules for employer contributions to most 401(k) and other defined contribution plans:- (i) Cliff Vesting:- this provides no vested benefit until the third year. After three years of employment, you reach the 'edge of the cliff', or vest 100 percent. (ii) Graded Vesting:- this provides no vested benefit until year two. For each additional year that you remain with your employer, your benefits vest 20 percent each year. Under this schedule, you'll be 100 percent vested if you remain with your employer for six years. Keep in mind that if your employer follows the 100 percent in year-three vesting schedule, you'll need to stay with your employer for three years before you are vested. Of course, any personal contributions that you make to your employer's savings plan are automatically fully vested and remain yours no matter how long you stay with the employer. Defined benefit (traditional pension) plans can have a five year cliff vesting schedule, or a three to seven year graded schedule. Keep in mind that your employer's plan can provide for faster (earlier) vesting than the law requires. And in some cases, faster vesting is required by law (for example, employer contributions to a SEP (Simplified Employee Pension plan), SIMPLE IRA (Savings Incentive Match Plan for Employees Individual Retirement Account), or SIMPLE 401(k) plan must be immediately vested). To find out about your specific plan's vesting schedule, check with your manager or human resources representative, or read your summary plan description. Vesting:- nonforfeitable ownership (or partial ownership) by an employee of the retirement account balances or benefits contributed on the employees behalf by an employer. The Tax Reform Act of 1986 established minimum vesting rights for employees based on their years of service – full vesting in five years or 20% vesting per year starting by the end of the third year. / Наделение Правами (Vesting):- наделение имущественными правами работника компании. Объём прав на получение вносимых работодателем сумм увеличивается с продолжительностью срока службы в компании. Например, права на выплаты из пенсионного фонда (pension fund), на участие в плане распределения прибыли (profit-sharing plan) или в другом плане или трасте с отстроченным налогообложением (qualified plan or trust). В соответствии с Законом о Налоговой Реформе от 1986 (Tax Reform Act of 1986), работники должны иметь 100% прав уже после 5-го года работы или получать 20% каждый год, начиная с 3-го года и до 100% процентов после 7 лет.

VESTING SCHEDULE = РАСПИСАНИЕ НАДЕЛЕНИЯ ПРАВАМИ (или ГРАФИК XX) – Vesting Schedule is a schedule setting forth when, and to what extent, options become exercisable or restricted stock or stock units are no longer subject to forfeiture, for example, 20% per year over five years.

VESTMENT = ОБЛАЧЕНИЕ (или НАРЯД, или ФОРМА) – Vestment is an outer garment, especially a robe of ceremony or office; (plural) clothing, garb; an article of ceremonial attire worn by ecclesiastical officiants and assistants indicative of their rank and appropriate to the rite being celebrated. / Облачение:- одежда служителей культа во время богослужения, а также (шутливо в разговоре) вообще то, что надето на ком-нибудь. Например, архиерей в полном облачении или явился в каком-то нелепом облачении. Наряд:- то же, что одежда, то есть совокупность предметов, которыми покрывают, облекают тело; или костюм. Например, шутовской наряд. Форма:- одинаковая по покрою, цвету одежда (у военных, у служащих одного ведомства, учащихся). Например, офицерская форма или парадная форма или школьная форма.

VESTURE = ОДЕЯНИЕ (или ОБЛАЧЕНИЕ) – Vesture is a covering garment, as a robe or vestment; clothing, apparel. / Одеяние:- то же, что одежда, то есть совокупность предметов, которыми покрывают, облекают тело. Например, в богатом одеянии или кто-нибудь в смешном одеянии.

VESUVIANITE = ВЕЗУВИАН (или ВЕЗУВИАНИТ) – Vesuvianite:- also called Idocrase common silicate mineral that occurs in crystalline limestones near their contacts with igneous rocks, and in beds of marble and calcsilicate granulite that are associated with gneiss and mica schist. Fine glassy crystals colored yellow, green, or brown have been found in the Ala Valley in the Piedmont, and on Monte Somma, Italy; the Vilyuy River, Siberia; Christiansand, Norway; Litchfield, Quebec; and Auburn, Maine, Amity, New York, and Franklin, New Jersey. For chemical formula and detailed physical properties, see Silicate Mineral (table). Transparent crystals of a good green or brown color are sometimes cut as gemstones. Cut stones resemble diopside or epidote but can be distinguished optically. A compact green variety resembling jade, found at several localities in California, is known as Californite. A sky-blue variety, cyprine, contains traces of copper. / Идокраз (Idocrase). Везувиан (по местонахождению на Везувии), или Идокраз, минерал, сложный природный силикат, содержащий в структуре изолированные тетраэдры SiO_4 и сдвоенные группы Si_2O_7. Выделяют разновидности:- хромовый везувиан (до 4.3% Cr_2O_3), бериллиевый везувиан (до 9.20% BeO), цериевый везувиан (до 16.7% Ce_2O_3), борсодержащий везувиан (до 4.14% B_2O_3). Кристаллизуется в квадратной системе. Образует кристаллы призматической или дипирамидального вида и зернистые сплошные массы. Цвет светло-жёлто-зелёный, буро-зелёный, ярко-зелёный, тёмно-бурый до чёрного, зависит от состава и примесей. Твёрдость по минералогической шкале 6.5. Плотность 3 350–3 450 кг/м^3. Образуется на контактах глубинных магматических пород с известняками и доломитами. Обычные спутники – гранат, хлориты, эпидот, магнетит, кальцит и другие.

VET = VOCATIONAL EDUCATION AND TRAINING

VET = ПРОВЕРИТЬ (или XX) – Vet is a state term that means to send for review. For example:- 'We need to vet this document to the Interagency Working Group (IWG) before the final presentation'.

VETCH = ГОРОШЕК (или ВИКА, или АСТРАГАЛ) – Vetch is:- (1) any of several mostly climbing plants belonging to the Genus Vicia, of the legume family, having pinnate leaves ending in tendrils and bearing pealike flowers, especially Vicia Sativa (Spring Vetch), cultivated for forage and soil improvement; (2) any of various allied plants, as Lathyrus Sativus, of Europe, cultivated for their edible seeds and for forage; and (3) the beanlike seed or fruit of any such plant. Vetch is a widely distributed scrambling herbaceous plant of the Pea Family, which is cultivated as a silage or fodder crop. Vicia is a Genus of about 140 Species of flowering plants that are part of the legume family (Fabaceae), and which are commonly known as Vetches. Member species are native to Europe, North America, South America, Asia and Africa. Some other genera of their Subfamily Faboideae also have names containing 'Vetch', for example the vetchlings (Lathyrus) or the milk-vetches (Astragalus). The broad bean (Vicia Faba) is sometimes separated in a monotypic Genus Faba; although not often used today, it is of historical importance in plant taxonomy as the namesake of the Order Fabales, the Fabaceae and the Faboideae. The tribe Vicieae in which the vetches are placed is named after the genus' current name. Among the closest living relatives of vetches are the Lentils (Lens) and the True Peas (Pisum). Vetch is a legume used primarily as a groundcover or as a green manure crop. Vetch is any of a Genus (Vicia) of herbaceous twining leguminous plants including some grown for fodder and green manure. Compare Crown Vetch, Hairy Vetch, and Milk Vetch. Vetch is a wild plant. Some types of vetch are sometimes grown as a crop. / Горошек или Вика (на Латинском Vicia) – крупный Род Цветковых Растений Семейства Бобовые (Fabaceae). Представители Рода распространены в умеренном климате земного шара – Евразия, Северная Африка,

Чили. В природе произрастают в умеренно влажных лесах, поймах рек, на лесных опушках, заливных лугах, в кустарниках, степях. Это говорит о принадлежности растения к экологической группе – эутрофы. Некоторые Виды –, например, Боб Садовый (Vicia Faba), – известны как широко распространённые пищевые и кормовые растения, культивируемые по всему свету. Вика, Виды травянистых растений Рода Горошек (Vicia) Семейства Бобовых. Название, распространённое в растениеводстве. В культуре известно 12 Видов Вики, которые встречаются также как дикорастущие. Наиболее распространены Вика Посевная, или Яровая, и Вика Мохнатая, или Озимая. Вика Посевная (Vicia Sativa) известна в культуре со времён Древнего Рима. В бывшем Союзе Советских Социалистических Республик (СССР) возделывается в лесной и лесостепной зонах Европейской части, в Сибири и на Кавказе. Стебель длиной от 40 до 110 сантиметров (см), тонкий, ветвистый, у молодых растений прямостоячий, позднее полегает и цепляется при помощи листовых усиков. Цветки сидячие (1–3) в пазухах листьев. Венчик фиолетово-пурпурный, сиреневый или розовый. Бобы удлинённоромбические с 4–10 семенами. Масса 1 000 семян – 50–60 граммов (г). Высевается на зерно в чистом виде в ранние сроки, на зелёный корм, сено и силос в смеси с Овсом, реже с Ячменём – в несколько сроков. В нечернозёмных районах часто используют как парозанимающую культуру, в Южных районах, обеспеченных влагой, – как пожнивную. Урожай зерна до 20 центнеров с одного гектара (ц/га), зелёной массы 200–250 ц/га. В 100 килограммов (кг) зелёной массы 20.0 кормовых единиц и 3.8 кг переваримого протеина, в 100 кг сена 45.8 кормовых единиц и 12.3 кг переваримого протеина. Районировано около 40 селекционных и местных сортов. Вику Мохнатую (Vicia Villosa) в СССР возделывали в Белоруссии, на Украине, Северном Кавказе и некоторых центральных районах РСФСР. Высевают на зелёный корм в смеси с озимой Рожью или Пшеницей. Урожай зелёной массы около 200 ц/га. Иногда засоряет посевы озимых Хлебов. Горошек или Вика (Vicia), Род однолетних, двулетних или многолетних Трав Семейства Бобовых. Стебли обычно слабые, лишь редко прямостоячие. Листья, как правило, парноперистосложные и заканчиваются усиками, при помощи которых они цепляются за окружающие растения или опору. Цветки – по 1 или 2–3 в пазухах листьев или же собраны в кисти. Свыше 150 Видов, преимущественно в умеренных областях Северного полушария, особенно в странах Средиземноморья; немногие в Южной Америке и в горах тропической Восточной Африки. В бывшем Союзе Советских Социалистических Республик (СССР) более 80 Видов, больше всего на Кавказе. Почти все Горошки хорошие медоносы и ценные кормовые Травы. Культивируемые Виды больше известны под названием Вика. Как декоративное растение разводят многолетний Горошек Однопарный (Vicia Unijuga). К Роду Горошка иногда относят Вид Vicia Faba – Бобы. Астрагал (Astragalus), Род Растений Семейства Бобовых. Однолетние или многолетние Травы, полукустарники, реже кустарнички и кустарники со сложными непарноперистыми листьями. Цветки в пазушных кистях, в головчатых, колосовидных или почти зонтиковидных соцветиях. Около 2 000 Видов, преимущественно в засушливых областях Северного полушария. В СССР более 900 Видов, большей частью в Средней Азии и на Кавказе. Колючие кустарники и кустарнички из Подрода Трагакант содержат в стеблях камедь, применяемую в текстильной, бумажной и других отраслях промышленности. Многие Виды – хорошие кормовые Растения, некоторые из них введены в культуру. Настой Астрагала Шерстистоцветкового применяется в медицине при сердечно-сосудистых заболеваниях и нефрите.

VETERANS ADMINISTRATION = АДМИНИСТРАЦИЯ ВЕТЕРАНОВ (или ВЕТЕРАНСКАЯ АДМИНИСТРАЦИЯ) – The Veterans Administration was formerly an independent government agency founded in 1930. Commonly referred to as 'the VA', the organization provided patient care, veterans' benefits, and other services to veterans of the US armed forces and their families. It also provided this group with disability compensation for those who were injured or contracted a disease while serving, education and training, medical, surgical, and rehabilitative care, readjustment counseling, bereavement counseling, surviving spouse benefits, care and benefits to homeless veterans, medical research, life insurance, vocational rehabilitation, headstones/burial markers, and home loan assistance. In 1988, it became a US cabinet department called the US Department of Veterans Affairs. To be eligible for a VA-guaranteed home loan, veterans must have served on active duty in the Army, Navy, Air Force, Coast Guard or Marines. The specific service requirements vary, depending on the time during which a veteran served. A certificate of eligibility is required to obtain a VA loan, and the loan can be obtained through any mortgage lender who participates in the VA home loan program. This is one of very few 0% down payment loans available (The USDA Rural Housing Loan is another – see How to Get a No-Down-Payment Mortgage). Veterans who were dishonorably discharged, as well as the imprisoned and parolees, may not be eligible for benefits, and benefits are not available to those with outstanding felony warrants. Veterans Administration (VA) is the federal agency charged with administering benefits provided by law for veterans of the armed forces. Veterans Administration is an agency of the federal government which provides a variety of services for United States veterans. One of the main services it provides is helping veterans and their families find and purchase housing through the use of VA loans. These loans allow the veterans to receive a lower interest rate on their mortgage payments, and usually also means they won't have to provide a down payment. Other services provided by the Veterans Administration include help with health insurance, medical needs, and education. / Департамент по Делам Ветеранов США.

VETERANS ADMINISTRATION MORTGAGE = ЗАКЛАДНАЯ АДМИНИСТРАЦИИ ВЕТЕРАНОВ – Veterans Administration Mortgage is a mortgage made by a private bank to a qualifying veteran that is guaranteed by the US Department of Veterans Affairs. In order to be eligible for a VA mortgage, the veteran cannot have been dishonorably discharged and must have served a certain number of years in one of the branches of the American military (the number varies by branch). During the credit crunch, obtaining a VA mortgage became the only way one could obtain a mortgage with no down payment. Veterans Administration (VA) Mortgage is a home mortgage loan granted by a lending institution to US veterans and guaranteed by the Veterans Administration. Veterans Administration (VA) Mortgage is a mortgage with no down payment requirement, available only to ex-servicemen and women, on which the lender is insured against loss by the Veterans Administration. Subject to a proviso, VA loans are advantageous for veterans who need a no-down-payment loan. In most areas, VA loanscan be larger than the US Federal Housing Administration (FHA) loans. FHA also requires at least 1% down and the insurance premium is higher than on VAs. Conventional loans with no down payment carry interest rates .75% higher and up, depending on the borrower's credit score. The proviso is that VA borrowers may pay a higher price (rate or points) than is available on either FHAs or conventionals. They shouldn't – in the competitive wholesale market where lenders quote prices to mortgage brokers, the prices are much the same. But the retail market is something else. Some loan providers view veterans who need no-down-payment loans, and who trust the loan provider to give them the market rate, as sheep to be fleeced. To protect themselves, veterans should consult a Web site that prices all three types of loans. There aren't many sites that price VAs, but one that does it well is www.countrywide.com. It shows about the same rate and points for VA, FHA, and conventional loans. Use it to shop. The VA Web site, www.homeloans.va.gov, will tell you who is eligible, how you go about obtaining a Certificate of Eligibility, whether eligibility can be used more than once, the types of properties that can be purchased with a VA loan, the range of insurance premiums for different categories of veterans and different loan purposes, the conditions under which VA loanscan be assumed by a buyer, the types of VA home loans, and more. / Закладная Администрации Ветеранов (АВ) – ипотечный заём, гарантируемый Администрацией По Делам Ветеранов. Ипотечный заём на покупку дома, предоставленный организацией-кредитором, имеющим на это право, ветеранам вооружённых сил США или пережившим их супругам и гарантированный АВ. Гарантия сокращает риск кредитора на часть или всю стоимость обычного дома, мобильного дома или квартиры (кондоминиума). Благодаря этой федеральной гарантии банки и финансовые организации могут позволить себе предоставлять 30-летние ипотечные ссуды под гарантии

Администрации Ветеранов на выгодных условиях – то есть с относительно низким первоначальным взносом, даже в периоды нехватки средств (tight money). Процентные ставки по ипотечным займам, гарантируемым Администрацией По Делам Ветеранов, ранее устанавливавшиеся Департаментом Жилья и Городского Развития (Department of Housing and Urban Development), на ипотечные займы – Федеральной Администрацией По Жилью (Federal Housing Administration (FHA)), сейчас определяются АВ. Ипотечные займы, гарантируемые АВ, представляют собой важную часть пула ипотечных ссуд, переоформленных и продаваемых в виде ценных бумаг такими квазигосударственными организациями, как Федеральная Корпорация По Закладным Под Жилищные Ссуды или Фрэди Мэк (Federal Home Loan Mortgage Corporation) и Правительственная Национальная Ассоциация По Закладным или Дьжини Мэй (Government National Mortgage Association).

VETERINARY BIOLOGICS (BIOLOGICALS) = ВЕТЕРИНАРНЫЕ БИОЛОГИЧЕСКИЕ ПРЕПАРАТЫ (БИОПРЕПАРАТЫ) – Veterinary Biologics (Biologicals):- are vaccines, bacterins, diagnostics, etc which are used to prevent, treat, or diagnose animal diseases. These products generally work through some immunological method or process. How are veterinary biologics regulated? The US Department of Agriculture (USDA) is authorized, under the 1913 Virus-Serum-Toxin Act as amended by the 1985 Food Security Act, to ensure that all veterinary biologics produced in, or imported into, the United States are not worthless, contaminated, dangerous, or harmful. Federal law prohibits the shipment of veterinary biologics unless these are manufactured in compliance with regulations contained in Title 9 of the Code of Federal Regulations, Parts 101 to 118. Veterinary biologics for commercial use must be produced at a USDA-approved establishment, and be demonstrated to be pure, safe, potent, and efficacious. Who regulates veterinary biologics? The Veterinary Biologics Program of the USDA's Animal and Plant Health Inspection Service (APHIS) oversees the veterinary biologics industry in the United States. This Program consists of the Center for Veterinary Biologics and allied services:- (i) Center for Veterinary Biologics-Policy, Evaluation and Licensing unit establishes licensing standards; reviews all prelicense documentation; reviews test methods and labels; and issues, suspends, or revokes licenses and permits. They also perform prelicense and surveillance testing; test product associated with field problems; and develop references, reagents, and test methods. (ii) Center for Veterinary Biologics-Inspection & Compliance unit inspects production facilities, methods, and records; and investigates suspected legal violations and consumer complaints. (iii) APHIS's Investigative & Enforcement Services investigates violations of Federal law. What licenses or permits are required to manufacture and sell veterinary biologics? Domestic manufacturers of veterinary biologics, for domestic use or for export, are required to possess a valid US Veterinary Biologics Establishment License and an individual US Veterinary Biologics Product License for each product produced for sale. Foreign manufacturers of veterinary biologics may export veterinary biologics to the United States, provided that the manufacturer's legal representative (Permittee) residing in the United States possesses a valid US Veterinary Biological Product Permit to import these products for general distribution and sale. The US Department of Agriculture may also issue veterinary biologics permits for research and evaluation or for transit shipment. How do I report an adverse event that occurs after use of a veterinary biologic? The Veterinary Biologics Pharmacovigilance Program is for the ongoing surveillance of adverse events associated with animal vaccines and other biologics, in cooperation with the veterinary profession and the veterinary biologics industry. An adverse event is any undesirable occurrence after the use of an biological product, including illness or reaction, whether or not the event was caused by the product. What documentation must be submitted to USDA for a biologics establishment and/or product license? Establishment and product license requirements are discussed in Veterinary Services Memorandum 800.50. What documentation must a permittee submit to USDA in order to obtain a permit to distribute and sell in the United States a veterinary biologic manufactured abroad? The requirements for a permit to distribute and sell imported product are largely the same as those for domestically produced product (i.e. Veterinary Services Memorandum 800.50). For additional details on permit requirements, see also Veterinary Services Memorandum 800.101. Are some veterinary biologics exempt from Federal regulation? A veterinary biologic may be exempt from Federal regulation in any of the following cases:- (i) the product was manufactured by veterinarians and intended solely for use with their clients' animals under a veterinarian-client-patient relationship; (ii) the product was manufactured by individuals or companies for use only in their own animals; and (iii) the product was manufactured in States with USDA-approved veterinary biologics regulatory programs, for sale only in those States. What is required to conduct research with non-exempted experimental veterinary biologics? An individual or firm must receive USDA authorization prior to conducting research in animals with non-exempted experimental veterinary biologics. The items that must be submitted to the CVB (short for the Center for Veterinary Biologics) to request such an authorization are discussed in Veterinary Services Memorandum 800.67. See also Biological Products.

VETERINARY CERTIFICATE = ВЕТЕРИНАРНОЕ СВИДЕТЕЛЬСТВО (или ВЕТЕРИНАРНЫЙ СЕРТИФИКАТ) – Veterinary Certificate is a document issued by the competent authority in the exporting country evidencing that live animals or birds are not infested or infected with disease, and giving details regarding their provenance, and of vaccinations and other treatment to which they have been subjected. / Ветеринарное Свидетельство – документ, выдаваемый компетентным органом страны-экспортёра и удостоверяющий, что живой скот или птица не заражены паразитами или болезнями, а также содержащий сведения относительно их происхождения и вакцинации и другой обработки, которой они подвергались.

VETERINARY SERVICES = ВЕТЕРИНАРНЫЕ СЛУЖБЫ – Veterinary Services (VS):- an Animal and Plant Health Inspection Service unit that protects the health of the nation's livestock and poultry resources by regulating the entry of imported animals and animal products. VS will take emergency action against foreign animal diseases, and with the states, operate eradication programs for domestic animal diseases. VS provides health certification for exported animals and animal products. VS also conducts diagnostic tests and issues licenses for veterinary biological products and manufacturers. / Ветеринарная Служба, совокупность организаций, учреждений ветеринарии в стране, в отдельных территориальных зонах или в отдельных отраслях народного хозяйства, на предприятиях, транспорте, государственных границах, в вооружённых силах, осуществляющих комплекс ветеринарных мероприятий. В административном отношении ветеринарная служба подчинена руководству того Союзного (республиканского, областного, краевого, районного) органа или министерства (ведомства, предприятия), в систему которого она входит, в специальном отношении – вышестоящему ветеринарному органу. Руководство Ветеринарной Службы в бывшем Союзе Советских Социалистических Республик (СССР) осуществляло Министерство Сельского Хозяйства СССР. Смотрите также Ветеринария.

VETERINARY TRAINING PROGRAM = ПРОГРАММА ВЕТЕРИНАРНОЙ ПОДГОТОВКИ – Veterinary Training Program:- The Farm Security and Rural Investment Act of 2002 (Sec. 10504) gives the USDA discretionary authority to establish a program to maintain a sufficient number of federal and state veterinarians who are well trained in recognition and diagnosis of endemic and exotic animal diseases.

VETO = ВЕТО – Veto is a privileged single vote that, according to some systems of rules for decision-making, has the effect of blocking or negating a majority decision. In the United States, the President may veto a bill passed by majorities in both houses of Congress, preventing it from becoming law unless each house then re-passes the bill by a two-thirds majority. In the United Nations Security Council, a negative vote (veto) by even one of the five permanent member states (the USA, Russia, Britain, France and China) has the effect of defeating any proposed Security Council resolution. See also Line-Item Veto. / Под Вето, от Латинского

слова Veto, означающее Запрещаю, понимается:- (1) в государственном праве запрет, налагаемый одним органом государственной власти (главой государства) на решения другого государственного органа. Институт Вето возник в Древнем Риме. В феодальную эпоху наиболее известно так называемое свободное – либерум – вето:- в Польше в XVII–XVIII веках решение сейма считалось принятым, если за него голосовали все депутаты. В современных государствах право вето обычно предоставляется главе государства в отношении законов, принятых парламентом. (2) Правом вето называется также предусмотренный Уставом ООН принцип единогласия постоянных членов Совета Безопасности ООН при принятии решений по непроцедурным вопросам. Вето:- в Древнем Риме право Римского Магистрата (так называемая Интерцессия) на постановления и действия другого магистрата. Особое значение имело право вето народных трибунов (смотрите Народные Трибуны). В Польше в XVII веке действовало, так называемое, Вето Либерум – обычай, требовавший полного единогласия в решениях сейма. В буржуазных государствах – право главы государства отказаться ввести в действие законопроект, принятый законодательным органом. Право Вето сложилось в монархических государствах в период известного равновесия сил между исполнительной властью, представляемой монархом, и парламентом. Монархи, как правило, имели право абсолютного вето, применение которого означало, что законопроект окончательно отпал и дальнейшему обсуждению в парламенте не подлежит. Установление в буржуазных странах режима парламентаризма, развенчание монархических традиций и сосредоточение полноты власти в руках правительств привели к прекращению практики применения вето монархом (в Англии, например, право вето было применено в последний раз в 1707) при формальном его сохранении. В большинстве современных буржуазных республик право вето принадлежит главе государства – президенту. Как правило, это отлагательное вето:- отказываясь придать обязательную силу законопроекту (то есть чаще всего подписать его), президент обязан вернуть его в парламент для нового рассмотрения. В случае, если законопроект будет вновь принят парламентом с соблюдением установленных конституцией условий, он вступает в силу без санкции главы государства. В ряде стран, в том числе в Соединённых Штатах Америки (США), где глава государства может осуществить своё право вето лишь в течение определённого срока, конституционная практика привела к возникновению, так называемого, карманного вето:- законопроект, не подписанный президентом в течение установленного срока, считается отпавшим, если к моменту истечения этого срока палаты парламента не заседают. В США за период с 1945 по 1966 год включительно право вето было применено в отношении 192 законопроектов, причём Конгресс сумел преодолеть вето (то есть провести законопроект вновь) президента всего 15 раз. За этот же период, так называемое, карманное вето было применено в 207 случаях. В социалистических странах, где право издания законов принадлежит высшему представительному органу (например, Верховному Совету Союза Советских Социалистических Республик (СССР)), конституции не предоставляют главе государства права вето. В международном праве иногда называют применением вето отсутствие единогласия 7 постоянных членов Совета Безопасности ООН (смотрите Принцип Единогласия). Вето:- право, часто согласно договору или соглашению, государства-участника или его представителя отвергать предлагаемое мероприятие.

VET, VETTED, VETTING = XX, XX, XX – Vet, Vetted, Vetting is to make a careful and critical examination of someone or something, e.g., a person prior to employment. Vet is:- (1) a doctor who practices veterinary medicine (veterinarian and veterinary (in Northern America), veterinary surgeon (in Great Britain); (2) a person who has served in the armed forces (veteran, ex-serviceman). Vet (verb) (vetted, vetting):- (1) to work as a veterinarian, e.g., 'she vetted for the farms in the area for many years'; (2) to examine carefully, e.g., 'someone should vet this report before it goes out'; (3) (in medicine) to provide (a person) with medical care; and (4) (in medicine) to provide veterinary care for.

VF = VERTICAL FLIGHT

VFI = VERTICAL FISCAL IMBALANCE

VFO = VARIABLE–FREQUENCY OSCILLATOR

V FORMATION = ФОРМИРОВАНИЕ (БУКВЫ) ВИ. (или КЛИНООБРАЗНАЯ ФОРМАЦИЯ, или ФОРМАЦИЯ (БУКВЫ) ВИ., или ОБРАЗОВАНИЕ (БУКВЫ) ВИ.) – V-Formation, in technical analysis, a chart formation caused by a sharp extended decline followed by a sudden upward movement. Some chartists believe a V-Formation is not generally a good indicator of a major change of direction in a security's price. These people believe that a major price reversal requires a period of testing low prices with succeeding price advances and declines. Only after this consolidation phase takes place can a new bull movement be assured. V Formation is a technical chart pattern that follows a letter V form, indicating that the security price has bottomed out, and is now in a bullish trend. V Formation, in technical analysis, is a situation in which a security steeply declines in price, and then steeply recovers. A V-Formation may be bullish, but many analysts believe that a V-Formation is risky because of the possibility that another steep decline could occur. See also V-Shaped Recovery, W-Shaped Recovery, and W-Type Bottom. / , от Латинского слова Formatio, означающее Вид или Образование, понимается . Формирование Буквы Ви. (V) – технический график Ви.-образной формы поведения цены. График в виде буквы Ви. говорит о том, что цены на акции, облигации или товарно-сырьевую продукцию достигли нижней точки и теперь движутся вверх. Перевёрнутый (инвертированный) график Ви. отражает тенденцию к понижению (указывает на спад на рынке). Смотрите также Дно (Bottom); и Технический Анализ (Technical Analysis). Формирование Буквы Ви. (V):- технический график в виде вуквы Ви. (V). Эта модель указывает на то, что обозначенные на графике акция, облигация, товар или сырьё прошли низшую точку падения цен и перешли к тенденции на повышение. Перевёрнутая буква Ви. обозначает рынок со снижающейся ценой.

VFR = VISUAL FLIGHT RULES

VG = BRITISH VIRGIN ISLANDS

VGM = VERIFIED GROSS MASS

VHAP = VOLATILE HAZARDOUS AIR POLLUTANT

VHF = VERTICAL HORIZONTAL FILTER

VHF = VERY HIGH FREQUENCY

VHP SUGAR = VERY HIGH POLARIZATION SUGAR

VHS = VERTICAL AND HORIZONTAL SPREAD MODEL

VHT = VEHICLE–HOURS OF TRAVEL

VHTR = VERY HIGH TEMPERATURE (GAS–COOLED) REACTOR

VI = IN BANKRUPTCY OR RECEIVERSHIP OR BEING REORGANIZED UNDER THE BANKRUPTCY ACT, OR SECURITIES ASSUMED BY SUCH COMPANIES

VI = THE UNITED STATES VIRGIN ISLANDS

VI = VESTED INTEREST

VI = VISCOSITY INDEX

VIABILITY = ЖИЗНЕСПОСОБНОСТЬ – Viability, in economics, is the capability of developing and surviving as a relatively independent social, economic or political unit.

VIABILITY = ЖИЗНЕСПОСОБНОСТЬ (или ПОСЕВНАЯ ГОДНОСТЬ) – Viability of seeds is the ability of seeds to germinate. Seeds just harvested or stored at a low temperature frequently do not germinate, although they have healthy embryos – that is, they are viable. Such seeds are in a period of dormancy, after which they can produce normal sprouts. The viability of seeds is determined by control seed analysis, the number of live seeds being expressed as a percent of the total number of seeds used in the analysis. The methods for determining the viability of seeds are specified by state standards. Viability (seed) is the potential of a seed to be able to germinate. See also Seed Viability. Seed Viability is the capability of plant structure (seed, cuttings etc) to show living properties like germination and growth. Viability testing is one of the major aspects of seed technology. If germination test is conducted to test viability, it requires long period, because of which seed processing and marketing is delayed. Hence the rapid method used to estimate or predict the germination behavior of seed is TZ test (short for the Tetrazolium Test). It estimates seed viability usually within 24 to 48 hours. Tetrazolium Test or TZ Test is a bio-chemical test. In this test, the indicator 'TZ' (a colorless solution of tetrazolium salt is used). TZ dyes living parts of seed with red color, while dead parts appear colorless. Sometimes partial coloration is also observed. Viability is the ability to grow and develop into an adult. Seed Viability:- quality seed is viable seed. Seed viability is high germination percentage and good seed vigor. Seed certification agencies prescribe the seed purity, moisture content and seed germination norms for each crop. Farmers should aware of those norms and test them before sowing the seeds. It is very important in farming. If germination is low plant stand in the field will be less and seed vigor also will be less it will affect the ultimate out put of the crop, which will result in low yields and losses. / Посевная Годность Семян – хозяйственная годность семян, количество (в процентах) пригодных для посева семян в семенном материале. Посевная годность семян устанавливают на основании показателей чистоты и всхожести семян (выраженных в процентах) путём их перемножения и деления на 100 (результат округляют до целых чисел). Посевная годность семян служит основанием для уточнения норм высева семян, которые для различных культур приняты из расчёта 100%-ной посевной годности. Используемые же на посев семена редко имеют посевную годность 100%, поэтому, вводя поправку на посевную годность семян, норму их высева увеличивают. Жизнеспособность – способность семян к прорастанию, которую устанавливают по количеству живых семян – всхожих и находящихся в состоянии покоя. Жизнеспособность определяют обычно у семян, не прошедших периода покоя, а также при необходимости срочного ориентировочного определения качества семян. Процент живых семян определяют с помощью красителей индигокармина, кислого фуксина или солей тетразола. Для лука используется экспресс-метод определения жизнеспособности семян. Для этого семена в течение 30 минут выдерживают в кипящей воде. У жизнеспособных семян появляется зародышевый корешок. Количество зародышевых корешков в анализируемой пробе является показателем жизнеспособности этих семян. Жизнеспособность:- (1) способность особи (или популяции) жить и давать потомство. Жизнеспособность популяции определяется плодовитостью, длительностью периода размножения и количеством достигших половозрелости особей. (2) Способность особи выживать до определённого момента жизненного цикла, например, до начала периода размножения. Мерилом жизнеспособности мутанта служит относительная частота доживания до этого периода мутировавших особей по сравнению с немутировавшими. Жизнеспособность Семян, свойство семян сохранять способность к прорастанию. Только что убранные или хранящиеся при низкой температуре семена часто не прорастают, хотя и имеют здоровый зародыш, то есть жизнеспособны. Это вызывается периодом покоя, после прохождения которого семена могут дать нормальные всходы. Жизнеспособность семян определяют при контрольно-семенном анализе, число живых семян выражают в процентах от общего числа семян, взятых для анализа. Методы определения жизнеспособности семян предусмотрены государственными стандартами.

VIABLE = ЖИЗНЕСПОСОБНОЕ (или ЖИЗНЕННОЕ) – Viable:- said of spore or seed that is able to germinate or grow under favorable conditions. / споры или семени, .

VIAGRA® = ВАЙЭГРЭ® (или ВИАГРА®) – Sildenafil Citrate or Viagra®:- sildenafil is a PDE5 Inhibitor (short for the phosphodiesterase type 5 inhibitor) drug. Sildenafil citrate, sold as Viagra®, Revatio® and under several other trade names, is a drug used to treat erectile dysfunction in men. Also, it is currently used for treating pulmonary arterial hypertension (PAH). It was developed by the biggest pharmaceutical company Pfizer. Its' primary competitors on the market are tadalafil (Cialis®) and vardenafil (Levitra®). / Вайэгрэ® (Viagra®), Рэвэйшио® (Revatio®). Фица (Pfizer). Сиалыс® (Cialis®) и Лэвитчра® (Levitra®).

VIAP = VESSEL INSURANCE ADDITIONAL PREMIUM

VIBRATION = ВИБРАЦИЯ – Vibration is a mechanical phenomenon whereby oscillations occur about an equilibrium point. The oscillations may be periodic such as the motion of a pendulum or random such as the movement of a tire on a gravel road. Vibration is occasionally 'desirable'. For example the motion of a tuning fork, the reed in a woodwind instrument or harmonica, or the cone of a loudspeaker is desirable vibration, necessary for the correct functioning of the various devices. More often, vibration is undesirable, wasting energy and creating unwanted sound – noise. For example, the vibrational motions of engines, electric motors, or any mechanical device in operation are typically unwanted. Such vibrations can be caused by imbalances in the rotating parts, uneven friction, the meshing of gear teeth, etc. Careful designs usually minimize unwanted vibrations. The study of sound and vibration are closely related. Sound, or 'pressure waves', are generated by vibrating structures, e.g., vocal cords; these pressure waves can also induce the vibration of structures, e.g., ear drum. Hence, when trying to reduce noise it is often a problem in trying to reduce vibration. Vibration:- oscillation – container floor stretches up and down in motion. Vibration is a periodic back-and-forth motion of the particles of an elastic body or medium, commonly resulting when almost any physical system is displaced from its equilibrium condition and allowed to respond to the forces that tend to restore equilibrium. Vibrations fall into two categories:- free and forced. Free vibrations occur when the system is disturbed momentarily and then allowed to move without restraint. A classic example is provided by a weight suspended from a spring. In equilibrium, the system has minimum energy and the weight is at rest. If the weight is pulled down and released, the system will respond by vibrating vertically. The vibrations of a spring are of a particularly simple kind known as Simple Harmonic Motion (SHM). This occurs whenever the disturbance to the system is countered by a restoring force that is exactly proportional to the degree of disturbance. In this case, the restoring force is the tension or compression in the spring, which (according to Hooke's Law) is proportional to the displacement of the spring. In simple harmonic motion, the periodic oscillations are of the mathematical form called Sinusoidal. Most systems that suffer small disturbances counter them by exerting some form of restoring force. It is frequently a good approximation to suppose that the force is proportional to the disturbance, so that SHM is, in the limiting case of small disturbances, a generic feature of vibrating systems. One characteristic of SHM is that the period of the vibration is independent of its amplitude. Such systems therefore are used in regulating clocks. The oscillation of a pendulum, for instance, approximates SHM if the amplitude is small. A universal feature of free vibration is damping. All systems are subject to frictional forces,

and these steadily sap the energy of the vibrations, causing the amplitude to diminish, usually exponentially. The motion is therefore never precisely sinusoidal. Thus, a swinging pendulum, left undriven, will eventually return to rest at the equilibrium (minimum-energy) position. Forced vibrations occur if a system is continuously driven by an external agency. A simple example is a child's swing that is pushed on each downswing. Of special interest are systems undergoing SHM and driven by sinusoidal forcing. This leads to the important phenomenon of resonance. Resonance occurs when the driving frequency approaches the natural frequency of free vibrations. The result is a rapid take-up of energy by the vibrating system, with an attendant growth of the vibration amplitude. Ultimately, the growth in amplitude is limited by the presence of damping, but the response can, in practice, be very great. It is said that soldiers marching across a bridge can set up resonant vibrations sufficient to destroy the structure. Similar folklore exists about opera singers shattering wine glasses. Electric vibrations play an important role in electronics. A circuit containing both inductance and capacitance can support the electrical equivalent of SHM involving sinusoidal current flow. Resonance occurs if the circuit is driven by alternating current that is matched in frequency to that of the free oscillations of the circuit. This is the principle behind tuning. For example, a radio receiver contains a circuit, the natural frequency of which can be varied. When the frequency matches that of the radio transmitter, resonance occurs and a large alternating current of that frequency develops in the circuit. In this way, resonating circuits can be used to filter out one frequency from a mixture. In musical instruments, the motion of strings, membranes, and air columns consists of a superposition of SHM's; in engineering structures, vibrations are a common, though usually undesirable, feature. In many cases, complicated periodic motions can be understood as the superposition of SHM at many different frequencies. / Осцилляция. Вибрация, от Латинского слова Vibratio, означающее Дрожание или Колебание, относится к механическим колебаниям в технике (конструкциях, машинах, механизмах и прочих). Различают полезную и вредную вибрацию. Полезная вибрация преднамеренно возбуждается вибраторами, рабочими органами вибрационных машин, и используется для выполнения различных технологических операций в машиностроении, медицине, строительстве и тому подобном. Вредная вибрация возникает, например, при движении транспортных средств, работе машин, двигателей, турбин и так далее. При большой интенсивности она может привести к нарушению режимов работы и даже к разрушению устройства. Воздействие вибрации на организм может быть как благотворным, так и вредным (вибрационная болезнь) в зависимости от частоты вибрации; она может вызвать быстрое утомление. В этой связи возникновение и действие вредной вибрации стараются предотвратить или уменьшить. Для защиты от вибрации используется виброизоляция в виде демпферов между источниками вибрации и защищаемыми объектами. Вибрация, механические колебания. В технике (машинах, механизмах, сооружениях, конструкциях и так далее) бывает полезная и вредная вибрации. Полезная Вибрация возбуждается преднамеренно вибраторами, используется в строительных, дорожных и других машинах (смотрите Вибрационная Машина) и для выполнения различных технологических операций (смотрите Вибрационная Решётка, Вибрационное Резание, Вибрационный Транспорт). Различают возбуждение вибрации динамическое, или силовое, когда внешние колеблющиеся силы или моменты сил, не зависящие от состояния вибрируемой системы, приложены к одному или нескольким инерционным элементам этой системы; кинематическое, когда одной или нескольким точкам вибрируемой системы извне сообщаются колебания, не зависящие от её состояния; параметрическое, когда вибрация системы возбуждается не зависящими от её состояния изменениями значения одного или нескольких параметров (например, коэффициент жёсткости, момента инерции, коэффициент сопротивления); самовозбуждение колебаний, или автоколебания, когда вибрацию поддерживают за счёт поглощения порции энергии от постоянного источника. В большинстве вибрационных устройств использованы первые два принципа возбуждения вибрации. Вредная Вибрация может возбуждаться каждым из перечисленных способов. Имеет место и смешанное возбуждение вибрации, например, совмещение кинематически вынужденных колебаний с автоколебаниями. Вредная вибрация, возникающая при движении транспортных средств, работе двигателей, турбин и других машин, иногда приводит к нарушению режима работы и даже разрушению устройств. Для подавления вредной вибрации и снижения её действия применяют различные меры защиты (смотрите Вибрационная Техника). Действие вибрации на организм различно в зависимости от того, вовлечён ли в неё весь организм (общая вибрация) или его часть (местная, или локальная, вибрация), и возникает при передвижении на поезде, самолёте и тому подобном, при работе с отбойным молотком и другими механизмами, а также во время старта и приземления при космических полётах. В зависимости от частоты, силы и продолжительности вибрации её воздействие может ограничиться ощущением сотрясения (паллестезия) или привести к изменениям в нервной, сердечно-сосудистой, опорно-двигательной системах. Биологическое действие вибрации зависит от её частоты:- колебания частотой до 15 Герц (Гц) вызывают смещение тела и органов, реакцию вестибулярного аппарата; до 25 Гц – воспринимаются ещё как отдельные толчки, вызывают костно-суставные изменения, от 50 до 250 Гц – влияют на нервную систему, вызывают сосудистые реакции (спазм), вибрационную болезнь; при более высоких, ультразвуковых частотах происходит переход механической энергии в тепловую, наблюдается бактерицидное, кавитационное действие вибрации.

