Viscometers measure the viscosity and flow properties of fluids. Viscosity arises from the internal friction of a fluid and is defined as a liquid's resistance to flow or shear stress. Applications Of Viscometers:- Viscometers have wide and varied applications in the materials science and chemical industries for materials such as oil, asphalt, plastics, wax, paints, coatings, and adhesives. They are also used for food and beverages and personal-care products such as cosmetics, shampoo, and toothpaste. Measuring viscosity is important when considering process conditions for materials that need to be pumped or piped. Viscosity also affects dipping and coating performance, which is particularly relevant to paints and inks. Viscosity is a very useful indirect measure of material properties including molecular weight and density, both of which affect flow behavior. Viscometers can therefore be used to monitor batch consistency and quality control. Example applications include:- (i) measuring the flow of engine oil under different temperature conditions; (ii) analyzing the flow properties of milk to design suitable piping systems; and (iii) checking the viscosity of jams and syrups to ensure batch consistency. Since changes in viscosity reflect changes to molecular weight, viscometers are used to characterize plastics. They are particularly useful in polymer synthesis since the flow rate can be used to determine the change of polymer length through different processes. In many industrially useful cases, viscosity decreases as enzymatic activity increases. Viscometers are used to determine the activity of enzymes such as cellulase, protease, amylase, and pectinase. Types Of Viscometers:- There are many ways to measure viscosity, but they break down into two basic methods. Either an object, such as a sphere or a rotor blade, moves through a stationary material, or the material flows through or past a stationary object. In either case, the resistance to flow is measured. Capillary Viscometers:- Also known as U-Tube or Glass Viscometers, capillary viscometers are often used in laboratory settings. Viscosity is measured by timing how long it takes for a transparent or translucent fluid to flow between two points of a capillary tube. For opaque liquids, it is hard to determine when the sample has passed a point in the tube, so it is necessary to use reverse-flow viscometers that only wet the timing section of the viscometer capillary during the actual measurement. The Cannon-Fenske Opaque, Zeitfuchs Cross-Arm, and BS/IP/RF Viscometers from CANNON Instrument Co. (State College, PA; www.cannoninstrument.com) are all reverse-flow types. Reverse-flow viscometers must be cleaned, dried, and refilled before a repeat measurement can be made. Capillary viscometers can be manual or automatic. Automatic instruments use infrared optical sensors for transparent samples, or thermal sensors for opaque samples. Rotational Viscometers:- Simple rotational viscometers, also known as Brookfield type viscometers, use a torsion spring to measure the torque required to rotate a spindle in the material. Changing rotor speed and size allows for the measurement of different ranges of viscosity. The SVM 3000 from Anton Paar (Ashland, VA; www.anton-paar.com) uses the Stabinger measuring principle. A lightweight magnetic rotor floats in a liquid-filled tube, which rotates at constant speed. The sample fluid's viscous forces drive the rotor, leading to an equilibrium rotor speed, which is recorded as a measure of the fluid's viscosity. Different spindle geometries such as cylindrical, coaxial cylinder, parallel plate, and cone-plate are used in rheometers to create different shear forces. Rheometers are more complex instruments than viscometers and are used to measure flow rate-dependent viscosity in non-Newtonian fluids. Rolling Ball, Falling Ball, Sphere, And Piston Viscometers:- The Lovis 2000 M/ME from Anton Paar is a microviscometer based on the rolling ball principle. A ball rolls through a closed, sample-filled capillary that is inclined at a defined angle. Inductive sensors determine the ball's rolling time between two marks. In a similar way, falling ball or sphere viscometers measure the time it takes for a ball or sphere to fall under gravity through a sample-filled tube inclined at an angle. Falling piston viscometers operate on a similar principle, but they measure the resistance to the piston falling through the material. Considerations For Purchasing Viscometers:- Choosing a viscometer is a complex process and will depend on the sample type, viscosity, opacity, available volume of sample, required throughput, and level of automation needed. At a minimum, the following factors should be considered:- (i) viscosity range; (ii) accuracy; (iii) temperature control; (iv) sample volume and microvolume capability; (v) automation and computer interfacing; and (vi) regulatory requirements and industry standards. Viscosity Range:- Viscosity is measured in Pascal seconds (Pa·s), in other words, the amount of pressure needed to achieve a given rate of flow. Viscosity is commonly stated in centiPoise (cP), which is the unit used by the standards agency ASTM International; 1 cP equals 1 mPa·s. Water at 20 °C has a dynamic viscosity of 1.002 cP. Kinematic viscosity is the ratio of dynamic viscosity