VIBRIO CHOLERAE = ВИБРИО ХОЛЕРАЭ (или ХОЛЕРНЫЙ ВИБРИОН) – Vibrio Cholerae is one of the Vibrio Bacteria, Vibrio Cholerae (as the name implies) is the agent of cholera, a devastating and sometimes lethal disease with profuse watery diarrhea. Like other Vibrio, Vibrio Cholerae moves about actively. The word 'Vibrio' in Latin means 'To Quiver'. / Холерный Вибрион:- Бактерия Рода Vibrio, возбудитель холеры. Под Вибрионами, от Французского слова Vibrion, от Латинского слова Vibro, означающее Дрожу или Извиваюсь или Колеблюсь, понимаются короткие (длина 1–5 мкм, толщина 0.3–0.6 мкм), изогнутые, похожие на запятую Бактерии, имеющие жгутики; входят в Род Vibrio. Обитают в воде, почве и содержимом кишечника животных и человека. К Вибрионам относятся более 100 Видов, среди которых очень много болезнетворных для человека, например, Vibrio Comma – возбудитель холеры. Некоторые Виды Вибрионов болезнетворны только для животных, например, Vibrio Metchnikovii, поражающий птиц; другие Виды Вибрионов патогенны для рыб и ряда беспозвоночных.

VIBROSCOPE = ВИБРОСКОП – Vibroscope is an instrument for determining the mass per unit length of a fiber. Vibroscope is:- (1) an instrument for observing or tracing vibrations; or (2) an instrument resembling the phenakistoscope. Vibroscope (Vibrate + Scope) is an instrument for observing and tracing (and sometimes recording) vibration. For example, a primitive mechanical vibroscope consists of a vibrating object with a pointy end which leaves a wave trace on a smoked surface of a rotating cylinder. Vibroscopes are used to study properties of substances. For examples, polymers' torsional modulus and Young's modulus may be determined by vibrating the polymers and measuring their frequency of vibration under certain external forces. Similar approach works to determine linear density of thread-shaped objects, such as fibers, filaments, and yarn. Vibroscopes are also used to study sound in different areas of the mouth during speech. / Под Виброскопом, от Латинского слова Vibro, означающее Колеблюсь, и Греческого слова Skopéō, означающее Смотрю, понимается инструмент для определения массы на единицу длины волокна.

VICARIANT PATTERN = ВИКАРИАНТНАЯ МОДЕЛЬ – Vicariant Pattern:- xxxxx. Vicariant (from Latin Vicārius (see Vicar) + -ant) is any of several closely related species, races, etc, each of which exists in a separate geographical area:- assumed to have originated from a single population that became dispersed by geological events. / Викариантный Образец:- замещающий экологический вид.

VICARIOUS LIABILITY = КОСВЕННАЯ ОТВЕТСТВЕННОСТЬ (или ОТВЕТСТВЕННОСТЬ ЗА ДЕЯНИЯ ДРУГИХ ЛИЦ, или УСЛОВНАЯ ОТВЕТСТВЕННОСТЬ) – Vicarious Liability:- Legal liability imposed on one person for torts or crimes committed by

another (usually an employee but sometimes an independent contractor or agent), although the person made vicariously liable is not personally at fault. An employer is vicariously liable for torts committed by his employees when he has authorized or ratified them or when the tort was committed in the course of the employees' work. Thus negligent driving by someone employed as a driver is a tort committed in the course of his employment, but if the driver were to assault a passing pedestrian for motives of private revenge, the assault would not be connected with his job and his employer would not be liable. The test is whether the tort is so closely connected with the employment that it would be fair and just to hold the employer vicariously liable (Lister v Hesley Hall (2002) 1 AC 215 (HL). Employers have been found vicariously liable for bullying in the workplace (Majrowski v Guy's and St Thomas's NHS Trust (2006) UKHL 34, (2006) IRLR 695) and for the stabbing of a guest by a bouncer outside a nightclub (Mattis v Pollock (t/a Flamingo's Nightclub) (2003) EWCA Civ 887, (2003) ICR 335). The purpose of the doctrine of vicarious liability is to ensure that an employer pays the costs of damage caused by his business operations. His vicarious liability, however, is in addition to the liability of the employee, who remains personally liable for his own torts. The person injured by the tort may sue either or both of them, but will generally prefer to sue the employer. Vicarious criminal liability may effectively be imposed by statute on an employer for certain offences committed by an employee in relation to his employment. Thus it has been held that an employer is guilty of selling unfit food under the Food Act 1984 when his employee does the physical act of selling (the employee is also guilty, though in practice is rarely prosecuted). Likewise, an employer may be guilty of supplying goods under a false trade description when it is his employee who actually delivers them. For an offence that normally requires mens rea, an employer will only be vicariously liable if the offence relates to licensing laws. For example, if a licensee has delegated the entire management of his licensed premises to another person, and that person has committed the offence with the necessary mens rea, the licensee will be vicariously liable. Vicarious liability for crimes may be imposed in certain other circumstances. The registered owner of a vehicle, for example, is expressly made liable by statute for fixed-penalty and excess parking charges, even if the fault for the offence was not his. If the offence is a regulatory offence of strict liability, the courts often also impose vicarious liability if the offence is defined in the statute in a way that makes this possible. / Листэ против Хэсли Хол (Lister v Hesley Hall (в 2002) 1 AC 215 (HL). Мэдьжровски против Гайз энд Сэйнт Томэсиз Эн.Эйч.Эс. Тчраст (Majrowski v Guy's and St Thomas's NHS Trust) (в 2006) UKHL 34, (в 2006) IRLR 695) и Мэтис против Полэк (Mattis v Pollock).

VICE PROPRE = INHERENT VICE

VICE VERSA = ВИЧЭ ВЭРСА (или НАОБОРОТ) – Vice Versa:- Latin for Conversely. Abbreviation:- VV. / Латинский термин, означающий Наоборот. Обозначение:- ВВ (VV).

VICKERS HARDNESS = ТВЁРДОСТЬ ПО ВИКЁЗ – Vickers Hardness is a measure of the hardness of a material, calculated from the size of an impression produced under load by a pyramid-shaped diamond indenter. Devised in the 1920s by engineers at Vickers, Ltd., in the United Kingdom, the diamond pyramid hardness test, as it also became known, permitted the establishment of a continuous scale of comparable numbers that accurately reflected the wide range of hardnesses found in steels. The indenter employed in the Vickers test is a square-based pyramid whose opposite sides meet at the apex at an angle of 136°. The diamond is pressed into the surface of the material at loads ranging up to approximately 120 kilograms-force, and the size of the impression (usually no more than 0.5 mm) is measured with the aid of a calibrated microscope. The Vickers number (HV) is calculated using the following formula:- HV = $1.854(F/D^2)$, with F being the applied load (measured in kilograms-force) and D^2 the area of the indentation (measured in square millimeters). The applied load is usually specified when HV is cited. The Vickers test is reliable for measuring the hardness of metals, and it is also used on ceramic materials. See also Knoop Hardness. Vickers Hardness Number (HV or VHN) or Vickers Pyramid Number (VPN) is a measure of the hardness of a metal introduced by Vickers in 1922. In the Vickers test (suitable for surface-hardened metals), a pyramidal diamond is pressed into the material being tested. The Vickers hardness is the amount of force applied to the diamond divided by the area of the indentation the diamond makes in the material; in practice the diagonal of the pyramidal indentation is measured and the result, computed in kilograms of force per square millimeter, is read from a table. (The reading should be stated as an empirical measurement, without units.) Up to about HV 500, the Vickers hardness is about 1.04 times the Brinell hardness. / Викёз, Эл.ти.ди. (Vickers, Ltd.). Смотрите также Твёрдость По Нюпу (Knoop Hardness). Метод Виккерса – один из способов определения твёрдости металлов.

VICS = VEHICLE INFORMATION AND COMMUNICATIONS SYSTEM

VICTOR = ВИКТА – Victor (pronunciation:- VIK-tah) or V is international nautical signal flag meaning:- I require assistance. With one or more numerals, speed in kilometers per hour. Meaning:- require assistance (not in distress).

VICTUALLING BILL = ОПИСЬ ПРОВИАНТА (или СЧЁТ ЗА ПРОВИАНТ) – Victualling Bill is a document showing bonded stores for the vessel's use. Victualling Bill is a permit granted by the Customs House authorities authorising the embarkation ... . Bill of Victualling, in its original meaning a list of all stores for shipment, but now an order from an export officer of the customs for the shipment from a bonded warehouse or for drawback of such stores as may be required and allowed with reference to the number of the crew and passengers on board a ship proceeding on an oversea voyage. It is made out by the master and countersigned by the collector of customs. Its object is to prevent frauds on the revenue. No such stores are supplied for the use of any ship nor any articles taken on board deemed to be stores unless they are borne upon the victualling bill, and any such stores relanded at any place in the United Kingdom without the sanction of the proper officers of the customs will be forfeited and the master and owner will each be liable to a penalty of treble the value of the stores or £100. A victualling bill serves as a certificate of clearance when there is nothing but stores on board the ship. / хозяин (или капитан). Документ, перечисляющий провиант, обеспеченный гарантией того, что он будет употребляться только на самом судне.

VICUÑA = ВИКУНЬЯ (или ВИГОНЬ) – The term Vicuña is applied to the fabrics manufactured from the wool of the animal, and also to textile fabrics made from the wool of the merino sheep in imitation of natural Vicuña. Such fabrics generally resemble serge in weave but are fuller and softer and have a distinct nap. Textile industry uses the fibers to manufacture the softest coat cloth in the world. The Vicuña mammal belongs to the Camel family. The animal is native to the Andes in South America, and is a close relative of the Llama. Vicuñas are small, slender animals with orange-red fur. They generally roam in small herds and have never been successfully domesticated. They are much hunted for their hides and for their wool, which is valued for weaving. Vicuña: - the most coveted of all specialty hair fibers, from the smallest and wildest member of the Llama family. This costly, luxurious fiber is finer than merino wool, with a rich, beautiful color that ranges from golden chestnut to cinammon. Each animal yields only a few ounces. The very limited supply of Vicuña is controlled by the Peruvian government. See also Llama. Vicuña:- (Lama, or Vicugna, Vicugna), South American member of the Camel Family, Camelidae (Order Artiodactyla), that is closely related to the Alpaca, Guanaco, and Llama (known collectively as Lamoids). Depending on the authority, the Llama, Alpaca, and Guanaco may be classified as distinct species of Llama (Lama Glama). Because of differences in the incisor teeth, however, some authorities place the Vicuña in a separate genus, Vicugna. Most Vicuñas inhabit Peru, with smaller numbers found in Bolivia, Chile, and Argentina. The Vicuña is covered with a remarkably long, fine, soft, and lustrous coat that varies in color from light cinnamon to a pale white, with long white fleece hanging from the lower flanks and the base of the neck. The annual yield of fleece sheared from domesticated Vicuñas shows a wide range of from 85 to 550 grams

(3 to 20 ounces) per animal. Vicuña fiber is strong and resilient, but it is highly sensitive to chemicals and is generally used in its natural color. The costly fiber is made into high-priced coats, dressing gowns, and shawls. The dense, silky fleece of the Vicuña, once reserved for the Incan nobility, provides excellent insulation against the temperature fluctuations the animal encounters in its natural habitat:- semiarid grasslands in the central Andes at altitudes of 3 600–4 800 meters (12 000–16 000 feet). A swift, graceful animal, the Vicuña is the smallest of the camelids, with a shoulder height of about 90 centimeters (36 inches) and a weight of about 50 kilograms (110 pounds). When in danger, they emit a high, clear whistle. Vision and hearing are more highly developed than their sense of smell. Like Guanacos, Vicuñas are wild, with temperaments that preclude domestication. The animals graze on low grasses and ruminate while resting. They travel in small bands of females, usually led by a male who acts as lookout and defends his territory against intruders. Vicuñas use communal dung heaps to mark their territorial boundaries. They spit frequently and noisily, like all Lamoids. A single young, born in February about 11 months after the parents have mated, remains close to the mother for at least 10 months. The life expectancy is about 15 to 20 years. Vicuñas have been hunted for centuries with a resulting decline in numbers. The Inca rounded the animals up, sheared their wool, and then released them; they also killed some for meat. In Spanish colonial times greater numbers of the animals were hunted and killed, and though protective legislation was introduced in the XIX century, poaching continued to reduce their total numbers, which declined from a million in Incan times to only about 10 000 by the late 1960s. Subsequent conservation efforts managed to increase the population to more than 80 000 by the late XX century. The vicuña is listed as vulnerable in the Red Data Book and is now protected effectively in South American countries. Vicuña is a fabric made of Vicuña wool or a sheep's wool imitation of Vicuna. The Vicuña (Vicugna), a beautiful wild animal, is the smallest species of the four South American Camelids and its habitat is constituted by the High Andes territory at an altitude of 3 800 to 5 000 meters. This territory includes, in Peru, 16 departments (namely:- Ancash, Apurimac, Arequipa, Ayacucho, Cajamarca, Cusco, Hunuco, Huancavelica, Ica, Junn, La Libertad, Lima, Moquegua, Pasco, Puno, Tacna). / Под Викуньей или Вигонью понимается парнокопытное животное рода Лам. Длиной около 1.5 метров (м). Обитала в высокогорьях Анд; в результате хищнического истребления (ценная шерсть) сохранилась лишь в некоторых местах (на Юге Перу и частично на Западе Боливии). Находится под охраной. Проводятся работы по одомашниванию. Викунья, скрещённая с Гуанако, одомашнена (Альпака). Вигонь или Викунья (Vicugna), Млекопитающее Семейства Верблюдовых. Высота 70–90 сантиметров (см), длина около 1.5 метров (м), весит до 65 килограммов (кг). Тело покрыто короткой, но мягкой и тонкой шерстью, состоящей преимущественно из пуховых волос, у взрослых животных – рыжеватой на спине и боках и светло-серой на брюхе. Руно весит до 800–1 000 граммов (г). Вигонь живёт небольшими стадами в высокогорных областях Анд. Самка рождает одного детёныша. В начале XIX века Вигонь была довольно широко распространена в Эквадоре, Перу, Боливии и Чили. В результате хищнического истребления ареал значительно сократился. Лучше сохранилась в некоторых малодоступных провинциях Перу. Викунья, млекопитающее Рода Лам; то же, что Вигонь. Под Ламой понимается понимается род парнокопытных животных семейства Верблюдовых. Длина 1.2–1.75 м. 2 Вида – Гуанако и Викунья, обитают в высокогорьях Анд; оба одомашнены – собственно Лама (одомашненный Гуанако) и Альпака (Гуанако, скрещённый с Викуньей). Лам используют как вьючных животных; очень ценится шерсть. Вигонь – ткань из шерсти и пуха Верблюда.

VIDELICET = ВИДЭЛИЧЭТ (или А ИМЕННО, или КАК СЛЕДУЕТ, или ХХ) – Videlicet (Viz.), which itself is a contraction from Latin of 'Videre Licet' meaning 'It Is Permitted To See'. Both forms introduce a specification or description of something stated earlier; this is often a list preceded by a colon (:). Although both forms survive in English, viz. is far more common than videlicet. A similar expression is scilicet, abbreviated as sc., which is Latin for 'it is permitted to know'. Viz. is usually used to elaborate or detail text which precedes it, while sc. provides a parenthetic clarification, removes an ambiguity, or supplies a word omitted in preceding text. In legal usage, scilicet appears abbreviated as ss. or, in a caption, as §, where it provides a statement of venue and is read as 'to wit'. Viz.:- namely. Used in tariffs to specify commodities. Viz. (also rendered viz without a full stop) and the adverb videlicet are used as synonyms for 'Namely', 'That Is To Say', and 'As Follows'. / Видэличэт (Videlicet) (Виз (Viz.)), Видэрэ Личэт (Videre Licet).

VIDEOCONFERENCING = ПРОВЕДЕНИЕ ВИДЕОКОНФЕРЕНЦИЙ – Videoconferencing (or Video Conference) means to conduct a conference between two or more participants at different sites by using computer networks to transmit audio and video data. For example, a point-to-point (two-person) video conferencing system works much like a video telephone. Each participant has a video camera, microphone, and speakers mounted on his or her computer. As the two participants speak to one another, their voices are carried over the network and delivered to the other's speakers, and whatever images appear in front of the video camera appear in a window on the other participant's monitor. Multipoint videoconferencing allows three or more participants to sit in a virtual conference room and communicate as if they were sitting right next to each other. Until the mid 1990s, the hardware costs made videoconferencing prohibitively expensive for most organizations, but that situation is changing rapidly. Many analysts believe that videoconferencing will be one of the fastest-growing segments of the computer industry in the latter half of the decade. See also Tele-Conferencing. Videoconferencing (VC) is a method of holding meetings that allows people who are in different cities, countries, etc, to hear each other and see each other on computer or television screens. Video Conferencing is a technology that allows users in different locations to hold face-to-face meetings without having to move to a single location. This technology is particularly convenient for business users in different cities or even different countries because it saves the time, expense and hassle associated with business travel. Uses for video conferencing include holding routine meetings, negotiating business deals and interviewing job candidates. Video conferencing's main advantage over teleconferencing is that users can see each other, which allows them to develop stronger relationships. When a video conference is held for informal purposes, it is called a Video Call or Video Chat. Video-Conferencing:- two way, real-time transmission of audio and video signals between specialized devices or computers at two or more locations via satellite (wireless) over a network such as a LAN or internet. Full motion (30 frames per second), full color videoconferencing requires a bandwidth of 6 MegaHertz (MHz) for analog signals and 1.54 Megabits per second (Mbps) of digital signals. Videoconferencing protocols are governed by the ITU-TSS standard H.261 and its successors. Also called Video Teleconferencing. / Под Видео-, от Латинского слова Video, означающее Вижу или Смотрю, в составных словах понимается приставка, указывающая на принадлежность слова (понятия) к области изображения телевизионных, радиолокационных и других сложных электрических сигналов на экране электроннолучевой трубки и другого; например, видеосигнал, видеоусилитель, и другие. Проведение Видеоконференций:- система, используемая в Великобритании и других странах, которая позволяет группе людей, находящихся далеко друг от друга, видеть друг друга и разоваривать друг с другом, то есть проводить собрания, семинары и так далее, не затрачивая времени и денег на поездки. Специальные студии не требуются; информация передаётся компанией Бритиш Тчэлэкам (British Telecom). Бритиш Телеком предлагает также для проведения видеоконференций систему Конфровидение (Confravision), оснащённую специальными студиями, размещёнными в нескольких главных городах.

VIDEOTEX = ВИДЕОТЭКС (или ВИДИОТЭКС) – Videotex is the interactive (e.g., via screen or PC) telecommunication system operated by SwissOnline. A number of banking services are also provided under the system. See also Telebanking. Videotex is an electronic data retrieval system in which usually textual information is transmitted via telephone or cable-television lines and displayed on a television set or video display terminal; especially:- such a system that is interactive. Compare Teletext. Videotex is an electronic information transmission and retrieval technology enabling interactive communication, for such purposes as data acquisition and

dissemination and electronic banking and shopping, between typically large and diverse computer databases and users of home or office display terminals connected to telephone or cable-television lines, or through use of broadcast television signals. / Под Видео-, от Латинского слова Video, означающее Вижу или Смотрю, в составных словах понимается приставка, указывающая на принадлежность слова (понятия) к области изображения телевизионных, радиолокационных и других сложных электрических сигналов на экране электроннолучевой трубки и другого; например, видеосигнал, видеоусилитель, и другие. Видеотэкс:- информационная система, в которой информация, посылаемая отдалённым компьютерам, передаётся на экран телевизионного приёмника. Существуют две разновидности системы:- (i) в системе Вьюдэйта (Viewdata) информация передаётся на экран телевизора по каналам телефонной связи или по кабелям; (ii) в системе Тэлэтэкст (Teletext) информация передаётся по нормальным телеканалам вместе с обычным сигналом телевизионной станции.

VIE = VARIABLE INTEREST ENTITY

VIE = VOLUNTARY IMPORT EXPANSION

VIENNA CONVENTION = ВЕНСКАЯ КОНВЕНЦИЯ – (1) Vienna Convention:- officially known as United Nations Convention on Contract for the International Sale of Good (CISG) is a 1980 international treaty signed by over 80 countries, between them most leading trading nations, that amounts to a virtual commercial code for international sale of goods transactions, but exclude contracts for services. Although the CIS is the default body of contract law when both the exporter/seller and the importer/buyer are nationals of countries that have ratified it, parties may opt out by explicitly stating so in their international sale contract. A separate but related agreement, the United Nations Convention on the Limitation Period of the International Sale of Gods, covers time limits for seller and buyer claims of breach, termination, or invalidity arising from contracts of international sale of goods. Parties desiring to opt out of either convention should specify the body of law they wish to use instead. Care must be taken when doing so, as the conventions may be part o the body of law the parties wish to use. See International Sale Contract. Vienna Convention is treaty governing international commerce that defines the rights of importers and exporters. The treaty includes a number of agreements that exporters and importers may adopt to set the rules for transactions. Also called the United Nations Convention on Contracts for the International Sale of Goods. Vienna Convention on the Law of Treaties, an international agreement governing treaties between states that was drafted by the International Law Commission of the United Nations and adopted on May 23, 1969, and that entered into force on January 27, 1980. A convention governing international treaties was one of the first efforts undertaken by the International Law Commission, and James Brierly was assigned as special rapporteur in 1949 to address the subject. After his resignation in 1952, each of his successors began the work anew. Sir Humphrey Waldock, appointed in 1961, produced six reports from which the commission was able to create a draft to submit to the UN General Assembly in 1966 with a recommendation that a conference be convened to conclude a convention based on the draft. The conference held its first meeting in 1968, and the convention was adopted at its second session the following year. The convention applies only to written treaties between states. The first part of the document defines the terms and scope of the agreement. The second part lays out the rules for the conclusion and adoption of treaties, including the consent of parties to be bound by treaties and the formulation of reservations – that is, declining to be bound by one or more particular provisions of a treaty while accepting the rest. The third part deals with the application and interpretation of treaties, and the fourth part discusses means of modifying or amending treaties. These parts essentially codify existing customary law. The most important part of the convention, Part V, delineates grounds and rules for invalidating, terminating, or suspending treaties and includes a provision granting the International Court of Justice jurisdiction in the event of disputes arising from the application of those rules. The final parts discuss the effects on treaties of changes of government within a state, alterations in consular relations between states, and the outbreak of hostilities between states as well as the rules for depositaries, registration, and ratification. It was necessary for 35 member states of the United Nations to ratify the treaty before it could go into effect. Although it took until 1979 to secure those ratifications, more than half of the UN members had agreed to the convention by early 2018. Even those members that had not ratified the document, such as the United States, generally followed the prescriptions of the agreement. Vienna Convention is the common name for the United Nations Convention on Contracts for the International Sale of Goods. They are a body of law governing the international sale of goods between parties domiciled in member countries. / Дьжеймз Брайэлы (James Brierly). Сэр Хамфри Волдак (Sir Humphrey Waldock).

(2) Vienna Convention of 1963:- Vienna Convention on Civil Liability for Nuclear Damage:- aims at harmonizing the national law of the Contracting Parties by establishing some minimum standards to provide financial protection against damage resulting from certain peaceful uses of nuclear energy. The Convention is designed to ensure that all Contracting Parties have laws and regulations in place conforming to the legal regime for civil liability for nuclear damage provided for in the Convention. The legal regime provided for in the Convention is based on the following general principles:- (i) exclusive liability of the operator of the nuclear installation concerned; (ii) 'absolute' or 'strict' liability, so that the injured party is not required to prove fault or negligence on the part of the operator; (iii) minimum amount of liability; (iv) obligation for the operator to cover liability through insurance or other financial security; (v) limitation of liability in time; (vi) equal treatment of victims, irrespective of nationality, domicile or residence, provided that damage is suffered within the geographical scope of the Convention; (vii) exclusive jurisdictional competence of the courts of the Contracting Party in whose territory the incident occurs or, in case of an incident outside the territories of Contracting Parties (in the course of transport of nuclear material), of the Contracting Party in whose territory the liable operator's installation is situated); and (viii) recognition and enforcement of final judgements rendered by the competent court in all Contracting Parties. Date of adoption:- 21 May 1963; place of adoption:- Vienna, Austria; date of entry into force:- 12 November 1977; Authentic Languages:- English, French, Russian and Spanish; and Depositary:- Director General of the International Atomic Energy Agency (IAEA). Protocol to Amend the Vienna Convention:- The Protocol aims at amending the Vienna Convention on Civil Liability for Nuclear Damage in order to provide for broader scope, increased amount of liability of the operator of a nuclear installation and enhanced means for securing adequate and equitable compensation. As between the Parties to the Protocol, the Vienna Convention and the Protocol are to be read and applied together as a single text and may be referred to as the '1997 Vienna Convention on Civil Liability for Nuclear Damage'. As requested by the Protocol, the IAEA Secretariat has established the consolidated text of the Vienna Convention as amended by the Protocol. All States, irrespective of whether or not they are Contracting Parties to the Vienna Convention, can consent to be bound by the Protocol. A State which is a Party to the Protocol but not a Party to the Vienna Convention shall be bound by the provisions of that Convention as amended by the Protocol in relation to other Contracting Parties to the Protocol. In addition, failing an expression of a different opinion at the time of deposit of an instrument expressing its consent to be bound, a State which is a Party to the Protocol but not a Party to the Vienna Convention shall also be bound by the provisions of the 1963 Vienna Convention in relation to States which are only Parties thereto. Date of adoption:- 12 September 1997; place of adoption:- Vienna, Austria; date of entry into force:- 04 October 2003; Authentic Languages: Arabic, Chinese, English, French, Russian, Spanish; and Depositary:- Director General of the International Atomic Energy Agency (IAEA). Optional Protocol Concerning the Compulsory Settlement of Disputes to the Vienna Convention:- Alongside the Vienna Convention, the 1963 International Conference also adopted an Optional Protocol concerning the Compulsory Settlement of Disputes. The Optional Protocol provides for the compulsory resolution of disputes arising out of the interpretation or application of the Vienna Convention by the International Court of Justice or, if the parties to the dispute agree, by arbitration or conciliation. The Optional Protocol is open to all

States which may become Parties to the Vienna Convention. Date of adoption:- 21 May 1963; place of adoption:- Vienna, Austria; date of entry into force:- 13 May 1999; Authentic Languages:- English, French, Russian, Spanish; and Depositary:- Director General of the International Atomic Energy Agency (IAEA). On 07 July 1992, the Republic of Slovenia had deposited a notification of succession to the Convention, with effect from 25 June 1991. On 09 November 2001, the Republic of Slovenia notified the Depositary of the termination of application of the Convention. Pursuant to Article XXV.2, the Convention ceased to apply to Slovenia as of 12 November 2002. The socialist Federal Republic of Yugoslavia had signed and ratified the Convention on 21 May 1963 and 12 August 1977, respectively. The Socialist Federal Republic of Yugoslavia had signed and ratified the Convention on 15 July 1980 and 14 May 1986, respectively. The Federal Republic of Yugoslavia (Serbia and Montenegro) had notified the Depositary of its succession to the Convention with effect from 27 April 1992. The Socialist Federal Republic of Yugoslavia (SFRY) had signed and ratified the Convention on 15 July 1980 and 14 May 1986, respectively. On 28 April 1992 the Federal Republic of Yugoslavia (Serbia and Montenegro) notified the Depositary inter alia that it intended to 'continue to fulfil all the rights conferred and obligations assumed by the SFRY in international relations, including = participation in international treaties ratified or acceded to by Yugoslavia'. Subsequently, on 05 February 2002 the Federal Republic of Yugoslavia deposited a notification of succession to the Convention, with effect from 27 April 1992. On 02 July 2006 the Republic of Serbia notified the Depositary that it intended 'to continue to exercise its rights and honour its commitments deriving from international treaties concluded by Serbia and Montenegro'. / Венская Конвенция 1963 о Гражданской Ответственности за Ядерный Ущерб, международная конвенция, принята на Международной Дипломатической Конференции по Гражданской Ответственности за Ядерный Ущерб (29 Апреля – 19 Мая 1963). Конвенция и факультативный протокол относительно осязательного урегулирования споров были открыты для подписания 21 Мая 1963. На 01 Октября 1969 конвенцию ратифицировали всего 8 стран (Югославия, Колумбия, Объединённая Арабская Республика (ОАР), Куба, Филиппины и другие). Бывший Союз Советских Социалистических Республик (СССР) подписал заключительный акт конференции и голосовал за принятие конвенции. В связи с тем, что ядерные объекты являются источниками повышенной опасности, конвенция предусматривает абсолютную ответственность за ядерный ущерб (то есть, ответственность за ядерный ущерб возникает независимо от наличия или отсутствия вины, причинения вреда). Устанавливается лишь одно исключение из этого общего правила:- оператор освобождается (частично или полностью) от возмещения ущерба, если ущерб возник вследствие тяжёлого стихийного бедствия исключительного характера (вооружённого конфликта, военных действий, гражданской войны или восстания, умысла или грубой неосторожности потерпевшей стороны). Конвенция исходит из принципа полного возмещения положительного ущерба в имуществе; лишь когда размер убытков превосходит сумму максимального предела возмещения, установленного конвенцией (5 миллионов Долларов США за каждый ядерный инцидент), компенсации подлежит только сумма в пределах установленного максимума. Предусмотрен 10-летний срок исковой давности; если ядерный ущерб причинён ядерным инцидентом, происшедшим с ядерным материалом во время его транспортировки и этот материал был похищен, утерян, выброшен или оставлен без присмотра, давностный срок увеличивается до 20 лет. Течение срока исковой давности начинается, как правило, со дня ядерного инцидента. В случае ядерного ущерба иски о возмещении ущерба рассматриваются только в той стране-участнице конвенции, в пределах территории которой произошёл ядерный инцидент.

VIENNA STOCK EXCHANGE = ВЕНСКАЯ ФОНДОВАЯ БИРЖА – Vienna Stock Exchange (VSX) is one of the world's oldest exchanges, which accounts for approximately 50% of Austrian stock transactions; the balance are traded OTC. See also Wiener Börse AG. Founded in 1771, Wiener Börse AG, the company that operates the Vienna Stock Exchange, is one of the oldest stock exchanges in the world. Today, it is a modern, customer and market-oriented company that plays a key role in the Austrian capital market. It is the driving force that contributes substantially to the further development of the local market. The Vienna Stock Exchange operates Austria's only securities exchange and also runs the Austrian power exchange EXAA under its license. It provides state-of-the-art infrastructure, market data and information to ensure the smooth and efficient execution of stock exchange transactions and facilitate the interaction among all market participants. The core business of the exchange is the operation of a cash market (equity market, bond market) as well as a market for trading in structured products. Additional services include data vending, index development and management, and specialized financial market seminars and training courses. The Basis of our Sustainable Success:- Values, Dialogue & CSR:- The highly qualified and motivated employees of the Vienna Stock Exchange are the foundation that makes it possible for the company to attain its corporate goals, with its work being guided by the values of prudence, transparency and trust. The Vienna Stock Exchange engages in a continuous dialogue with its stakeholders, and all its activities are oriented towards their needs. Corporate social responsibility is part of the Vienna Stock Exchange's business model. It has adopted a corporate social responsibility policy that covers the company and its employees, and also contributes to the environmentally-friendly, socially and economically sustainable development of Austria. / Вина Бёрзэ А.Ге. (Wiener Börse AG).

VIETNAMESE DONG = ВЬЕТНАМСКИЙ ДОНГ – Vietnamese Dong (VND) is the three-letter currency ISO code representing the currency of Vietnam which is commonly known as the Dong. . / Вьетнамский Донг – национальная валюта Социалистической Республики Вьетнам (обозначается знаком VND). Один Вьетнамский Донг равен 10 Хао и 100 Су. В обращении находятся банкноты номиналом 100, 200, 500, 1 000, 2 000, 5 000, 10 000, 20 000, 50 000, 100 000, 200 000 и 500 000 Вьетнамских Донгов; монеты номиналом 200, 500, 1 000, 2 000 и 5 000 Донгов. Разменные единицу Хао и Су вышли из обращения из-за инфляции ещё в 1980-е. Современный Вьетнамский Донг введён в обращение в 1978. Название 'Донг' изначально имело значение во Вьетнамском языке 'Медь' или 'Бронза', а в переносном смысле означало 'Деньги'. Это название денежная единица Вьетнама носила со Средневековья. В колониальный период денежной единицей во Вьетнаме служил Индокитайский Пиастр, введённый в обращение в 1886, которому предшествовал Кохинхинский Пиастр, имевший хождение на территории Южного Вьетнама, составлявшей Французскую Кохинхину. При этом в обращении оставались Донги в виде медных, бронзовых и цинковых монет. На территории Северного Вьетнама в 1947 национальной валютой был объявлен Донг, на территории Южного Вьетнама Донг стал национальной валютой с 1975. Индокитайский Пиастр обменивался на Донг в Северном Вьетнаме по курсу 1:1. В Южном Вьетнаме в 1955 была введена в обращение новая денежная единица – Южно-Вьетнамский Пиастр, которую обменивали на Индокитайские Пиастры по курсу 1:1. Индокитайский Пиастр был привязан к Французскому Франку:- с 1945 по 1953 соотношение составляло 1:17, с 1953 года и до выхода из обращения – 10:1. При этом Индокитайские Пиастры оставались в обращении на территории Северного Вьетнама до 1954, а на территории Южного Вьетнама – до 1957. В Северном Вьетнаме в 1951 была проведена деноминация по курсу 10:1, затем в 1959 была проведена деноминация по курсу 10 000:1. В 1978 после объединения Северного и Южного Вьетнама, был введён обращение новый, общий Донг:- обмен Донга Северного Вьетнама производился по курсу 1:1, обмен Донга Южного Вьетнама производился по курсу 10:8. В 1985 в СРВ была проведена деноминация по курсу 10:1. С 1991 курс Вьетнамского Донга стал плавающим и в первый же год девальвировался к Доллару Соединённых Штатов Америки (США) более чем вдвое:- от соотношения 5 555:1 до соотношения 12 000:1. До 2009 темпы роста девальвации Вьетнамского Донга были относительно невысоки:- на 01 Января 2009 соотношение Вьетнамского Донга к Доллару США составило 16 749:1. Затем темпы роста инфляции начали ускоряться.

Исторический минимум вВьетнамского Донга зафиксирован 02 Января 2019:- соотношение к Доллару США составило 23 448:1. С 2003 Вьетнам сменил хлопковые банкноты на синтетические полимерные банкноты для повышения износостойкости.

VIEW = VISIBILITY INVESTIGATIVE EXPERIMENT IN THE WEST

VIEWDATA = ВЬЮДЭЙТА (или ВЬЮДАТЭ, или СМОТРОВЫЕ ДАННЫЕ) – Viewdata is a trademark an interactive form of Videotex that sends information from a distant computer along telephone lines, enabling shopping, booking theatre and airline tickets, and banking transactions to be conducted from the home. Viewdata is a Videotex system usually employing telephone lines. Viewdata is a system by which information can be stored at a central point and retrieved by the use of a telephone line linked toword processors. It enables the user to call up thousands of pages of information. Viewdata is a news and information service in which computer data is sent by a telephone link and displayed on a monitor. / Вьюдэйта:- система Видеотэкс (Videotex), в которой информация посылается отдалённым компьютерам по каналам телефонной связи или по кабелям. Информация поступает на экран телевизора. Система Вьюдэйта даёт огромный поток общей информации, например, прогнозы погоды, новости, биржевые курсы и информацию о путешествиях, а также позволяет получить доступ к специализированным базам данных, содержащим медицинскую информацию для докторов, правовую информацию длч юристов и данные, необходимые агентам бюро путешествий. Кроме того, система даёт возможность своим пользователям сделать покупки, не выходя из дома, заказать билеты в театр и управлять своим банковским счётом из дома. Смотрите также Прэстэл (Prestel).

VIEWING CONDITIONS = УСЛОВИЯ НАБЛЮДЕНИЯ – Viewing Conditions are the conditions under which a visual observation is made, including the angular subtense of the specimen at the eye, the geometric relationship of light source, specimen, and eye, the photometric and spectral character of the light source, the photometric and spectral character of the field of view surrounding the specimen, and the state of adaptation of the eye.

VIEW TO RESALE = ВЗГЛЯД НА ПЕРЕПРОДАЖУ – View To Resale:- xxxxx. / Взгляд На Перепродажу – намерение перепродать.

VIGINTILLION = ВИГИНТИЛЛИОН – Vigintillion is a unit of quantity equal to 10^{63} (1 followed by 63 zeros).