to density; the unit of measurement is the Stoke (St). Thermo Scientific Gilmont Falling-ball Viscometers (Thermo Fisher Scientific, Waltham, MA; www.thermoscientific.com) offer a simple, accurate, economical, absolute method for measuring viscosity of clear fluids up to 200 cP. The Viscotek DSV from Malvern Instruments (Malvern, UK; www.malvern.com) directly measures the relative viscosity of dilute polymer solutions using pressure sensing technology and has a viscosity range of <1 mPa·s to 20 mPa·s. In most glass capillary viscometers, the samples flow under gravity, but vacuum viscometers can be used to measure highly viscous materials. Vacuum viscometers require a very accurately controlled vacuum to pull the liquid through the capillary. CANNON Digital Vacuum Regulators (DVRs) can be used in conjunction with vacuum viscometers for the measurement of asphalt cement at 60 °C (140 °F) according to ASTM D 2171. The torque range for rotational viscometers dictates the range of viscosity that the instrument can measure. The High Shear CAP-2000+ from Brookfield Engineering Laboratories (Middleboro, MA; www.brookfieldengineering.com) offers a choice of torque range with a standard torque of 181 000 dyne·cm or a low torque of 7 970 dyne·cm. The speed of rotation varies between 5 and 1 000 rpm, resulting in a viscosity measurement range of 0.2–15 000 cP. Accuracy:- The accuracy of a viscometer is dependent not only on the engineering of the instrument itself, but also on how precisely temperature can be controlled. It is common to make repeated viscosity measurements that are averaged to achieve a result with an associated accuracy. Viscosity standards are used to check the accuracy of a viscometer and can be important for verifying compliance with industry quality systems. Check that the manufacturer provides standards suitable for your application. BrookfieldSilicone and Mineral Oil Standards provide a fluid viscosity value that is constant at 25 °C. The company recommends replacing viscosity standards on an annual basis. Temperature Control:- The viscosity of most materials reduces as temperature increases. Materials such as engine oils are subject to routine temperature variations in use, and the measurement of viscosity is required at different temperatures. Therefore, it is very important for viscometers to have precise temperature controls. The Black Pearl Viscometer from ATS RheoSystems (Bordentown, NJ; www.atsrheosystems.com) comes with built-in Peltier temperature control for all measuring systems. Some systems have the option of adding cooling equipment, leading to temperature ranges below 0 °C. Sample Volume And Microvolume Capability:- Sample volume is important for biological samples, especially in the clinical laboratory. The SV-A Series from A&D Weighing (San Jose, CA; www.andonline.com/weighing) allows for the accurate measurement of sample sizes as small as 2 mL with 1% accuracy. The Cannon-Manning Semi-Micro Extra Low Change U-tube Viscometer from CANNON Instrument Co. will measure kinematic viscosity with as little as 0.5 mL of sample. Automation And Computer Interfacing:- The simplest viscometers allow one measurement at a time, but for continuous measurements, or measurements at different temperatures, it is useful to have an automated system. Semi-Automatic Kinematic Viscosity Systems from UIC, Inc. (Joliet, IL; www.uicinc.com) can determine the viscosities of up to 12 samples simultaneously and independently. Some automated instruments can be interfaced to a PC. Check whether the manufacturer's software can be interfaced to your in-house laboratory system if required. WinCT-Viscometer software from A&D Weighing uses an RS232C interface to display measurement progress from the SV series Sine-wave Vibro Viscometer in real time on a PC. Measured results can be saved or analyzed. The DV2T Viscometer from Brookfield Engineering Laboratories features a 5-in. color display to guide users through test creation and data gathering. Multistep test protocols can be created using the Program Generator software and uploaded to the DV2T through a USB flash drive. Test data can be printed or sent to a PC. Regulatory Requirements And Industry Standards:- Be sure that your chosen viscometer is certified for your required ASTM or ISO industry standards. The Thermo Scientific HAAKE Falling Ball Viscometer type C from Thermo Fisher Scientific measures the

viscosity of transparent Newtonian liquids and gases. It meets the ISO 12058 standard and is accepted as an official reference instrument. The PolyVISC® Automatic Glass Capillary Viscometer from CANNON Instrument Co. is a benchtop unit for dilute solution polymer viscosity analysis. Both transparent and opaque samples can be measured with the accuracy required by ASTM D 2857. Viscometer or Viscosimeter is an apparatus for determining the viscosity of a fluid. Viscometer is an instrument for measuring the viscosity (resistance to internal flow) of a fluid. In one version, the time taken for a given volume of fluid to flow through an opening is recorded. In the capillary tube viscometer, the pressure needed to force the fluid to flow at a specified rate through a narrow tube is measured. Other types depend on measurements of the time taken for a sphere to fall through the fluid, or of the force needed