VIGNETTE = ВИНЬЭТ (или ВИНЬЕТКА) – Vignette is a symbol or pictorial representation of the corporation on a stock certificate. Usually a complicated and artistic design, it is meant to make the counterfeiting of stock certificates as difficult as possible.

VIGOR = ЖИЗНЕННОСТЬ (или СИЛА, или МОЩНОСТЬ, или ЭНЕРГИЯ) – Vigor is:- (i) for plants:- to have active, healthy, well-balanced growth; and (ii) for seeds:- the capacity for natural growth and survival. See also Heterosis. / Жизненность в фитоценологии, мера соответствия условий данного биоценоза потребностям изучаемой популяции Растений. Критериями жизненности могут служить:- способность особей Вида проходить в данных условиях полный цикл развития, сроки созревания репродуктивных органов, величина годичного прироста, оптимальная численность особей и тому подобное. Обычно жизненность квалифицируют, пользуясь шкалами в три–пять баллов. Имеются попытки оценивать жизненность популяции путём определения жизненности отдельных особей с последующим выведением среднего балла. В этом случае основой для оценки жизненности служит интенсивность жизнепроявлений особи, выражающаяся объёмом или массой тела, энергией роста и прочим. Энергия прорастания семян, способность семян сельскохозяйственных культур к быстрому дружному прорастанию. Определяется одновременно со всхожестью (смотрите Семенной Контроль) числом проросших семян (в %) в течение определённого для каждой культуры срока, например, для полевых растений 3–5 суток.

VIGOR INDEX = ИНДЕКС ПО ЖИЗНЕННОСТИ – Vigor Index is a measure of early-season growth of Cotton Plants, typically by evaluating plant height over time, or plant height in relation to the number of main-stem nodes, e.g., height-tonode ratio. Other parameters used in assessing vigor index include elongation rate (change in height occurring between two sample dates divided by change in number of main-stem nodes), and length of the uppermost five main-stem nodes. These parameters are attempts to determine the rate of growth of the most recently developed nodes.

VILLOUS = ВОРСИНЧАТОЕ (или ВОЛОСИСТОЕ) – Villous:- bearing long and soft, usually curved or curly, hairs. Villous:- with long soft hairs. Villous (buds, leaf lower surface, leaf upper surface, phyllaries, sepals, young twigs) (pubescence type):- with slender curved or wavy, but not matted hairs.

VIN = VEHICLE IDENTIFICATION NUMBER

VINACEOUS = ВИННОЕ (или БОРДОВОЕ, или ВИННО–КРАСНОЕ, или ХХ) – Vinaceous:- of the color wine, or a dark red.

VINAL FIBER = ВИНАЛОВОЕ ВОЛОКНО (или ВОЛОКНО ВИНАЛ) – Vinal Fiber is a manufactured fiber in which the fiber forming substance is any long-chain synthetic polymer composed of at least 50% by weight of vinyl alcohol units, (–CH2CH(OH)–)X, and in which the total of the vinyl alcohol units and any one or more of the various acetal units is at least 85% by weight of the fiber. Vinal fibers show good chemical resistance but soften at comparatively low temperatures. Vinal fibers are used for apparel, industrial goods, and fishnets. Characteristics And Vinal Fiber Uses:- Vinal fibers soften at low temperatures but have high resistance to chemicals. This makes them suitable for certain industrial uses. In some countries other than the United States, vinal fibers are referred to as polyvinyl alcohol fibers. Vinal fiber is not produced in the United States. Vinal is the generic name for a man-made fiber derived from polyvinal alcohol. Vinal fibers soften at low temperatures, but resist chemicals. Although vinal is no longer made in the United States, it is made in Japan and is found in tires, some home furnishings, and industrial products. Vinal Fiber is manufactured fiber in which the fiber-forming substance is any long chain synthetic polymer composed of at least 50% by weight of vinyl alcohol units and in which the total of the vinyl alcohol units and any one or more of the various acetal units is at least 85% by weight of the fiber. Polyvinyl alcohol (PVOH) was first made in Germany in 1924 and, in 1931 it was sold as Synthofil, a water-soluble fiber. In 1939, a formaldehyde treatment process was developed to make the vinal fibers insoluble. The fibers are very flexible, durable and have a high tensile strength. Most commercially available vinal fibers are made in Japan. Vinal is used primarily for raincoats, jackets, umbrellas, tarpaulins, fishnets, and awnings. Synonyms and Related Terms:- Vinal Fibre; Poly(Vinyl Alcohol) Fibers; Polyvinyl Alcohol Fibers; Polyvinyl Alcohol Fibre; Vinylon; Synthofil (Wacker Chemie); Kuravilon (Kurashiki Rayon); Mewlon (Nichibo); Sovron; Vilon; Vinol; Vinylal; Cremona; Fibras Vinal (Esp.). Other Properties:- Good chemical resistance. Attacked by formic acid, phenol, cresol and hydrogen peroxide. Resistant to microorganisms and insects. Fibers are smooth. Cross section = round, bean-shaped or u-shaped. Tenacity = 3.0–8.5 g/denier (dry); 3.2–7.6 (wet); Elongation = 9–26 (dry); 10-27 (wet); Moisture regain = 3.0–9.0%. Melting Point:- 220–230. Density:- 1.26–1.30. Nonflammable. / Синтофиль (Synthofil; Вака Хеми (Wacker Chemie)); Куравилон (Kuravilon; Куращики Рэйон (Kurashiki Rayon)); Мьюлон (Mewlon; Ничибо (Nichibo)); . Найлан^{TЗ} (Nylon^{TM}).

VINDICATION = ВИНДИКАЦИЯ (или ВИНДИКАЦИОННЫЙ ИСК) – Vindication is:- (1) the act of vindicating or the condition of being vindicated; (2) the defense, such as evidence or argument, that serves to justify a claim or deed; (3) a means of exoneration from an accusation; and (4) a fact, evidence, circumstance, etc, that serves to vindicate a theory or claim. / Под Виндикацией, от

Латинского слова Vindicatio, от Vindico, означающее Защищаю или Заявляю Претензию или Требую, или Виндикационным Иском, в гражданском праве понимается способ защиты собственности, с помощью которого собственник может истребовать своё имущество из чужого незаконного владения. Эта форма иска сложилась ещё в Римском праве. В бывшем Союзе Советских Социалистических Республик (СССР) виндикация регламентировалась Статьёй 28 Основ Гражданского Законодательства Союза ССР и Союзных республик 1961, Ст. 151–155 ГК РСФСР и аналогичными статьями ГК других Союзных республик. Собственник может виндицировать своё имущество от недобросовестного, а если имущество приобретено безвозмездно, то и от добросовестного приобретателя независимо от того, каким путём оно вышло из его владения. От добросовестного приобретателя, который возмездно приобрёл имущество, оно может быть истребовано лишь в случае, если было утеряно собственником или лицом, которому сам собственник передал это имущество во владение (например, во временное пользование), похищено у того или другого, либо выбыло из их владения каким-либо иным путём, но помимо их воли. Это ограничение распространяется только на виндикацию личной собственности; государственное имущество, а также имущество колхозов и иных кооперативных и общественных организаций может быть истребовано от любых приобретателей. Деньги и ценные бумаги на предъявителя подлежат виндикации во всех случаях только от недобросовестного приобретателя. Собственник вправе потребовать возврата не только имущества, но и возмещения доходов, которые незаконный владелец извлёк или должен был извлечь за всё время владения (если владелец недобросовестный) или со времени, когда он узнал или должен был узнать о неправомерности владения (если владелец добросовестный). В свою очередь владелец имущества вправе требовать от собственника возмещения произведённых им необходимых затрат на содержание имущества с того времени, с какого собственнику причитаются доходы от этого имущества. Аналогичным образом в основном регламентируется виндикация и в большинстве других социалистических стран. В буржуазных странах континентальной Европы, реципировавших Римское право, виндикация имеет только известное внешнее сходство с виндикацией в социалистическом праве, отличаясь от неё своим социально-экономическим содержанием. В праве Великобритании и большинства штатов США понятие Виндикационного Иска отсутствует.

VINE = ЛОЗА (или ВЬЮЩЕЕСЯ, или ПЛЕТЬ) – Vine is a plant with a weak trailing stem which relies on other plants or structures for vertical support. Vine (plants) (habit):- a perennial plant with long woody or herbaceous stems that are flexible (at least initially), and are supported by other plants or structures, or that trail across the ground. / Виноград (Vitis) . Под Лозой понимается удлинённый гибкий стебель (вызревший побег) или ветвь некоторых кустарников, преимущественно Винограда, Ивы. Лозой также иногда называется всё растение Винограда, что неправильно. Лоза:- (1) кустарники или небольшие деревья Рода Ива с гибкими, хлыстовидными побегами. (2) Удлинённый гибкий стебель (побег) или ветвь некоторых кустарников, преимущественно Ивы или Винограда. Плети у растений, стелющиеся по земле, иногда укореняющиеся, травянистые побеги, например, у Тыквы, Арбуза, Огурца. Плети отличаются от столонов более короткими междоузлиями. Под Плетьми понимаются стелющиеся по земле стебли растений с короткими междоузлиями; специализированные органы вегетативного размножения, например, Арбуза, Огурца, Тыквы. Плети, как правило, несут листья обычной срединной формации; в каждом узле формируются придаточные корни. К концу вегетационного периода или после перезимовки стеблевая часть плети, в противоположность усам, может не отмирать, и в этом случае часто трудно определить границу особи.

VINEGAR = УКСУС – Vinegar is a sour liquid that is made by the fermentation of any of numerous dilute alcoholic liquids into a liquid containing acetic acid. Vinegar may be produced from a variety of materials:- apples or grapes (wine or cider vinegar); malted barley or oats (malt vinegar); and industrial alcohol (distilled white vinegar). There are also vinegars made from beer, sugars, rice, and other substances. As a commercial product, however, vinegar was probably first made from wine (French Vin, ‘Wine’; Aigre, ‘Sour’). Vinegar can be made from any liquid that is capable of being converted into alcohol in a two-step process. The fruit juice or other liquid contains sugar, which is converted into alcohol and carbon dioxide gas by the actions of yeast enzymes. The alcohol thus formed combines with atmospheric oxygen by the action of Acetobacter bacteria, forming acetic acid and water. Organic acids and esters derived from the fruit or other source material are also present and are responsible for the flavour and aroma variations of vinegar. Table vinegar contains approximately 4 percent acetic acid. In 1864 the French physicist Louis Pasteur showed that it is Acetobacter Bacteria that cause the conversion of alcohol to acetic acid. These bacteria work together symbiotically, producing enough acetic acid to prevent invasion by other organisms. Despite its ancient origin, the technology of vinegar production advanced slowly, improvements consisting principally of better methods of aeration. The Orleans process, best-known of the old methods, used a barrel of about 50 gallons (200 l) capacity. A mash consisting of wine or other alcoholic liquid was poured into the barrel, and a small amount of vinegar containing a mass of vinegar bacteria, called Mother Of Vinegar, was added to start the reaction. One or two small air holes drilled above the liquid level exposed the surface to aeration. The finished vinegar was drawn off through a wooden spigot near the bottom. Care was taken in refilling the barrel with the new charge of raw ingredients to avoid breaking up the surface film of bacteria. Early in the XVIII century, a Dutch technologist, Hermann Boerhaave, found that the rate of acid production in the vinegar process was directly proportional to the amount of surface exposed to air. Thus, subsequent methods attempted to introduce more air into the casks. In the XX century, continuous aeration – air bubbles pumped through the mash – was developed. Vinegar’s principal uses are the flavouring of foods and the preservation, or pickling, of meat products, fish, fruit, and vegetables. For use as a condiment, vinegar is often flavoured with garlic, onions, tarragon, or other herbs and spices. Mixed with oil and seasonings it becomes a classic cold sauce – vinaigrette – used as a dressing on vegetable salads and served as a sauce with cold cooked vegetables, meats, and fish. Vinegar is also a common ingredient in marinades and is widely used in the pickling of cucumbers and other vegetables. Vinegar is a dilute acetic acid, typically around 5%. Vinegar is a convenient acid for many dyeing processes, although a lot may be required because it is so dilute. Much of the white vinegar sold is made by diluting concentrated acetic acid produced by synthesis from natural gas. Vinegar diluted with 10 parts of water will give a pH of around 4.2. / В 1864 Французский физик Люи Пастэр (Louis Pasteur). Датский технолог Хэрман Бурхафэ (Hermann Boerhaave). Под Уксусом понимается столовый уксус – водный раствор (3–15%) пищевой уксусной кислоты. В промышленности готовят разбавлением водой уксусной эссенции. Применяется при изготовлении консервов, маринадов, приправ.

VINIFERA = ВИНИФЭРА – Vinifera:- Grapevine Species of European origin. Members of this Species are known for their ability to produce the finest grapes for wine. Also Vitis Vinifera. / Смотрите также Витис Винифэра (Vitis Vinifera).

VINYL = ВИНИЛ (или ВИНИЛОВОЕ) – Vinyl:- any fabric made with a base of vinyl, including those listed as vinal and vinyon. The term usually is used to refer to thick fabrics coated with a vinyl-based coating used for such purposes as upholstery and raincoats. Vinyl is a univalent radical, (CH_2=$CH_–$), derived from ethylene. Vinyl (Naugahyde) is a durable, leather-like, synthetic material made from polyvinyl chloride (PVC). It will endure many conditions and therefore is a preferred upholstery fabric for boat cushions, car interiors and porch furniture.

VINYL ACETATE = ВИНИЛАЦЕТАТ – Vinyl Acetate is an organic compound with the formula $CH_3CO_2CH=CH_2$. This colorless liquid is the precursor to polyvinyl acetate, an important industrial polymer. Vinyl Acetate is a colorless, liquid organic compound, the polymer of which is polyvinyl acetate. Vinyl Acetate is primarily used as a monomer in the production of polyvinyl acetate and polyvinyl alcohol.

Acute (short-term) inhalation exposure of workers to vinyl acetatehas resulted in eye irritation and upper respiratory tract irritation. Chronic (long-term) occupational exposure did not result in any severe adverse effects in workers; some instances of upper respiratory tract irritation, cough, and/or hoarseness were reported. Nasal epithelial lesions and irritation and inflammation of the respiratory tract were observed in mice and rats chronically exposed by inhalation. No information is available on the reproductive, developmental, or carcinogenic effects of vinyl acetate in humans. An increased incidence of nasal cavity tumors has been observed in rats exposed by inhalation. In one drinking water study, an increased incidence of tumors was reported in rats. The US EPA (short for the Environmental Protection Agency) has not classified vinyl acetate for carcinogenicity. Vinyl Acetate is a clear colorless liquid. Flash point 18 °F. Density 7.8 lb/gal. Slightly soluble in water. Vapors are heavier than air. Vapors irritate the eyes and respiratory system. May polymerize if heated or contaminated. If polymerization occurs inside a container, the container may violently rupture. Used to make adhesives, paints, and plastics. / Винилацетат, виниловый эфир уксусной кислоты, CH_2 = CHOCO CH_3, бесцветная жидкость со слабым слезоточивым действием; tкип 73 °C, tпл –84 °C, плотность при 20 °C 0.934 г/см^3. Винилацетат ограниченно растворим в воде (2.5%), в органических растворителях – хорошо. Винилацетат легко полимеризуется и сополимеризуется с другими винильными производными. Винилацетат получают винилированием уксусной кислоты ацетиленом в присутствии катализаторов:- CH ° CH + $HOCOCH_3$ ® CH_2 = CH–$OCOCH_3$. Полимеры и сополимеры винилацетата широко применяют для приготовления клеев, лаков, пропиток, плиток для полов, патефонных пластинок и другого. Продукт полимеризации винилацетата – поливинилацетат – служит исходным сырьём для получения поливинилового спирта.

VINYLAL = ВИНИЛАЛЬНОЕ (или ВИНИЛОВОЕ) – Vinylal:- a term used to describe fibers composed of synthetic linear macromolecules of polyethenol (poly vinyl alcohol) with different levels of acetalization. Vinylal is a synthetic fiber. Alphabetic code – PVAL; and relevant commercial allowance – 5.00 (refers to European Union Directives on Textile Labelling). / поливинилового спирта .

VINYL CHLORIDE = ВИНИЛ ХЛОРИД (или ХЛОРИСТЫЙ ВИНИЛ) – Vinyl Chloride:- also called Chloroethylene a colorless, flammable, toxic gas belonging to the family of organic halogen compounds, and used principally in making polyvinyl chloride, an important synthetic resin. Vinyl chloride was first prepared in 1835 by the reaction of ethylene chloride with caustic potash; its slow transformation into a flaky solid when exposed to sunlight also was noted but not recognized as polymerization until many years later. An industrial process for making vinyl chloride from acetylene and hydrogen chloride in the presence of mercury(II) chloride was discovered early in the XX century, but commercial production was not begun until World War II, when substitutes for natural rubber were required. The process based on acetylene has remained important in Europe, but in the United States vinyl chloride is commonly manufactured from ethylene chloride, either by heating it to temperatures of 480–510 °C (900–950 °F) or by treating it with a dilute solution of caustic soda. Its chemical properties are similar to those of olefins, but, apart from its conversion to polymers, its only important reaction is that with hypochlorous acid, forming chloroacetaldehyde, which is used in making pharmaceuticals such as sulfathiazole. Prolonged exposure of humans and laboratory animals to vinyl chloride vapor has been linked to several forms of cancer. Vinyl Chloride is a chemical compound, used in producing some plastics, that is believed to be carcinogenic. / Винилхлорид или Хлористый Винил, CH_2 = CHCl; бесцветный газ со слабым запахом, напоминающим запах хлороформа; $t_{кип}$ –13.8 °C; $t_{пл}$ –153.8 °C, плотность при –15 °C 0.973 0 г/см^3. Винилхлорид плохо растворим в воде, в органических растворителях – хорошо; пределы взрываемости винилхлорида в смеси с воздухом 4–22% (по объёму). По двойной связи к винилхлориду легко присоединяются галогены, галогеноводороды и другие. Винилхлорид полимеризуется и сополимеризуется с винилиденхлоридом, винилацетатом и другими. В промышленности винилхлорид получают парофазным (реже жидкофазным) гидрохлорированием ацетилена в присутствии $HgCl_2$ на угле или дегидрохлорированием дихлорэтана. Полученный продукт, содержащий не менее 99% винилхлорида, самопроизвольно не полимеризуется. Винилхлорид широко применяют для производства поливинилхлорида и сополимеров с другими винильными соединениями – важных материалов, находящих применение в самых различных отраслях промышленности.

VINYL COMPOUND = ВИНИЛЬНОЕ СОЕДИНЕНИЕ (или ВИНИЛОВОЕ СОЕДИНЕНИЕ) – Vinyl Compound is any of various organic chemical compounds, including acrylic compounds and styrene and its derivatives, that are useful in making plastic film; sheeting; upholstery; floor tile; inflatable and solid toys; buttons; molded and extruded articles; fibers for weaving into fabric; insulation for wire; screening; tubing, especially for chemicals; substitutes for rubber; and components of water-base paints and textile finishes. Vinyl compounds contain the hydrocarbon vinyl group (CH_2=CH–). The molecules of a single vinyl compound can be made to polymerize; that is, to join end to end, forming a polyvinyl compound such as polyvinyl chloride. The molecules of two different compounds can also be made to link up, forming a copolymer, such as the plastic Vinylite and the textile fiber vinyon. See also Polyvinyl Acetate; Polyvinyl Alcohol; Polyvinyl Chloride; Vinyl Chloride; and Vinylidene Chloride.

VINYL FIBER = ВИНИЛОВОЕ ВОЛОКНО – Vinyl Fiber is a man made artificial fiber. Vinyl fibers are those man-made fibers spun from polymers or copolymers of substituted vinyl monomers and include vinylon, vinyl, vinylon-vinyl matrix (Polychlal), saran, and polytetrafluoroethylene fibers. The vinyl fibers are generally specialty fibers due to their unique properties and use. All of these fibers have a polyethylene hydrocarbon backbone with substituted functional groups that determine the basic physical and chemical properties of the fiber. / Найлан^{T3} (Nylon^{TM}).

VINYL FLUORIDE = ВИНИЛ ФТОРИД (или ФТОРИСТЫЙ ВИНИЛ) – Vinyl Fluoride:- also called Fluoroethylene a colorless, flammable, nontoxic, chemically stable gas belonging to the family of organic halogen compounds and used as the starting material in making polyvinyl fluoride, a plastic used in films for coating structural materials. Vinyl fluoride, first prepared in 1901, is manufactured by the reaction between acetylene and hydrogen fluoride. / Винил Фторид (C_2H_3F; молекулярная масса:- 46.1) – бесцветный сжатый сжиженный газ с характерным запахом. Физическая Опасность:- пар тяжелее воздуха и может стелиться по земле; возможно возгорание на расстоянии. Химическая Опасность:- вещество может полимеризоваться свободно. Вещество разлагается при разогреве и при сжигании с образованием токсичных газов (фтористого водорода). При утечке содержимого очень быстро достигается опасная концентрация этого газа в воздухе. Вещество может всасываться в организм при вдыхании. Жидкость может вызвать обморожение. Воздействие может вызвать потерю сознания. Вещество, вероятно, канцерогенно для человека. Температура кипения:- –72 °C. Температура плавления:- –161 °C. Растворимость в воде:- нерастворимо. Относительная плотность пара (воздух = 1):- 1.6. Температура вспышки:- Горючий газ. Температура самовоспламенения:- 385 °C. Пределы взрываемости, объём% в воздухе:- 2.6–21.7.

VINYLIDENE CHLORIDE = ВИНИЛИДЕН ХЛОРИД (или ХЛОРИСТЫЙ ВИНИЛИДЕН) – Vinylidene Chloride:- also called 1,1-Dichloroethylene a colorless, dense, toxic, volatile, flammable liquid belonging to the family of organic halogen compounds, used principally in combination with vinyl chloride, acrylonitrile, or methyl methacrylate for the manufacture of a class of plastics called saran. Vinylidene chloride is also used as a starting material for making methylchloroform, or 1,1,1-trichloroethane, a solvent useful in cleaning electrical machinery. Vinylidene chloride is produced by the reaction of 1,1,2-trichloroethane (itself derived from acetylene or ethylene) with lime or with caustic soda; it usually is prepared only as it is needed because it is rapidly attacked by oxygen to form

peroxides that catalyze the formation of undesired polymers. Vinylidene Chloride is a chemical material obtained from ethylene, a petroleum product, and from chlorine. It is used for the manufacture of textile monofilaments and film. It is more commonly identified in the United States as Saran. See also Saran Fiber. / мононить (monofilament). Под Винилиден Хлоридом или Хлористым Винилиденом, $H_2C=CCl_2$, понимается бесцветная жидкость, $t_{кип}$ 31.7 °C. Применяется главным образом для получения поливинилиденхлорида и сополимеров винилиденхлорида, например, с винилхлоридом, акрилонитрилом. Винилиденхлорид или Хлористый Винилиден, 1,1-дихлорэтилен, $CH_2=CCl_2$; бесцветная жидкость с запахом, напоминающим запах хлороформа:- $t_{кип}$ 31.7 °C, плотность при 20 °C 1.212 г/см^3; пределы взрываемости винилиденхлорида в смеси с воздухом 7–16% по объёму. На воздухе винилиденхлорид самопроизвольно полимеризуется; поэтому его хранят в присутствии ингибиторов, например, гидрохинона. Винилиденхлорид получают дегидрохлорированием 1,1,2-трихлорэтана (~100 °C):- $2CH_2Cl – CHCl_2 + Ca(OH)_2$ ® $2CH_2 = CCl_2 + CaCl_2 + 2H_2O$. Применяют винилиденхлорид для получения поливинилиденхлорида и сополимеров с винилхлоридом, акрилонитрилом и других технически важных сополимеров.

VINYL SULFONE = ВИНИЛ СУЛЬФОН (или ВИНИЛ СУЛЬФОНОВЫЙ) – Vinyl Sulfone (or Sulphone) is a of reactive dyes, generally used for cellulosic fibers but with some use for wool. Vinyl sulfone reactive dyes are intermediate in reactivity, so they are applied above room temperature, but well below the boiling point of water. They are quite non-reactive until exposed to alkaline pH, so they can be stored as solutions for much longer periods than highly reactive dyes like MX. Washfastness may be somewhat inferior to some other reactive dyes. Vinyl sulfone dyes can be a good choice for dyeing the background color for discharge, since they are quite easy to discharge with reducing agents. There are also simple chemical resists, that work well with these dyes, preventing fixation to the fiber, so they find application in printing processes. Remazol® is a popular brand name. / Щелочное (Alkaline). Винил Сульфоновый Краситель (Vinyl Sulfone Dye или vinyl Sulphone Dye). Римэзол® (Remazol®).

VINYON FIBER = ВИНЬОНОВОЕ ВОЛОКНО (или ВОЛОКНО ВИНЬОН) – Vinyon Fiber:- (i) first US commercial Vinyon fiber production:- 1939, FMC Corporation, Fiber Division (formerly American Viscose); (ii) Federal Trade Commission definition for Vinyon Fiber:- a manufactured fiber in which the fiber forming substance is any long-chain synthetic polymer composed of at least 85% weight of vinyl chloride units $(–CH_2CHCl–)_X$; (iii) characteristics and Vinyon Fiber uses:- vinyon fibers soften at low temperatures but have high resistance to chemicals. They are most commonly used in industrial applications as a bonding agent for non-woven fabrics and products. (iv) In some countries other than the United States, vinyon fibers are referred to as Polyvinyl Chloride Fibers. Vinyon Fiber is a manufactured fiber in which the fiber-forming substance is any long chain synthetic polymer composed of at least 85% by weight of vinyl chloride units. Vinyon is the generic name for a man-made fiber derived from polyvinyl chloride, a derivative of natural salt, water, and petroleum. Vinyon fibers soften at low temperatures and resist chemicals. Vinyon is often referred to as Polyvinyl Chloride. Its primary use is in commercial products. / Виньон – общее торговое название группы синтетических волокон.

VIOLACEA = ФИАЛКОВОЕ (или ФИОЛЕТОВОЕ) – Violacea:- violet colored. / Фиалковое:- фиолетового окраса.

VIOLACEOUS = ФИАЛКОВОЕ (или ФИОЛЕТОВОЕ) – Violaceous:- of the color violet.

VIOLATION OF A TRENDLINE = НАРУШЕНИЕ ЛИНИИ ТЕНДЕНЦИИ – Violation Of A Trendline:- when a currency trades below an uptrend line or above a downtrend line. / В техническом анализе биржевых рынов Нарушение Линии Тенденции проявляется в тех случаях, когда актив или инструмент начинает торговаться соответственно ниже или выше линии тенденции.

VIOLATION SHORT SALE = НАРУШЕНИЕ ПРОДАЖЕЙ ВКОРОТКУЮ – Violation Short Sale:- xxxxx. FINRA® = Financial Industry Regulatory Authority. Short Sale Violations (in NASD FINRA Rules 7230A and 7330, and Regulation SHO):- Principal Considerations in Determining Sanctions:- See Principal Considerations in Introductory Section. While respondents are responsible for the systems that they use and the third-party vendors that they employ, the appropriate level of sanctions will depend on whether the respondent diligently chose, installed, and tested a system that nevertheless malfunctioned; the frequency and thoroughness with which the respondent ensured that the system was operating in compliance with applicable rules; and the care that the respondent exercised in undertaking all necessary steps to correct systems-related malfunctions. The same considerations apply to a respondent that has relied on a third-party vendor's products or services. Monetary Sanction*:- First Action**:- Fine of USD5 000 to USD15 000. Second Action Fine of USD10 000 to USD73 000. Subsequent Actions Fine of USD10 000 to USD146 000***. In all egregious cases, whether a first, second or subsequent action, consider a fine greater than or equal to the high end of the range for a first, second or subsequent action. Also consider imposing the fine on a 'per violation' basis. (Notes:- * In cases in which the violations:- (1) involve a pattern or patterns of misconduct; (2) can be quantified by number or percentage; or (3) can be compared to the standard maintained by industry peers, Adjudicators may consider deviating from the fine structure recommended in this guideline for first, second, or subsequent actions. Imposition of monetary sanctions greater than those recommended in this guideline may be particularly appropriate in cases involving violations that occurred during two or more examination or review periods or violations that occurred over an extended period of time. Similarly, in cases in which the respondent acted intentionally or recklessly, and in cases in which the respondent's compliance rate is significantly lower than its peers, Adjudicators may impose a monetary sanction in excess of the recommended range. ** Adjudicators should consider actions concerning violative events that occurred within the three years prior to the misconduct at issue. Events that are more recent in time, however, should be given more weight than less recent events. *** If respondent's second or subsequent action involves a violation that is less serious than a prior violation, includes conduct that demonstrates that respondent is improving its compliance rate, or involves mitigation that did not exist in a prior action, Adjudicators may consider imposing a fine that is less than the fine imposed in the prior action.) Suspension, Bar or Other Sanctions:- If the short-selling customer is not subject to FINRA jurisdiction, in egregious cases or those with evidence of willful misconduct, consider adding the amount of the short-selling customer's 'transaction profit' to the fine for the executing member or associated person. In egregious cases, consider suspending the firm with respect to any or all relevant activities or functions or suspending the responsible individual in any or all capacities for up to two years or expelling the firm or barring the responsible individual. ('Transaction Profit' means the profit that the short-selling customer realized. This amount is separate and distinct from the respondent's financial benefit, as described in General Principle No. 6.). / Нарушение Продажей Вкороткую – запрещённая короткая продажа – торговец может получить такое сообщение в окне системы ввода распоряжений. Появляется оно в ситуации, когда торговец попытался осуществить короткую продажу акций по цене 'один тик вниз', что противоречит правилам NASD (National Association of Securities Dealers). Распоряжение немедленно автоматически отменяется.

VIOLET = ФИОЛЕТОВОЕ (или ЛИЛОВОЕ) – Violet:- any of a group of colors of reddish blue hue, low lightness, and medium saturation.

VIP = VERY IMPORTANT PERSON

VIP = VOLUME INCENTIVE PROGRAMME

VIP COTTON = ХЛОПЧАТНИК ВИ.АЙ.ПИ. (или ХЛОПЧАТНИК ВИБ) – VIP (short for the Vegetative Insecticidal Protein) Cotton is an alternate to Bollgard® and Bollgard II® that has been developed by Syngenta to control insects. Although the VIP protein (exotoxin)

is derived from the same soil bacterium as the Bollgard® genes, it is structurally, functionally and biochemically different than Bt d-endotoxins. The VIP protein is expressed in the entire Cotton plant, including the floral parts, to provide protection against target species. When pest larvae feed on VIP Cotton, the protein is ingested and causes the larvae to stop feeding and die. VIP Cotton is a Cotton variety that has been genetically altered to express an endotoxin that is produced during the vegetative stage of bacterial growth (Vip3A protein) and is effective against a wide spectrum of caterpillar pests. These varieties offer enhanced bollworm control, compared to Bollgard®, but low activity against the European Corn Borer. The VIP Cotton is an alternate technology to control insects that are controlled by Bollgard® or Bollgard II®. The difference is that the VIP Cotton contains a vegetative insecticidal protein (VIP) that controls target insects through a novel mode of action. The Syngenta Group Company discovered the VIP protein in 1994. The VIP protein is an exotoxin, but still derived from the same soil bacterium Bacillus Thuringiensis (BT). As an exotoxin, the VIP protein is structurally, functionally and biochemically different than Bt d-endotoxins. The VIP protein is expressed in the entire Cotton plant, including the floral parts, to provide protection against the target species. When pest larvae feed on VIP Cotton, the protein is ingested and causes the larvae to stop feeding and die soon. / Болгард® (Bollgard®). виды (species). Синьгеньта Груп Кампэни (Syngenta Group Company). Бациллус Туринги энсис.

VIP3A COTTON = ХЛОПЧАТНИК ВИ.АЙ.ПИ.СРИ.ЭЙ. (или ХЛОПЧАТНИК ВИБЗА) – VIP3A Cotton:- one of three proteins produced in Bollgard 3 Cotton plants that is derived from a common soil Bacterium and that is toxic to specific insects.

VIPERINA = ЗМЕИНОЕ (или ЗМЕЕОБРАЗНОЕ, или ВИПЕРИНА) – Viperina:- snake-like. The Viperinae or Viperines, are a subfamily of venomous vipers endemic to Europe, Asia and Africa. They are distinguished by their lack of the heat-sensing pit organs that characterize their sister group, the Subfamily Crotalinae. / Виперы – Семейство Змей; то же, что Гадюки.

VIRAL = ВИРУСНОЕ – (1) Viral:- of, relating to, or caused by a virus.

(2) Viral:- self-propagating practice or pattern of Internet use that moves from person to person. Works best in consumer e-commerce because of easy adoption. Longer sales cycle for b2b e-commerce makes viral practices less important. Example:- HotMail's explosive growth. / Вирусное:- .

VIRAL AGENT = ВИРУСНЫЙ АГЕНТ – Viral Agent:- an agent that is know to cause particular diseases, which may be used for example as a biological warfare agent. See also Disease Agent. Viral Agents As Biological Weapons And Agents Of Bioterrorism:- Multiple viral agents have been classified by the CDC as potential weapons of mass destruction or agents for biologic terrorism. Agents such as smallpox, viral hemorrhagic fever viruses, agents of viral encephalitis, and others are of concern because they are highly infectious and relatively easy to produce. Although dispersion might be difficult, the risk is magnified by the fact that large populations are susceptible to these agents and only limited treatment and vaccination strategies exist. Although the risk of large-scale bioterrorism using viral agents is small, public health programs and health care providers must be prepared for this potentially devastating impact on public health. / Вирусный Агент:- .

VIRAL ENCEPHALITIS = ВИРУСНЫЙ ЭНЦЕФАЛИТ – Viral Encephalitis is an inflammation of the brain as a result of virus infection. There are many viruses that cause viral encephalitis. / Вирусный Энцефалит:- воспаление головного мозга, вызванное вирусным агентом. Под Энцефалитами, от Греческого слова Enképhalos, означающее Головной Мозг, понимается группа воспалительных заболеваний головного мозга человека и животных, обусловленных главным образом вирусами, Бактериями, простейшими и другими болезнетворными микроорганизмами. Различают первичные и вторичные энцефалиты. К первичным относят энцефалиты, которые развиваются вследствие внедрения в головной мозг нейротропных вирусов (эпидемические энцефалиты, клещевые энцефалиты, комариные энцефалиты и энцефалиты, вызываемые вирусами герпеса и опоясывающего лишая, и других). Для большинства первичных энцефалитов характерны наличие резервуара вируса в природе (обычно грызуны, птицы и другие), переносчика вируса (Комары, Клещи) и связанные с этим природная очаговость и сезонность заболевания. Возбудители первичных энцефалитов проникают в головной мозг гематогенным путём, то есть через кровь, реже – по нервным волокнам. Вторичные энцефалиты – следствие поражения головного мозга при общей или местной инфекции, например, при ревматизме, гриппе, кори, краснухе, ветряной оспе и других. Определённую роль в развитии вторичных энцефалитов, по-видимому, играет сенсибилизация организма к определённому антигену, возникающая при той или иной инфекции. Воспалительным процессом может поражаться преимущественно белое вещество или преимущественно серое вещество головного мозга (черепные нервы, подкорковые ганглии), например, при эпидемическом летаргическом или клещевом энцефалите. Большинство энцефалитов протекает остро. Основные проявления:- повышение температуры тела, головная боль, тошнота, рвота, нередко расстройство сознания; судороги и другие неврологические симптомы (парезы, расстройства чувствительности, функций черепных нервов и другие). Кроме того, для эпидемического летаргического энцефалита Экономо (название по имени описавшего его Австрийского психиатра и невролога Румынского происхождения Константина Фрайхэ фон Экономо (Constantin Freiherr von Economo или Константин Экономо фон Сан Зэф (Constantin Economo von San Serff); 1876–1931)) характерны поражение глазодвигательных нервов и сонливость; для ревматического энцефалита – гиперкинезы и так далее. В некоторых случаях после острой стадии наблюдается нарастание или появление новой неврологической симптоматики, например, развитие постэнцефалитического паркинсонизма при эпидемическом энцефалите. Неблагоприятно протекают так называемые склерозирующие энцефалиты (возникают в детском и юношеском возрасте, характеризуются расстройствами памяти, интеллекта, эпилептическими припадками и другим), гнойные и некротические энцефалиты, при которых происходит гибель значительных участков головного мозга. При клещевом энцефалите обычно через 10–12 суток (сут) после заражения (при укусе инфицированного клеща в природных очагах клещевого энцефалита) появляются мышечная слабость и онемение участков кожи, повышение температуры тела (держится несколько суток); характерны развитие парезов или параличей шейно-плечевой мускулатуры, поражение черепных нервов, симптомы раздражения оболочек мозга. Во многих случаях заболевание протекает в лёгкой форме. Для лечения энцефалитов применяют лекарственные средства, обладающие противовоспалительным, антимикробным, десенсибилизирующим действием (гормоны, салицилаты, антибиотики, сульфаниламиды, димедрол и другие). Профилактика энцефалитов, характеризующихся природной очаговостью:- борьба с переносчиками, иммунизация, средства индивидуальной защиты от Клещей, Комаров (репелленты, защитные костюмы) и тому подобное.