to rotate the inner cylinder of a coaxial pair (the space between the two cylinders being filled with the fluid under test), or of the rate at which oscillations of a disk vibrating in the fluid die out. Viscometer is a device designed to measure the viscosity (resistance to flow) of the fluid. Many types exist from simple calibrated glass tubes to extensively instrumented, on-line shear viscometers. Stephen Moulton Babcock (1886) at the New York State Agricultural Experiment Station (now part of Cornell University) devised a Viscometer consisting of a hollow brass cylinder 6.4 cm long that was suspended from a 1.1 m long torsion wire. The cylinder was immersed in milk and caused to oscillate and the degree of damping used to measure the viscosity of milks. Babcock's viscometer design was used by Fritz Wilhelm Woll (1895) at the University of Wisconsin who studied the effects of processing milk and cream on their viscosity. / из 1.1 метра длины скрученной проволоки. Антон Паа Ге.эм.бе.Ха. (Anton Paar GmbH, Graz, Austria). Канэн Инстчрумэнт Ко. (CANNON Instrument Co.). Ю.Ай.Си., Инк. (UIC, Inc.). Фритц Вильхэльм Воль (Fritz Wilhelm Woll). Американский учёный, Заслуженный Профессор Стивэн Малтчэн Бэбкок (Emeritus Professor Stephen Moulton Babcock) изобрёл Вискометр, прибор для определения вязкости масла. Под Вискозиметром, от позднелатинского слова Viscosus, озанчающее Вязкий, и Греческого слова Métron, означающее Мера, от Metréo, означающее Измеряю, понимается прибор для определения Вязкости. Наиболее распространены:- Капиллярные Вискозиметры, Ротационные Вискозиметры, Вискозиметры С Падающим Шариком, Ультразвуковые Вискозиметры. Определение вязкости Капиллярными Вискозиметрами основано на Законе Пуазёйля (смотрите Закон Пуазёйля) и состоит в измерении времени протекания известного количества (объёма) жидкости или газа через узкие трубки круглого сечения (капилляры) при заданном перепаде давления. Капиллярными вискозиметрами измеряют вязкость от 10^{-5} Н·сек/м^2 (газы) до 10^4 Н·сек/м^2 (консистентные смазки, ныне пластичные смазки). Относительная погрешность образцовых капиллярных вискозиметров ±0.1–0.3%, рабочих приборов ±0.5–2.5%. В капиллярных вискозиметрах указанных типов течение жидкости происходит под действием силы тяжести (в начальный момент уровень жидкости в одном колене вискозиметра выше, чем в другом). Время опорожнения измерительного резервуара определяют как промежуток между моментами прохождения уровня жидкости мимо меток на верхних и нижних концах резервуара. В капиллярных автоматических вискозиметрах (непрерывного действия) жидкость поступает в капилляр от насоса постоянной производительности. Перепад давления на капилляре, измеряемый манометром, пропорционален искомой вязкости. В Ротационных Вискозиметрах исследуемая вязкая среда находится в зазоре между двумя соосными телами (цилиндры, конусы, сферы, их сочетание), причём одно из тел (ротор) вращается, а другое неподвижно. Вязкость определяется по крутящему моменту при заданной угловой скорости или по угловой скорости при заданном крутящем моменте. Ротационные вискозиметры применяют для измерения вязкости смазочных масел (при температурах до –60 °С), нефтепродуктов, расплавленных силикатов и металлов (до 2 000 °С), высоковязких лаков и клеев, глинистых растворов и так далее. Относительная погрешность наиболее распространённых ротационных вискозиметров лежит в пределах 3–5%. Например, у ротационного вискозиметра РВ-7 (пределы измерений – от 1 до 10^5 Н·сек/м^2, погрешность ±3%). Действие вискозиметра с движущимся в исследуемой среде шариком основано на Законе Стокса (смотрите Закон Стокса); вязкость определяется по скорости прохождения падающим шариком промежутков между метками на трубке вискозиметра. К приборам этого типа относится широко распространённый Универсальный Вискозиметр Гепплера со 'скользящим' шариком. Пределы измерений вискозиметра этого типа $6 \cdot 10^{-4}$–250 Н·сек/м^2, погрешность ±1–3%. Действие ультразвуковых вискозиметров основано на измерении скорости затухания колебаний в пластинке из магнитострикционного материала, погруженной в исследуемую среду. Колебания возникают от коротких (длительность 10–30 мксек) импульсов тока в катушке, намотанной на пластинку. При колебаниях пластинки в этой же катушке наводится электродвижущая сила (эдс) (смотрите Магнитострикция), которая убывает со скоростью, зависящей от вязкости среды. При уменьшении эдс до некоторого порогового значения в катушку поступает новый возбуждающий импульс. Вязкость среды определяют по частоте следования импульсов. Ультразвуковыми Вискозиметрами измеряют вязкость в диапазоне от 10^{-3} до 500 Н·сек/м^2 с относительной погрешностью 5%. Помимо вискозиметров, позволяющих выразить результаты измерений в единицах динамической или кинематической вязкости, существуют вискозиметры для измерения вязкости жидкостей в условных единицах. Такой вискозиметр представляет собой сосуд с калиброванной сточной трубкой; вязкость оценивается по времени истечения определённого объёма жидкости. Например, с помощью вискозиметров типа ВЗ-1 и ВЗ-4, предназначенных для исследования лаков и красок, вязкость выражают в секундах, а с помощью вискозиметра типа ВУ (Энглера) для нефтепродуктов – в Градусах Энглера. Перевод условных единиц в единицы вязкости Международной Системы Единиц (Н·сек/м^2 и м^2/сек) возможен, но неточен.

VISCOSE = ВИСКОЗА – (1) Viscose is a cellulose fiber obtained from cellulose or other materials through the viscose process. Wood pulp or cotton linters is dissolved in caustic soda, the resulting salt is treated in carbon bisulphate, which is pressed through small holes and rinsed. The fibers produced by means of these various chemical processes are intended to imitate silk by their gloss. Artificial silk was invented by Count Chardonnet in 1884, who took collodion as basis; the fiber produced, however, was very dangerous, due to its inflammability. At the present time wood pulp or cotton linters is used mostly as source of cellulose for the artificial silk. (1924). The third method, historically, of making rayon yarn. The product manufactured by this method is a pure regenerated cellulose. A man-made fiber spun from regenerated cellulosic material. Viscose is cellulose fiber obtained by the viscose process. Alphabetic code – CV; and relevant commercial allowance – 13.00. Viscose is the most common type of refined rayon. Viscose rayon typically has a soft and silky feel. Rayon is often used in linings for high quality garments. Viscose is also absorbent and drapes well. See also Rayon Fiber. Viscose is the most common type of rayon. It is produced in much greater quantity than cuprammonium rayon, the other commercial type. Viscose is not a synthetic fiber made from petroleum; but rather it's a 'regenerated cellulosic fiber' made from cellulose – most commonly wood pulp, but many plants can be used, such as Bamboo. The cellulose is broken down, and then 'regenerated' into a fiber. One of the major advantages of viscose over synthetics is that it is biodegradable. Viscose from Bamboo has an added benefit of being anti-bacterial and anti-fungal and is hypoallergenic. In the viscose process, cellulose is treated with caustic soda (aka:- sodium hydroxide) and carbon disulfide (which can cause nervous system damage). This process converts the cellulose into a highly viscous liquid about the color and consistency of honey. Think of making paper mache. Then the mixture is forced through fine holes in a spinerette (think shower head) which produces long filaments of yarn. These yarn filaments are dumped into a chemical bath of sulfuric acid which hardens the filaments, the viscose yarn. When Bamboo viscose was introduced a few years ago, it was a big hit, and American synthetic yarn manufacturers correctly pointed out that the process can be extremely polluting. The environmental burden comes in disposing of the process chemicals:- the sodium hydroxide, though not toxic to humans, is harmful to the environment if dumped into our rivers as untreated effluent. Carbon disulfide is toxic to the nervous system; and sulfuric acid is a component of acid rain. There are emissions – air pollution – of these chemicals as well, which contribute to greenhouse gasses. These chemicals do not

necessarily remain as a residue on the fibers. Viscose can be Oeko-Tex certified, a certification which verifies that the finished fiber has been tested for and contains no residual chemicals which may be harmful to health. Oeko-Tex certifies only the final product, i.e. the fibers or the fabric. It does not examine the production process, which is where most of the environmental burden is found. We use Bamboo as our source of cellulose. We have mentioned some of the (considerable) negatives of the production process above. Positives include the fact that Bamboo is one of the fastest growing plants in the world, absorbing about 5 times the amount of carbon dioxide as an equivalent stand of trees. Bamboo grows with no irrigation and no pesticides or synthetic inputs. And currently there are no known genetically modified organisms (GMO) variants of Bamboo. We have ensured that our Bamboo does not come from stands that endanger Panda habitat. We decided that the addition of Bamboo to the world's fiber set was a positive development, and that the positives outweighed the negatives. It is important that Bamboo come from FSC (the Forest Stewardship Council) certified stands, important now given the sudden popularity of Bamboo for fabric. Some (not yet all!) of the Bamboo viscose fiber we use is produced in a process that has no water pollution or solid waste disposal problems, and that has only minimal air pollution. Viscose is the most prevalent type of refined rayon, it usually has a silky feel and drapes well. It is used for linings of high-quality garments and is absorbent. Viscose is a type of rayon. Viscose is the generalized term for a regenerated manufactured fibre, made from cellulose, obtained by the viscose process, it is neither truly natural (like cotton, wool or silk) nor truly synthetic (like nylon or polyester) – it falls somewhere in between. Viscose is a low-cost fabric, which is popular and can be found in cotton end uses such as feminine hygiene products, in tyre cords as well as in velvets and taffetas. / каустическая сода или едкий натр (caustic soda). Искусственное волокно, произведённое из регенерированного целлюлозного материала. Под Вискозой, от позднелатинского слова Вискозус (Viscosus), означающее Вязкий или Клейкий, понимается высоковязкий раствор продукта взаимодействия щелочной целлюлозы с сероуглеродом (ксантогената целлюлозы) в разбавленном водном растворе едкого натра. Применяется главным образом для получения вискозного волокна, плёнки (целлофан) и искусственной кожи (кирзы). Под Вискозой понимается концентрированный раствор ксантогената целлюлозы в разбавленном растворе NaOH. Состав вискозы характеризуется содержанием целлюлозы и гидроксида натрия. Практически в вискозе содержится ксантогенат целлюлозы, но так как в процессе дальнейшей обработки вискозы (фильтрация, обезвоздушивание) степень этерификации ксантогената целлюлозы непрерывно понижается, то и концентрация ксантогената в растворе соответственно непрерывно изменяется. Состав вискозы в зависимости от вида волокна (текстильная нить, штапельное волокно, техническая нить) может быть различным. Как правило, больше целлюлозы и меньше гидроксида натрия содержат вискозы, предназначенные для изготовления штапельных волокон и целлофана. Минимальное количество целлюлозы и максимальное количество гидроксида натрия находится в вискозе, предназначенной для производства технической нити. С экономической точки зрения целесообразно повышение содержания целлюлозы в вискозе и снижение в ней содержания гидроксида натрия, так как при этом уменьшается не только объём вискозы и ёмкость аппаратуры, но