VIRAL HEMORRHAGIC FEVER = ВИРУСНАЯ ГЕМОРРАГИЧЕСКАЯ ЛИХОРАДКА – Viral Hemorrhagic Fever is a syndrome caused by infection with one of a number of viruses that can cause increased permeability of the blood vessels resulting in bleeding into the skin, internally, or from the mouth or other orifices. The bleeding is usually not life-threatening. Viral Hemorrhagic Fever (VHF) is a syndrome caused by infection with one of a number of viruses that can cause increased permeability of the blood vessels resulting in bleeding into the skin, internally, or from the mouth or other orifices. The bleeding is usually not life-threatening. Other signs and symptoms of viral hemorrhagic fever (VHF) may also include high fever, weakness, dizziness, and myalgia. In severe cases, there may be shock, coma, delirium, seizures, and death. The viruses that cause VHF belong to four families:- the arenaviruses, filoviruses, bunyaviruses, and flaviviruses. The arenaviruses include the Lassa fever virus and Machupo, Junin, Guanarito, and Sabia hemorrhagic

fever viruses. Among the filoviruses are the notorious Ebola virus and Marburg virus. The bunyaviruses include Rift Valley fever (RVF), Crimean-Congo hemorrhagic fever (CCHF), and hantaviruses. The viruses of yellow fever and dengue are Among the flaviviruses. These are all RNA viruses that are covered, or enveloped, in a fatty (lipid) coating. The ability of these viruses to survive depends on an animal or insect host. These viruses are geographically restricted to the areas where their host species live. Humans are infected when they come into contact with infected hosts. However, with some of these viruses, after the transmission from the natural host, there can be person-to-person transmission. Human cases or outbreaks of hemorrhagic fevers caused by these viruses occur sporadically and irregularly. The occurrence of outbreaks cannot be easily predicted. With a few exceptions, there is no established drug treatment for VHFs. Ribavirin, an anti-viral drug, has been effective in treating some patients with Lassa fever. Treatment for most of the VHFs is largely supportive. / Вирусная Геморрагическая Лихорадка:- заболевание, вызываемое вирусами ряда семейств:- Arenavirus, Filoviridae, Bunyaviridae, Flavivirus. Геморрагические Лихорадки, группа передающихся от животных человеку природноочаговых вирусных заболеваний, объединённых общими клиническими признаками – повышением температуры (лихорадка), подкожными и внутренними кровоизлияниями. По возбудителю, а также по способу распространения инфекции различают несколько видов. Геморрагические лихорадки с почечным синдромом (геморрагический нефрозо-нефрит) встречается в Европе и Азии в виде групповых вспышек и спорадических (единичных) случаев. Механизм передачи недостаточно выяснен; предполагается возможность передачи через гамазовых Клещей. Природные очаги могут образовываться в различных ландшафтах (лес, степь, тундра). Резервуар инфекции – некоторые виды мышевидных грызунов. Инкубационный период 11–24 дня. Крымская геморрагическая лихорадка встречается в виде спорадических случаев в Южных степных районах бывшего Союза Советских Социалистических Республик (СССР) (Крым, Таманский Полуостров, Ростовская Область, РСФСР, Южный Казахстан, Узбекская ССР, Киргизская ССР, Туркменская ССР, Таджикская ССР), а также в Болгарии, то есть там, где распространены иксодовые Клещи (Hyalomma). Заражение происходит в весенне-летний период. Инкубационный период 2–7 дней. Возбудитель обнаруживается в крови больных в течение всего лихорадочного периода. Сыворотка крови выздоравливающих обладает специфическими противовирусными свойствами. Омская геморрагическая лихорадка описана у жителей приозёрных посёлков Сибири, у охотников и членов их семей, в Барабинской степи (у непривитых). Встречается в осенне-зимний период в виде вспышек, которые связаны с эпизоотиями у промысловых животных. Переносчики болезни – иксодовые Клещи (Dermacentor). Инкубационный период 3–7 дней. У человека вирус обнаруживают в течение всего лихорадочного периода. Клещевая Индийская лихорадка (Киасапурская лесная болезнь) вызывается вирусом, сходным с возбудителем Омской геморрагической лихорадки. Наблюдается в весенне-летний период в виде спорадических случаев. Инкубационный период 4–8 дней. Вирус выделен от больных людей, обезьян, нескольких видов лесных грызунов и птиц, от иксодовых и гамазовых Клещей. Аргентинской, или Боливийской, геморрагической лихорадкой заболевают преимущественно сельскохозяйственные рабочие и члены их семей в период уборки Кукурузы. Вирус выделен от людей, полевых грызунов и паразитирующих на них гамазовых Клещей (Haemophysalis). Инкубационный период 2–11 дней. Близко к геморрагическим лихорадкам примыкают комариные лихорадки, встречающиеся в отдельных странах Азии, Африки и Океании. По течению заболевания комариные лихорадки несколько отличаются от геморрагических лихорадок. По всей вероятности, они также передаются человеку от животных, но резервуары инфекции в природе ещё не выяснены. Передача возбудителя (вирус) осуществляется Комарами. Вирус комариных лихорадок выделен от больных людей (в ранние сроки заболевания) и от Комаров. Заболевание геморрагической лихорадкой в большинстве случаев начинается остро:- появляются озноб, лихорадка (Омская, Индийская, а иногда комариные), головная боль, резкая слабость; возникают кровотечения (носовые, желудочные, кишечные, маточные, почечные, полостные, из дёсен, подкожные) или геморрагические сыпи на коже и слизистых оболочках. Отмечаются изменения в крови (лейкопения, а для геморрагической лихорадки с почечным синдромом – лейкоцитоз), внутренних органах (геморрагическая лихорадка с почечным синдромом сопровождается поражением почек, что проявляется резкими болями в пояснице, а иногда, вследствие изменений в почечных канальцах, прекращением отделения мочи), в нервной системе (геморрагическая лихорадка с почечным синдромом, Крымская, Аргентинская и комариные часто сопровождаются коллапсом и шоком). У переболевших геморрагической лихорадкой остаётся прочный иммунитет. Лечение симптоматическое:- поддержание сердечной деятельности и борьба с кровоточивостью. При Аргентинской и геморрагической лихорадке с почечным синдромом – борьба с обезвоживанием (введение больших доз нормальной плазмы крови, электролитов; гормональные препараты – кортикостероиды). При Крымской геморрагической лихорадке положительные результаты даёт введение специфической сыворотки. Профилактика:- уничтожение Клещей и грызунов; применение средств, отпугивающих Насекомых (акарицидные репелленты). Против Омской геморрагической лихорадки применяют специальную вакцину, обеспечивающую длительный и прочный иммунитет.

VIRAL TRANSACTIVATING PROTEIN = ВИРУСНЫЙ ТРАНСАКТИВИРУЮЩИЙ БЕЛОК – Viral Transactivating Protein is the specific protein used by a lytic virus to ‘switch on’ the cascade of gene regulation by which that virus ‘takes over’ a healthy cell and subverts its molecular processes (machinery) to produce virus components. This (transactivating) protein is key to the whole lytic cycle of the virus and therefore a potential target for therapeutic intervention. / Вирусный Трансактивирующий Белок:- специфический белок вирусов, запускающий каскад регуляторов активности генов клетки, позволяющий вирусу реплицировать собственные компоненты.

VIRESCENT = ЗЕЛЕНОВАТОЕ – Virescent:- young seedlings that are nearly white or slightly yellow as a result of delayed development of chloroplasts. Later the plant gradually turns green.

VIRGATE = ПРУТЬЕВИДНОЕ (или СТЕРЖНЕОБРАЗНОЕ) – Virgate:- slender, twiggy or wand like. Hence:- Virgatus (-a, -um). / Сплетённое или Плетёное или Полосатое (Латинский – Virgatus).

VIRGIN COAL = ЦЕЛИК УГЛЯ (или НЕПОДРАБОТАННЫЙ ПЛАСТ УГЛЯ, или ПЕРВОЗДАННЫЙ УГОЛЬ) – Virgin Coal is a coal that has not been accessed by mining. Virgin Coal is an area of coal that is in place (in situ) and unimpaired by mining activities.

VIRGIN FIBERS = ВПЕРВЫЕ ПРОИЗВЕДЁННЫЕ ВОЛОКНА (или ПЕРВИЧНЫЕ ВОЛОКНА, или ПЕРВОЗДАННЫЕ ВОЛОКНА, или ПЕРВОРОДНЫЕ ВОЛОКНА) – Virgin Fibers are the fibers never made into fabric before. The term is used primarily for wool fibers to differentiate between these and reclaimed, reprocessed, and reused fibers. See also Reprocessed Fibers, Reclaimed Fibers, and Reused Fibers.

VIRGIN LAND = ЦЕЛИННАЯ ЗЕМЛЯ (или ЦЕЛИНА) – Virgin Land is a land that has not been used for agricultural purposes or disturbed by humans at all. The Virgin Lands campaign was a huge operation designed to open up a vast tract of steppe land, mainly in Northern Kazakhstan and the Altai region of the RSFSR, for grain cultivation. The area initially plowed up in 1954, the first year of the campaign, was no less than 19 million hectares (47 million acres). An additional 14 million hectares were plowed in 1955. More than 300 000 people, primarily from Ukraine and the RSFSR, were recruited by the Komsomol to settle and cultivate the arid steppe. They would be joined by even larger contingents of students, soldiers, and truck and combine-drivers who were transported to the virgin lands on a seasonal basis. The campaign bore the stamp of Nikita Khrushchev and his efforts to rekindle popular identification with and

participation in state economic initiatives. As such, it led to strains within the party leadership, particularly after the disappointing 1955 harvest. But the following year's harvest, the largest in Soviet history up to that point, seemed to vindicate Khrushchev's gamble. Over half of the 125 million tons of grain produced came from the new regions. Results thereafter never quite reached the level of 1956. By the early 1960s, reliance on single-crop cultivation had taken its toll on the fertility of the soil, and failure to adopt anti-erosion measures led to millions of tons of soil simply blowing away. The Virgin Lands campaign also had an important demographic dimension. Aside from the indigenous Kazakhs and settlers recruited from the Slavic population, the campaign relied on the labor of Chechens, Ingush, Kalmyks, Crimean Tatars, Volga Germans, and others deported from their homelands either before or during the Great Patriotic War. The concentration of young males in an unfamiliar (to many) environment and competition over economic and cultural resources provoked ethnic and racial friction and even pogroms. Although after 1956 some of these groups were permitted to return to their native regions, authorities considered Crimean Tatars and Volga Germans too valuable to the Virgin Lands program to be released from what was for all intents and purposes internal exile. / Под Целиной понимается земля, покрытая естественной растительностью, которая веками не распахивалась. Освоение целины в бывшем Союзе Советских Социалистических Республик (СССР) (Казахская ССР, Поволжье, Сибирь, Урал и другие районы) проводилось в 1954–60. Было распахано около 41.8 миллионов гектаров (га) земли. Целина, покрытые естественной растительностью земли, которые веками не распахивались. В отличие от старопахотных земель, почвы целины содержат в корнеобитаемом слое повышенное количество гумуса, азота и других элементов питания растений, более структурны и более уплотнены, менее засорены семенами сорняков, отличаются пониженной жизнедеятельностью микроорганизмов и своеобразным водным режимом:- в засушливых районах они сильнее иссушены, в увлажнённых – влажность их высокая. Основные типы целины в бывшем Союзе Советских Социалистических Республик (СССР):- степная целина на чернозёмах и каштановых почвах – в Европейской части встречается почти исключительно в заповедниках (Аскания-Нова в Херсонской Области, Каменная Степь в Воронежской Области); в Азиатской части (Северные, Западные и Северо-Восточные районы Казахстана, Сибирь, Зауралье) также почти полностью освоена (смотрите Целинные И Залежные Земли). Целина Южных степей и полупустынь приурочена к сильно засушливым районам со светло-каштановыми, бурыми полупустынными почвами и серозёмами (Центральный и Южный Казахстан, Средняя Азия, Азербайджанская ССР и другие); освоение целины здесь связано с применением орошения и специальных мероприятий для улучшения засоленных почв. Пойменная целина распространена в Нечерноземье, меньшие площади в других природных зонах; при её освоении проводят осушение и культуртехнические работы. Целинные земли болот в Нечернозёмной зоне Европейской части, в Сибири, на Дальнем Востоке, в Закавказье (Колхида) также нуждаются в предварительном осушении и окультуривании. Целинные И Залежные Земли в бывшем Союзе Советских Социалистических Республик (СССР), земельные массивы, пригодные под распашку и посев сельскохозяйственных культур (смотрите Целина, Залежь). Их освоение – один из важных факторов увеличения производства зерна и других сельскохозяйственных продуктов; в крупных масштабах проводилось в 1954–60 в Казахстане, районах Поволжья, Урала, Западной и Восточной Сибири, Дальнего Востока. Это мероприятие вошло в историю как одно из героических свершений Коммунистической Партии и Советского народа, в котором реализовались Ленинские идеи о необходимости использования обширных земельных ресурсов в интересах развития производительных сил страны. На торжественном заседании в Алма-Ате, посвящённом 20-летию освоения целинных и залежных земель (Март 1974), Генеральный Секретарь Центрального Комитет Коммунистической Партии Советского Союза (ЦК КПСС) Леонид Ильич Брежнев (1906–1982) отметил, что освоение целинных и залежных земель в Казахстане, Алтайском и Красноярском краях, Новосибирской и Омской областях, в Поволжье, на Урале и Дальнем Востоке, в других районах страны представляет одну из самых ярких страниц в летописи созидательного труда Советского народа. На пустовавших извечно землях выросли сотни совхозов, построены промышленные предприятия, организованы современные научные центры. Это не только позволило создать новую крупную зерновую базу на Востоке страны, но и коренным образом изменило экономику, культуру, весь облик огромных районов. До Октябрьского государственного переворота (так называемой Октябрьской Революции) 1917 степи Восточных районов на небольших площадях осваивались переселенцами из густонаселённых областей России. Суровые климатические условия и бедность крестьянских хозяйств позволяли заниматься здесь лишь примитивным земледелием, основанным на залежной системе (землю распахивали и несколько лет занимали зерновыми культурами, а затем, когда их урожаи резко снижались, переводили в залежь, часто на 20, 25 лет и более). В годы Советской власти постепенно создавались необходимые предпосылки для массового освоения целинных и залежных земель. В соответствии с Постановлением Февральско-Мартовского (1954) Пленума ЦК КПСС 'О дальнейшем увеличении производства зерна в стране и об освоении целинных и залежных земель' в Восточные районы направлялись сотни тысяч энтузиастов, в том числе свыше 500 000 – по комсомольским путёвкам; быстрыми темпами стали создаваться новые совхозы, оснащённые мощной техникой. В 1954–60 было распахано 41.8 миллион гектаров (га) целины и залежи, в том числе 16.3 миллионов га в РСФСР (Западная Сибирь – 6.2 миллиона га, районы Урала – 4.2 миллиона га, Восточная Сибирь и Дальний Восток – 4.2 миллиона га, Поволжье – 1.7 миллиона га) и 25.5 миллионоа га в Казахстане (главным образом в Северных областях – Кустанайской, Северо-Казахстанской, Кокчетавской, Павлодарской, Целиноградской). В результате расширения и интенсивного использования пашни в этих районах увеличились площади под зерновыми культурами, возросли валовые сборы и государственные закупки зерна. Освоение целинных и залежных земель потребовало значительных капитальных вложений (37.4 миллиардов Рублей за 1954–59); однако уже в 1961 государство за счёт дополнительно полученной продукции не только компенсировало затраченные средства, но имело свыше 3.3 миллиардов Рублей чистого дохода. Целинные хозяйства стали крупными поставщиками дешёвого товарного зерна; товарность хлеба в Казахстане в 1971–74 достигала в среднем 59%. Наряду с зерновым хозяйством во многих районах (Алтайский Край, Башкирская АССР, Саратовская Область, Казахская ССР и другие) развилось производство сахарной Свёклы, Подсолнечника и других сельскохозяйственных культур. Созданы благоприятные условия для животноводческих отраслей. После Мартовского (1965) Пленума ЦК КПСС, наметившего меры по интенсификации сельского хозяйства, основным фактором дальнейшего роста производства зерна в целинных районах стало повышение урожайности зерновых культур, которая за 1961–65 увеличилась почти вдвое. Большое значение придаётся размещению сельскохозяйственных культур в севооборотах, семеноводству и другим мероприятиям по повышению устойчивости зернового производства. В результате возросшей культуры земледелия валовые сборы зерна в целинных районах РСФСР увеличились за 1954–74 в 2.5 раза, в Казахской ССР – в 6.2 раза; с освоенных земель получено свыше 500 миллионов тонн хлеба. Освоение и использование целинных и залежных земель строятся на научной основе, благодаря чему сводятся к минимуму отрицательные последствия, возникающие при нарушении естественного биогеоценоза. Об освоении земель в Нечернозёмной зоне РСФСР и орошаемых районах смотрите в статьях Сельское Хозяйство, Мелиорация, Орошение, Осушение. Залежь, необрабатываемая длительный период пашня. Кратковременная (8–15 лет) залежь в степных районах называется Перелогом, в лесостепных – Залогом. В первые 2–3 года пашня зарастает одно- и двулетними растениями (Бурьянистый Перелог), в последующие 5–7 лет на ней господствуют корневищевые растения, которые по мере уплотнения почвы сменяются сначала рыхлокустовыми, затем плотнокустовыми злаками. В дальнейшем развивается растительность, характерная для природных луговых или степных условий. На залеже накопляется органическое вещество, образуется дернина, почва становится более плотной и структурной. Часть пашни при залежной системе земледелия в

малонаселённых степных районах периодически оставлялась под залежь. Это восстанавливало плодородие почвы и помогало бороться с сорняками. Освоение залежей в степных районах бывшего Союза Советских Социалистических Республик (СССР) позволило значительно увеличить производство зерна. Обработка залежи заключается в глубокой вспашке плугами с предплужниками весной или в начале лета с последующей обработкой дисковыми орудиями.

VIRGIN POINT OF CONTROL = ПЕРВОЗДАННЫЙ ПУНКТ КОНТРОЛЯ – The Virgin Point of Control (VPOC) is a Point of Control (POC) that has not had a trade at that price since the day that that POC was formed. Say a POC is formed at a price of 1 120.00 on Monday. On Tuesday the market trades above this price all day and forms a POC at 1 145.00. On Wednesday the market trades above 1 145.00 all day and forms a POC at 1 165.00. On Thursday the market trades in the 1 150.00 to 1 170.00 range. So the situation on Thursday is that the POC's that were formed on Monday and Tuesday are VPOC's because their prices have not been touched since they were formed. However, the POC created on Wednesday is NOT a VPOC because the market has traded at that price since it was formed. The Virgin Point of Control is sometimes referred to as the Naked Point of Control (NPOC).

VIRGIN SOIL = ЦЕЛИННАЯ ПОЧВА (или ПОЧВА ЦЕЛИНЫ) – Virgin Soil is a soil that has never been cultivated or disturbed for crop production or any other purpose.

VIRGIN TIMBER = XX (или ПЕРВОЗДАННАЯ ДРЕВЕСИНА) – Virgin Timber is a timber from an original forest that has not been previously disturbed or influenced by human activity.

VIRGIN WOOL = ДЕВСТВЕННАЯ ШЕРСТЬ (или ШЕРСТЬ, ВПЕРВЫЕ ПЕРЕРАБОТАННАЯ НА ПРЯЖУ И ТКАНЬ, или НАТУРАЛЬНАЯ ШЕРСТЬ) – Virgin Wool is a wool that has been clipped from a live sheep and that has not been previously processed to the stage where it contains twist. Noil is merely separated from long fibers in combing and is considered virgin wool. Virgin Wool is a new wool that has never been used before, or reclaimed from any spun, woven, knitted, felted, manufactured or used products. Virgin Wool is simply wool that's never been used before–but that difference matters. It's better than recycled wool because it's stronger and higher quality. Pure virgin wool is naturally breathable in both cold and warm weather, water-repellent, durable and insulating. It also resists wrinkles, stains and odors. Even though you can dry-clean wool shirts, many people simply hang them up and let them air out, finding that to be just as effective. Since virgin wool fibers haven't been shredded like recycled wool, they're more resilient – they don't break or wrinkle as easily and can provide more stretch. A shirt made of virgin wool can last for decades – some Pendleton Woolen Mills (USA) customers pass down their Board Shirts through several generations. Not something you can say about cotton or synthetic materials, right? Recycled Wool:- You wouldn't necessarily think of wool in the same category as paper bags, aluminum cans and plastic bottles, but like those three, it's recyclable. Recycled wool got a burst of popularity during World War II, when fabrics were rationed because wool was needed for military uniforms. As a result, civilians would recycle wool blankets into coats, or use the yarn from wool socks to knit sweaters. Very resourceful, right? Recycled wool is also called 'Reclaimed Wool' or 'Shoddy Wool'. Recycled wool is exactly what it sounds like:- wool that's been used to make one product, then used to make something else. Recycled wool is great for insulation, cloth diaper covers, DIY & Crafts rugs, polishing metal, applying wood stain, absorbing spills and more. However, recycled wool isn't the best for clothing and blankets if softness is your goal. To recycle wool, the fibers are torn apart and respun, which lowers the quality. Recycled wool can be 'a little more harsh or fuzzy', explains a wool crafting site. Adds one yarn site, 'Most recycled wool goods have a harsh feel to them'. At Pendleton, our goal is soft, premium wool clothing and blankets, which is why we exclusively use pure virgin wool. Today, companies are legally required by the Federal Trade Commission to specify if wool is recycled. So if a wool garment isn't specified as virgin or recycled, it's probably virgin wool. Virgin Wool is a term applicable to fabrics or products that do not use wastes from preliminary processing of new wool. It is new wool made into yarns and fabrics for the first time. Virgin Wool is the wool taken from a lamb's first shearing. This is the softest and finest wool produced. There is another meaning of virgin wool – it can refer to wool that has never been used, processed, or woven before. This type of virgin wool can come from an adult sheep. The Difference Between Virgin Wool And Wool? Virgin Wool is wool that has not previously been processed or woven, whereas wool can be made from recycling existing wool fabric and respinning the resulting fibers. There is a limited world supply of virgin wool which results in more use of recycled wool. The items made from virgin wool are more expensive as compared with those made of regular wool. Wool is a natural fiber that has been clipped from sheep for over 5 000 years. 'Pure New Wool' is a designation that can only be awarded to wool that is won from living, healthy sheep by clipping. 'All Wool', on the other hand, can be obtained from dead or sick animals or even from recycled wool: tretford uses new wool exclusively. The idea of recycled wool in one's clothing is alien to many these days. These days clothing is cheap and raw materials plentiful. If you walk into a department store and look at a selection of sweaters in a rainbow array of colors, chances are very few will be labeled 'Virgin Wool' but at the same time not one will have a single recycled fiber in it. It wasn't always so, however. One of the biggest pushes towards fiber and garment recycling was a result of World War II. Many things were rationed beyond food. The effect on a decade's worth of fashion was profound as governments restricted the amount of fabric which could be used to make new garments commercially, and restricted the raw materials for home producers. Wool was needed for uniforms, silk for parachutes, etc and even after the war economic troubles prevented an immediate cessation of rationing. Instead of buying new clothing people took to recycling clothing out of necessity. An adult's sweater could be unraveled and turned into children's sweaters, gloves, socks, and any number of useful things. An older girl's dress could be smocked and taken in to fit a younger child. And there was no stigma in this. It was patriotic, and considered a part of the war effort. These days, wool production is going strong, but some people continue to recycle wool and many even sell it or the garments made from it. This is as much a result of excess as the previous recycling was from dearth. High quality yarn tends to be expensive. At the same time, many designers make and sell sweaters which just don't do their fibers justice. Many fiber artists on a budget find items in used clothing stores and spend a few Dollars and some effort to come away with fiber which would otherwise have cost hundreds of Dollars. They spend time instead of money, which can be worth it if cash flow is a problem. That ill-conceived orange cashmere blend men's sweater becomes hundreds of yards of potential wound into balls. Of course, with so much recycled material being sold during and after the war, the assurance of the reverse became a valued selling point. 'Virgin Wool' became a signifier of something luxurious and good. In these days of plenty however, it can be a bit misleading since the virgin wool may be nothing special compared to the recycled yarn from a USD300 sweater that had been worn once before it was sent to Goodwill. In the mean time, these days regulation decrees that garments made from recycled materials need to be labeled as such. It's up to the buyer to decide what 'new' is worth. Wool that has had no previous use is described as new wool, or, in the United States, as Virgin Wool. / развод (или потёк (stain)). Пэндэлтчэн Волэн Милз (Pendleton Woolen Mills).

VIRID = ЗЕЛЕНЬ (или ЗЕЛЁНОЕ) – Virid:- vividly green; verdant. Virid (-is, -i):- green.

VIRIDESCENS = ЗЕЛЕНЕТЬ (или СТАНОВИТЬСЯ ЗЕЛЁНЫМ) – Viridescens:- becoming green.

VIRIDESCENT = ЗЕЛЕНОВАТОЕ (или XX) – Viridescent:- slightly green; greenish. / :- слегка зелёное; зеленоватое.

VIRIDIAN = ВИРИДИАН (или ОКИСЬ ХРОМА) – Viridian is a deep blue-green color with a hue toward green. The name comes from the Latin word Viridis which means 'Green'. Meaning of Viridian:- (i) Viridian is a pigment used in art. (ii) Viridian is a popular color for painting dining rooms. (iii) Viridian:- the color is similar to the color forest green, and both colors are thought of as having to do with

forests and woods. (iv) Viridian represents the Viridian Design Movement, an effort to encourage green architecture – architecture based on ecological principles. Viridian:- a chrome green that is probably a hydrated oxide of chrome. Viridian is a blue-green pigment, a hydrated chromium(III) oxide, of medium saturation and relatively dark in value. It is composed more of green than blue. Specifically, it is a dark shade of spring green, the color between green and cyan on the color wheel, or, in paint, a tertiary blue-green color. Viridian takes its name from the Latin Viridis, meaning 'Green'. The first recorded use of Viridian as a color name in English was in the 1860s (exact year uncertain). / Окислы Хрома или Оксиды Хрома, соединения хрома с кислородом:- CrO, Cr_2O_3, CrO_2, CrO_3 и другие. Закись хрома, CrO, чёрные кристаллы; $t_{пл}$ 1 550 °C. Нерастворима в воде и горячих концентрированных HCl и H_2SO_4. Сильный восстановитель. Гидрат закиси хрома Cr $(OH)_2$ при обезвоживании окисляется до Cr_2O_3. Получают CrO разложением гексакарбонила хрома Cr $(CO)_6$ при 300 °C в вакууме. Применения не находит. Окись хрома, Cr_2O_3, тёмно-зелёные кристаллы; плотность 5.21 г/см^3, $t_{пл}$ 1 990 °C. В воде нерастворима. Обладает амфотерными свойствами. При сплавлении с сульфатами щелочных металлов даёт сульфат хрома, со щёлочами – хромиты. Окиси хрома соответствует гидроокись $Cr_2O_3x6H_2O$; могут быть получены и другие гидратные формы, например, $Cr_2O_3x5H_2O$, $Cr_2O_3x7H_2O$. Cr_2O_3 является конечным продуктом термического разложения большинства соединений хрома; в технике её получают термическим разложением CrO_3 при 500 °C или прокаливанием дихроматов (например, $K_2Cr_2O_3$, $Na_2Cr_2O_7$) с древесным углём. Окись хрома используют как сырьё при алюминотермическом способе получения хрома, в производстве стойких к свету красок, для окраски стёкол и керамики, в качестве полирующего материала, катализатора в неорганическом и органическом синтезе (при дегидрогенизации, ароматизации, гидрировании, крекинге и так далее). Двуокись хрома, CrO_2, кристаллы чёрного цвета; плотность 4.8 г/см^3. Получают CrO_2 нагреванием CrO_3 или хлористого хромила CrO_2Cl_2 до 360–400 °C и под высоким давлением в атмосфере кислорода. Трёхокись хрома, хромовый ангидрид, CrO_3, тёмно-красные кристаллы; плотность 2.8 г/см^3; $t_{пл}$ 196 °C. Гигроскопична, расплывается на воздухе. С водой образует хромовые кислоты. Сильный окислитель. Получают действием H_2SO_4 на дихромат натрия $Na_2Cr_2O_7$ (реже $K_2Cr_2P_7$). Применяют для получения хрома электролизом, электролитического хромирования. Трёхокись хрома, так же как и другие соединения Cr (VI), ядовита.

VIRIDIFLORUS = ВИРИДИФЛОРУС (или ЗЕЛЕНОЦВЕТКОВОЕ) – Viridiflorus (-a):- with green flowers.

VIRIDIFOLIUS = ВИРИДИФОЛИУС (или ЗЕЛЕНОЛИСТНОЕ) – Viridifolius:- with green leaves.

VIRIDIFUSCUS = ВИРИДИФУСКУС (или ГРЯЗНО–ЗЕЛЁНОЕ, или ТЁМНО–ЗЕЛЁНОЕ) – Viridifuscus:- green-brown.

VIRIDISSIMUS = ВИРИДИССИМУС (или ДЕЙСТВИТЕЛЬНО ЗЕЛЁНОЕ, или НАСЫЩЕННО ЗЕЛЁНОЕ) – Viridissimus:- very green. / очень зелёное.

VIRIDITY = ЗЕЛЕНЬ (или СВЕЖЕСТЬ, или ХХ) – Viridity:- the color of grass or foliage.

VIRIDULUS = ВИРИДУЛЮС (или ЗЕЛЕНОВАТОЕ) – Viridulus:- somewhat green.

VIRION = ВИРИОН – Virion is an entire virus particle, consisting of an outer protein shell called a Capsid and an inner core of nucleic acid (either ribonucleic or deoxyribonucleic acid – RNA or DNA). The core confers infectivity, and the capsid provides specificity to the virus. In some virions the capsid is further enveloped by a fatty membrane, in which case the virion can be inactivated by exposure to fat solvents such as ether and chloroform. Many virions are spheroidal – actually icosahedral – the capsid having 20 triangular faces, with regularly arranged units called Capsomeres, two to five or more along each side; and the nucleic acid is densely coiled within. Other virions have a capsid consisting of an irregular number of surface spikes and the nucleic acid loosely coiled within. Virions of most plant viruses are rod-shaped; the capsid is a naked cylinder (lacking a fatty membrane) within which lies a straight or helical rod of nucleic acid. Virion is a virus particle. Virion is an intact virus particle (e.g., prior to it entering a cell to 'infect' the cell). A virion consists of a protein coat (known as a Capsid) around a central core composed of genetic material (DNA or RNA). / Под Вирионом понимается полностью сформированная вирусная частица, состоящая из нуклеиновой кислоты и белковой оболочки (капсида). Хранит и переносит генетический материал вируса от одной клетки к другой. Иногда вирион называют Вироспорой. Вирион, зрелая вирусная частица, или элементарное тельце вируса. Вирион состоит из нуклеиновой кислоты (РНК или ДНК) – наследственного (генетического) материала, заключённого в футляр из белковых субъединиц (молекул или агрегатов молекул); вирионы более сложно организованных вирусов могут иметь внешние оболочки (содержащие белки, липиды, углеводы) или специальные образования, как у бактериофагов. Вирион – полноценная внеклеточная вирусная частица.

VIROIDS = ВИРОИДЫ – Viroid is an infectious particle smaller than any of the known viruses, an agent of certain plant diseases. The particle consists only of an extremely small circular RNA (ribonucleic acid) molecule, lacking the protein coat of a virus. Viroids appear to be transmitted mechanically from one cell to another through cellular debris. Viroids are of much interest because of their subviral nature and their obscure mode of action. Potato spindle tuber disease is viroid-induced. Whether viroids occur in animal cells is still uncertain. Viroids are small, low-molecular weight ribonucleic acid that can infect plant cells, replicate themselves, and cause disease. A term Viroid refers to certain plant pathogens (i.e. plant-disease-causing virus-like entities) capable of reproducing on their own (unlike a true virus). / Вироид – патогенная нуклеиновая кислота, лишённая белковой оболочки.

VIROLOGIST = ВИРОЛОГ (или ВИРУСОЛОГ) – Virologists are microbiologists who study microorganisms that quickly duplicate, resulting in the rapid spreading of viruses. Their primary work is to figure out how diseases like AIDS, SARS and hepatitis spread, in order to prevent more rampant development and to assist in vaccine development. While a bachelor's degree usually gets you a job as a lab assistant, advanced research positions in virology normally require a master's or doctoral degree. Median pay for all microbiologists was USD65 920 in 2010, according to the US Bureau of Labor Statistics. Virologists study viruses that affect humans, animals, insects, bacteria, fungi and plants, in community, clinical, agricultural and natural environments. Virologists typically work in research or teaching, and many split their time between these two activities. Virologists may also work as science writers or pursue additional training to work in pharmaceutical business or law. Virology researchers study a broad range of issues, including viral pathology, viral oncology, emerging viruses, virotherapy, viral replication, virus-cell interactions and plant virology. Researchers may be employed by universities, government agencies or health organizations. Some virologists work in industry research and develop new medications. Medical doctors focusing on virology may carry out clinical research and work with patients afflicted with viruses. Virologist is a scientist or doctor who studies or specializes in viruses. A Virologist is a research professional. Preparing, conducting and overseeing studies of microorganisms is a core duty. Research studies normally are done with scientific equipment in labs. Virologists observe Bacteria that has become host to a virus by applying different levels of moisture, temperatures and air conditions to see how it reacts. This helps them discern what contributes to growth and spreading of the virus in the bacteria, so they can better predict the evolution of the virus in populations. Virologists usually supervise a team of researchers, especially in university settings or in larger private lab facilities. Biological technologists, technicians and lab assistants are among the common scientific roles held by people managed by virologists. In larger labs, the virologist spends more time planning, coordinating and supervising the research process, as opposed to actively participating in it. Coaching and training the research team on equipment use and proper procedures is vital to research project success. Once research projects are completed, the virologist assumes primary responsibility for

communicating results to his employer. Some virologists work in bigger labs where a variety of health research is conducted. His technical reports and presentations may go to other researchers, lab administrators or government health agencies. At the highest level, virology contributes to plans developed by the federal Centers for Disease Control, or CDC, to control outbreaks of influenza and other viral infections. Many virologists work in hospitals or in large medical clinics. They often collaborate with other medical staff who deal with individual patient cases. Once a viral condition is identified by medical doctors, virologists collect samples for study. Once research is completed, the virologist must give an opinion regarding treatment and controlling an outbreak. In extreme cases, the virologist may recommend a patient be quarantined to prevent contamination of the hospital, staff and other patients and visitors. Microbiologists earned a median annual salary of USD66 850 in 2016, according to the US Bureau of Labor Statistics. On the low end, microbiologists earned a 25th percentile salary of USD48 920, meaning 75 percent earned more than this amount. The 75th percentile salary is USD97 050, meaning 25 percent earn more. In 2016, 23 200 people were employed in the United States as microbiologists.

VIROLOGY = ВИРОЛОГИЯ (или ВИРУСОЛОГИЯ, или ИНФРАМИКРОБИОЛОГИЯ) – Virology is a branch of microbiology that deals with the study of viruses. Although diseases caused by viruses have been known since the 1700s and cures for many were (somewhat later) effected, the causative agent was not closely examined until 1892, when a Russian bacteriologist, Dmitry Iosifovich Ivanovski (1864–1920), observed that the causative agent (later proved to be a virus) of tobacco mosaic disease could pass through a porcelain filter impermeable to Bacteria. Modern virology began when two bacteriologists, Frederick William Twort (1877–1950) in 1915 and Félix d'Hérelle (1873–1949) in 1917, independently discovered the existence of bacteriophages (viruses that infect bacteria). Direct visualization of viruses became possible after the electron microscope was introduced about 1940. In 1935 tobacco mosaic virus became the first virus to be crystallized; in 1955 the poliomyelitis virus was crystallized. (A virus 'crystal' consists of several thousand viruses and, because of its purity, is well suited for chemical studies.) Virology is a discipline of immediate interest because many human diseases, including smallpox, influenza, the common cold, and AIDS, as well as a host of economically important plant and animal diseases, are caused by viruses. Virology is the study of viral infections, such as rubella, herpes, hepatitis and HIV. Virology is the study of viruses – submicroscopic, parasitic particles of genetic material contained in a protein coat – and virus-like agents. It focuses on the following aspects of viruses:- their structure, classification and evolution, their ways to infect and exploit host cells for reproduction, their interaction with host organism physiology and immunity, the diseases they cause, the techniques to isolate and culture them, and their use in research and therapy. Virology is considered to be a subfield of microbiology or of medicine. History Of Virology:- The word Virus appeared in 1599 and originally meant 'Venom'. A very early form of vaccination known as Variolation was developed several thousand years ago in China. It involved the application of materials from smallpox sufferers in order to immunize others. In 1717 Lady Mary Wortley Montagu observed the practice in Istanbul and attempted to popularize it in Britain, but encountered considerable resistance. In 1796 Edward Jenner developed a much safer method, using cowpox to successfully immunize a young boy against smallpox, and this practice was widely adopted. Vaccinations against other viral diseases followed, including the successful rabies vaccination by Louis Pasteur in 1886. The nature of viruses however was not clear to these researchers. In 1892, the Russian biologist Dmitry Ivanovsky used a Chamberland filter to try to isolate the Bacteria that caused tobacco mosaic disease. His experiments showed that crushed leaf extracts from infected Tobacco plants remained infectious after filtration. Ivanovsky reported a minuscule infectious agent or toxin, capable of passing the filter, may be being produced by a bacterium. In 1898 Martinus Beijerinck repeated Ivanovski's work but went further and passed the 'filterable agent' from plant to plant, found the action undiminished, and concluded it infectious – replicating in the host – and thus not a mere toxin. He called it Contagium Vivum Fluidum. The question of whether the agent was a 'living fluid' or a particle was however still open. In 1903 it was suggested for the first time that transduction by viruses might cause cancer. In 1908 Bang and Ellerman showed that a filterable virus could transmit chicken leukemia, data largely ignored till the 1930s when leukemia became regarded as cancerous. In 1911 Peyton Rous reported the transmission of chicken sarcoma, a solid tumor, with a virus, and thus Rous became 'father of tumor virology'. The virus was later called Rous sarcoma virus 1 and understood to be a retrovirus. Several other cancer-causing retroviruses have since been described. The existence of viruses that infect Bacteria (bacteriophages) was first recognized by Frederick Twort in 1911, and, independently, by Félix d'Herelle in 1917. As Bacteria could be grown easily in culture, this led to an explosion of virology research. The cause of the devastating Spanish flu pandemic of 1918 was initially unclear. In late 1918, French scientists showed that a 'filter-passing virus' could transmit the disease to people and animals, fulfilling Koch's postulates. In 1926 it was shown that scarlet fever is caused by a Bacterium that is infected by a certain bacteriophage. While plant viruses and bacteriophages can be grown comparatively easily, animal viruses normally require a living host animal, which complicates their study immensely. In 1931 it was shown that influenza virus could be grown in fertilized chicken eggs, a method that is still used today to produce vaccines. In 1937, Max Theiler managed to grow the yellow fever virus in chicken eggs and produced a vaccine from an attenuated virus strain; this vaccine saved millions of lives and is still being used today. Max Delbrück, an important investigator in the area of bacteriophages, described the basic 'life cycle' of a virus in 1937:- rather than 'growing', a virus particle is assembled from its constituent pieces in one step; eventually it leaves the host cell to infect other cells. The Hershey–Chase experiment in 1952 showed that only DNA and not protein enters a bacterial cell upon infection with bacteriophage T2. Transduction of bacteria by bacteriophages was first described in the same year. In 1949 John F. Enders, Thomas Weller and Frederick Robbins reported growth of poliovirus in cultured human embryonal cells, the first significant example of an animal virus grown outside of animals or chicken eggs. This work aided Jonas Salk in deriving a polio vaccine from deactivated polio viruses; this vaccine was shown to be effective in 1955. The first virus that could be crystalized and whose structure could therefore be elucidated in detail was tobacco mosaic virus (TMV), the virus that had been studied earlier by Ivanovski and Beijerink. In 1935, Wendell Stanley achieved its crystallization for electron microscopy and showed that it remains active even after crystallization. Clear X-ray diffraction pictures of the crystallized virus were obtained by Bernal and Fankuchen in 1941. Based on such pictures, Rosalind Franklin proposed the full structure of the tobacco mosaic virus in 1955. Also in 1955, Heinz Fraenkel-Conrat and Robley Williams showed that purified TMV RNA and its capsid (coat) protein can self-assemble into functional virions, suggesting that this assembly mechanism is also used within the host cell, as Delbrück had proposed earlier. From the 1950s–60's, Chester M. Southam, a leading virologist and cancer researcher, injected cancer patients, healthy individuals, and prison inmates from the Ohio Penitentiary with HeLa cancer cells in order to observe if cancer could be transmitted. Additionally, in hopes of creating a vaccine for cancer, he observed if the subjects could become immune to cancer by developing an acquired immune response. This experiment was highly controversial, as the cancer patient subjects were unaware that they were being injected with cancer cells. In 1963, the Hepatitis B virus was discovered by Baruch Blumberg who went on to develop a hepatitis B vaccine. In 1965, Howard Temin described the first retrovirus:- a virus whose RNA genome was reverse transcribed into complementary DNA (cDNA), then integrated into the host's genome and expressed from that template. The viral enzyme reverse transcriptase, which along with integrase is a distinguishing trait of retroviruses, was first described in 1970, independently by Howard Temin and David Baltimore. The first retrovirus infecting humans was identified by Robert Gallo in 1974. Later it was found that reverse transcriptase is not specific to retroviruses; retrotransposons which code for reverse transcriptase are abundant in the genomes of all eukaryotes. About 10-40% of the human genome derives from such retrotransposons. In 1975 the functioning of oncoviruses was clarified considerably. Until that time, it was thought that these viruses carried certain genes called Oncogenes which, when inserted into the host's genome, would cause cancer. Michael Bishop and Harold Varmus showed that the oncogene of Rous sarcoma virus is in fact not specific to the virus but is contained in the genome of healthy animals of many species.