и кубатура химического цеха и количество воды, поступающей с вискозой в осадительную ванну (которую в дальнейшем приходится выпаривать) при формовании волокна. Однако выбор оптимальной концентрации целлюлозы в вискозе связан не только с экономическими показателями, но и с технологическими факторами – лёгкостью переработки вискозы и качеством готового волокна. Так, при увеличении концентрации целлюлозы в вискозе выше определённого предела значительно возрастает вязкость вискозы. Например, при повышении содержания целлюлозы с 7–8 до 11–11.5% вязкость вискозы повышается с 40–50 до 200–300 с; это затрудняет переработку вискозы на обычном оборудовании. При снижении содержания гидроксида натрия в вискозе следует также учитывать влияние этого компонента на качество волокна. Содержание NaOH влияет на стойкость и скорость созревания вискозы. Значительное снижение концентрации гидроксида натрия в вискозе отрицательно сказывается на её устойчивости и фильтруемости. В тех случаях, когда формование производится из 'молодых' вискоз с высоким значением f, например технической нити, снижать содержание гидроксида натрия в вискозе вообще нецелесообразно. Вискоза применяется для прядения вискозных неволокнистых изделий (целлюлозная плёнка, пластифицированная глицерином – целлофан), вискозного волокна. Вискозное волокно (от Латинского слова Viscosus, означающее Клейкий), искусственное целлюлозное волокно, получаемое переработкой природной целлюлозы. В конце 1880-х ботаниками Негели было установлено, что хлопковое волокно состоит из целлюлозы. Это открытие привело к мысли о возможности вырабатывать волокно, подобное хлопковому, но из более дешёвого целлюлозного сырья – из древесины. Попытки получения такого волокна увенчались успехом в 1892, когда Американцы Кросс, Бивен и Бидл запатентовали вискозный способ получения гидратцеллюлозных волокон, который впоследствии непрерывно совершенствовался и модернизировался. Процесс получения вискозного волокна состоит из следующих стадий:- (i) получение из целлюлозы прядильного раствора – вискозы (ксантогената целлюлозы); (ii) формование мокрым методом нити продавливанием вискозы через фильеры в кислотную ванну с регенерацией целлюлозы; и (iii) отделка и сушка. Важным отличием вискозного волокна от хлопкового является более рыхлая структура, связанная с меньшей упорядоченностью главных цепей (степень кристалличности = 0.5–0.38). Обычно достигаемое при формовании нитей расположение их оказывается не столь плотным, как у хлопкового или льняного волокна. Всё это приводит к значительным особенностям в свойствах вискозных волокон. Они более гигроскопичны, сильнее набухают в воде и вследствие этого в мокром состоянии значительно (на 50–60%) теряют прочность. Вискозные волокна ещё более нестойки (вследствие низких значений СП) к действию щёлочей. Разбавленные (до 1%) растворы гидроксида натрия вызывают резкое набухание и снижают прочность волокна. Концентрированные (более 3%) растворы приводят к разрушению волокна. При обработке жидким аммиаком увеличивается набухание волокна и наблюдается растворение низкомолекулярных фракций. Минеральных и органических кислот, а также к большинству органических растворителей. Гидратцеллюлозные волокна более устойчивы к воздействию повышенных температур, чем хлопок. При длительном нагревании в течение 100 ч при температуре 150 °С разрывная нагрузка обычного вискозного волокна снижается на 34.5%, вискозного высокомодульного – на 57.6%, а хлопкового волокна – на 63.5%. Различие в термической устойчивости тканей из хлопкового и вискозных волокон объясняется различиями в составе целлюлозы и особенностями их надмолекулярной и молекулярной организации. Вискозные волокна, состоящие из более чистой по химическому составу и однородной целлюлозы, характеризуются более высокой термической стабильностью. Гидратцеллюлозные волокна менее устойчивы к действию окислителей, чем хлопковое волокно. Скорость деструкции при воздействии на вискозное волокно таких окислителей, как NaClO, Cl_2, H_2O_2, определяется концентрацией их в растворе, pH и температурой. Для гидратцеллюлозных волокон наиболее опасны щелочные среды, поэтому при белении изделий из вискозных волокон рекомендуется использовать твёрдые перекисные соединения (монопероксигидрат мочевины, персинтам, персульфаты, а также соли хлоризоциануровой кислоты), которые обладают высокой белящей способностью в нейтральной и слабощелочных средах. К недостаткам вискозных волокон следует отнести потерю прочности в мокром состоянии (до 60%), сминаемость волокон и изделий из них, высокую теплопроводность. Для обычного вискозного волокна характерна структурная неоднородность, связанная с условиями формования, а именно наличие так называемой ориентационной оболочки вследствие большой плотности агрегатов макромолекул и более высокой степени ориентации на поверхности волокна. Вискозные высокомодульные волокна в отличие от обычных имеют высокую прочность и высокий начальный модуль упругости в мокром состоянии), модуль упругости характеризует упругие свойства волокна и его способность оказывать сопротивление растяжению, обеспечивающие меньшее набухание, усадку при мокрых обработках, потерю прочности в

мокром состоянии, а также большую устойчивость в щелочных растворах по сравнению с обычным вискозным волокном. Для получения высокомодульного вискозного волокна применяют высококачественную целлюлозу и несколько иную технологию, чем для обычного вискозного волокна. При этом большое внимание уделяется термофиксации волокна, которая проводится в режиме пластификационной вытяжки. Прочность сиблона в сухом состоянии 1.5 раза, а в мокром в 2 раза больше, чем прочность обычного вискозного волокна. Коэффициент полимеризации высокомодульного волокна 350–400. Полинозные волокна по показателям основных свойств, особенно прочности, стабильности размеров и стойкости к растворам щёлочей, приближаются к хлопку. Степень полимеризации составляет 450–500. По прочности в мокром состоянии полинозное волокно превосходит высокомодульное, однако существенно уступает хлопку. По формоустойчивости изделия из полинозных волокон превосходят изделия из высокомодульных волокон. Оно отличается более высокой степенью упорядочности макромолекул и однородностью структуры. Надмолекулярная структура полинозного волокна подобна хлопковому, поперечный срез более круглый и однородный. Это объясняется более высоким модулем упругости в мокром состоянии (200 сН/текс). Ткань из полинозного волокна имеет низкую усадку, равноценную усадке хлопчатобумажной ткани, и отличается повышенной несминаемостью. По внешнему