The oncovirus can switch this pre-existing benign proto-oncogene on, turning it into a true oncogene that causes cancer. 1976 saw the first recorded outbreak of Ebola virus disease, a highly lethal virally transmitted disease. In 1977, Frederick Sanger achieved the first complete sequencing of the genome of any organism, the bacteriophage Phi X 174. In the same year, Richard Roberts and Phillip Sharp independently showed that the genes of adenovirus contain introns and therefore require gene splicing. It was later realized that almost all genes of eukaryotes have introns as well. A worldwide vaccination campaign led by the UN World Health Organization resulted in the eradication of smallpox in 1979. In 1982, Stanley Prusiner discovered prions and showed that they cause scrapie. The first cases of AIDS were reported in 1981, and HIV, the retrovirus causing it, was identified in 1983 by Luc Montagnier, Françoise Barré-Sinoussi and Robert Gallo. Tests detecting HIV infection by detecting the presence of HIV antibody were developed. Subsequent tremendous research efforts turned HIV into the best studied virus. Human Herpes Virus 8, the cause of Kaposi's sarcoma which is often seen in AIDS patients, was identified in 1994. Several antiretroviral drugs were developed in the late 1990s, decreasing AIDS mortality dramatically in developed countries. Treatment that exists for HIV includes a multitude of different drugs collectively termed Highly Active Antiretroviral Therapy (HAART). HAART attacks many different aspects of the HIV virus, effectively reducing its effects below the limit of detection. However, when the administration of HAART is discontinued, HIV will bounce back. This is because HAART does not attack latently infected HIV cells, which can reactivate. The Hepatitis C virus was identified using novel molecular cloning techniques in 1987, leading to screening tests that dramatically reduced the incidence of post-transfusion hepatitis. The first attempts at gene therapy involving viral vectors began in the early 1980s, when retroviruses were developed that could insert a foreign gene into the host's genome. They contained the foreign gene but did not contain the viral genome and therefore could not reproduce. Tests in mice were followed by tests in humans, beginning in 1989. The first human studies attempted to correct the genetic disease severe combined immunodeficiency (SCID), but clinical success was limited. In the period from 1990 to 1995, gene therapy was tried on several other diseases and with different viral vectors, but it became clear that the initially high expectations were overstated. In 1999 a further setback occurred when the US 18-year-old Jesse Gelsinger (1981–1999) died in a gene therapy trial. He suffered a severe immune response after having received an adenovirus vector. Success in the gene therapy of two cases of X-linked SCID was reported in 2000. In 2002 it was reported that poliovirus had been synthetically assembled in the laboratory, representing the first synthetic organism. Assembling the 7741-base genome from scratch, starting with the virus's published RNA sequence, took about two years. In 2003 a faster method was shown to assemble the 5386-base genome of the bacteriophage Phi X 174 in 2 weeks. The giant mimivirus, in some sense an intermediate between tiny prokaryotes and ordinary viruses, was described in 2003 and sequenced in 2004. The strain of Influenza A virus subtype H1N1 that killed up to 50 million people during the Spanish flu pandemic in 1918 was reconstructed in 2005. Sequence information was pieced together from preserved tissue samples of flu victims; viable virus was then synthesized from this sequence. The 2009 flu pandemic involved another strain of Influenza A H1N1, commonly known as 'Swine Flu'. By 1985, German virologist and professor emeritus Harald zur Hausen (1936–) had shown that two strains of Human papillomavirus (HPV) cause most cases of cervical cancer. Two vaccines protecting against these strains were released in 2006. In 2006 and 2007 it was reported that introducing a small number of specific transcription factor genes into normal skin cells of mice or humans can turn these cells into pluripotent stem cells, known as Induced Pluripotent Stem Cells. The technique uses modified retroviruses to transform the cells; this is a potential problem for human therapy since these viruses integrate their genes at a random location in the host's genome, which can interrupt other genes and potentially causes cancer. In 2008, Sputnik virophage was described, the first known Virophage:- it uses the machinery of a helper virus to reproduce and inhibits reproduction of that helper virus. Sputnik reproduces in amoeba infected by mamavirus, a relative of the mimivirus mentioned above and the largest known virus to date. An endogenous retrovirus (ERV) is a retrovirus whose genome has been permanently incorporated into the germ-line genome of some organism and that is therefore copied with each reproduction of that organism. It is estimated that about 9 percent of the human genome have their origin in ERVs. In 2015 it was shown that proteins from an ERV are actively expressed in 3-day-old human embryos and appear to play a role in embryonal development and protect embryos from infection by other viruses. Virology is the scientific discipline concerned with the study of the biology of viruses and viral diseases, including the distribution, biochemistry, physiology, molecular biology, ecology, evolution and clinical aspects of viruses. Virology is the study of viruses and virus-like agents, including (but not limited to) their taxonomy, disease-producing properties, cultivation and genetics. It is often considered a part of microbiology or pathology. In the early years this discipline was dependent upon advances in the chemical and physical sciences, but viruses soon became tools for probing basic biochemical processes of cells. Viruses have traditionally been viewed in a rather negative context as agents responsible for disease that must be controlled or eliminated. However, viruses also have certain beneficial properties that can be exploited for useful purposes (for example in gene therapy or vaccinology). / Английский бактериолог и вирусолог Фрэдэрик Вильэм Твот (Frederick William Twort; 1877–1950). Саркома Капощи (Kaposi's sarcoma; впервые описана Венгерским врачом дерматологом Моритцем Капощи (Moritz Kaposi; 1837–1902)). 18-летняя Американка Дьжэси Гелсиндьжё (Jesse Gelsinger; 1981–1999). Немецкий Харальд цуа Хаузэн (Harald zur Hausen; 1936–). Под Вирологией или Вирусологией или Инфрамикробиологией, от Латинского слова Virus, означающее Яд, и Греческого слова Lógos, означающее Слово или Учение, понимается наука о вирусах – субмикроскопических внутриклеточных паразитах; только в середины XX века выделилась в самостоятельную дисциплину. Первоначально Вирусология Человека, Животных и Бактерий развивалась в рамках микробиологии, а вирусология высших Растений – как раздел фитопатологии. Вирусология занимает важное место среди медико-биологических наук, так как вирусные болезни широко распространены у Человека, Животных и Растений; кроме того, вирусы служат моделями, на которых изучаются основные проблемы генетики и молекулярной биологии. Первые монографии по вирусным болезням Животных опубликованы Томэсом Эм. Ривёзом (Thomas M. Rivers; 1888–1962) (Лондон, 1928), Советским микробилогом Николаем Фёдоровичем Гамалея (1859–1949) (Москва, 1930), по вирусным болезням Растений – Советским биологом, ботаником и вирусологом Виталием Леонидовичем Рыжковым (1896–1977) (Москва, 1933), Кенисом Мэнли Смисом (Kenneth Manley Smith; 1892–1981) (Лондон, 1933). Первая лаборатория (по вирусным болезням растений) организована в 1930 при Украинском Институте Защиты Растений; в 1932 лаборатории по вирусным болезням человека появились в ряде институтов медицинской микробиологии. Институт Вирусологии имени Дмитрия Иосифовича Ивановского существует в Москве с 1946. Первая конференция по вирусным болезням растений состоялась в Марте 1935 в Харькове, Украина, первая конференция по ультрамикробам, фильтрующимся вирусам и бактериофагу – в Декабре того же года в Москве, Россия. В 1966 на 9-м Международном Конгрессе по Микробиологии впервые избран Международный Комитет по Номенклатуре Вирусов; в 1968 состоялся 1-й Международный Конгресс по Вирусологии в Хельсинки, Финляндия. В методическом отношении вирусология существенно отличается от микробиологии, так как вирусы не удаётся культивировать на искусственных питательных средах. Для опытов с вирусами приходится использовать чувствительных к ним Животных и Растения, куриные эмбрионы (1932) и изолированные ткани (с 1913 и особенно с 1925). Успехи вирусологии зависели, прежде всего, от разработки удобного метода культивирования вирусов. Так, изучение вируса гриппа продвинулось вперёд, когда определили, что к этому вирусу чувствительны Хорьки (1933) и Белые Мыши (1934). В изучении вирусов полиомиелита и кори, а также в создании предохранительных вакцин против этих болезней решающее значение имело культивирование вирусов в изолированных тканях Обезьян и Человека. Для количественного учёта вируса и динамики его размножения применяют различные методы титрования. Важнейшие из них основаны на том, что вирус, размножаясь в клетках, вызывает видимые простым глазом поражения. Бактериальные вирусы (бактериофаги) титруют по числу стерильных пятен (Французско-Канадский микробиолог Феликс Юбэр дЁрэлле (Félix Hubert d'Hérelle; 1873–1949) в 1917), вирусы растений – по числу некрозов на заражённом вирусом листе (Фрэнсис Оу. Холмз (Francis O. Holmes; 1897–1990) в 1929), вирусы Животных и Человека – на однослойных культурах тканей (Американский вирусолог Итальянского происхождения Рэнато Дульбэкко (Renato Dulbecco; 1914–2012) в 1952). Впервые химическим путём был очищен Американским вирусологом и биохимиком, лауреатом Нобелевской Премии Вэндэлом Мэрэдисом Стэнли (Wendell Meredith Stanley; 1904–1971) в 1935 вирус мозаичной болезни Табака. Создание ультрацентрифуг облегчило концентрацию вирусов и определение массы вирусных частиц. Так называемое Градиентное, или Фракционированное, Центрифугирование в растворах сахарозы или солей металлов дало возможность 'рассортировать' вирусные частицы, так как даже при незначительном различии их веса они распределяются слоями на разных уровнях раствора. Этот метод сыграл большую роль в изучении стадий размножения вирусов. Для изучения физиологических условий размножения вирусов предложен (Советский биолог Виталий Леонидович Рыжков (1896–1977), в 1938) метод метаболитов и антиметаболитов, которым стали определять, как влияют на размножение вируса вещества, стимулирующие или подавляющие отдельные биохимические процессы. Применение изотопов (преимущественно радиоактивных) позволило проследить, из каких источников черпает вирус вещества для построения своего тела. Отдельные этапы размножения вируса изучают в бесклеточных препаратах, содержащих, кроме вируса, рибосомы, ферменты клетки и вещества, нужные для построения белков и нуклеиновых кислот. Электронная микроскопия (с 1938) позволила увидеть вирусные частицы, а возможность приготовлять ультратонкие срезы – изучать развитие вируса в тканях (1945). Вирусология тесно связана с морфологией и физиологией клеток, так как для вирусов клетки являются средой обитания; с другой стороны, размеры вирусных частиц близки к размерам крупных молекул, и это даёт возможность изучать их методами, применяемыми к молекулам (Рентгеноструктурный анализ и тому подобное). Основные проблемы современной вирусологии – это систематика вирусов и химиотерапия вирусных заболеваний, а также вопросы, связанные с генетикой и молекулярной биологией.

VIROTHERAPY = ВИРОТЕРАПИЯ – Virotherapy is an emerging branch of medicine which explores the use of viruses to kill cancers. Oncolytic virotherapy means the elimination of malignant cells by viral propagation inside the tumor. The biological basis of this phenomenon is virus tropism, which means that different viruses have selective preferences for particular cells. This results in the differences in disease manifestation from virus to virus. Most viruses in nature have a tropism for malignant cells, which makes them suitable for oncolysis. Oncolytic viruses include oncolytic measles virus, oncolytic vaccinia viruses, oncolytic HSV (short for Herpes Simplex Virus), reovirus and so on. In some trials, oncolytic viruses have been combined with chemotherapy or radiation. Normal Antiviral Responses:- The body normally responds to viral infection by slowing or stopping cell metabolism, so as to prevent virus replication, and entering apoptosis, or programmed cell death. Tumor cells, however, resist apoptosis, and do not suppress protein synthesis following viral infection, making them more susceptible to damage and death. This is the basis of oncolytic virus therapy. Even attenuated viruses can propagate inside tumor cells, where they could not inside a normal cell. However, the immune responses in most cancer cells are only partially inactivated, so most tumors show only limited sensitivity to viral infection. To overcome this, researchers encode virulence factors which are complementary to each other, or which originate from competing virus strains. At the same time, they need to build in protection for normal cells against viral infection. Mechanisms Of Oncolysis In Virotherapy:- The viruses used in oncolysis must be capable of replication, and selective infection of tumor cells. Oncolytic viruses use many means to kill cancer cells, either directly, or through immune mechanisms which destroy the infected tumor cells. Normally, viruses utilize cell destructive processes like autophagy, apoptosis or necrosis, but only after they have fully used up all cell resources to replicate themselves. In addition, viruses destroy uninfected cells as well, through indirect means, such as disrupting the blood supply to the area, amplifying the existing immune responses against the cancer to make them more powerful, and through specific actions by

genetically engineered viruses on the cancer cells. The Viremic Threshold:- The two important areas of research into oncolytic viruses concern virus delivery to the tumor, and spread of the virus through the tumor. It is known that effective virus delivery involves the so-called 'viremic threshold' dose which needs to be exceeded. The safety record of oncolytic virotherapy is good so far. The greatest challenge in virotherapy, however, is making sure that viruses reach the tumor in sufficient doses to extravasate from blood vessels into the tumor, replicate in tumor cells to create infectious centers, which then expand outwards and merge to destroy the tumor, or perform effective tumor debulking. The doses of virus used for injection are constantly increasing. The injected dose of viruses must be therefore cross the threshold dose. The major obstacles to this quest are:- (i) sequestration of virus in the liver and spleen, which may be overcome by saturating the mononuclear phagocytic system receptors; (ii) neutralization of viruses by serum immune factors; (iii) the need for viruses to selectively bind to vascular endothelium of the tumor blood vessels; and (iv) the need for highly selective increase in the permeability of tumor vascular endothelium, so as to optimize virus extravasation but avoid systemic inflammation. Reporter Genes:- The spread of the virus, the number and location of virus-infected cells inside the body can be tracked by monitoring certain inserted genes. These are called Reporter Genes, and help researchers trace the virus spread repeatedly and in a non-invasive way. One example is the gene which encodes the thyroidal sodium iodide symporter (NIS), which concentrates radioactive iodide in the form of radioisotopes such as 125I, 123I, 124I and 99mTcO4. It can be inserted and then used to monitor the spread of the virus. This approach has been proved valid with the use of CT/SPECT imaging to follow the spread of the oncolytic virus with inserted NIS. Newer Developments And Challenges:- Radiovirotherapy is another approach under investigation which uses 131I in the form of NIS expression in a virus genome. This will increase the efficacy of the oncolytic virus therapy by adding the administration of high-energy beta particles into the virus-infected tumor, to the virus infection. The large size of most viruses forms a physical barrier to cell infection, while their ability to evoke an immune response limits their capacity to infect many cells. However, they can both amplify and prime other forms of host immunity, and thus stimulate a general antiviral immune response in the host. Cell carriers are being developed to overcome the physical size barrier. The use of immunosuppressive drugs is also being researched, to encourage intratumoral spread of the virus. Challenges exist, since with the diminishing of host immunity, the immune-stimulating power of oncolytic virus therapy is also reduced. Moreover, the need of the situation is to develop tumor models which can accurately reflect what is happening in the human body affected by a tumor which has been infected by an oncolytic virus. A term Virotherapy refers to the use of viruses (i.e. modified to prevent any harm to patent) in the treatment of a disease (e.g., cancer). Oncolytic Virotherapy is an effective cancer treatment using a special virus, which is capable of finding and destroying malignant tumour cells in the body. There are only three live virus-containing medication in the world and Latvian Rigvir® is the first registrated and still the one and only genetically unmodified virus available worldwide. After being administered, the virus finds and infects malignant tumour cells in a process called Oncotropism. The virus replicates itself in the cells of a malignant tumour destroying them in a process called Oncolysis. Viruses not only destroy cancer cells but also activate the body's natural immune system, which also targets the malignant cells. The goal of virotherapy, not unlike that of radiation therapy and chemotherapy, is to destroy cancer cells, but virotherapy has several distinct advantages:- (i) virotherapy destroys tumour cells selectively without affecting the healthy cells of the body; (ii) virotherapy stimulates the body's natural defence mechanisms by activating the immune system, which is often supressed by other treatment methods; (iii) virotherapy can be used against tumours that don't respond well to radiation or chemotherapy, such as melanomas; and (iv) virotherapy can be used at various stages throughout the treatment process:- before or after surgery and also between radiation or chemotherapy treatments. Virotherapy is recognised as a safe and efficient cancer treatment method. / Ригвир® (Rigvir®).

VIRTUAL CLOSE = ВИРТУАЛЬНОЕ ЗАКРЫТИЕ – A Virtual Close involves the use of fully integrated company-wide accounting systems to produce financial statements at any time, on demand. This approach requires not only enterprise resources planning (ERP) systems, but also a great deal of effort to ensure that the underlying information is correct. The required investment is so large that you rarely see a virtual close in smaller companies. The virtual close requires particular attention to the following areas:- (i) Centralized Accounting:- it is nearly impossible to achieve a virtual close without a great deal of accounting centralization combined with ERP software. Conversely, that means you cannot have accounting operations scattered throughout the business that operate on different accounting software. (ii) Standardized Accounting:- business transactions must be defined and treated the same way everywhere. Otherwise, the accounting staff must spend time investigating transaction irregularities submitted by the various subsidiaries. (iii) Error Tracking:- any errors found must be tracked down and their underlying causes eliminated. Otherwise, there are too many problems with the virtual close financial statements to place much reliance on them. The results of a virtual close may not be completely accurate, since some expense accruals, cost allocations, and reserves are difficult to automate. A virtual close differs from a soft close in that the soft close requires a limited number of closing steps; and because of those closing steps, the soft close is usually only used at month-end. Since a virtual close is essentially automated, there are no closing steps, which allows you to run financial statements for any time period at all; thus, daily financial statements are possible. The expense and long-term effort required to create a virtual close are not a good investment in slower-growth industries where there is little new competition and product cycles are lengthy. However, this cost can be worthwhile in the reverse situation, where the business environment is changing with great rapidity, and management can use daily financial statements to make ongoing course corrections to the overall direction of the business. However, even in the latter case, a virtual close is only worth the effort if management is actually going to use the information to make decisions in a timely manner; if that is not the case, then a more traditional closing process may be a better and less expensive solution.

VIRTUAL CORPORATION = ВИРТУАЛЬНАЯ КОРПОРАЦИЯ – Virtual Corporation is a partnership among several enterprises sharing complementary expertise created expressly to produce a product with a short perspective life span with the production of the product being controlled through a computerized network. The corporation is disbanded with the conclusion of the product's life span. Virtual Corporation:- as information and communications technologies overcome the constraints of time and distance, it becomes possible to create virtual organizations. Virtual is usually taken to be something that does not exist in reality. So a typical definition of a Virtual Corporation (taking the dimension of time) is:- (i) 'a temporary network of independent companies linked by IT to share skills, costs, and access to one another's markets' (Business Week). However, another definition relates to an organization not having a clear physical locus. Here a typical definition is:- (ii) 'an organization distributed geographically and whose work is coordinated through electronic communications'. Both definitions show how information and communications technologies can be used to exploit the dimensions of time and space. A virtual corporation is a specific example of a networked organization. Many smaller companies are now realising the benefits of being part of a virtual corporation, which can give them the benefits of the resources of a large organization while retaining the agility and independence of a small one. Benefits:- (i) gives access to a wide range of specialized resources; (ii) can present a unified face to large corporate buyers; (iii) individual members retain their independence and continue to develop their niche skills; (iv) they can reshape and change members according to the project or task in hand; and (v) there is no need to worry ponderously about 'divorce settlements' as in formal joint ventures. The development of business networks as virtual corporations is well developed in Denmark, and is now evolving in other countries. David Skyrme Associates is itself a member of several virtual corporations, including ENTOVATION International. Members of the ENTOVATION Researching and Consulting Networking combine forces to create virtual knowledge teams and virtual corporations, according to project and client needs. Virtually A

Success:- Working in virtual corporations comes naturally to small company entrepreneurs and managers who are effective networkers. They are difficult for those with the conventional corporate mind to fathom out. Some of the ingredients for developing a succeeding virtual corporation are:- (i) each partner must have some distinctive added value to bring to the corporation; (ii) members must develop high degree of mutual trust and understanding; thus, very often the same people will work together again and again; (iii) projects should be the focus of the corporation; usually they will be for clients, but some projects, e.g., marketing, can be done by a few members on behalf of the corporation as a whole; (iv) 'rules of engagement' need to be defined fairly broadly up-front, in terms of inputs to the corporation and rewards expected, though the momentum is lost if these are too formalised too soon; (v) members of the corporation should recognise the need for coordination roles, and either commit time to develop and nurture these or pay one of the members to undertake them on behalf of the corporation; and (vi) a clear interface needs to be developed with 'non virtual' customers – they like tidy relationships and clear contracts. Thus either one member of the virtual corporation must act on behalf of the others (using them as subcontractors) or create a joint company to act as their contracts and administration service. In bringing together many virtual corporations, the role of a network broker can be important (it is, for example, something strongly advocated in the Denmark model). However, in our experience many virtual corporations will evolve naturally out of working relationships that have developed over years. / Бизнэс Вик (Business Week). Интовэйшэн Интёнэшэнэл (ENTOVATION International).

VIRTUAL CURRENCY = ВИРТУАЛЬНАЯ ВАЛЮТА – Virtual Currency is a type of digital currency that is only available in electronic form and not in physical form. It is stored and transacted in only through designated software, mobile or computer applications, or through dedicated digital wallets, and the transactions occur over the Internet or over secure dedicated networks. Virtual currency is considered to be a subset of the digital currency group, which also includes cryptocurrencies. Virtual currency can be defined as an electronic representation of monetary value that may be issued, managed and controlled by private issuers, developers, or the founding organization. Such virtual currencies are often represented in terms of tokens and may remain unregulated without a legal tender. Unlike regular money, it relies on a system of trust and may not be issued by a central bank or other banking regulatory authority. Due to the lack of a centralized regulatory authority, such virtual currencies are prone to wide swings in their valuations. They derive their value based on the underlying mechanism, like mining in cases of cryptocurrencies, or the backing by the underlying asset. The term came into existence around 2012, when the European Central Bank (ECB) defined virtual currency to classify types of 'digital money in an unregulated environment, issued and controlled by its developers and used as a payment method among members of a specific virtual community', according to Bitcoins News. Along with use by the common public, a virtual currency can have restricted usage, and it may be in circulation only among the members of a specific online community or a virtual group of users who transact online on dedicated networks. Virtual currencies are mostly used for peer-to-peer payments and are finding increasing use for purchase of goods and services. Difference Between Digital, Virtual, And Crypto Currencies:- Digital currency is the overall superset that includes virtual currency, which in turn includes cryptocurrencies. Compared to a virtual currency, a digital currency covers a larger group that represents monetary assets in digital form. Digital currency can be regulated or unregulated. In the former case, it can be denominated to a sovereign currency – that is, a country's central bank can issue a digital form of its fiat currency notes. On the other hand, a virtual currency often remains unregulated and hence constitutes a type of digital currency. Cryptocurrencies like Bitcoin and Ethereum are considered to be a part of the virtual currency group. A cryptocurrency uses cryptography technology that keeps the transactions secure and authentic, and also helps to manage and control the creation of new currency units. Such cryptocurrencies exist and are transacted over dedicated blockchain based networks which are open to the common public. Anyone can join and start transacting in cryptocurrencies. See also Virtual Currency Option.

VIRTUAL CURRENCY OPTION = ОПЦИОН НА ВИРТУАЛЬНУЮ ВАЛЮТУ (или ВИРТУАЛЬНЫЙ ВАЛЮТНЫЙ ОПЦИОН) – Virtual Currency Option is a new option contract introduced by the PHLX in 1994 that is settled in US Dollars rather than in the underlying currency. These options are also called 3-Ds (Dollar-Denominated Delivery). Virtual Currency Option:- an option contract that is typically settled in US Dollar rather than in the stated underlying currency. These options are also called 3-Ds (Dollar-Denominated Delivery). The virtual currency option was first introduced by the Philadelphia Stock Exchange (PHLX) in 1994. See also Virtual Currency.

VIRTUAL HTS = VIRTUAL HIGH–THROUGHPUT SCREENING

VIRTUAL POPULATION ANALYSIS = АНАЛИЗ ВИРТУАЛЬНОЙ ПОПУЛЯЦИИ (или ВИРТУАЛЬНЫЙ АНАЛИЗ ПОПУЛЯЦИИ) – Virtual Population Analysis (VPA) is a widely used model for the analysis of fished populations. While there are very many VPA techniques, they vary in the way they use data and fit the model rather than in the form of the model itself. This manual describes the common VPA model and the assumptions on which it is based, together with descriptions of associated diagnostic procedures and common reference points. More importantly, the manual describes the numerical techniques which can be used to fit the model based on weighted least-squares, which is the basis for the ADAPT approach. (ADAPT = Adaptive Framework – a general approach to fitting VPA models. ADAPT is based on minimising the sumof-squares over any number of indices of abundance to find best-fit parameters). The techniques are described so that they are readily implemented in a spreadsheet. General methods and specific examples are given to enable the readers to develop an approach suitable for their own data and fisheries. There are a variety of VPA-type methods, which form powerful tools for stock assessment. At first sight, the large number of methods and their arcane names can put off the newcomer. However, this complexity is based on simple common components. All these methods use age-structured data to assess the state of a stock. The stock assessment is based on a population dynamics model, which defines how the age-structure changes through time. This model is the simplest possible description of numbers of similar aged fish where we wish to account for decreases in stock size through fishing activities. The diversity of VPA methods comes from the way they use different types of data and the way they are fitted. This manual is structured to describe the different components that make up a VPA stock assessment model:- (1) Population Model (Analytical Model):- the population model is the common element among all VPA methods. The model defines the number of fish in a cohort based on the fishing history and age of the fish. A cohort is a set of fish all having (approximately) the same age, which gain no new members after recruitment, but decline through mortality. The fisheries model attempts to measure the impact catches have on the population. The population model usually will encapsulate the time series aspects of change and should include any random effects on the population (process errors), if any. (2) Link Model:- only rarely can variables in which we are interested be observed directly. Usually data consists of observations on variables that are only indirectly linked to variables of interest in the population model. The models linking the population model to observable variables are many and varied. They, in general, separate the different VPA approaches. The most common observable variable is CPUE (Catch per Unit of Effort), which is often thought to be related to stock size. The link model in most cases will be associated with an observation error. (3) Error Model:- finally, the model needs to be fitted to observations. The error model defines the criteria to do this, so that some objective best-estimate for the parameters and stock status are obtained. In VPA, weighted least-squares is often used as the fitting procedure, and this is the method discussed in this manual. A broadening of this approach allows the population and link models to describe parameters in any likelihood function. Although this latter approach may be preferred, it is more complicated and not discussed in detail in the manual. The reason for discussing the models as separate components is because there is no general prescriptive VPA method. Instead, the readers

should be able to use the components to develop VPAs suitable for their own fisheries. This manual aims to provide the readers with a degree of understanding so that they will be able to use spreadsheets and other software tools to carry out the numerical procedures necessary to conduct a non-standard VPA. The methods explained are for illustration only and should not be taken as an endorsement of any method in any particular case. In some of the examples, data presented were extracted from ICES (short for the International Council for the Exploration of the Sea, based in Copenhagen, Denmark) assessment working group reports. These data do not represent all information available for stock assessment, as they were selected to illustrate the methods only. The results differ from the ICES stock assessment results and should not be used for anything other than illustrating calculations. It is hoped that the readers will be given enough insight to evaluate methods for themselves and see whether any technique is applicable to their own data and fishery. Virtual Population Analysis (VPA) is a method used by biologists to assess the physical data on stocks of fish. It employs data on catches from different cohorts of the same stock, together with data on catch per unit effort. Virtual Population Analysis (VPA) is a technique employed to calculate fishing mortality rates and stock sizes (abundance) of a yearclass (the fish hatched in a given year) at successive ages, given the known or assumed natural mortality rate and catch (in numbers) at each age and given the knoltm (Knol^{TM}) or assumed fishing mortality rate at the oldest age. In order to describe the technique, it is first necessary to define some basic terms and equations relating to mortality rates, stock size, and catch. / Кнол^{ТЗ} (Knol^{TM}).

VIRTUAL SAFE SETTING = ВИРТУАЛЬНАЯ НАДЁЖНАЯ УСТАНОВКА – Virtual Safe Setting is a virtual environment providing remote execution facilities. Synonym of Remote Data Laboratory. See also Remote Data Laboratory.

VIRTUOUS CYCLE = ДЕЙСТВЕННЫЙ ЦИКЛ – A Virtuous Cycle in the economy means that higher wages stimulate consumption, leading to higher prices and larger corporate profits. This is typically distinguished as a shortage of labor driven cycle rather than a mere cost-push cycle that was indicative of the 1970s driven by the external increase in oil prices. The A virtuous cycle is one where wages drive the cycle rather than external factors or even an increase in money supply due to fiscal mismanagement. Some people have distorted this qualification and applied it to merely increased wages without regard to the cause. It has been used in immigration arguments but the theory is different. Legalize the illegal labor that will generate more taxes and they then assume their wages would rise. Interesting concept, but it fails completely under the real definition of a virtuous cycle that is a shortage of labor, not merely a rise in wages. They confuse the result with the cause. A Virtuous Cycle is a cycle of growth where success in successive elements in the loop of the cycle promotes overall success of the system. / Действенный Цикл:- понятие, характеризующее род действий, которые по мнению некоторых банкиров, следует предпринимать правительству с целью минимизации последствий колебаний валютных курсов. Такие действия предполагают проведение разумной экономической политики, которая повышает экономическую эффективность, а следовательно, устойчивость валюты, что в свою очередь ведёт к большей экономической эффективности.

VIRULENCE = ВИРУЛЕНТНОСТЬ – Virulence is the ability of an agent of infection to produce disease. The virulence of a microorganism is a measure of the severity of the disease it causes. Virulence is a capacity of a pathogen or insect to incite a disease or injury to the host. Degree or measure of pathogenicity. Virulence is one of a number of possible outcomes of host-microbe interaction. As such, microbial virulence is dependent on host factors, as exemplified by the pathogenicity of avirulent microbes in immunocompromised hosts and the lack of pathogenicity of virulent pathogens in immune hosts. Pathogen-centered views of virulence assert that pathogens are distinguished from nonpathogens by their expression of virulence factors. Although this concept appears to apply to certain microbes that cause disease in normal hosts, it does not apply to most microbes that cause disease primarily in immunocompromised hosts. The study of virulence is fraught with the paradox that virulence, despite being a microbial characteristic, can only be expressed in a susceptible host. Thus, the question ‘What is a pathogen?’ begs the question, ‘What is the outcome of the host-microbe interaction?’ We propose that host damage provides a common denominator that translates into the different outcomes of host-microbe interaction. The words Virulence and Virulent derive from the Latin word Virulentus, meaning Full Of Poison. Virulentus derives from the Latin words Virus (Poison) and Lentus (Fullness), and, in turn, the term Virus may be related to the Sanskrit word Visham, meaning Poison. The word Virulence currently is used to characterize the relative capacity of a microbe to cause disease and has traditionally been used to describe a microbial characteristic. This usage is consistent with the ancient meaning of virulence as a microbial characteristic that implies an ability to deliver poison and thereby to cause disease. Currently, this concept has been extended to imply that it is the characteristic of virulence that distinguishes pathogens, which are thought to be virulent, from nonpathogens, which are thought to be avirulent. The Problem With Virulence:- Virulence has been difficult to define since the early days of the microbial theory of disease. Half a century ago, Watson and Brandly concluded that ‘there is no uniformity of agreement among students of infectious disease on the meaning of the word virulence’. This situation still exists today, because there is considerable confusion regarding what is meant by virulence. The confusion stems from the fact that virulence is considered to be a microbial property, yet it is expressed only in a susceptible host. Therefore, rather than being an independent variable, virulence is a dependent variable that is contingent on the availability of a susceptible host and the context and nature of the host-microbe interaction. This paradox also has been acknowledged by others, who noted that virulence is ‘a host-centered measure of a phenomenon that is neither host nor parasite but of the host parasite complex’. The concept that virulence is an intrinsic microbial property that distinguishes pathogenic from nonpathogenic microbes is difficult to apply in the face of increasing evidence that host factors are critical determinants of the outcome of host-microbe interactions. For example, so-called Virulent Microbes are avirulent in hosts with specific immunity, and microbes that are usually avirulent cause disease in impaired hosts. Thus, virulence is not a separate microbial characteristic but, rather, a complex, dynamic, and changeable phenomenon that includes both host and microbial factors. Furthermore, host-microbe interactions can range from the elimination of the microbe to the death of the host encompassing the states of latency, colonization, and commensalism, which can evolve to cause disease. Thus, the view that virulence is a single characteristic is difficult to reconcile with the fact that the host-microbe interaction is continuous and subject to further change on the basis of host, microbial, and exogenous factors, such as medical intervention. Classical Attributes Of Virulence:- The recognition that virulence is a multifaceted characteristic of certain microbes, but not of others, led to efforts to define its attributes. Early definitions of virulence were based on descriptions of microbial characteristics, including its degree of pathogenicity; its capacity to overcome host defenses; the severity of the disease that it caused; the percentage of death an infection with it induced; its invasive power; its infectivity or the damage it induced; and its capacity to grow and multiply in a host. For example, Kolmer suggested that virulence arose from 2 microbial factors, toxicity and aggressiveness (or invasive power), and Falk defined virulence as the inverse of resistance. Nonetheless, the basis of the aforementioned definitions of virulence was the presence of certain microbial attributes that appear to have been consistently noted. (1) Toxicity:- the view that virulence depended on the elaboration of poisonous substances from microbes was common in the early XX century. Kolmer proposed that the term Toxicity applied to the type and amount of poison or toxin produced; he further proposed that soluble poisons could be released from a microbe or were endogenous within the body of the microorganism itself. The classification of bacterial toxins involved a consideration of their immunogenicity and ability to produce antitoxins, although it was recognized that toxin-producing microbes could kill their hosts quickly, presumably before the development of an immune response. Karsner and Ecker described 4 types of bacterial toxins:- ptomains, produced by decomposition; exotoxins or true toxins; endotoxins that developed after the death of bacteria; and poisonous bacterial proteins. Ptomains consisted of small

molecules, such as methylamines, putrescine, and cadavarin, which did not elicit humoral immunity. Endotoxins elicited antibody responses that could agglutinate the microbe of origin, but such responses were seldom protective. In contrast, true toxins were substances produced by the 'life activity of Bacteria' that elicited protective antitoxin responses. This terminology reflects the fact that early investigators discerned that exotoxins represented a special virulence attribute distinguishable from media-related toxins or the toxicity that ensues after inoculation of dead bacteria. Stewart provided a broader definition for the attribute of toxicity by defining it as the capacity to damage host tissue. According to Stewart, toxicity included not only damage from microbial toxins but also damage from toxic metabolic end products, production of substances that elicited allergic reactions, and interference with nutrition of host cells. (2) Aggressiveness:- the ability of a microorganism to invade, survive, and multiply in the tissues of a host was considered to be the attribute of aggressiveness. Although aggressiveness was considered to be different than toxicity, the 2 terms were often difficult to separate, possibly because some toxins contributed to the ability of the microbe to invade, survive, and multiply in the host. For instance, it was noted that Staphylococcus Aureus and Streptococcus Pyogenes made toxins called Leukocidins that killed host leukocytes, but they were not toxic in the sense of diphtheria toxin, which was seen to directly promote tissue invasion. However, other organisms provided clear examples that aggressiveness and toxicity were different attributes. Streptococcus Pneumoniae was considered to be highly aggressive and moderately toxic, whereas the toxin-producing Bacteria Clostridium Tetani and Corynebacterium Diphtheriae were considered to be highly toxic but only slightly aggressive. A microbial capsule was thought to contribute to the aggressiveness of a microorganism, because it allowed for survival in the host by promoting resistance to phagocytosis. In contrast, Stewart defined aggressiveness as the capacity of bacteria to multiply in tissues, but interestingly, he noted that replication alone was not sufficient to cause disease unless damage resulted. Presumably, any factor that contributed to the ability of a microbe to grow in tissue also would contribute to aggressiveness. Bails's 'aggressin' theory was based on the observation that bacterial exudates contained toxic substances (for a review of Bails's experiments in English). 'Aggressins' was a term used for substances produced by microorganisms that had the power to inhibit or destroy the ability of the host to defend itself against microbes. Although Bails's 'aggressins' were subsequently shown to be endotoxins, his 'aggressin' theory can be regarded as the intellectual ancestor of today's concept that pathogenic microbes have virulence factors that mediate their pathogenicity. The attribute of invasiveness has not been well defined and appears to be a newer formulation of the term Aggressiveness, which was used in the earlier literature. In one definition, the term refers to the capacity of a microbe to replicate in host tissues, which, in turn, is dependent on the capacity of the microbe to resist host defense mechanisms. In another definition, the term meant the ability to disseminate from a portal of entry. By the 1920s, it was clear that not all pathogenic microbes produced toxins, and further attempts were made to separate virulence from toxicity. By 1949, toxigenicity, infectivity, communicability, and invasiveness were each considered to be attributes of virulence. (3) Replication And Transmission:- contagiousness has been considered to be as important as replication for certain microbes to persist in their hosts. This concept led to the incorporation of infectiousness and the ability of microbes to reproduce and adapt in their hosts into the definition of virulence. Although it has been stated that virulence reflects selection for characteristics that have maximized microbial fitness via transmission, there is some controversy as to whether in vivo microbial growth per se is a sufficient condition for virulence. The relationship between microbial virulence and transmissibility is complex and currently unresolved for most pathogens. Some authorities have considered the role of the microorganism in contagiousness to be a passive one, suggesting that communicability should not be considered to be an attribute of virulence. On the other hand, there are proponents of the view that the mode of microbial transmission itself – for example, symptoms of diseases that transmit microbes from one host to another – are attributes of virulence. However, this view cannot apply to all pathogens. For example, the fungus Cryptococcus neoformanscan cause life-threatening meningoencephalitis, yet it is not contagious. Contagiousness is presumably a function of the route of transmission, location of the infectious process, ability of the microorganism to disseminate from one host to another, and immune status of the host. The ability of certain organisms to replicate and sustain themselves in protozoan, invertebrate, or nonhuman mammalian vectors is consistent with the concept that virulence is linked to the mode of transmission and may be greater for microbes that do not require host fitness for transmission. In this category, one could also consider the phenomenon of microbe-mediated alterations in host behavior, fitness, or both that facilitate transmission. For example, rats infected by Toxoplasma Gondii lose their fear of cats, an event that can lead to increased predation and a higher likelihood of the parasite entering its definitive host to complete its reproductive cycle. Along the same lines, a Yersinia Pestis gene locus increases the feeding of its flea vector, which, in turn, can promote transmission of the microbe. The latter phenomenon also is found among other microbes that replicate in insect vectors. (4) Adherence And Attachment:- for many microbes, adherence to host tissue is believed to be essential for virulence, and the microbial characteristics that promote adherence to mucosal surfaces are considered to be attributes of virulence. This attribute may be particularly important for the virulence of certain bacterial strains, such as enterotoxigenic strains of Escherichia Coli. For some microorganisms, virulence has been defined in terms of the capacity to regulate the expression of adherence factors. However, the fact that many commensal microbes also adhere to host cells but are not virulent underscores that some form of host damage is required for microbial virulence. (5) Antigenic Variation:- microbes can adapt to evade selective pressures in the host was illustrated by trypanosomal phase variation and the emergence of bacterial strains resistant to serum during infection. Other examples include variation in the expression of surface proteins by Neisseria Spp. and the mutability of viral agents, such as retroviruses and hepatitis C virus. Antigenic variation can increase microbial fitness by enhancing the ability of the microbe to evade host defenses and to survive in a host. (6) Immunologic Reactions As Manifestations Of Virulence:- the ability of certain microbes to elicit deleterious immune responses has been considered to be an attribute of virulence. Hoeprich characterized pathogenic host-microbe interactions, depending on their relative invasiveness, intoxication, and hypersensitivity and considered hypersensitivity to be as important for virulence as toxicity and invasiveness. Consistent with this concept, hypersensitivity reactions, such as the occurrence of Arthuslike phenomena, the development of vasculitis in people convalescing from streptococcal infections, and the intense cellular reaction and tissue destruction in tuberculosis, are all proposed to reflect the virulence of these microorganisms. In general, Virulence is the degree of toxicity or the injury-producing potential of a microorganism. The words virulence and pathogenicity are often used interchangeably. The virulence of Bacteria usually relates to their capability of producing a powerful exotoxin or endotoxin. / Ватсэн энд Брэндли (Watson and Brandly). Казнё и Экя (Karsner and Ecker). Хоэприч (Hoeprich). Под Вирулентностью, от Латинского слова Virulentus, означающее Ядовитое, понимается степень болезнетворности (патогенности) данного штамма микроорганизма в отношении определённого вида животных или растений при естественном или искусственном заражении. Вирулентность включает совокупность болезнетворных свойств Бактерий:- инфекционность, инвазивность, агрессивность, токсигенность (токсичность). Зависит от инфекционных свойств агента и от восприимчивости заражаемого организма (сопротивляемости организма). Искусственное изменение вирулентности микробов применяется при получении вакцин. Вирулентность – степень патогенности микроорганизма. Под Вирулентностью, от Латинского слова Virulentus, означающее Ядовитый, понимается степень болезнетворности (патогенности) данного инфекционного агента (штамма микроба или вируса). Вирулентность зависит как от свойств инфекционного агента, так и от восприимчивости (чувствительности) инфицируемого организма. О величине вирулентности судят по тяжести вызываемых микробом или вирусом заболеваний, в экспериментах на животных – по смертельной дозе инфекционного агента. Вирулентность определяется не только способностью микроорганизма внедряться в организм восприимчивого животного, размножаться и распространяться в нём, но и тем, что микроб (или вирус)

вырабатывает ядовитые продукты жизнедеятельности – токсины. Вирулентность – не видовой признак микроба (вируса) и может колебаться в широких пределах у разных штаммов. Изменение вирулентности может быть вызвано искусственными воздействиями, например, нагреванием, облучением, химическим и другим, которые применяются для получения живых вакцин. С этой же целью многократно пересевают инфекционный агент (например, вирус уличного бешенства – через мозг Кроликов, в результате чего вирулентность вируса для человека снижается и он может быть использован для прививок против бешенства).

VIRULENT = ВИРУЛЕНТНОЕ – Virulent (of a disease) dangerous and spreading quickly, or (of poison) having an effect very quickly:- a virulent strain of flu. Virulent:- strongly pathogenic. Virulent:- (1) a:- marked by a rapid, severe, and destructive course; a virulent infection; or b:- able to overcome bodily defensive mechanisms; markedly pathogenic; virulent Bacteria. (2) Extremely poisonous or venomous or intensely noxious; a virulent insect bite. (3) Full of malice:- Malignant; virulent racists. (4) Objectionably harsh or strong; virulent criticism. Virulent:- fierce and full of hate:- virulent speech. For example:- several newspapers mounted virulent attacks.

VIRULENT GENE = ВИРУЛЕНТНЫЙ ГЕН – Virulent Gene is a gene in pest which is able to break down the gene for pest resistance in the plant and thus allows the pest to use the plant as a host.

VIRULIFEROUS = СОДЕРЖАЩИЙ ВИРУС (или НОСИТЕЛЬ ВИРУСА) – Viruliferous is a term used to describe a virus-carrying insect. It denotes an insect that has been given access to a virus source. / термин, используемый для описания насекомого, переносящего вирус. Он означает насекомое, которому был дан доступ к источнику вируса.

VIRUS = ВИРУС – (1) Virus is a simple, noncellular particle (entity) that can reproduce only inside living cells (of other organisms); which was first proved to exist in 1892 by Dimitry Ivanovsky. The simple structure of viruses is their most important characteristic. Most viruses consist only of a genetic material – either DNA (deoxyribonucleic acid) or RNA (ribonucleic acid) – and a protein coating. This (combination) material is categorized as a nucleoprotein. Some viruses also have membranous envelopes (coatings). They are able to 'inject' their genetic material into (host) cells because the internal pressure inside viruses is greater than inside the host cells. Viruses are 'alive' in that they can reproduce themselves – although only by taking over a cell's 'synthetic genetic machinery' – but they have none of the other characteristic of living organisms. Viruses cause a large variety of significant diseases in plants and animals, including humans. Viruses can (e.g., as one part of the disease) cause gene silencing. Virus is the smallest form of microorganisms capable of causing disease. Virus is a simple parasitic micro-organism consisting of little more than a package of genetic material (DNA or RNA) in a protein or lipid envelope, capable of invading the host's cells and replicating only by harnessing their biochemical machinery. Some viruses carry several genes for synthesis of virus-specific proteins. Others (e.g., Potato spindle tuber virus) consist of a circle of DNA which is too small to carry any structural genes. Virus is a submicroscopic infectious agent consisting of particles made up of DNA or RNA which are usually covered by protein and reproduce only in living cells; cannot be separated by filters. Virus is an infectious agent of small size and simple composition that can multiply only in living cells of animals, plants, or bacteria. The name is from a Latin word meaning Slimy Liquid or Poison. The earliest indications of the biological nature of viruses came from studies in 1892 by the Russian scientist Dmitry Iosifovich Ivanovski (1864–1920) and in 1898 by the Dutch scientist Martinus Willem Beijerinck (1851–1931). Beijerinck first surmised that the virus under study was a new kind of infectious agent, which he designated Contagium Vivum Fluidum, meaning that it was a live, reproducing organism that, nevertheless, differed from other organisms. Both of these investigators found that a disease of tobacco plants could be transmitted by an agent, later called Tobacco Mosaic Virus, passing through a minute filter that would not allow the passage of bacteria. This virus and those subsequently isolated would not grow on an artificial medium and were not visible under the light microscope. In independent studies in 1915 by the British investigator Frederick W. Twort (1877–1950) and in 1917 by the French-Canadian scientist Félix Hubert d'Hérelle (1873–1949), lesions in cultures of bacteria were discovered and attributed to an agent called Bacteriophage ('Eater of Bacteria'), now known to be viruses that specifically infect bacteria. The unique nature of these organisms meant that new methods and alternative models had to be developed to study and classify them. The study of viruses confined exclusively or largely to humans, however, posed the formidable problem of finding a susceptible animal host. In 1933 the British investigators Wilson Smith (1897–1965), Sir Christopher Howard Andrewes (1896–1987), and Sir Patrick Playfair Laidlaw (1881–1940) were able to transmit influenza to ferrets, and the influenza virus was subsequently adapted to mice. In 1941 the American scientist George Keble Hirst (1909–1994) found that influenza virus grown in tissues of the chicken embryo could be detected by its capacity to agglutinate (draw together) red blood cells. A significant advance was made by the American scientists John Franklin Enders (1897–1985), Thomas Huckle Weller (1915–2008), and Frederick Chapman Robbins (1916–2003), who in 1949 developed the technique of culturing cells on glass surfaces; cells could then be infected with the viruses that cause poliomyelitis (poliovirus) and other diseases. (Until this time the poliovirus could be grown only in the brains of chimpanzees or the spinal cords of monkeys.) Culturing cells on glass surfaces opened the way for the diagnosis of diseases caused by viruses identified by their effects on cells (cytopathogenic effect) and by the presence of antibodies to them in the blood. Cell culture then led to the development and production of vaccines (preparations used to elicit immunity against a disease), such as the poliovirus vaccine. Scientists were soon able to detect the number of bacterial viruses in a culture vessel by measuring their ability to break apart (lyse) adjoining bacteria, which resulted in a clearing, or 'Plaque', in an area of bacteria (lawn) overlaid with an inert gelatinous substance, called Agar. The American scientist Renato Dulbecco (1914–2012) in 1952 applied this technique to measuring the number of animal viruses that could produce plaques in layers of adjoining animal cells overlaid with agar. In the 1940s the development of the electron microscope permitted individual virus particles to be seen for the first time, leading to the classification of viruses and giving insight into their structure. Advancements that were made in chemistry, physics, and molecular biology since the 1960s have revolutionized the study of viruses. For example, electrophoresis on gel substrates gave a deeper understanding of the protein and nucleic acid composition of viruses. More sophisticated immunologic procedures, including the use of monoclonal antibodies directed to specific antigenic sites on proteins, gave a better insight into the structure and function of viral proteins. The progress made in the physics of crystals that could be studied by X-ray diffraction provided the high resolution required to discover the basic structure of minute viruses. Applications of new knowledge about cell biology and biochemistry helped to determine how viruses use their host cells for synthesizing viral nucleic acids and proteins. The revolution that took place in the field of molecular biology allowed the genetic information encoded in nucleic acids of viruses – which enables viruses to reproduce, synthesize unique proteins, and alter cellular functions – to be studied. In fact, the chemical and physical simplicity of viruses has made them an incisive experimental tool for probing the molecular events involved in certain life processes. This article discusses the fundamental nature of viruses:- what they are, how they cause infection, and how they may ultimately cause disease or bring about the death of their host cells. For more detailed treatment of specific viral diseases, see the article infection. General Features:- Definition:- viruses occupy a special taxonomic position:- they are not plants, animals, or prokaryotic bacteria (single-cell organisms without defined nuclei), and they are generally placed in their own kingdom. In fact, viruses should not even be considered organisms, in the strictest sense, because they are not free-living (i.e. they cannot reproduce and carry on metabolic processes without a host cell). All true viruses contain nucleic acid, either DNA (deoxyribonucleic acid) or RNA (ribonucleic acid), and protein. The nucleic acid encodes the genetic information unique for each virus. The infective, extracellular (outside the cell) form of a virus is called the Virion. It contains at least one unique protein synthesized by specific genes in the nucleic

acid of that virus. In virtually all viruses, at least one of these proteins forms a shell (called a Capsid) around the nucleic acid. Certain viruses also have other proteins internal to the capsid; some of these proteins act as enzymes, often during the synthesis of viral nucleic acids. Viroids (meaning 'Viruslike') are disease-causing organisms that contain only nucleic acid and have no structural proteins. Other viruslike particles called Prions are composed primarily of a protein tightly complexed with a small nucleic acid molecule. Prions are very resistant to inactivation and appear to cause degenerated brain disease in mammals, including humans. Viruses are quintessential parasites; they depend on the host cell for almost all of their life-sustaining functions. Unlike true organisms, viruses cannot synthesize proteins, because they lack ribosomes (cell organelles) for the translation of viral messenger RNA (mRNA; a complementary copy of the nucleic acid of the nucleus, which associates with ribosomes and directs protein synthesis) into proteins. Viruses must use the ribosomes of their host cells to translate viral mRNA into viral proteins. Viruses are also energy parasites; unlike cells, they cannot generate or store energy in the form of adenosine triphosphate (ATP). The virus derives energy, and all other metabolic functions, from the host cell. The invading virus uses the nucleotides and amino acids of the host cell to synthesize its nucleic acids and proteins, respectively. Some viruses use the lipids and sugar chains of the host cell to form their membranes and glycoproteins. The true infectious part of any virus is its nucleic acid, either DNA or RNA but never both. In many viruses, but not all, the nucleic acid alone, stripped of its protein coat (capsid), can infect (transfect) cells, although considerably less efficiently than can the intact virions. The virion capsid has three functions:- (1) to protect the viral nucleic acid from digestion by certain enzymes (nucleases), (2) to furnish sites on its surface that recognize and attach (adsorb) the virion to receptors on the surface of the host cell, and (3), in some viruses, to provide proteins that form part of a specialized component which enables the virion to penetrate through the cell surface membrane or, in special cases, to inject the infectious nucleic acid into the interior of the host cell. Host Range And Distribution:- logic originally dictated that viruses be identified on the basis of the host they infect. This is justified in many cases, but not in others, and the host range and distribution of viruses are only one criterion for their classification. It is still traditional to divide viruses into three categories:- those that infect animals, plants, or bacteria. Virtually all plant viruses are transmitted by insects or other organisms (vectors) that feed on plants. The hosts of animal viruses vary from protozoa (single-celled animal organisms) to humans. Many viruses infect either invertebrate animals or vertebrates, and some infect both. Certain viruses that cause serious diseases of animals and humans are carried by arthropods. These vector-borne viruses multiply both in the invertebrate vector and the vertebrate host. Certain viruses are limited in their host range to the various orders of vertebrates. Some viruses appear to be adapted for growth only in ectothermic vertebrates (animals commonly referred to as Cold-Blooded, such as fishes and reptiles), possibly because they can only reproduce at low temperatures. Other viruses are limited in their host range to endothermic vertebrates (animals commonly referred to as Warm-Blooded, such as mammals). Size And Shape:- the amount and arrangement of the proteins and nucleic acid of viruses determine their size and shape. The nucleic acid and proteins of each class of viruses assemble themselves into a structure called a Nucleoprotein, or nucleocapsid. Some viruses have more than one layer of protein surrounding the nucleic acid; still others have a lipoprotein membrane (called an Envelope), derived from the membrane of the host cell, that surrounds the nucleocapsid core. The protein and nucleic acid constituents have properties unique for each class of virus; when assembled, they determine the size and shape of the virus for that specific class. Viruses vary in diameter from 20 nanometers (0.000 000 8 inch) to 250–400 nanometers. Only the largest and most complex viruses can be seen under the light microscope at the highest resolution. Any determination of the size of a virus also must take into account its shape, since different classes of viruses have distinctive shapes. Shapes of viruses are predominantly of two kinds:- rods, or filaments, so called because of the linear array of the nucleic acid and the protein subunits; and spheres, which are actually 20-sided (icosahedral) polygons. Most plant viruses are small and are either filaments or polygons, as are many bacterial viruses. The larger and more complex bacteriophages, however, contain as their genetic information double-stranded DNA and combine both filamentous and polygonal shapes. Figure 1 shows the classical T4 bacteriophage, composed of a polygonal head, which contains the DNA genome, and a special-function rod-shaped tail of long fibers. Structures such as these are unique to the bacteriophages. Animal viruses exhibit extreme variation in size and shape. The smallest animal viruses belong to the family Parvoviridae, which measure about 20 nanometers in diameter, and the family Picornaviridae, about 30 nanometers in diameter. Viruses of these two families are icosahedrons and contain nucleic acids with limited genetic information. Viruses of the family Poxviridae are about 250 to 400 nanometers in their longest dimension, and they are neither polygons nor filaments. Poxviruses are structurally more complex than, and resemble, simple bacteria. The only animal viruses that have rod-shaped (helical) nucleocapsids are those enclosed in an envelope; these viruses are found in the families Paramyxoviridae, Orthomyxoviridae, Coronaviridae, and Rhabdoviridae. Not all enveloped viruses contain helical nucleocapsids, however; those of the families Herpesviridae, Retroviridae, and Togaviridae have polygonal nucleocapsids. Most enveloped viruses appear to be spherical, although the rhabdoviruses are elongated cylinders. The criteria used for classifying viruses into families and genera are primarily based on three structural considerations:- (1) the type and size of their nucleic acid, (2) the shape and size of the capsids, and (3) the presence of a lipid envelope, derived from the host cell, surrounding the viral nucleocapsid. The Nucleic Acid:- as is true in all forms of life, the nucleic acid of each virus encodes the genetic information for the synthesis of all proteins. In almost all free-living organisms, the genetic information is in the form of double-stranded DNA arranged as a spiral lattice joined at the bases along the length of the molecule (a double-helix). Double-stranded DNA also carries the genetic information for some viruses, although probably in most the genetic information of the virion is RNA. In extracellular virions, the DNA and RNA are called Genomes, and they can be double- or single-stranded. In all double-stranded DNA viruses, the nucleic acid is a single large molecule. Most, if not all, of the double-stranded RNA viruses have segmented genomes; each segment usually is a single gene, which encodes the information for synthesizing a single protein. Those DNA viruses in which the genomic DNA is single-stranded are usually small, with limited genetic information. Some single-stranded DNA viruses are composed of two populations of virions, each consisting of complementary single-stranded DNA of polarity opposite to that of the other. The virions of most plant viruses and many animal and bacterial viruses are composed of single-stranded RNA. In most of these viruses, the genomic RNA is termed a plus strand because the genomic RNA acts as mRNA for direct synthesis (translation) of viral protein. Several large families of animal viruses, and one that includes plant viruses (the Rhabdoviridae), however, contain genomic single-stranded RNA, termed a negative strand, which is complementary to mRNA. All of these negative-strand RNA viruses have an enzyme, called an RNA-Dependent RNA Polymerase (Transcriptase), which must first catalyze the synthesis of complementary mRNA from the virion genomic RNA before viral protein synthesis can occur. These variations in the nucleic acids of viruses form one central criterion for classification of all viruses. A distinctive large family of single-stranded RNA viruses is called Retroviridae; the RNA of these viruses is positive, but the viruses are equipped with an enzyme, called a Reverse Transcriptase, that copies the single-stranded RNA to form double-stranded DNA. The Protein Capsid:- the protein capsid provides the second major criterion for the classification of viruses. The capsid surrounds the virus and is composed of a finite number of protein subunits known as Capsomers, which usually associate with, or are found close to, the virion nucleic acid. There are two major classes of viruses based on the protein capsid:- (1) those in which a single (or segmented) linear nucleic acid molecule with two free ends is essentially completely extended or somewhat coiled (a helix) and (2) those in which the nucleic acid, which may or may not be a covalently closed circle, is wound tightly into a condensed configuration, like a ball of yarn. These two classes of virus assume in the first case a long, extended rodlike structure and in the second case a symmetrical polygon. The helical nucleic acids of rod-shaped viruses are tightly enclosed in a sheath of protein molecules. By far the best-studied example of a helical rod-shaped virus is the tobacco mosaic virus, which was crystallized by the

American biochemist Wendell Meredith Stanley (1904–1971) in 1935. Figure 2 shows a model of the tobacco mosaic virus, the genome of which is single-stranded RNA encased by 2,130 molecules of a single protein; there are 16 1/3 protein molecules for each turn of the RNA helix in the ratio of three nucleotides for each protein molecule. Under the right environmental conditions, viral RNA and protein molecules in liquid suspension will assemble themselves into a perfectly formed and fully infectious virus. The length of the virus capsid is determined by the length of the nucleic acid molecule, which is the framework for the assembly of the capsid protein. The various helical viruses have different lengths and widths depending on the size of the nucleic acid as well as on the mass and shape of the protein molecule. Some of these helical viruses form rigid, and others flexuous, rods, depending on the properties of the assembled proteins. Polygonal viruses vary greatly in size, from 20 to 150 nanometers in diameter, essentially proportional to the size of the nucleic acid molecule coiled up inside the virion. Most, if not all, of the polygonal viruses are icosahedral; like a geodesic dome, they are formed by equilateral triangles, in this case 20. Each triangle is composed of protein subunits (capsomers), often in the form of hexons (multiples of six) that are the building blocks of the capsid. There are 12 vertices (the apical junctions of these 20 triangles), each comprising a penton (five subunits). These icosahedral virions have three axes of fivefold, threefold, and twofold rotational symmetry. The number of subunits (capsomers) is a basis for taxonomic classification of these virus families. Certain icosahedral viruses, usually those that are more complex, contain internal proteins adhering to the nucleic acid that are not accessible at the surface of the virions. The Lipoprotein Envelope:- surrounding viruses of either helical or icosahedral symmetry are lipoprotein envelopes, unit membranes of two lipid layers interspersed with protein molecules (lipoprotein bilayer). These viral membranes are composed of phospholipids and neutral lipids (largely cholesterol) derived from the cell membrane during the process known as the Budding of the virus from the outermost cell membrane. Virtually all proteins of the cell membrane, however, are replaced by proteins of viral origin during budding. Although all the viral envelope lipids originate from the cell, their relative proportions vary from those in the cell membrane because the viral proteins select only certain lipids during budding. Associated with the virion membrane are ‘integral’ glycoproteins, which completely traverse the lipid bilayer, and ‘peripheral’ matrix proteins, which line the inner surface. The glycoproteins contain regions of amino acids that, in the first step of viral infection, recognize host-cell receptors. Matrix proteins appear to function in the selection of regions of the cell membrane to be used for the viral membrane. The Cycle Of Infection:- viruses can reproduce only within a host cell. The parental virus (virion) gives rise to numerous progeny, usually genetically and structurally identical to the parent virus. The actions of the virus depend both on its destructive tendencies toward a specific host cell and on environmental conditions. In the vegetative cycle of viral infection, multiplication of progeny viruses can be rapid. This cycle of infection often results in the death of the cell and the release of many virus progeny. Certain viruses, particularly bacteriophages, are called Temperate because the infection does not immediately result in cell death. The viral genetic material remains dormant or is actually integrated into the genome of the host cell. Cells infected with temperate viruses are called Lysogenic because the cells tend to be broken down when they encounter some chemical or physical factor, such as ultraviolet light. In addition, many animal and plant viruses, the genetic information of which is not integrated into the host DNA, may lie dormant in tissues for long periods of time without causing much, if any, tissue damage. Viral infection does not always result in cell death or tissue injury; in fact, most viruses lie dormant in tissue without ever causing pathological effects, or they do so only under other, often environmental, provocations. Although the reproductive pathways of different viruses vary considerably, there are certain basic principles and a particular series of events in the cycle of infection for most, if not all, viruses. The first step in the cycle of infection is that the invading parental virus (virion) must attach to the surface of the host cell (adsorption). In the second step, the intact virion either penetrates the outer membrane and enters the cell’s interior (cytoplasm), or it injects the genetic material of the virus into the interior of the cell while the protein capsid (and envelope, if present) remains at the cell surface. In the case of whole-virion penetration, a subsequent process (uncoating) liberates the genetic material from the capsid and envelope, if present. In either case, the viral genetic material cannot begin to synthesize protein until it emerges from the capsid or envelope. Certain bacterial viruses, such as the T4 bacteriophage, have evolved an elaborate process of infection:- following adsorption and firm attachment of the virus’s tail to the bacterium surface by means of proteinaceous ‘pins’, the musclelike tail contracts and the tail plug penetrates the cell wall and underlying membrane and injects virus (phage) DNA into the cell. Other bacteriophages penetrate the cell membrane by different means, such as injecting the nucleic acid through the male (sex) pili of the bacterium. In all bacterial viruses, penetration transmits the viral nucleic acid through a rigid bacterial cell wall. Plant cells also have rigid cell walls, which plant viruses cannot ordinarily penetrate. Plant viruses, however, have not evolved their own systems for injecting nucleic acids into host cells, and so they are transmitted by the proboscis of insects that feed on plants. In the laboratory, plant viruses penetrate plant cells if the cell walls have been abraded with sandpaper or if cell protoplasts (plasma membrane, cytoplasm, and nucleus) are devoid of walls. Penetration of animal cells by viruses involves different processes because animal cells are enclosed not by walls but by a flexible lipoprotein bilayer membrane. Most animal viruses, whether or not they are encased in lipid envelopes, penetrate cells in an intact form by a process called Endocytosis. The membrane invaginates and engulfs a virus particle adsorbed to a cell, usually in an area of the membrane called a Coated Pit, which is lined by a special protein known as Clathrin. As the coated pit invaginates, it is pinched off in the cytoplasm to form a coated vesicle. The coated vesicle fuses with cytoplasmic endosomes (membrane-enclosed vesicles) and then with cell organelles called Lysosomes, which are membrane-enclosed vesicles containing enzymes. In an acidic environment, the membrane of an enveloped virus fuses with the endosome membrane, and the viral nucleocapsid is released into the cytoplasm. Nonenveloped viruses presumably undergo a similar process, by which the protein capsid is degraded, releasing the naked viral nucleic acid into the cytoplasm. The order of the stages of viral replication that follows the uncoating of the genome varies for different virus classes. For many virus families the third step in the cycle of infection is transcription of the genome of the virus to produce viral mRNA, followed by the fourth step, translation of viral mRNA into proteins. For those viruses in which the genomic nucleic acid is an RNA that can serve as a messenger (i.e. positive-strand RNA viruses), the third step is the translation of the RNA to form viral proteins; some of these newly synthesized viral proteins are enzymes that synthesize nucleic acids (polymerases), which carry out a fourth step, the transcription of more mRNA from the viral genome. For the more complicated DNA viruses, such as adenoviruses and herpesviruses, some regions of the genome synthesize ‘early’ mRNAs, which are translated into polymerases that initiate the transcription of ‘late’ regions of the DNA into mRNAs, which are then translated into structural proteins. Regardless of how the third and fourth steps proceed, the fifth step in the cycle of infection is replication (reproduction of the parental genome to make progeny genomes). The sixth step is the assembly of the newly replicated progeny genomes with structural proteins to make fully formed progeny virions. The seventh and last step is the release of progeny virions by lysis of the host cell through the process of either extrusion or budding, depending on the nature of the virus. In a host animal or cell culture this seven-step process may be repeated many times; the progeny virions released from the original site of infection are then transmitted to other sites or to other individuals. For most animal and plant RNA viruses, all replicative events take place in the cytoplasm; in fact, many of these RNA viruses can grow in host cells in which the nucleus has been removed. Replication of most animal and plant DNA viruses, and the RNA influenza virus, takes place in the nucleus. In these viruses transcription takes place in the nucleus, the mRNA migrates to the cytoplasm where it is translated, and these viral proteins migrate back to the nucleus, where they assemble with newly replicated progeny genomes. Migration of newly translated viral proteins from the cytoplasm to the nucleus is generally a function of specific amino acid sequences called ‘Signals’, which translocate the protein through pores in the nucleus membrane. Viral DNA Integration:- Lysogeny:- many bacterial and animal viruses lie dormant in the infected cell, and their DNA may be

integrated into the DNA of the host cell chromosome. The integrated viral DNA replicates as the cell genome replicates; after cell division, the integrated viral DNA is duplicated and usually distributed equally to the two cells that result. The bacteria that carry the noninfective precursor phage, called the Prophage, remain healthy and continue to grow until they are stimulated by some perturbing factor, such as ultraviolet light. The prophage DNA is then excised from the bacterial chromosome and the phage replicates, producing many progeny phages and lysing the host bacterial cell. This process, originally discovered in temperate bacteriophages in 1950 by the French microbiologist André Michel Lwoff (1902–1994), is called Lysogeny. The classic example of a temperate bacteriophage is called Lambda (λ) Virus, which readily causes lysogeny in certain species of the bacterium Escherichia Coli. The DNA of the λ bacteriophage is integrated into the DNA of the Escherichia Coli host chromosome at specific regions, called Attachment Sites. The integrated prophage is the inherited, noninfectious form of the virus; it contains a gene that represses the lytic functions of the phage and thus assures that the host cell will continue to replicate the phage DNA along with its own and that it will not be destroyed by the virus. Ultraviolet light, or other factors that stimulate the replication of DNA in the host cell, causes the formation of a recA protease, an enzyme that breaks apart the λ phage repressor and induces λ phage replication and, eventually, destruction of the host cell. Excision of the prophage DNA from the host chromosomal DNA (as an initial step in the synthesis of an infective, lytic virus) sometimes results in the removal of some of the host cell DNA, which is packaged into defective bacteriophages; part of the bacteriophage DNA is removed and replaced at the other end by a gene of the host bacterium. Such a virus particle is called a Transducing Phage because, when it infects a bacterial cell, it can transmit the gene captured by λ phage DNA into the next bacterial cell it infects. Transduction by bacteriophages is an efficient means for transferring the genetic information of one bacterial cell to another. This means of transferring genetic information, called Lysogenic Conversion, imparts genes with special functions to bacterial cells without such functions. It is common in bacteria and is an important aspect of the epidemiology (incidence, distribution, and control) of infectious diseases. For example, the bacterium Corynebacterium diphtheriae is the causative agent of diphtheria, but only when it contains the prophage of bacteriophage β, which codes for the toxin that is responsible for the disease. Malignant Transformation:- a phenomenon analogous to bacterial cell lysogeny occurs in animal cells infected with certain viruses. These animal viruses do not generally cause disease immediately for certain animal cells. Instead, animal cells are persistently infected with such viruses, the DNA of which (provirus) is integrated into the chromosomal DNA of the host cell. In general, cells with integrated proviral DNA are converted into cancer cells, a phenomenon known as malignant transformation. As is the case with bacterial prophages, the transformed animal cell contains no infectious virus but only the integrated provirus DNA, which replicates along with the dividing cell's chromosomes. Therefore, following mitosis of the transformed cell, each new cell receives a copy of the proviral DNA. The hallmark of these transformed animal cells is that their growth is uncontrollable; unlike normal cells, their growth is not inhibited by contact with other cells, and they lose their capacity to adhere (anchor) to certain surfaces. Growth of normal tissues and organs is also controlled by a genetic phenomenon called Programmed Cell Death, or apoptosis, in which a certain number of cells will die and be eliminated after a finite number of divisions. Malignant transformation can impede programmed cell death, thus allowing the cells to grow uncontrolled, resulting in cancer. Among the animal viruses that cause malignant transformation by integration of proviral DNA are several families of DNA viruses and one large family of RNA viruses, the Retroviridae. Viruses of the family Papovaviridae were perhaps the first to be associated with malignancy (causing death or illness) in animals. Polyoma virus is widespread in mice; it can infect other rodents, and it can cause tumours in infected animals. Another virus of the family Papovaviridae is simian virus 40 (SV40), originally isolated from cells of the African green monkey (Cercopithecus Sabaeus), where it grows rapidly and kills the cells. Infection of rodent or human cells, however, results in an abortive infection (an incompatibility between the virus and the host cell) but sometimes induces malignancy (sarcomas or lymphomas) in the occasional cell that is transformed. Viruses related to polyoma virus and SV40 have been isolated from humans, one of which, the JC virus, appears to be the causative agent of a fatal neurological disease called Progressive Multifocal Leukoencephalopathy. In general, however, the human papovaviruses are not clearly associated with disease. Other viruses of the family Papovaviridae include the papillomaviruses, which are also small polygonal viruses containing circular double-stranded DNA. The papillomaviruses are associated with usually benign (nonthreatening) but widespread tumours, called Papillomas or Polyps, occurring in human skin and the genital tract. Specific papillomaviruses have been identified in humans in common warts and in genital warts (condylomata acuminata). Cancers of the human genital tract, particularly uterine cancer of the cervix, are frequently found in association with human papillomavirus type 16 (HPV16); the virus undoubtedly is transmitted as a venereal disease. Certain viruses of the family Adenoviridae, originally found in the tonsils and adenoids of humans, cause malignant transformation in certain cells. This phenomenon of cancer induction under laboratory conditions has been studied widely, but there is no evidence that the common adenoviruses cause cancers in humans. The common viruses of the family Herpesviridae, however, including the common herpes simplex viruses that cause cold sores and the venereal disease genital herpes, are suspected of being causative agents of cancer. Like the adenoviruses, the herpesviruses can cause malignant transformations, and their DNA is integrated into the host cell chromosome. A herpesvirus known as the Epstein-Barr Virus (EBV; was named after British scientists Michael Anthony Epstein (1921–) and Yvonne Barr (1932–2016)) causes a frequently fatal childhood cancer called Burkitt's Lymphoma as well as the nonmalignant disease infectious mononucleosis. The herpesvirus cytomegalovirus lies dormant in the tissues of most humans and can be induced to cause fatal diseases in infants and immunocompromised adults. A different herpesvirus causes chicken pox (varicella); the same virus lies latent in the tissues for long periods of time (perhaps years or decades) and later undergoes recrudescence (the recurrence of symptoms after they have abated) to cause the painful skin and neurological disease called Herpes Zoster, or Shingles. In addition, there are herpesviruses that cause disease in animals – for example, the widespread and usually fatal disease in chickens called Marek's Disease (named after József Marek (1868–1952), a Hungarian veterinarian and scientist). The widespread distribution of viruses of the family Herpesviridae is evident from other diseases in monkeys and frogs. The viruses of the family Retroviridae are perhaps the most widely distributed of the transforming viruses that infect eukaryotic cells ranging from yeast to humans. It was suggested early in the XX century that viruses cause leukemias and lymphomas in birds. In 1911 the American pathologist Francis Peyton Rous (1879–1970) first described a virus that causes sarcomas in chickens. The virions of retroviruses are spherical (or polygonal) and are surrounded by a lipid membrane containing a glycoprotein that recognizes and binds to cell receptors of a particular species (type-specific glycoproteins). Retrovirus genomes consist of two identical RNA molecules, each with 7 000 to 10 000 nucleotides. Associated with the virion RNA is an enzyme, an RNA-dependent DNA polymerase, also called a Reverse Transcriptase. Using the virion RNA as a template, the reverse transcriptase catalyzes the synthesis of a linear DNA molecule, complementary to the virion RNA. The new complementary strand of DNA also serves as a template for the reverse transcriptase, which makes a second anticomplementary DNA molecule, thus forming double-stranded DNA. The genomic RNA of fully infectious bird retroviruses, those that can replicate autonomously, has four genes that code sequentially for group-specific antigens, the reverse transcriptase, the envelope glycoprotein, and the sarcoma-transforming protein. At each end of the genome are homologous flanking nucleotide sequences, known as long terminal repeats (LTR), which code for double-stranded DNA that can recognize host cell DNA sequences for integration of the proviral DNA into the host cell chromosome. Many retroviruses are defective and cannot replicate in cells without helper (nondefective) retroviruses. The helper retroviruses generally transform fibroblastic cells, resulting in malignant sarcomas, whereas the defective retroviruses transform blood-cell precursors, resulting in leukemias. Many different retroviruses have been identified as causative agents of cancers in birds, rodents (particularly mice), domestic cats, monkeys, and humans. Certain lymphatic