виду это волокно напоминает мерсеризационный хлопок. В различных странах полинозные волокна производят под различными торговыми названиями:- Айрон, Зантрел, Койлон, ПЛ, Поликот. В России разработан процесс получения волокна полинозного типа Вислен (вискозный лен). Наметилась тенденция вытеснения обычных гидратцеллюлозных волокон новым поколением хлопкоподобных волокон типа Лиоцелл. Технологический процесс их получения экологически безопасен, а по своим свойствам волокна Лиоцелл выгодно отличаются от традиционных гидратцеллюлозных волокон:- имеют ярко выраженную фибриллярную структуру, высокую кристалличность и ориентацию, обладают повышенным влагопоглощением. Процесс получения вискозных штапельных волокон состоит из четырех основных технологических стадий:- получение и подготовка прядильного раствора вискозы; формование и ориентационная вытяжка волокна; отделка; сушка и упаковка. Технологический процесс получения вискозы состоит из нескольких операций:- (1) мерсеризация целлюлозы; (2) ксантогенирование щелочной целлюлозы; (3) растворение ксантогената; и (4) созревание вискозы. В качестве сырья для получения вискозного волокна используют преимущественно древесную целлюлозу, широко распространённую в природе. Она входит в состав одно- и многолетних растений. Целлюлозу, пригодную для производства вискозных волокон, так называемую ‘вискозную целлюлозу’, получают путём химической переработки древесины хвойных, а также лиственных деревьев – Бука, Берёзы, Осины. Целлюлозу можно также получать из камышей и соломы, однако такая целлюлоза характеризуется более низким качеством по сравнению с древесной. Древесную целлюлозу обрабатывают 18%-ным раствором едкого натра, измельчают и выдерживают в течение некоторого времени при определённой температуре с целью некоторого снижения СП целлюлозы за счёт окислительной деструкции. Затем щелочную целлюлозу обрабатывают сероуглеродом (ангидридом дитиоугольной кислоты) в герметически закрытых аппаратах. Полученный эфир ксантогената целлюлозы растворяют в 4–6%-ном растворе едкого натра и оставляют на некоторое время для созревания. При этом происходит постепенный гидролиз сложного эфира. После того как масса достаточно созрела и приобрела надлежащую вязкость, её фильтруют, освобождают от пузырьков воздуха и продавливают через фильеры, выходящие из отверстия фильер тонкие струйки превращаются в твёрдые нити в осадительной ванне, содержащей раствор серной кислоты и сульфатов натрия и цинка, где вискоза быстро коагулирует. В процессе формования нити подвергаются вытягиванию с целью создания в волокне определённой надмолекулярной структуры и сообщения волокну необходимых физико-механических свойств. Непосредственно после формования получаются волокна серого цвета, без блеска, жёсткие на ощупь. В последующих операциях отделки материал подвергается промывке и затем десульфированию – обработке раствором сернистого натрия или сульфита натрия для растворения серы, отложившейся на нитях. В результате этих обработок удаётся снизить содержание серы до 0.05–0.1%. Далее следует беление нитей, мыловка или замасливание для смягчения нити, улучшения условий её дальнейшей механической обработки и, наконец, высушивание. Вискоза, от позднелатинского слова Viscosus, означающее Вязкий, высоковязкий концентрированный раствор ксантогената целлюлозы в разбавленном растворе NaOH. При обработке кислотой вискозы ксантогенат целлюлозы разрушается с выделением исходной целлюлозы, выделяющейся из раствора. Вискоза применяется для производства искусственной кожи (кирза), вискозных неволокнистых изделий (целлюлозная плёнка, пластифицированная глицерином в целлофан) и для прядения вискозного волокна. Из волокон, полученных искусственным образом, скручивают нити, которые ложатся в основу этого приятного на ощупь материала. Блеск вискозы сопоставим с шёлковым, за что её называют ‘искусственным шёлком’. Искусственная шерсть из вискозы в 1930-х годах называлась ‘вистра’. Вискозу можно назвать самым натуральным искусственным волокном, потому что она представляет собой восстановленную целлюлозу, то есть состав вискозы очень близок к составу натуральных растительных волокон. Свойства чистой вискозы больше всего напоминают свойства хлопка. Ткань приятна на ощупь, гигроскопична и воздухопроницаема. Чистая вискоза полупрозрачная и блестящая и этим похожа на шёлк. Для избавления от блеска (если он нежелателен) вискозу обрабатывают дополнительно или вводят в раствор матирующие добавки. Вискоза не накапливает статического электричества. Вискозное волокно легче, чем хлопковое, окрасить в любые яркие цвета, ведь краситель можно ввести непосредственно в раствор, из которого будет восстановлена нить. Однако недостатки натуральной ткани не обошли стороной и вискозу:- она легко сминается и разрушается под воздействием атмосферных факторов в результате совместного действия воды, кислорода, оксидов воздуха и ультрафиолетового излучения. Подобным воздействиям подвергается и натуральный хлопок, однако в его составе кроме целлюлозы есть природные антиоксиданты и защита от солнечного света, поэтому хлопок устойчивее чистой вискозы к воздействиям внешней среды. Производители пряжи и тканей из вискозы учитывают эту особенность чистой вискозы и вводят в неё дополнительные компоненты:- химические антиоксиданты и фильтры ультрафиолетового излучения, что позволяет продлить срок жизни волокну и, соответственно, вещи, из него изготовленной. При добавлении в раствор вискозы сульфата меди и гидрооксида аммония получают медноаммиачное волокно. Ткань из вискозы на ощупь мягкая и приятная. Она образует красивые складки. Вискоза отличается ярким привлекательным ‘шёлковым’ блеском, если в ней не содержатся матирующие добавки. Вискозу также отличает крайне высокая гигроскопичность. Вискоза впитывает в два раза больше влаги, чем, например, хлопок. Ткань из вискозы очень легко окрашивается в самые яркие цвета. При увлажнении чистая вискоза становится менее прочной, однако, эта проблема полностью решается вплетением специальных укрепляющих волокон. Плотность нетканого полотна из вискозы может варьироваться от 1.53 г/см^3 до 4.5 г/см^3. Эластичность вискозы не превышает 2–3%. Вискозная нетканка не теряет своих свойств при нагревании вплоть до 150 °C. Вискозное волокно очень хорошо сочетается с другими волокнами, что позволяет улучшать различные свойства материи:- крепкость, мягкость, гигроскопичность. Вискоза не электризуется. Вискоза – концентрированный раствор натриевого ксантогената целлюлозы $C_6H_7O_2(OH)_2OC(S)Na$ в водном растворе NaOH. Вязкая оранжево-жёлтая жидкость; плотность 1 120 кг/м^3. Получают обработкой целлюлозы раствором NaOH (мерсеризация), окислительной деструкцией щелочной целлюлозы (созревание) и её взаимодействием с CS_2 (ксантогенирование). Применяется в производстве вискозных волокон, плёнки (целлофан), искусственной кожи (кирза). Под Вискозой, от позднелатинского слова Viscosus, означающее Вязкий или Клейкий, от Латинского слова Viscum, означающее Клей, понимается концентрированный раствор ксантогената целлюлозы в разбавленном растворе едкого натра. Вискозу применяют