leukemias in humans are caused by human T-cell leukemia virus (HTLV); acquired immune deficiency syndrome (AIDS) is caused by a retrovirus called Human Immunodeficiency Virus (HIV). Retroviruses originated from genes in many different species of animals and even lower forms of life. Individual retroviruses are limited in their host range and do not readily cross species barriers. Virtually every retrovirus studied to date is analogous to the genes normally found in animals (including humans), known as Proto-Oncogenes, genes that are involved with regulating normal cell growth and development that also have the potential to change into cancer-causing genes. These proto-oncogenes have deoxynucleotide sequences closely, but not entirely, homologous (i.e. of the same type and order) to the nucleotide sequences of a corresponding viral cancer-causing gene, called an Oncogene. Integration of retrovirus DNA into cell chromosomes results in cancer, but the proto-oncogenes do not become cancer-causing genes unless triggered by another event. Cancers caused by chemical or physical carcinogens in the environment probably often, if not invariably, are due to alterations in the sequences of proto-oncogenes that have converted them to oncogenes. Some of the DNA tumour viruses, such as SV40 or adenoviruses, may induce malignant transformation when their DNA is integrated in proximity to the site of a proto-oncogene. All cancers studied to date appear to be due to either mutations in proto-oncogenes or the inheritance of mutated tumour suppressor genes, which normally regulate the function of proto-oncogenes. Disease:- although viruses were originally discovered and characterized on the basis of the diseases they cause, most viruses that infect bacteria, plants, and animals (including humans) do not cause disease. In fact, bacteriophages may be helpful in that they rapidly transfer genetic information from one bacterium to another, and viruses of plants and animals may convey genetic information among similar species, helping their hosts survive in hostile environments. In the future this could also be true for humans. Recombinant DNA biotechnology shows great promise for the repair of genetic defects. Afflicted persons are injected with cells transformed by viruses that carry a functional copy of the defective human gene. The virus integrates the normal gene into the DNA of the human cell. Of those viruses that cause disease, some cause short-term (acute) diseases and others recurring or long-term (chronic) diseases. Some viruses cause acute disease from which there is fairly rapid recovery but may persist in the tissues, remaining dormant for long periods of time, and then become active again, bringing about serious disease decades later. Slowly progressive viruses have long incubation periods before the onset of disease. As mentioned above, the DNA of certain viruses becomes integrated into the genome of the host cell, often resulting in malignant transformation of cells, which become cancers. The nature of the disease caused by a virus is generally a genetic property of the virus as well as of the host cells. Almost all viruses, however, can remain dormant in the tissues of the host (latency). Viruses that cause acute disease are generally, but not always, those that rapidly harm or destroy cells (cytopathic effects) and have the capacity to shut off protein or nucleic acid synthesis within the host cell. Human poliovirus and related picornaviruses that infect other animal species are examples of acute infectious agents that shut down protein synthesis in the host cell soon after infection; these picornaviruses also inhibit cellular RNA and DNA synthesis. Another virus that rapidly kills the infected cell is the negative-strand vesicular stomatitis virus (VSV) of the family Rhabdoviridae; viral RNA newly synthesized by infectious VSV rapidly shuts off cellular RNA synthesis and, to a somewhat lesser extent, cellular protein synthesis. In both poliovirus and VSV, the infected cell dies within hours of the inhibition of cellular RNA and protein synthesis. Other viruses that inhibit cellular macromolecule synthesis and produce acute infections include the poxviruses, reoviruses, togaviruses, adenoviruses, and herpesviruses; the latter two persist in host tissues for long periods of time and cause chronic infection as well. On the other hand, certain viruses, such as the influenza viruses, do not have the drastic effects on the synthesis of cellular macromolecules, such as proteins, but they still cause acute, usually self-limiting, infections. Many, if not most, diseases resulting from viral infection of vertebrates are caused not by a direct effect of the virus but rather by a secondary immune response. Essentially all viral proteins are recognized by vertebrate animals as immunologically foreign, and the immune systems of these animals mount two kinds of immune response, humoral and cellular. In humoral immunity, B lymphocytes, usually triggered by helper T lymphocytes, make antibodies (proteins that recognize and bind foreign molecules) to the viral protein. The antibody synthesized as a result of the immune response against a specific viral antigen usually benefits the infected host because that antibody can neutralize the infectivity of the specific virus in the blood and tissues of the infected host. Viruses inside the cell are not accessible to the antibody, because it cannot cross the cell membrane barrier. In cellular immunity, a killer T cell recognizes and kills a virus-infected cell because of the viral antigen on its surface, thus aborting the infection because a virus will not grow within a dead cell. If the virus-infected cells are not essential for host functions, the killer T cell can prevent the spread of the infecting virus to other cells and distant tissues. Not nfrequently, the virus-specific T lymphocyte kills vital cells such as nerve cells (neurons), muscle cells, and liver cells, all of which carry out important functions. In addition, the death of cells results in an inflammatory response, which also can damage vital tissues. Therefore, the cellular immune response to a viral infection can cause disease. In general, diseases caused by chronic viral infections, but also occasionally by subacute (between acute and chronic) viral infections, are caused by cellular immune responses that damage the virus-infected tissue. Infectious Patterns:- acute viral infections are of two types – local and systemic – both usually resulting from a direct effect of the invading virus on host tissue cells. Acute local infections generally occur at the site of viral infection. For example, acute respiratory infections include (1) the common cold, in which the rhinovirus infects only the nasal mucosa, (2) influenza, in which the virus is found in both nasal and bronchial mucosa, where severe damage can result in death, (3) grippelike illnesses caused by adenoviruses localized in lymphoid tissue of the throat (although infection also can occur in the intestine and the eye or be spread to the heart), and (4) severe respiratory infections of infants and children, caused by parainfluenza viruses or respiratory syncytial viruses, which cause severe croup that may be life-threatening. Examples of acute infections localized to the intestine include those that result in enteritis (bowel inflammation), which may be accompanied by diarrhea; these are often caused by rotoviruses and coronaviruses. Many viruses transmitted by the respiratory route (from sneezes and coughs, for example) and limited to humans begin their cycle of infection in the upper respiratory tract (nose and throat) and then enter the bloodstream, where they are spread to distant tissues. Examples of such diseases are measles, mumps, and chicken pox, in which the growth of the specific virus in the mucosal cells of the throat during the first few days of infection usually results in mild fever and achiness; this stage is called the Prodromal Period of the illness. During the next few days the virus enters the draining lymph nodes and then the bloodstream, where it is spread throughout the tissues of the body, resulting in fever and rash (in the case of measles and chicken pox) and inflammation of the parotid glands and, less frequently, the testes, ovaries, and joints (in the case of mumps). Varicella (chicken pox) virus rarely causes pneumonia, but all these viruses can cause meningitis and, rarely, encephalitis. A similar pattern of infection formerly occurred with smallpox, a disease that was more frequently fatal but now, ostensibly, has been eradicated. A large number of viruses of the digestive tract (enteroviruses), among them poliovirus, Coxsackie viruses, and echoviruses (enteric cytopathic human orphan virus), also cause a two-phase illness. Enteroviruses grow initially in the intestinal tract and are transmitted by mouth through water, food, and other materials contaminated with feces. The viruses are resistant to the acid normally found in the stomach and thus reach the intestinal tract, where they multiply in living mucosal cells. This initial period of viral invasion and growth in the intestine causes either an initial mild febrile illness or is asymptomatic. Over the next few days these enteroviruses are spread from the intestinal mucosa to the draining lymph nodes, from which they invade the bloodstream, resulting in a condition known as Viremia. From the bloodstream the viruses are widely spread to all tissues, but in most cases no symptomatic disease occurs. Poliovirus in less than 1 percent of cases affects the spinal cord or brain, resulting in paralysis or death. Different types of Coxsackie viruses and echoviruses can cause acute, usually nonfatal, illnesses such as meningitis, carditis, pleurisy, or rashes. Many viral diseases are transmitted by bites of insects or other arthropods, and these infections usually begin in the skin or lymph nodes and rapidly invade the bloodstream. The nature of

the disease caused by these arthropod-borne viruses (arboviruses) is determined by the affinity (tropism) of each virus for specific organs. Many that have an affinity for brain tissue cause encephalitis or meningitis, but others primarily infect the muscles, liver, heart, or kidneys. Virtually all these diseases are epidemic in character, and the viruses that cause them are the primary pathogens of birds and mammals. The insect, usually a certain Species of mosquito, takes a blood meal from the infected host bird or mammal and shortly thereafter bites a human, thus transmitting the virus. These arboviruses do not ordinarily multiply in the insect but simply reside on its proboscis. Examples of human epidemic diseases resulting from transmission of these arboviruses are encephalitis caused by viruses of the family Togaviridae and Flaviviridae and often fatal, yellow fever and dengue caused by viruses of the family Flaviviridae, and hemorrhagic fevers caused by viruses of the families Bunyaviridae and Arenaviridae. Of considerable interest and concern are the identification of new strains of viruses, particularly a hantavirus of the Bunyaviridae family that is responsible for an epidemic in the early 1990s in the southwestern United States that resulted in considerable numbers of fatal human infections. Latency:- inapparent infections (those that do not cause specific signs and symptoms) often result after exposure to picornaviruses, influenza viruses, rhinoviruses, herpesviruses, and adenoviruses but less frequently to measles and chicken pox viruses. In cases of inapparent infection, long-lasting immunity develops, but only to the strain of virus that has the same antigenic composition as the original infecting virus. Certain of these viruses persist in the tissues of the host after the initial infection despite the presence of circulating antibodies to it in the blood and tissues. Such viruses probably reside inside cells, where they are protected from antibodies that cannot penetrate the cell membrane. Among persistent viruses are adenoviruses, measles virus, and, in particular, many kinds of herpesviruses. The genetic information of herpesviruses and adenoviruses can be integrated into the genome of the host cell, but it is believed that these viruses frequently, and the measles virus invariably, reside in cells in the form of extrachromosomal genes (genes not integrated in chromosomes). These dormant viruses can be activated by many factors, such as trauma, another infection, emotional stress, menstruation, excessive exposure to sunlight, and various illnesses. The phenomenon of latency and reactivation is particularly common among viruses of the family Herpesviridae, which cause chronic or recurrent diseases:- (1) herpes simplex virus type 1, which causes recurrent cold sores, (2) herpes simplex virus type 2 in genital tissue, which causes repeated herpetic infections of the vagina or penis, (3) cytomegalovirus, which usually produces an inapparent infection activated by simultaneously occurring disease to cause severe liver, lung, or nervous-system disease, and (4) varicella virus, which is the causative agent of chicken pox but which can be activated decades later to produce herpes zoster (shingles). A rare, but invariably fatal, disease of the nervous system is subacute sclerosing panencephalitis (SSPE), which is a progressive, degenerative condition caused by measles virus (a paramyxovirus) lying dormant in brain cells for many years and then reactivated, usually in adolescence. There is no simple explanation why latent viruses, such as those in the family Herpesviridae, that are present in the tissues of most adult humans can be activated to cause disease in some people but not in others. Chronic And Slowly Progressive Diseases:- although some viruses multiply slowly, this is not always the explanation for the chronicity or the slow progression of the diseases caused by these viruses. Hepatitis, for example, is a subacute or chronic disease, with a long latent period, that is caused by at least five viruses with different properties. Hepatitis A is caused by a picornavirus usually transmitted by the fecal-oral route in a manner similar to that of poliovirus. Hepatitis B is caused by a small DNA virus that contains its own DNA polymerase and is transmitted by transfusion of blood and other blood products, by the sharing of nonsterile hypodermic needles among drug users, by sexual intercourse, or from mother to neonate. Hepatitis B virus is classified with similar viruses of birds in the family Hepadnaviridae. Most cases of hepatitis spread by the transfusion of blood or blood products or by needles shared by drug users are caused by a third, completely distinct virus, originally called Non-A, Non-B Hepatitis but now known to be a member of the virus family Flaviviridae designated hepatitis C virus. A fourth unique agent that causes hepatitis is designated hepatitis delta virus, which has not yet been classified taxonomically but is a small, enveloped virus containing a circular RNA genome; hepatitis B virus serves as a helper for replication of hepatitis delta virus, the virions of which contain hepatitis B surface antigen (HB_sAg). The fifth causative agent of viral hepatitis, largely occurring in Asia and Africa, is a small RNA virus tentatively classified as a member of the family Caliciviridae and designated hepatitis E virus. Many other agents that appear to cause chronic and slowly progressive diseases, particularly those affecting the nervous system, have been tentatively identified. A fatal neurological disorder of sheep, called Scrapie, has an incubation period of years and may be caused by a heat-resistant protein complexed with nucleic acid, called a Prion, which is postulated to activate latent genes that cause the disease. Similar, rather obscure agents have been identified for two uncommon, fatal disorders of the nervous system, called Creutzfeldt-Jakob Disease (CJD; the disease was first described by German neuropathologist Hans Gerhard Creutzfeldt (1885–1964) in 1920 and shortly afterward by German neurologist Alfons Maria Jakob (1884–1931), giving it the name Creutzfeldt-Jakob) and Kuru. The disease now known as AIDS was first recognized in homosexuals and hemophiliacs about 1981 and continues to be disseminated throughout the world to become one of the most devastating epidemics of all time. AIDS is caused by HIV, a member of a genetically more complex group of the Family Retroviridae called Lentiviruses. Closely related viruses of monkeys and cats cause similar diseases. HIV is transmitted by blood and other body fluids and infects primarily helper T lymphocytes and other cells with CD4 (short for the Cluster Of Differentiation 4) surface receptors, to which the virus binds. After the virus has been dormant for years, destruction of T lymphocytes results in drastic depression of the immune system. Death almost invariably results from ‘opportunistic’ infections such as pneumonia – caused by ordinarily nonpathogenic organisms such as Pneumocystis Carinii – or tuberculosis or by cancers such as Kaposi’s sarcoma and lymphomas. Prevention:- the spread of many viral diseases can be prevented by hygienic factors such as efficient sanitation facilities, effective waste disposal, clean water, and personal cleanliness. Active immunization by vaccines (antigen-containing preparations that elicit the synthesis of antibodies and thus immunity) has been useful in preventing common epidemics caused by acutely infectious viruses. The best example of such a preventable disease is smallpox, caused by a disease-producing virus that at one time was found worldwide. In 1796 the English physician and scientist Edward Jenner (1749–1823) discovered that the milder cowpox virus could serve as a live vaccine (an antigenic preparation consisting of viruses whose disease-producing capacity has been weakened) for preventing smallpox; Jenner published his findings in 1798. The program of vaccination that resulted from Jenner’s discovery is one of the greatest success stories in the annals of medicine; in 1980 the World Health Organization declared that the disease had been eliminated. A different prospect is presented by rabies, an invariably fatal viral disease mentioned in ancient Greek literature and in the Bible. Transmitted by the bite of dogs and other domestic and wild animals, the rabies virus is more difficult to eradicate because it is present in wild animals throughout the world, except in certain island countries such as Great Britain and Australia. Influenza virus is also distributed worldwide, but, of the three major immunologic types, only one (type A) is responsible for large epidemics. The worldwide epidemic (pandemic) of influenza at the end of World War I is estimated to have caused 20 million deaths, mostly of adolescents and young adults. Because of virus mutations that produce minor antigenic changes every few years and major antigenic shifts about every 10 years, influenza viruses have the capacity to resist inactivation by antibodies acquired by previous infection or vaccination. Development of effective vaccines to combat influenza is a difficult task, although existing vaccines are partially effective and are recommended for people at high risk (i.e. the elderly and those with chronic disease of the respiratory or circulatory systems). Vaccines are most successful when directed against those viruses that do not mutate and that infect only humans. In addition to smallpox, a successful vaccine program has been carried out against poliomyelitis. Polioviruses exist in only three antigenic types, each of which has not changed significantly for decades. The vaccines available are the ‘killed’ (Salk) vaccine, composed of inactivated virus of the three types, and the ‘live’ (Sabin) vaccine, composed of genetically attenuated viruses of the three types. These vaccines,

which were introduced in the 1950s, have lowered the incidence in developed countries of paralysis resulting from poliomyelitis. The disease still occurs in developing countries and recurs in some developed countries where vaccination programs have not been enforced. Rare cases of poliomyelitis occur, particularly in the United States, from the Sabin vaccine strain of type-3 poliovirus, which is genetically unstable and occasionally reverts to the virulent form. Vaccination can prevent diseases caused by strictly human viruses that exist in only one antigenic and stable type. Measles has been prevented in developed countries with routine vaccination. Measles, however, may still be the major cause of death in children in developing countries. Vaccination for mumps and chicken pox promises to be successful because the causative viruses of these diseases show little tendency to vary antigenically and are confined to humans. On the other hand, development of vaccines for the common cold caused by rhinoviruses, similar to polioviruses, will be a formidable, if not impossible, task because there are at least 100 antigenic types of the rhinovirus. Also daunting is the task of developing a vaccine against HIV. The major antigenic component of this virus is a surface membrane-inserted glycoprotein (gp120), which has a startling rate of mutation. The extreme antigenic diversity that results from the mutability of the gene that codes for this protein would prevent HIV from being identified and attacked by circulating antibodies or killer T lymphocytes. Treatment:- unlike bacteria, viruses mimic the metabolic functions of their host cells. Antibiotics and other antimicrobial agents are, therefore, ineffective against viruses because the chemical compounds that inhibit the multiplication of viruses generally also slow the functions of, and are toxic to, the host cell. The only chemotherapeutic agents (drugs used to control or eliminate disease) that exert a selectively greater effect on viral replication than they do on cell replication are certain synthetic compounds, such as ribavirin, acyclovir, or zidovudine (azidothymidine (AZT)). These drugs have been partially effective in improving, if not curing, viral diseases without causing major toxic side effects. AZT has been used with some success in prolonging the lives of patients with AIDS. Certain natural products of cells, called Interferons, may have potential antiviral and anticancer properties. Interferons are proteins normally synthesized by the cells of vertebrates, including humans, either intrinsically and without stimulation or in response to certain viral infections, chemicals, or immune reactions. In general, the multiplication of viruses is inhibited by interferons, some to a much greater extent than others. Interferons are generally species-specific; i.e. they are effective in inhibiting viral infection only in cells of the same species that naturally synthesize the interferon. There are three classes of interferons:- α-interferons, produced by blood leukocytes; β-interferons, produced by tissue cells and fibroblasts; and γ-interferons (also called Immune Interferons or Interleukins), produced by immune reactions in blood lymphocytes. Interferons are now known to be a subset of a large group of natural cellular substances called Cytokines, which signal cells to perform specific functions. Until recently, interferons were difficult to produce commercially because cells and tissues synthesize only small amounts of them. Through recombinant DNA technology, however, large amounts of interferon can be produced. There has been some success in using interferons to treat viral diseases, such as colds caused by rhinoviruses, infections caused by herpesviruses, and benign tumours and warts caused by papillomaviruses. Local administration at the sites of viral infection affords the best results, although injections of large amounts of interferons can be harmful, probably because they tend to inhibit protein synthesis in the host cell. Evolution:- owing to their simplicity, viruses were at first considered to be the primordial life-forms. This concept is almost certainly incorrect because viruses are completely devoid of the machinery for life processes; therefore, they could not have survived in the absence of cells. Viruses probably evolved from cells rather than cells from viruses. It seems likely that all viruses trace their origins to cellular genes and can be considered as pieces of rogue nucleic acids. Although it is easier to imagine the cellular origin of DNA viruses than RNA viruses, the RNA viruses conceivably could have had their origins from cellular RNA transcripts made from cellular DNA. In fact, the discovery that many cells contain reverse transcriptase capable of converting RNA to DNA seems to suggest that conversion of RNA to DNA and DNA to RNA is not rare. Indeed, some speculate that RNA is the primordial genetic information from which DNA evolved to produce more complex life-forms. Other possible progenitors of viruses are the plasmids (small circular DNA molecules independent of chromosomes), which are more readily transferred from cell to cell than are chromosomes. Theoretically, plasmids could have acquired capsid genes, which coded for proteins to coat the plasmid DNA, converting it into a virus. In brief, it is likely that viruses originated from the degradation of cellular nucleic acids, which acquired the property of being readily transferable from cell to cell during the process of evolution. The fact that normal proto-oncogenes of a cell have nucleic acid sequences that are almost identical to the oncogenes of retroviruses lends credence to the theory that viruses originated from cellular genes. Classification:- Distinguishing Taxonomic Features:- viruses are classified on the basis of their nucleic acid content, their size, the shape of their protein capsid, and the presence of a surrounding lipoprotein envelope. The primary taxonomic division is into two classes based on nucleic acid content:- DNA viruses or RNA viruses. The DNA viruses are subdivided into those that contain either double-stranded or single-stranded DNA. The RNA viruses also are divided into those that contain double-stranded or single-stranded RNA. Further subdivision of the RNA viruses is based on whether the RNA genome is segmented or not. If the viruses contain single-stranded RNA as their genetic information, they are divided into positive-strand viruses if the RNA is of messenger sense (directly translatable into proteins) or negative-strand viruses if the RNA must be transcribed by a polymerase into mRNA. All viruses falling into one of these nucleic acid classifications are further subdivided on the basis of whether the nucleocapsid (protein coat and enclosed nucleic acid) assumes a rodlike or a polygonal (usually icosahedral) shape. The icosahedral viruses are further subdivided into families based on the number of capsomers making up the capsids. Finally, all viruses fall into two classes depending on whether the nucleocapsid is surrounded by a lipoprotein envelope. Some virologists adhere to a division of viruses into those that infect bacteria, plants, or animals; these classifications have some validity, particularly for the unique bacterial viruses with tails, but there is otherwise so much overlap that taxonomy based on hosts seems unworkable. Classification based on diseases caused by viruses also is not tenable, because closely related viruses frequently do not cause the same disease. Eventually, it is likely that the classification of viruses will be based on the nucleotide sequences of their nucleic acids rather than on structural components, as is now the case. The basic taxonomic group is called a Family, designated by the suffix -viridae. The major taxonomic disagreement among virologists is whether to segregate viruses within a family into a specific Genus and further subdivide them into Species names. Most virologists believe that a binomial nomenclature, as used for bacteria, into italicized and Latinized genera and species is unwarranted. For this reason, no Latin names are used in the classification of viruses presented here. Moreover, only the well-characterized viruses of animals are presented. Annotated Classification:- (1) DNA Viruses:- Family Poxviridae:- large viruses of complex structure with dimensions of 400 x 200 nm, the genome of which is linear double-stranded DNA. Virions contain at least 40 proteins and lipid, as well as internal structures called Lateral Bodies. The 2 subfamilies are called Chordopoxvirinae, which infect vertebrates and are closely related antigenically, and Entomopoxvirinae, which infect arthropods. The Chordopoxvirinae are composed of groups called Orthopoxviruses (vaccinia), parapoxviruses, avipoxviruses of birds, and many others that infect sheep, rabbits, and swine. Family Adenoviridae:- nonenveloped virions of icosahedral symmetry, about 80 nm in diameter, and capsids containing 252 capsomers with 12 vertices to which are attached glycoprotein fibers 10–30 nm in length with knobs at the ends (see Figure 5). The genome is linear double-stranded DNA. Classified in 2 Subgroups:- Mastadenoviruses, which infect mammals, and Aviadenoviruses, which infect birds. Common acute respiratory and gastrointestinal pathogens of humans, and some types cause malignant transformation of cultured cells and can cause cancer in animals. Family Herpesviridae:- icosahedral virion with capsid about 105 nm in diameter and 162 capsomers surrounded by a floppy envelope containing glycoprotein spikes. Genome composed of linear double-stranded DNA. There are 3 known subfamilies:- Alphaherpesvirinae, consisting of human herpes simplex viruses types 1 and 2, bovine mamillitis virus, SA 8 virus and monkey B virus, pseudorabies virus, equine herpesvirus, and varicella-zoster virus; Betaherpesvirinae, composed of species of cytomegaloviruses; and

Gammaherpesvirinae, composed of genera familiarly called Epstein-Barr Virus, baboon herpesvirus, chimpanzee herpesvirus, Marek's disease virus of chickens, turkey herpesvirus, herpesvirus saimiri, and herpesvirus ateles. Family Iridoviridae:- large enveloped or nonenveloped icosahedral virions measuring 130–150 nm in diameter and containing linear double-stranded DNA. Genera include iridovirus and chloridirovirus, which infect insects, African swine fever virus, and lymphocytic disease virus. Family Hepadnaviridae:- small enveloped spherical virions about 42 nm in diameter containing circular double-stranded DNA with a single-stranded DNA region and a DNA-dependent DNA polymerase that repairs the single-stranded DNA gap and is essential for replication. Also characteristic are the use of reverse transcriptase for replication and an abundance of a soluble protein (HB_sAg). Genera include human hepatitis B virus, woodchuck hepatitis virus, ground squirrel hepatitis virus, duck hepatitis virus, and several others thus far less well documented. Family Papovaviridae:- icosahedral, nonenveloped virions with 72 capsomers comprising 2 genera:- the polyomaviruses (SV40 and polyoma virus), measuring 45 nm in diameter; and the papillomaviruses, measuring 55 nm in diameter. Virions of both genera contain covalently linked circular DNA. The polyomaviruses produce malignant transformation of infected cells, whereas the papillomaviruses, which do not grow in cell culture, usually cause warts and benign papillomas, which can also lead to cancer. Family Parvoviridae:- small icosahedral, nonenveloped virions with 32 capsomers measuring 18–26 nm in diameter that contain single-stranded DNA. Viruses of this family infect vertebrates and insects, the latter sometimes designated densoviruses. The vertebrate viruses fall into 2 Classes:- those that replicate autonomously and those that replicate only in the presence of helper adenoviruses or herpesviruses, designated adenoassociated viruses (AAV) or dependoviruses. (2) RNA Viruses:- Family Picornaviridae:- small icosahedral, nonenveloped virions 27–30 nm in diameter, composed of 60 capsomers and containing nonsegmented single-stranded, plus-strand RNA. There are 4 recognized Genera designated enteroviruses (polioviruses, Coxsackie viruses, echoviruses), cardioviruses, rhinoviruses (common cold viruses), and aphthoviruses (foot-and-mouth disease virus of cattle). Family Caliciviridae:- icosahedral, nonenveloped virions about 38 nm in diameter, composed of 32 capsomers and 180 molecules of a single capsid protein. The genome consists of single plus-strand RNA. The prototype virus of this family is the vesicular exanthema of swine virus. Family Togaviridae:- small enveloped virions spherical in shape with icosahedral nucleocapsid of 32 capsomers about 30 nm in diameter. The genome is single plus-strand RNA. There are 2 recognized genera:- 1 transmitted by arthropods (exclusively mosquitoes) and designated alphaviruses (prototypes Sindbis virus, eastern and western equine encephalitis viruses), the other nonarthropod-borne and designated rubivirus (the causative agent of German measles). Family Flaviviridae:- viruses of this family are enveloped and spherical in shape, with a genome consisting of nonsegmented single plus-strand RNA. These viruses are transmitted by either insects or arachnids and cause severe diseases such as yellow fever, dengue, tick-borne encephalitis, and Japanese B encephalitis. Recently characterized members of this family are nonarthropod-borne hog cholera virus (pestivirus) and hepatitis C virus of humans. Family Coronaviridae:- enveloped virions 60–220 nm in diameter with helical nucleocapsid containing single plus-strand RNA genome. Club-shaped glycoprotein spikes in envelope give crownlike (coronal) appearance. Viruses of this family are important agents of gastrointestinal disease in humans, poultry, and bovines. Family Orthomyxoviridae:- enveloped virions about 100 nm in diameter with helical nucleocapsid containing 8 segments of negative-strand RNA and endogenous RNA polymerase. The lipoprotein envelope contains 2 glycoproteins, designated hemagglutinin (major antigen) and neuraminidase. The only viruses in this family are influenza viruses of 3 distinct antigenic types (A, B, and C). Family Paramyxoviridae:- enveloped virions varying in size from 150 to 300 nm in diameter with a helical nucleocapsid containing a single negative-strand nonsegmented RNA and an endogenous RNA polymerase. The lipoprotein envelope contains 2 glycoprotein spikes designated hemagglutinin-neuraminidase (HN) and fusion factor (F). The major genus is paramyxovirus and is composed of human parainfluenza viruses and mumps virus, as well as Newcastle disease virus of poultry. The genus morbillivirus contains the agents that cause measles in humans, distemper in dogs and cats, and rinderpest in cattle. The third genus, pneumovirus, causes the serious respiratory syncytial virus disease in human infants and is also classified in the subfamily Pneumovirinae. Family Rhabdoviridae:- enveloped virions, usually bullet-shaped, 180–300 x 65 nm, containing a helical nucleocapsid with single minus-strand RNA and an endogenous RNA polymerase. The lipoprotein envelope contains a single glycoprotein, which is the type-specific antigen. Viruses of this family are widely infectious for plants and for animals varying from insects to humans. Two animal genera are designated vesiculovirus, which includes the virus that causes vesicular stomatitis in cattle, swine, and equines, and lyssavirus, which includes the causative agent of rabies. Family Filoviridae:- enveloped virions, variably elongated filaments 650–14 000 nm in length and pleomorphic in shape, containing a helical nucleocapsid with single minus-strand RNA (about 19 kilobases in length), and an endogenous RNA polymerase. Much like the Rhabdoviridae, the lipoprotein envelope contains a single glycoprotein, which is the type-specific antigen. The family consists of 1 genus, filovirus, that contains the Marburg and Ebola viruses. These viruses have been isolated from African monkeys, and both are among the most dangerous pathogens. Some strains cause severe hemorrhagic fevers in humans; the mortality rate from these diseases is as high as 88 percent. Human infections with Marburg virus have been traced to laboratory monkeys, but human outbreaks of fatal Ebola virus infection in Congo (Kinshasa) and The Sudan have not been traced to monkeys. Family Arenaviridae:- enveloped virions 100–200 nm in diameter with a helical nucleocapsid in 2 segments containing minus-strand RNA, an endogenous RNA polymerase, and small amounts of ribosomal RNA. There are 4 genera, with viruses widely distributed in animals and causing serious human diseases, many transmitted by insects. Family Bunyaviridae:- enveloped virions about 95 nm in diameter with a 3-segment helical nucleocapsid containing single-stranded RNA of negative sense and endogenous RNA polymerase. Many viruses (about 350 Species) grouped in 5 genera:- bunyavirus, phlebovirus, nairovirus, taspovirus, and hantavirus. Most of these viruses are transmitted by arthropods and cause serious human disease. Family Retroviridae:- enveloped virions about 90 nm in diameter with 2 identical copies of single plus-strand RNA in nondefective virions and a reverse transcriptase, which promotes synthesis of double-stranded DNA from the viral RNA template. A hallmark of the virion RNA templates is long terminal repeat (LTR) nucleotide sequences, which serve for integration of the DNA in chromosomes of the host cell. Retroviridae cause cancers in many species of animals, including humans, and are probably derived from normal cell nucleotide sequences called proto-oncogenes. Certain retroviruses of the lentivirus group cause AIDS in humans, monkeys, felines, and cattle. Family Reoviridae:- nonenveloped icosahedral virions with outer and inner protein shells 60–80 nm in diameter and containing double-stranded RNA in 10 to 12 segments. Viruses in this family infect many species of plants and animals. The animal Reoviridae are divided into 4 genera, designated orthoreoviruses, orbiviruses (widely distributed in insects and vertebrates, including bluetongue virus disease of sheep), rotaviruses (widespread causative agents of gastroenteritis in mammals, including humans), and cypovirus (prototype causes cytoplasmic polyhedrosis disease in insects). / в 1892 Российским учёным Дмитрием Иосифовичем Ивановским (Dmitry Iosifovich Ivanovski; 1864–1920) и в 1898 Нидерландским учёным Мартинасом Вилемом Байэринком (Martinus Willem Beijerinck; 1851–1931)). Английский бактериолог и вирусолог Фрэдэрик Вильэм Твот (Frederick William Twort; 1877–1950). Французско-Канадский микробиолог Феликс Юбэр дЁрэлле (Félix Hubert d'Hérelle; 1873–1949). В 1933 Британские исследователи Вилсон Смис (Wilson Smith; 1897–1965), Сэр Кристофё Хавод Эндрюз (Sir Christopher Howard Andrewes; 1896–1987), и Сэр Патрик Плэйфэа Лэйдло (Sir Patrick Playfair Laidlaw; 1881–1940) были способны . В 1941 Американский учёный Дьжодьж Кибэл Хёст (George Keble Hirst; 1909–1994) обнаружил, что . сделано Американскими учёными Дьжоном Фрэньклыном Эндёзом (John Franklin Enders; 1897–1985), Томэсом Хакэлом Вэло (Thomas Huckle Weller; 1915–2008), и Фрэдэриком Чапмэном Робинзом (Frederick Chapman Robbins; 1916–2003). В 1952 Американский учёный, родившийся в Италии, Рэнато Дульбэкко (Renato Dulbecco; 1914–2012) . , который был кристаллизован Американским биохимиком Вэндэлом

Мэрэдисом Стэнли (Wendell Meredith Stanley; 1904–1971) в 1935. в 1950 Французским микробиологом Андрэ Мишэль Львоф (André Michel Lwoff; 1902–1994), . Вирус Эпстайна-Бара (ВЭБ; Epstein-Barr Virus (EBV); названный в честь Британских учёных Майкэла Энтони Эпстайна (Michael Anthony Epstein; 1921–) и Иваном Баром (Yvonne Barr; 1932–2016)). Болезнь Марэйкя (Marek's Disease; названная в честь Венгерского ветеринара и учёного Ёжэфа Марэйкя (József Marek; 1868–1952)). В 1911 Американский патолог (pathologist) Фрэнсис Пэйтчэн Раус (Francis Peyton Rous; 1879–1970). ; болезнь была впервые описана Немецким невропатологом Хансом Герхадом Кройцфэльдом (Hans Gerhard Creutzfeldt; 1885–1964) в 1920 и вскоре после него Немецким неврологом Альфонсом Мариа Якобом (Alfons Maria Jakob; 1884–1931), давшим ей название Болезнь Кройцфэльда-Якоба (Creutzfeldt-Jakob). В 1796 Британский врач и учёный Эдвод Дьженё (Edward Jenner; 1749–1823) . Под Вирусами, от Латинского слова Virus, означающее Яд, понимаются мельчайшие неклеточные частицы, состоящие из нуклеиновой кислоты (ДНК или РНК) и белковой оболочки (капсида). Форма палочкообразная, сферическая и другие. Размер 15–350 нм и более. Открыты (вирусы табачной мозаики) в 1892 одним из основоположников вирусологии – Российским физиологом растений и микробиологом Дмитрием Иосифовичем Ивановским (1864–1920). Термин Вирус введён в 1899 Нидерландским ботаником и микробиологом Мартинасом Вилемом Байэринком (Martinus Willem Beijerinck; 1851–1931). Вирусы – внутриклеточные паразиты: размножаясь только в живых клетках, они используют их ферментативный аппарат и переключают клетку на синтез зрелых вирусных частиц – вирионов. Распространены повсеместно. Вызывают болезни растений, животных и человека. Вирусы Бактерий (бактериофаги) – классический объект молекулярной биологии. Вирус:- неклеточная форма жизни, представляющая собой крайне упрощённую паразитическую структуру, способную проникать в живую клетку и размножаться внутри неё. Вирусы, фильтрующиеся вирусы, ультравирусы, возбудители инфекционных болезней растений, животных и человека, размножающиеся только в живых клетках. Вирусы мельче большинства известных микробов; почти все вирусы проходят через бактериальные фильтры. В отличие от Бактерий, вирусы не удаётся культивировать на обычных питательных средах. Для экспериментальных и медицинских целей (получения вакцин и других) вирусы культивируют в животных и растительных организмах, куриных эмбрионах и в культурах тканей и клеток. Вирусы вызывают многие заболевания:- оспу, корь, грипп, полиомиелит, чуму рогатого скота и птиц, бешенство, ряд заболеваний рыб и земноводных, желтуху шёлкопряда, мозаичную болезнь Табака, закукливание Овса, многие заболевания Грибов и сине-зелёных водорослей и других (смотрите Вирусные Болезни, Вирусные Болезни Растений). Обширный отряд вирусов, поражающих Бактерии, составляют бактериофаги. Существование проходящих через бактериальные фильтры возбудителей инфекционных болезней было впервые показано в 1892 Российским физиологом растений и микробиологом Дмитрием Иосифовичем Ивановским (1864–1920), открывшим фильтруемость возбудителя мозаичной болезни Табака. Вскоре была доказана фильтруемость возбудителей ящура (в 1897), чумы рогатого скота (в 1899), оспы птиц (в 1902), бешенства (в 1903) и других. В современном смысле слово 'Вирус' впервые применил Нидерландский ботаник и микробиолог Мартинас Вилем Байэринк (Martinus Willem Beijerinck; 1851–1931) (в 1899); раньше вирусами иногда называли и болезнетворных микробов, например, возбудителя туберкулёза. По мере изучения вирусов всё более уточняется и суживается понятие о них. Возбудители ряда болезней, относимые ранее к вирусам, например, риккетсии и возбудители пситтакоза, исключены из этой группы организмов. Зрелые частицы вирусов – вирионы, или вироспоры, приспособлены к перенесению неблагоприятных условий вне организма и не обнаруживают на этой стадии никаких признаков жизни. Попав в организм, в чувствительные к вирусам клетки, вироспоры переходят в стадию развития и размножения, которая завершается образованием дочерних зрелых частиц вирусов. Строение И Состав Частиц Вирусов:- Форма вирионов очень разнообразна. У многих бактериофагов они состоят из головки и отростка, у вируса оспы они прямоугольные, у вируса герпеса и гриппа – шарообразные, у вируса мозаичной болезни Табака – палочкообразные, у вируса мозаичной болезни Картофеля – нитевидные, у вируса полиомиелита и жёлтой мозаики Турнепса – многогранные шарики, у вируса бешенства, а также мозаики Пшеницы и Люцерны – очертаниями похожи на палочки Бактерий или напоминают пулю. По размерам вирусы делят на крупные (300–400 нм в диаметре), средние (80–125 нм) и мелкие (20–30 нм). Крупные вирусы можно видеть в световой микроскоп (обычный, фазово-контрастный, люминесцентный); остальные изучают только с помощью электронного микроскопа. Данные о размерах частиц вирусов получены методами ультрафильтрации, фракционного и аналитического ультрацентрифугирования, электрофореза в гелях и электронной микроскопии. В строении разных вирионов есть много общего. Все они имеют белковую оболочку – капсид и внутреннее содержимое – нуклеокапсид, состоящее главным образом из нуклеиновой кислоты (НК) – ДНК или РНК. Многие вирусы имеют поверхностную оболочку, покрывающую белковую. Отдельные элементы белковой оболочки называются Капсомерами. У некоторых вирусов (например, мозаичной болезни Табака) НК в виде спирали включена в белковую оболочку, без разрушения которой не может быть освобождена. У других вирусов (например, жёлтой мозаики Турнепса) спирально закрученная нить НК лежит в капсиде, как в коробочке, и может выйти оттуда без разрушения оболочки. НК – носители наследственной информации о строении и свойствах вирусов; белки вирусов защищают НК, а также обусловливают ферментативные и антигенные свойства вирусов (смотрите Антигены, Ферменты). Строение вирусных частиц, приспособленных к перенесению неблагоприятных условий, может быть и более сложным; таковы, например, полиэдры, образуемые некоторыми вирусами Насекомых (они состоят из оболочки, кристаллической белковой массы и включённых в неё частиц вирусов). Химический состав разных вирусов неодинаков. Одни вирусы содержат липиды; среди них есть вирусы с ДНК (оспы, герпеса и других), с РНК (гриппа, птичьей чумы, саркомы Рауса, бронзовости Помидора, жёлтой карликовости Картофеля и других). У других вирусов липиды отсутствуют. В этой группе также есть вирусы с ДНК (аденовирусы, большинство бактериофагов, вирус желтухи шёлкопряда) и с РНК (полиомиелита, ящура; большинство вирусов, вызывающих болезни растений; некоторые бактериофаги). Кроме липидов, белка и нуклеиновой кислоты, в вирусах встречаются в небольшом количестве полиамины (путресцин, спермидин и другие), иногда витамины (витамин B_2, фолиевая кислота), а также ряд металлов; в некоторых вирусах содержатся соединения белка с полисахаридами. Размножение вирусов происходит в клетках. Бактериофаги растворяют оболочку Бактерии и вводят в Бактерию нить НК, причём капсид фага остаётся вне клетки. Многие вирусы поглощаются клеткой путём пиноцитоза. Попав в клетку, они освобождаются от оболочки. Первые этапы развития вируса в клетке в общих чертах состоят в том, что строятся так называемые Ранние Белки, то есть Белки-Ферменты, необходимые вирусам для репликации (удвоения) их НК. Так называемые Поздние Белки участвуют в образовании белковых оболочек дочерних вироспор. Из ферментов у вирусов, содержащих ДНК, одним из первых синтезируется полимераза РНК, которая строит на нити ДНК информационную РНК (и-РНК). Эта РНК попадает на рибосомы клетки, где и происходит синтез других белков вирусной частицы (смотрите Белки, раздел Биосинтез). Вирусы, содержащие РНК, синтезируют полимеразу, катализирующую синтез новых частиц вирусной РНК; эта РНК переходит на рибосомы и контролирует синтез белка капсида. Таким образом, вирусы, содержащие РНК, не нуждаются в ДНК для размножения и передачи генетической информации потомству. От этой общей схемы размножения вирусов имеются различные отклонения. Так, некоторые вирусы содержат белки-ферменты; вирус осповакцины синтезирует в клетке хозяина двойные нити РНК и так далее. Многие особенности размножения вирусы ещё не выяснены. Существуют, например, особые очаги размножения нитей НК, и при созревании частиц вируса синтезируется белок, охватывающий отдельные отрезки НК. Иногда этот процесс идёт несовершенно, образуются неполноценные частицы вируса, в которых нет или мало содержимого, это – так называемые