для получения вискозных волокон и плёнок (целлофана), искусственной кожи (кирзы) и другого. Основное сырьё – древесная целлюлоза. Вначале целлюлозу обрабатывают водным раствором едкого натра (мерсеризация) до образования так называемой щелочной целлюлозы, которую затем измельчают (для увеличения реакционной способности) и подвергают в среде воздуха окислительной деструкции (с целью уменьшения её молекулярной массы). После этого целлюлозу обрабатывают сероуглеродом, в результате чего образуется её ксантогенат, который далее растворяют в водном растворе едкого натра (при t 10–12 °C). Все эти процессы проводят в одном или нескольких аппаратах непрерывного и периодического действия. В СССР разработан (конец 1940-х) и способ получения вискозы в одном аппарате (ВА-аппарат). Вискозу подвергают 2–3-кратной фильтрации для удаления загрязнений и тщательно освобождают от пузырьков воздуха (обычно под вакуумом), которые затрудняют её последующую переработку. Вискоза – высоковязкий раствор с плотностью 1.12 г/см^3, ярко-оранжевого, а при наличии примесей бурого или зеленоватого цвета. Обычно вискоза, применяемая для формования волокон и плёнок, содержит 6.5–9% целлюлозы (в виде её ксантогената), 6.5–7.5% едкого натра и около 2–2.5% связанной серы; остальное приходится на долю воды и небольшого количества примесей (сернистые соединения натрия, карбонаты, соли кальция, сернистое железо, растворённая гемицеллюлоза). Вязкость растворов вискозы колеблется в пределах 3–10 н·сек/м^2 (30–100 пз) и резко возрастает с увеличением содержания целлюлозы; кроме того, значение вязкости находится в прямой зависимости от степени полимеризации (молекулярной массы целлюлозы) и количества едкого натра в вискозе. Свободный сероуглерод в вискозе постепенно связывается с едким натром и превращается в тритиокарбонат и другие сернистые примеси. Благодаря этому происходит так называемое созревание вискозы, то есть частичный гидролиз ксантогената целлюлозы. В результате гидролиза понижается степень этерификации ксантогената целлюлозы, соответственно уменьшается содержание в нём серы и натрия. Зрелость вискозы непрерывно повышается с увеличением времени созревания. Существенное влияние на скорость созревания оказывает температура. Для получения вискозных волокон и плёнок (целлофана) время созревания вискозы должно быть соответственно в пределах 35–45 часов и 80–90 часов. В некоторых случаях в вискозу добавляют различные вещества, например, матирующие агенты (для устранения стеклянного блеска в готовом волокне), красители (для равномерной и устойчивой окраски готовых изделий), модификаторы и поверхностно-активные вещества (при производстве высокопрочных и структурно однородных волокон). Вискозные Волокна – искусственные волокна, получаемые формованием вискозы. Устойчивы к действию большинства органических растворителей, слабо подвержены действию моли, разрушаются в концентрированных неорганических кислотах. В мокром состоянии теряют до 50% исходной прочности. Вискозное волокно выпускается в виде штапельного волокна обычного, высокопрочного и высокомодульного, и текстильной нити обычной и высокопрочной. Ткани из вискозного волокна легко окрашиваются и благодаря гигроскопичности превосходят ткани из синтетических волокон по гигиеническим свойствам. Применяются (часто в смеси с природным или синтетическими волокнами) для выработки корда, одёжных, подкладочных, корсетных тканей, бельевого трикотажа и так далее. Хлопкоподобные виды вискозного волокна (так называемое полинозное волокно и высокомодульное, или ВВМ-волокно) используют в смеси с хлопком или полиэфирными волокнами для изготовления трикотажа, бельевых и сорочечных тканей. Вискозные Волокна – волокна, получаемые химической переработкой природной целлюлозы. В зависимости от назначения вискозные волокна производят в виде текстильных и кордных нитей, а также штапельного волокна. Производство вискозных волокон складывается из следующих основных технологических операций:- получения прядильного раствора (вискоза), формования нитей по мокрому методу, отделки и сушки. Ткани из вискозных волокон легко окрашиваются в различные цвета, отличаются высокими гигиеническими свойствами (гигроскопичностью), что особенно важно для изделий народного потребления. Доступность исходного сырья и низкая стоимость химических реагентов, а также удовлетворительные текстильные свойства и широкие возможности модификации обеспечивают высокую экономичность производства вискозных волокон и их широкое распространение. Недостатки Вискозных Волокон:- большая потеря прочности в мокром состоянии, лёгкая сминаемость, недостаточная устойчивость к трению и низкий модуль упругости, особенно в мокром состоянии. Эти недостатки могут быть устранены модификацией вискозных волокон. Модифицированным вискозным волокнам (например, полинозным волокнам) свойственны значительно более высокая прочность в сухом и мокром состоянии (потеря прочности в мокром состоянии составляет 20–25% против 40–50% у обычного вискозного волокна), большая износоустойчивость и повышенный модуль упругости. У извитых штапельных вискозных волокон устойчивее извитость, что упрощает производство из них пряжи в смеси с натуральными волокнами. Сминаемость вискозных волокон может быть уменьшена их последующей обработкой различными составами. В производстве товаров народного потребления вискозное волокно широко используют для выработки шёлковых и штапельных тканей, трикотажных изделий, тканей различного назначения из смесей вискозного волокна с хлопком или шерстью, а также с другими химическими волокнами. Высокопрочное кордное вискозное волокно используют для получения широкого ассортимента технических изделий. Например, при замене хлопчатобумажного корда, выполняющего роль силового каркаса в шинах, высокопрочным вискозным кордом повышается срок службы шин и уменьшается расход каучука для их изготовления. В 1968 мировое производство вискозного волокна составило 3 103 400 тонн (42.6% от общего выпуска химических волокон). Промышленное производство вискозного волокна началось в 1905 году в Англии.