Неинфекционные Вирусы. Во многих случаях очаги размножения вирусов хорошо видны в клетке под микроскопом. Эти очаги называются Внутриклеточными Включениями, или Х-Телами. Когда Х-Тело заканчивает своё развитие, в нём образуется вироспора. У многих вирусов вироспоры образуют в Х-телах кристаллические агрегаты, у других вирусов они неизвестны. Некоторые вирусы размножаются в ядре клетки, другие – в её цитоплазме, третьи – и в ядре, и в цитоплазме. НК находится в вироспоре в специально закрученном состоянии. Длина нити НК у разных вирусов различна. Так, у вируса оспы она достигает 83 мкм, у крупных бактериофагов, например, T_4 – 70 мкм. У мельчайших бактериофагов нить НК имеет длину около 2 мкм. В зависимости от длины нити НК (что определяет объём наследственной информации, которой располагает тот или иной вирус), то есть от способности вируса синтезировать более или менее разнообразные молекулы белков, различна степень участия составных частей клетки-хозяина в размножении вирусов и их построении. Вирусы, имеющие нить НК значительной длины, могут синтезировать многие вещества. Так, некоторые бактериофаги синтезируют в клетке несколько десятков разных белков. Все вирусы, содержащие ДНК, синтезируют собственную РНК. Даже если клетка-хозяин имеет необходимые для вирусов ферменты, вирусы очень часто синтезируют собственные ферменты, обладающие подобным действием. Мельчайшие фаги обладают информацией для синтеза только трёх собственных белков; например, фаг МЗ-2 синтезирует зависящую от РНК полимеразу и два белка, необходимые для построения зрелых частиц вируса. Таким образом, степень зависимости вирусов от различных ферментов клетки-хозяина различна. Некоторые вирусы так бедны наследственной (генетической) информацией, что могут размножаться в клетке только в присутствии других вирусов. Зависимость вирусов не только от клетки, но и от других вирусов существует, например, между вирусом некроза Табака и его спутником, вироспоры которого мельче вироспор некроза Табака. Ещё более тесные взаимоотношения существуют между некоторыми вирусами, поражающими животных и человека. Среди вирусов, способных вызывать злокачественные опухоли (смотрите Опухолеродные Вирусы), известны вирусы с дефектной частицей, которая не может образовывать собственную белковую оболочку. Эти вирусы достигают зрелого состояния, только если они размножаются в присутствии других вирусов (таковы отношения, например, между опухолеродным обезьяньим вирусом S-40 и некоторыми аденовирусами). НК опухолеродного вируса в этом случае включается в капсид аденовируса и вместе с ним попадает в чувствительную клетку. Выход вируса из клетки в одних случаях совершается только при разрушении клетки (многие фаги, вирус оспы), в других – частицы вируса покидают клетку, не убивая её при этом (миксовирусы, некоторые мелкие фаги). Если в клетку попадают вирусы, различающиеся по тем же или другим генам (различие может быть результатом мутации), то в потомстве можно наблюдать вирусы, соединяющие свойства двух и больше исходных форм. Это указывает на наличие обмена (перекомбинации) признаков таких форм при размножении вирусов в одной клетке. Закономерности этих процессов изучает генетика вирусов (смотрите Генетика Микроорганизмов). Устойчивость вироспор к внешним воздействиям различна, но по большей части велика. Некоторые вирусы инактивируются только при нагревании до 90 °С (вирусы мозаичной болезни Табака), легко переносят очень низкие температуры (–70 °С и ниже), а также высушивание. Способы распространения вирусов в природе различны:- многие из них могут непосредственно заражать чувствительный организм (вирусы гриппа, оспы, мозаичной болезни Табака, бактериофаги), иные циркулируют в природе более сложным образом и переносятся при помощи других организмов. Так, вирус некроза Табака передаётся при помощи обитающего в почве Грибка Олпидиум (Olpidium):- последний, проникая в корни растения, вносит и вирус. Многие вирусы передаются паразитирующими у растений нематодами. Вирусы животных, человека и растений переносят также Клещи и Насекомые. Передача одних вирусоы сосущими членистоногими носит механический характер; в других случаях вирусы проделывают часть своего развития в переносчике и даже могут передаваться с яйцами переносчика из поколения в поколение. Многие вирусы, поражающие человека и домашних животных, обитают и в диких животных; поражающие культурные растения – в диких растениях и сорняках. Попытки обнаружить жизнедеятельность вироспор вне клетки, естественно, не увенчались успехом:- известно, что покоящиеся формы жизни вообще не обнаруживают жизнедеятельности (смотрите Анабиоз). В бесклеточных системах можно воспроизвести отдельные этапы размножения вирусов, получить саморепродукцию вирусной НК, а также под контролем этой НК – синтез белков, характерных для вирусов. Но эти процессы идут только в присутствии извлечённых из клетки рибосом; следовательно, эти системы, хотя и являются бесклеточными, не могут рассматриваться как вполне искусственно синтезируемые. О происхождении вирусов имеются различные предположения. Некоторые считают, что вирусы могут спонтанно зарождаться в организме хозяина под влиянием неблагоприятных условий. Но это мнение опровергается следами длительной эволюции вирусов (их приспособление к циркуляции в природе), а также отсутствием переходных форм между вирусами и органоидами клетки. Другие исследователи думают, что вирусы – потомки простейших форм жизни, однако и это предположение маловероятно, так как выраженный паразитический характер вирусов предполагает существование более высокоорганизованных существ, в которых вирусы могли бы жить и размножаться. Поэтому наиболее вероятно, что вирусы возникли от свободно живущих более сложно организованных форм, и простота вирусов вторична, она – результат приспособления к паразитическому образу жизни. Такая вторичная простота, связанная с утратой приспособленности к самостоятельному питанию и усилением способности к размножению, вообще очень характерна для паразитов. В пользу древности вирусов и длительной их эволюции говорит также то, что они вступают в сложные взаимоотношения с другими видами животных и растений (трансмиссивные вирусы, передаваемые различными животными). Систематика Вирусов:- Общепринятой классификации и обозначения вирусов ещё нет. Им дают, как и другим животным и растениям, родовые и видовые названия, пользуются народными обозначениями, различными сокращениями или ставят родовое название организма, поражаемого вирусом, и номер (например, Nicotiana virus I – вирус мозаичной болезни Табака). Поэтому каждый вирус может иметь несколько названий. Первую попытку систематики вирусов сделал Чешский учёный зоолог и паразитолог Станислав Провазэк (Stanislav Provázek; 1875–1915) (в 1907); он отнёс вирусы к животным, к группе Chamydozoa. К середине XX века сложилось 3 главных направления в систематике вирусов. Сторонники одного в основу системы вирусов кладут свойства вирионов; при этом учитывают присутствие в них РНК или ДНК, симметрию нуклеокапсида, наличие или отсутствие пеплоса (особой оболочки капсида), диаметр нуклеокапсида (у спиральных вирионов), число граней и капсомеров (у кубических вирионов). Представители второго направления (нумерическая система), учитывая по возможности все признаки, объединяют те вирусы, у которых больше общих признаков. Сторонники третьего направления, сохраняя принципы классической систематики, объединяют вирусы в группы на основе существенных признаков, характеризующих их родство (химическая близость, сходства морфологических стадий развития и способов циркуляции в природе). Международный Комитет по Номенклатуре Вирусов предлагает пользоваться бинарной номенклатурой, добавляя к родовому названию слово ‘Вирус’ (например, Род Вируса оспы – Poxvirus). Многие общепринятые названия сохраняют, хотя они и не соответствуют бинарной номенклатуре. Сторонники нумерической системы предлагают пользоваться криптограммами, которые в условных обозначениях расшифровывают важнейшие свойства вирусов. Так, вирус табачной мозаики обозначают так:- R/1, 2/5, E/E, S/0. Первый член показывает, что этот вирус содержит РНК (R) и она в нём одноniточная (1); второй член – молекулярную массу РНК в миллионах и % РНК в частице; третий – что форма этой частицы удлинённая с параллельными сторонами и концы не закруглены, а также что подобную форму имеет и нуклеокапсид; последний член указывает, что вирус поражает высшие растения (S) и распространяется без переносчика (0).

(2) A computer Virus is generally defined as a program that modifies other programs to contain a (possibly altered) version of itself, an approximation to a mathematical definition given by Dr. Frederick Cohen (1956–; American computer scientist and best known as the inventor of computer virus defense techniques) in his doctoral thesis. In other words, a virus requires a host to attach itself to, either by modifying the host, or inserting itself in some way into the 'chain of command'. In this way, the virus not only ensures that it's executed whenever its host is launched, but is also able to self-replicate, as infected files are copied, downloaded or otherwise transferred to other computer systems. Its name is based on the fact that its behavior is very roughly analogous to that of biological viruses. There are several categories of computer viruses, depending on what type of files they infect and how. Virus is a code that recursively replicates a possibly evolved copy of itself. Viruses infect a Host File or system area, or they simply modify a reference to such objects to take control and then multiply again to form new generations. In computing terms, a Virus is any program or piece of code that runs without your knowledge or permission, often with the intent of causing some sort of damage to your computer. Viruses can be loaded onto your computer in a variety of ways, all of which are designed to be invisible to you. For example, they may be piggybacked on the download of a benign program or uploaded via a streaming video link. Antivirus software is used to detect and remove viruses. See also Malware. Computer viruses are like chicken pox; those who are not vaccinated become infected. This is what we do for you. We obtain every conceivable virus and then develop a remedy for it. This keeps your PC safe from unnecessary 'illnesses'. We bait viruses around the clock in order to provide Avira AntiVir software with the latest virus definitions as quickly as possible. In order to ensure that our software continually retains its high level of quality, it is continuously examined in detail by our technical team. What are the characteristics of a comprehensive virus protection solution? Its detection performance, of course. But even the best virus scanner is worthless if it cannot be used flexibly. Anti-virus software is to the computer what the peephole is to a house's front door – it even functions according to the same principle. Whoever wants to enter is checked first. Viruses appear in the most unexpected places. This can apply to virus protection as well. In order to stop the spread of malware, many hardware manufacturers integrate protection software. Hardware and software producers who are concerned with product quality, supply their products with an integrated virus protection solution. / данное Доктором Фрэдэриком Коэном (Dr. Frederick Cohen; 1956–). Авира ЭнтайВир (Avira AntiVir). Вирус, от Латинского слова Virus, означающее Яд. Компьютерные Вирусы – это программы или фрагменты программного кода, которые, попав на компьютер, могут вопреки воле пользователя выполнять различные операции на этом компьютере – создавать или удалять объекты, модифицировать файлы данных или программные файлы, осуществлять действия по собственному распространению по локальным вычислительным сетям или по сети Интернет. Модификация программных файлов, файлов данных или загрузочных секторов дисков может осуществляться таким образом, что последние сами становятся носителями вирусного кода и в свою очередь могут осуществлять вышеперечисленные операции. Такая модификация называется заражением (инфицированием) и является важнейшей функцией компьютерных вирусов. В зависимости от типов заражаемых объектов выделяются различные типы вирусов.

VIRUS–CERTIFIED STOCK = ЗАПАС, СЕРТИФИЦИРОВАННЫЙ НА ВИРУС – Virus-Certified Stock is plants for planting and propagation produced under an official virus testing and certification program. Virus Free And Certified Stock:- via tissue culture techniques basic material is produced for large scale production. The requirement for this type of basic material is high:- It must be disease free and identity of material must be guaranteed. Therefore a quality system is used which are also externally certified. / разведение или распространение (propagation).

VIRUS DISEASE = ВИРУСНАЯ БОЛЕЗНЬ (или ВИРУСНОЕ ЗАБОЛЕВАНИЕ) – Virus Disease is a disease caused by a virus. Viral Disease is a disease caused by viruses. Long-term immunity usually follows viral childhood diseases (see also Chickenpox). The common cold recurs into adulthood because many different viruses cause its symptoms, and immunity against one does not protect against others. Some viruses mutate fast enough to reinfect people after recovery (see also Influenza) or to keep the immune system from fighting them off (see also AIDS). Certain cancers are caused by viruses. Vaccines can prevent some viral diseases. Antiviral drugs work only against specific viruses; antibiotics are ineffective against viral diseases. See also Polio, and Smallpox. / Вирусное Заболевание:- заболевание, вызванное вирусным агентом. Вирусные Болезни, широко распространённые в природе болезни людей, животных, птиц, рыб, насекомых, растений, простейших и даже Бактерий, вызываемые вирусами. К вирусным болезням человека относятся:- натуральная оспа и ветряная оспа, корь, герпес, грипп, краснуха, паротит эпидемический, полиомиелит, гепатит вирусный, эндемические энцефалиты (клещевой, комариный и другие), трахома, жёлтая лихорадка. В 1950–60-е открыты вирусы парагриппа, острого заразного насморка, аденовирусных и респираторных синцитиальных инфекций, вызывающие острые катары верхних дыхательных путей (смотрите Катар Дыхательных Путей), острый бронхит, фаринго-конъюнктивальную лихорадку, эпидемический кератоконъюнктивит. Ряд других заболеваний дыхательных путей вызывают некоторые типы кишечных вирусов, являющиеся также возбудителями асептического серозного менингита, некоторых желудочно-кишечных расстройств и других. Бешенством, ящуром, эндемическими энцефалитами, геморрагическими лихорадками и везикулярным стоматитом человек может заражаться от животных, орнитозом и пситтакозом – от птиц. При поступлении вируса в организм в нём происходят сложные процессы, приводящие либо к развитию острого инфекционного заболевания с выраженной клинической картиной, либо к заболеванию, протекающему бессимптомно, либо к длительно текущему хроническому заболеванию. Таким образом, механизм развития и клинические проявления вирусных болезней весьма разнообразны и зависят от природы вирусов, их вирулентности, путей проникновения в организм, 'тканевого тропизма' (различают дермотропные вирусы, размножающиеся в коже, пневмотропные – в лёгких, и нейротропные – в нервной системе) и преодоления естественных защитных барьеров организма (кожа, слизистые оболочки, реактивность клеток и другие). Инкубационный период вирусных болезней от 2–3 дней (грипп, некоторые энцефалиты и другие) до 30 дней и более (бешенство, эпидемический гепатит и другие). Заражение может происходить через воздух, пищу, молоко, воду или различные предметы, через укусы кровососущих членистоногих (комаров, москитов и клещей). Иммунитет при вирусных болезнях отличается тем, что вирус, хотя и поглощается лейкоцитами (смотрите Фагоцитоз), в них не разрушается; наиболее существенное значение в противовирусном иммунитете имеют специфические тканевые и гуморальные антитела, выработка которых в организме связана с функциональной активностью ретикуло-эндотелиальной системы как реакция на внедрение возбудителя. Один из факторов естественной защиты клеток от вирусов – выработка клетками интерферона – вещества, создающего резистентность клетки к вирусу, хотя это защитное действие и кратковременно. Лечение в основном симптоматическое. При некоторых вирусных болезнях (клещевой энцефалит) применяют специфическую сыворотку, содержащую антитела к возбудителю, специфическую вакцину (лечение упорных форм трахомы, герпетического конъюнктивита), интерферон (при вирусных конъюнктивитах). Антибиотики на вирус не действуют, применение их при вирусных болезнях целесообразно лишь для предупреждения бактериальных осложнений. Профилактика:- раннее выявление и госпитализация больных; уничтожение больных животных – источников инфекции, переносчиков, а также специфическая вакцинация живыми или убитыми вакцинами. Большинство вирусных болезней подлежит обязательной регистрации и статистическому учёту. В отношении натуральной оспы и жёлтой лихорадки существуют международные карантинные конвенции. Вирусные Болезни растений, заболевания растений, вызываемые вирусами. Поражают представителей различных Семейств Цветковых Растений, Хвойных, Папоротников, Водорослей и Грибов. Часто резко снижают урожай

сельскохозяйственных культур и его качество. Вирусные болезни растений делят на мозаики и желтухи. Основной симптом мозаик – мозаичная (неравномерная) окраска листьев, обусловленная нарушениями в пластидном аппарате клеток ассимиляционной паренхимы листьев. Из болезней этой группы наиболее вредоносны:- мозаика Табака, мозаика и стрик Томата, морщинистая и полосчатая мозаики Картофеля, мозаика Свёклы и другие (смотрите Мозаичные Болезни Растений). Для желтух характерны:- общий хлороз листьев; расстройство (нередко карликовость) роста; скручивание, курчавость листьев; чрезмерное скопление в них углеводов, вызывающее их жёсткость и хрупкость. К желтухам относят желтуху свёклы, закукливание злаков, скручивание листьев картофеля и так далее (смотрите Желтуха Растений). Из этой группы вирусных болезней растений исключены бывшие в ней ранее желтуха Астр, столбур Томата и другие, вызываемые микоплазмоподобными возбудителями. Мозаики легко передаются с соком больных растений во время пикировки рассады, при пасынковании, при соприкосновении больных и здоровых растений и лёгком взаимном травмировании их, например, при ветре, иногда через семена, а также сосущими Насекомыми (главным образом Тлями). Перенос вируса при этом происходит чисто механически. Желтухи распространяются преимущественно Насекомыми-переносчиками, главным образом Цикадами. Передача вирусов происходит биологически после предварительного размножения вируса в теле насекомого (инкубационного периода). Переносчиками вирусных болезней растений могут быть и растительноядные Клещи, Нематоды, низшие Грибы. Возможна передача вирусов Повиликой. Почти все вирусные болезни растений легко передаются потомству при вегетативном размножении, прививках. Вирусы зимуют в растениях, в их отмерших остатках, в переносчиках, в посевном и посадочном материале. На скорость размножения вирусов в растительных тканях и на проявление симптомов болезни большое влияние оказывают возраст растений (наиболее восприимчивы молодые растения), условия их питания и другие факторы внешней среды. Меры Борьбы:- использование иммунных сортов; регулирование сроков сева и уборки (например, в Южных областях ранние сорта Картофеля при ранней посадке и ранней (в Июле) уборке наименее поражаются вирусами); прочистка семенных участков от больных растений; борьба с переносчиками и сорняками, прогревание окулировочного материала, другие специальные мероприятия.

VIRUS REPLICATION = РЕПЛИКАЦИЯ ВИРУСА – Virus Replication is the process of intracellular viral multiplication, consisting of the synthesis of proteins, nucleic acids, and sometimes lipids, and their assembly into a new infectious particle. Virus Replication:- As viruses are obligate intracellular pathogens they cannot replicate without the machinery and metabolism of a host cell. Although the replicative life cycle of viruses differs greatly between species and category of virus, there are six basic stages that are essential for viral replication. (1) Attachment:- Viral proteins on the capsid or phospholipid envelope interact with specific receptors on the host cellular surface. This specificity determines the host range (tropism) of a virus. (2) Penetration:- The process of attachment to a specific receptor can induce conformational changes in viral capsid proteins, or the lipid envelope, that results in the fusion of viral and cellular membranes. Some DNA viruses can also enter the host cell through receptormediated endocytosis. (3) Uncoating:- The viral capsid is removed and degraded by viral enzymes or host enzymes releasing the viral genomic nucleic acid. (4) Replication:- After the viral genome has been uncoated, transcription or translation of the viral genome is initiated. It is this stage of viral replication that differs greatly between DNA and RNA viruses and viruses with opposite nucleic acid polarity. This process culminates in the De Novo synthesis of viral proteins and genome. (De Novo is a Latin phrase, literally translating to 'From The New', but implying 'Anew', 'From Scratch', or 'From The Beginning'.) (5) Assembly:- After De Novo synthesis of viral genome and proteins, which can be posttransrciptionally modified, viral proteins are packaged with newly replicated viral genome into new virions that are ready for release from the host cell. This process can also be referred to as Maturation. (6) Virion Release:- There are two methods of viral release:- lysis or budding. Lysis results in the death of an infected host cell, these types of viruses are referred to as cytolytic. An example is Variola Major also known as Smallpox. Enveloped viruses, such as influenza A virus, are typically released from the host cell by budding. It is this process that results in the acquisition of the viral phospholipid envelope. These types of virus do not usually kill the infected cell and are termed cytopathic viruses. After virion release some viral proteins remain within the host's cell membrane, which acts as potential targets for circulating antibodies. Residual viral proteins that remain within the cytoplasm of the host cell can be processed and presented at the cell surface on MHC class-I molecules, where they are recognised by T cells. / Репликация Вируса – размножение вируса. Дэ Ново (De Novo). Репликация (от позднелатинского слова Replicatio, означающее Повторение, от Латинского слова Replico, означающее Обращаюсь Назад или Повторяю), редупликация, ауторепродукция, аутосинтез, протекающий во всех живых клетках процесс самовоспроизведения (самокопирования) нуклеиновых кислот, генов, хромосом. У вирусов и фагов, имеющих однонитевую ДНК, репликация идёт особым образом. После внедрения в клетку хозяина одноцепочечной ДНК, которую называют (+)-цепью, на ней, как на матрице, синтезируется комплементарная ей (–)-цепь. На образовавшейся двухспиральной молекуле (репликативная форма) синтезируются новые одноцепочечные (+)-цепи, включающиеся в новые вирусные частицы. По такому же принципу происходит репликация РНК-содержащих вирусов и фагов. Таким образом, во всех известных случаях репликация ДНК и РНК проходит через стадию двухцепочечных молекул.

VIRUS–SERUM–TOXIN ACT OF 1913 = АКТ О ВИРУСАХ–СЫВОРОТКАХ–ТОКСИНАХ ОТ 1913 – Virus-Serum-Toxin Act (VSTA) of 1913 (21 USC §§ 151-159):- signed into law March 04, 1913, and amended by Sec.1768 of the Food Security Act of 1985 and the United States-Canada Free Trade Agreement Implementation Act of 1988. The Act prohibits the preparation and sale of worthless or harmful products for domestic animals and establishes licensing and import requirements. See also Biological Products. The Viruses, Serums, Toxins, Antitoxins, and Analogous Products Act (21 USC 151-159), also known as the Virus-Serum-Toxin Act (VSTA), is intended to assure the safe and effective supply of animal vaccines and other biological products. The act and its applicable regulations are administered by the Animal and Plant Health Inspection Service (APHIS) of the United States Department of Agriculture (USDA). The VSTA was enacted in 1913, and revised once in 1985. A 2002 law affected the VSTA by transferring border and import inspection functions from USDA to the Department of Homeland Security.

VIRUS X–TESTED = ИСПЫТАННОЕ НА ВИРУС ИКС. – Virus X-Tested:- tested for and found to be within tolerance for the Potato virus X (PVX) using approved testing methods.

VISA = VOLUNTARY INTERMODAL SEALIFT AGREEMENT

VISA = ВИЗА (или ВИСА) – (1) Visa are required by many countries for entry of a foreigner. A visa is a stamp in a foreign national's passport issued by a US consular officer which creates a legal presumption that there are no apparent reason to deny entry into the United States. Regardless of the stamp, the final decision to grant admission is made by an officer of the US Immigration Service at the port of entry. / выданная должностным лицом консульства США . Под Визой, от Латинского слова Висус (Visus), означающее Увиденный или Просмотренный, в зависимости от контекста понимается:- (i) официальная отметка в паспорте о разрешении на въезд в данное государство, проезд или выезд из него; или (ii) надпись на каком-либо документе или акте, удостоверяющая его подлинность и придающая ему силу.

(2) VISA or Visa Card is the worldwide credit card organization whose facilities are included with the cards issued by national major banks. VISA is a global credit card system. Cashless, secure and flexible means of payment accepted worldwide. Offered by UBS

(Swiss bank) under the label UBS VISA Card. On top of the credit card (monthly settlement) and cash-card functions, the UBS VISA card provides numerous extra benefits such as KeyClub membership, insurance cover and reduced rates for car rental. It can also be used as a phonecard. / Ю.Би.Эс. ВИЗА Кард (UBS VISA Card). ВИЗА Интёнэшэнэл Сёвис Эсосиэйшэн (VISA International Service Association) – всемирная организация кредитных карт, чьи условия включены в карты, выдаваемые крупными национальными банками.

(3) Visa:- an invoice properly validated by the Minister of Trade in regard to quota entries.

VISA WAIVER = ОТКАЗ ОТ ВИЗ – Visa Waiver is a program of selected countries to eliminate the visa requirement on a test basis. The Visa Waiver Program (VWP), administered by the US Department of Homeland Security (DHS) in consultation with the State Department, permits citizens of 38 countries to travel to the United States for business or tourism for stays of up to 90 days without a visa. In return, those 38 countries must permit US citizens and nationals to travel to their countries for a similar length of time without a visa for business or tourism purposes. Important Notice:- Travelers in the following categories are no longer eligible to travel or be admitted to the United States under the Visa Waiver Program (VWP):- (i) Nationals of VWP countries who have traveled to or been present in Iran, Iraq, Sudan, Syria, Libya, Somalia and Yemen on or after March 01, 2011 (with limited exceptions for travel for diplomatic or military purposes in the service of a VWP country); (ii) Nationals of VWP countries who are also nationals of Iran, Iraq, Sudan, or Syria. In addition, as of April 01, 2016, you must have an e-passport to use the VWP. An e-Passport is an enhanced secure passport with an embedded electronic chip. You can readily identify an e-Passport, because it has a unique international symbol on the cover. Electronic System for Travel Authorization (ESTA) is an automated system that determines the eligibility of visitors to travel to the United States under the Visa Waiver Program (VWP). Authorization via ESTA does not determine whether a traveler is admissible to the United States. The US Customs and Border Protection officers determine admissibility upon travelers' arrival. The ESTA application collects biographic information and answers to VWP eligibility questions. ESTA applications may be submitted at any time prior to travel, though it is recommended that travelers apply as soon as they begin preparing travel plans or prior to purchasing airline tickets. The Visa Waiver Program (VWP) enables nationals of certain countries, including Australia, New Zealand, and the United Kingdom, to travel to the United States for tourism or business for stays of 90 days or less without obtaining a visa, if certain requirements are met. Under the VWP, time spent in Canada, Mexico, and adjacent islands counts towards the maximum of 90 days stay allowed under the program. You must be a citizen or national of the following countries to be eligible to travel to the United States under the VWP:- Andorra, Australia, Austria, Belgium, Brunei, Chile, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Monaco, Netherlands, New Zealand, Norway, Portugal, San Marino, Singapore, Slovakia, Slovenia, South Korea, Spain, Sweden, Switzerland, Taiwan*, United Kingdom**. Notes:- *With respect to all references to 'country' or 'countries' on this page, it should be noted that the Taiwan Relations Act of 1979, Pub. L. No. 96-8, Section 4(b)(1), provides that 'whenever the laws of the United States refer or relate to foreign countries, nations, states, governments, or similar entities, such terms shall include and such laws shall apply with respect to Taiwan'. 22 USC § 3303(b)(1). Accordingly, all references to 'country' or 'countries' in the Visa Waiver Program authorizing legislation, Section 217 of the Immigration and Nationality Act, 8 USC 1187, are read to include Taiwan. This is consistent with the United States' one-China policy, under which the United States has maintained unofficial relations with Taiwan since 1979. **To be eligible to travel under the VWP, British citizens must have the unrestricted right of permanent abode in England, Scotland, Wales, Northern Ireland, the Channel Islands, and the Isle of Man.

VISBREAKING = ВИСБРЕКИНГ – Visbreaking is a thermal cracking process in which heavily atmospheric or vacuum-distillation bottoms are cracked at moderate temperatures to make light products and produce a lower viscosity residue than the initial feed to the unit. Visbreaking is a process for refining crude oil residues (tars and semi-tars) by shallow thermal decomposition. The main product of visbreaking is boiler fuel, which is obtained by lowering viscosity of the inputs through cracking. Visbreaking is essentially a mild thermal cracking operation at mild conditions where in long chain molecules in heavy feed stocks are broken into short molecules thereby leading to a viscosity reduction of feedstock. Now all the new visbreaker units are of the soaker type. Soaker drum utilizes a soaker drum in conjunction with a fired heater to achieve conversion. Visbreaking is a non-catalytic thermal process. It reduces the viscosity and pour point of heavy petroleum fractions so that product can be sold as fuel oil. It gives 80–85% yield of fuel oil and balance recovered as light and middle distillates. The unit produces gas, naphtha, heavy naphtha, visbreaker gas oil, visbreaker fuel oil (a mixture of visbreaker gas oil and vsibreaker tar). A given conversion in visbreaker can be achieved by two ways:- (i) High temp., low residence time cracking:- Coil Visbreaking; and (ii) Low temp., high residence time cracking:- Soaker visbreaking. Reaction in visbreaking CH_3-CH_2-CH_2-CH_2-CH_2-CH_2-CH_3 $\rightarrow$ CH_3-CH_2-CH=CH_2 + CH_3-CH_2-CH_3 Soaker Visbreaking Process The furnace operators at a lower outlet temperature and a soaker drum is provided at the outlet of the furnace to give adequate residence time to obtain the desired conversion while producing a stable residue product, thereby increasing the heater run and reducing the frequency of unit shut down for heater decoking. The products from soaker drum are quenched and distilled in the downstream fractionator. Process diagram for visbreaking with soaker is shown in Figure M-VI 4.1. Objective:- To lower the viscosity of heavy residues under relatively milder cracking condition than the conventional cracking processes. Feed Atmospheric residues $\rightarrow$ To get gasoline and diesel oil. Vacuum residues $\rightarrow$ To reduce viscosity. Reaction:- (i) Splitting of C-C bond; (ii) Oligomerization and cyclisation to naphthenes of olefinic compounds; and (iii) Condensation of the cyclic molecules to polyaromatics. Side reactions:- foramation of H_2S, thiophenes, mercaptans, phenol. Products:- The cracked product contains gas, naphtha, gas oil and furnace oil, the composition of which will depend upon the type of feedstock processed. A typical yield pattern may be gas 1–2%, naphtha 2–3%, gas oil 5–7%, furnace oil 90–92%. Visbreaking Conditions:- Inlet Temperature:- 305–325 °C (15–40 bar); Exit:- 480–500 °C (2–10 bar); With soaking 440–460 °C (5–15 bar); Feed:- 90 °C $\rightarrow$ pretreated with VB tar to 335 °C. Visbreaking Furnace:- Convection zone $\rightarrow$ top $\rightarrow$ to thermal efficiency. Radiation zone $\rightarrow$ bottom tubes. Avg. heat flow $\rightarrow$ 22–30 kw/m^2. Variables:- Variables in visbreaker are feed rate, furnace transfer temperature, visbreaker tar quench to transfer line, fractionation pressure, fractionation top temperature, circulation, reflux flow, visbreaker tar quench to fractionator bottom, visbreaker tar quench to visbreaker tar stripper bottom, stabilizer temperature and pressure. The purpose of visbreaking is to produce lower viscosity fuel oil. Soaking Drum Soaking drum is used to lengthen the feed residence time so that the furnace can operate at lower temperature. Soaker results in saving of energy because of the lower temperature with less coke tendency, larger gas oil yield. Advantages:- (i) 15% reduction in fuel oil; (ii) larger running time between two decoking operations; coke deposit rate 3–4 times slower than in conventional units; (iii) better selectivity towards gas and gasoline productivity. Coil Visbreaker:- In coil visbreaking process the desired cracking is achieved in the furnace at high temperature and the products of cracking are quenched and distilled in a downstream fractionator. Advances in visbreaker coil heater design now allows for the isolation of one or more heater passes for decoking, eliminating the need of shut the entire visbreaker down for furnace decoking. Integration of the coil visbreaking process with vacuum units is also being considered in many areas of the world. Visbreaking is a thermal cracking process in which heavy atmospheric or vacuum-still bottoms are cracked at moderate temperatures to increase production of distillate products and reduce viscosity of the distillation residues. There are two types of Visbreaking processes:- coil or soaker visbreaking. Figure 6.5a shows a schematic diagram of the coil visbreaking process. For visbreaking, the feedstock is introduced into the coil heated in the furnace where the thermal cracking reactions take place. At the furnace outlet, the reaction

products are immediately quenched using a portion of the gas oil product from the fractionator to stop the thermal cracking reactions. The quenched products are sent to the fractionator for separation into gas, gasoline, light gas oil, and visbroken residue streams. A steam stripper can be used with the fractionator for better separation of the visbreaking products. In the soaker visbreaking process, a soak drum is placed after the furnace, Figure 6.5b. Most of the thermal cracking reactions in this case take place in the soaker drum. Depending on the process objectives and feedstock characteristics, reaction temperatures range from 450 °C to 485 °C and pressures range from 3 to 10 bar. Higher temperatures and lower residence times are used in the coil visbreaking process. Residence times can vary from 1 min (associated with high temperatures in coil visbreaking) to 10 min (for lower temperatures used in soaker visbreaking). Similar to deasphalting and distillation, the environmental impact of visbreaking is associated with burning fuel in the furnace to provide energy for thermal cracking, and, to a lesser extent, burning off the coke deposited in the coil or soaker drum leading to emissions of CO_2, oxides of nitrogen (NO_x), and oxides of sulfur (SO_x) in the flue gases. / Висбрекинг это процесс переработки нефтяных остатков (гудронов и полугудронов) путём неглубокого термического разложения сырья. Основным продуктом висбрекинга является котельное топливо, получаемое в результате снижения вязкости исходного остатка в результате крекинга.

VISCA = VISAYAS STATE COLLEGE OF AGRICULTURE

VISCARIA = ВИСКАРИА (или ЛИПКОЕ) – Viscaria (in Latin):- the Latin specific epithet viscaria means sticky.

VISCARIA = ВИСКАРИЯ (или СМОЛКА) – Viscaria is a Genus of alpine or boreal plants with viscous stems and foliage that are usually included in the Genus Lychnis. / Вискария, или как её ещё называют в народе – Смолка – одно из многочисленных растений, которое активно используется в ландшафтном дизайне. Этот цветок, в зависимости от вида и сорта, высаживается в групповых посадках на зелёном газоне, смешанных клумбах, в кашпо и горшках. Вискария отлично подходит для декорирования балконов. На сегодняшний день известно более 400 Видов Вискарии. Ботаническое Описание Вискарии:- Вискария принадлежит к Семейству Гвоздичных. Цветок выращивается как однолетник и как многолетнее растение. Среди садоводов одинаково популярны низкорослые и высокорослые сорта Вискарии. Стебли у Вискарии необычные – они ворсистые и липкие. Высота растения колеблется от 25 сантиметров (см) до 1 метра (м). Цветы мелкие, имеют самый разный окрас, внешне похожи на Гвоздику. Наиболее распространённый цвет – голубой, белый, синий. Вискария очень быстро разрастается, образуя пёстрый цветочный ковёр. При этом растение не имеет аромата а, следовательно, безопасно для аллергиков. Размножается Вискария семенами и черенкованием.

VISCID = ЛИПКОЕ (или КЛЕЙКОЕ, или ВЯЗКОЕ, или ТЯГУЧЕЕ) – Viscid (-a, -m):- covered with a sticky secretion. Viscid:- glutinous; sticky. / покрытое липким экссудатом.

VISCOELASTIC DIVERTING ACID = ВЯЗКОУПРУГАЯ ОТКЛОНЯЮЩАЯ КИСЛОТА – Viscoelastic Diverting Acid (VDA) is a self-diverting, polymer-free acidizing fluid used for high fluid efficiency during acid fracturing processes. Viscoelastic Diverting Acid (VDA):- Applications:- (i) Stimulation of:- (a) oil and gas carbonate reservoirs; (b) reservoirs with multiple layers, long production intervals, or permeability variation; (c) horizontal and vertical wells; (ii) Multilayered and reservoirs with long production intervals; and (iii) Bullheading or pumping through coiled tubing. Benefits:- (i) Self-diverting acid system; (ii) Operation as sole treating fluid or in combination with other fluids; (iii) Increased zonal coverage; (iv) No residual formation damage; (v) Single treatment fluid for simplified operations; (vi) Easy fluid recovery and well cleanup; (vii) Solids- and polymer-free; (viii) Rated to 300 degF (149 °C); (ix) Rapid viscosity development on acid spending; and (x) Viscosity reduction on contact with hydrocarbon. In matrix stimulation of oil and gas carbonate formations, the objective is total zonal coverage. While the use of diverters has been well-proven, most diverter methods use particulates that, post-treatment, can damage the formation. For cost effectiveness and ease of operation, the ideal system is one that can be bullheaded, is self-diverting, and leaves no residual damage. Unique Properties For Extended Application:- Existing technologies for self-diverting systems rely on polymer-based fluids that can result in post-treatment residual damage. Additionally, conventional acid systems are limited to bottom hole conditions of approximately 200 degF (93 °C). The VDA* viscoelastic diverting acid is rated to 300 degF and eliminates the damage associated with solids and polymers in matrix treatment. (Note:- *Mark of Schlumberger.) VDA acid can be used as the sole treating fluid or with other treating acids for diversion. Diverted Flow For Ideal Treatment:- VDA acid maintains an ideal thin consistency while being pumped into the well. Upon acid spending, the fluid rapidly develops viscosity in situ and becomes self-diverting. The viscosity buildup serves as a barrier to reduce the development of dominating wormholes and allows fluid movement to stimulate other untreated zones. Furthermore, VDA acid can be bullheaded and still provide total zonal coverage. In horizontal and extended-reach wells, VDA acid is ideal for pumping through coiled tubing as these wells contain no solids that could cause bridging. In reservoirs with multiple layers or long production intervals, the rapid buildup in viscosity creates a temporary barrier that diverts the remaining fresh acid into the more highly damaged or lower-permeability zone. It is the development of viscosity that reduces fluid leakoff and gives the fluid its self-diverting property, which ensures coverage of the entire interval. Low-Pressure Cleanup:- Following treatment, the barrier is broken down by hydrocarbon production or by dilution with formation fluids, giving rise to easy recovery and well cleanup. Because only low pressures are required for well cleanup, operations are simplified and cleanup costs are reduced. Effective Chemical Diversion Results In Uniform Production, Minimal Drawdown:- In a recent application, the effects of VDA acid diversion to increase zonal coverage and improve permeability were evaluated by a major customer. On an existing single completion trial candidate in the Middle East, the test demonstrated that VDA acid helped achieve not only diversion goals but stimulation objectives as well. Interpretive results from this test would determine whether the advanced VDA acid could provide effective chemical diversion for use in dual completions that were scheduled. The test well had five different sets of perforations totaling 133 ft and extending through varying lithologies; the permeability contrast among the five zones varied from 3 to 600 mD. A treatment design consisting of VDA acid for diversion and SXE* emulsified acid for deep penetration was selected. (Note:- *Mark of Schlumberger.) Prior to treatment, a pressure buildup analysis showed a large skin of +100; following stimulation using VDA acid and SXE acid, a second well test showed that skin was reduced to –3. Comparisons of the prewell and postwell production logging and test analyses showed an oil production increase, from 510 to 1 730 bbl/d at the same choke size. Additionally, the wellhead pressure showed a five-fold increase; flowing bottomhole pressure doubled. The self-diverting VDA acid reached all producing zones. An increase in wellbore flowing pressure and the shape of the buildup curve also showed a reduction in formation skin. Before treatment, the production logging tool density and spinner curves indicated that the bottom set of perforations was not producing fluid. Data also indicated that only some of the perforations within the upper four zones contributed to total flow. Production logs after the acid treatment with VDA acid and SXE acid showed that all perforations throughout the five zones now contributed to total flow. As a result of this field trial, VDA acid was deemed appropriate for use without coiled tubing in dual completions and raised expectations for future self-diverting VDA acid treatments in the area. / Шламбёжей Лимитид (Schlumberger Limited, Houston, State of Texas (TX), The United States).

VISCOMETER = ВИСКОМЕТР (или ВИСКОЗИМЕТР) – Viscometers are instruments used to measure viscosity. Since viscosity cannot be measured directly, viscometers are instead used to measure an experimental parameter that is related to viscosity in a known manner. Although there are many different kinds of viscometers, this module will focus on the three most common types.