(2) A coagulating bath used in the viscose method of making rayon; sometimes the coagulating bath used in any of the three methods of making rayon.

VISCOSE PROCESS = ВИСКОЗНЫЙ ПРОЦЕСС (или ВЫРАБОТКА ВИСКОЗЫ) – Viscose Process is:- (1) one of the methods of producing rayon. See also Rayon Fiber. (2) The chemical process used in the manufacture of cellophane. See also Viscose Solution. Viscose Process describes the production of rayon fibers from purified cellulose. / Современный Вискозный Процесс является самым вредным в промышленности химических волокон. В качестве одного из альтернативных вариантов вискозному процессу предложено использовать для растворения целлюлозы ортофосфорную кислоту, на базе которой получены концентрированные 5–8 масс.% растворы целлюлозы. Новый бессероуглеродный процесс производства гидратцеллюлозных и структурно-смешанных волокон основан на использовании ортофосфорной кислоты в качестве растворителя целлюлозы. Новый процесс в отличие от существующих производств гидратцеллюлозных волокон является экологически безопасным и замкнутым. Позволяет сократить объёмы водопотребления более чем в 100 раз и полностью ликвидировать газообразные выбросы в атмосферу.

VISCOSE RAYON = ВИСКОЗНЫЙ РЭЙОН (или ВИСКОЗНАЯ ГИДРАТЦЕЛЛЮЛОЗА) – Viscose Rayon:- filaments of regenerated cellulose coagulated from a solution of cellulose xanthate. The raw material can be cotton linters, or chips of spruce, pine, or hemlock. More than 98 per cent of regenerated rayon is made on the viscose method; the remainder is cuprammonium rayon made on the Stretch System. Viscose Rayon is one type of rayon. It is produced in far greater quantity than cuprammonium rayon, the other commercial type. See also Rayon Fiber. Viscose Rayon is a Rayon fabric. While processing the viscose process is used. Most of today's rayons are viscose rayons.

VISCOSE SOLUTION = РАСТВОР ВИСКОЗЫ – Viscose Solution is the solution obtained by dissolving cellulose xanthate in caustic soda, from which viscose filaments and cellophane are produced. / каустическая сода или едкий натр (caustic soda). Вискоза – высоковязкий раствор ярко-оранжевого, а при наличии примесей бурого или зеленоватого цвета.

VISCOSE STAPLE FIBER = ВИСКОЗНОЕ ШТАПЕЛЬНОЕ ВОЛОКНО – Viscose Staple Fibers (VSF) are a product that shows very specific characteristics, distinguishing it from any other fiber. In the context of the market investigation carried out by the EU Commission, a high number of customers pointed to these characteristics. The prime feature of VSF is its high moisture absorbency combined with its high liquid retention capacity, which goes beyond the absorption capacities of all other fibers regarded as close substitutes by the notifying party, namely cotton, polyester and polypropylene. This feature makes VSF eligible for a wide variety of applications both in the textile area (due to the resulting wearing comfort) and in the non-woven area (household applications, medical and hygienic applications, personal care products, and industrial applications such as filters or inside support material for artificial leather). A feature distinguishing VSF from polyester and polypropylene is its biodegradability which is a relevant factor particularly in the area of disposable nonwoven applications. As compared with cotton, it is VSF's softness and drape which is of particular relevance in the textile area. Furthermore, VSF has particular dyeing characteristics distinguishing it, both in the area of textile and non-woven applications, from cotton and polyester. On the other hand, VSF also has distinctive product characteristics which limit its use in certain areas of application. For instance, VSF's high wet elongation and low wet tenacity render it unsuitable for machine washing in its pure state. Facilitated by its good processability, VSF is a popular material for blending, both with cotton and with polyester, thus making use of the respective advantages and minimising the disadvantages of each individual fiber. This in itself can be seen as an indication of VSF's distinctiveness, especially when taking into account that VSF is more expensive than other fibers:- if the use of VSF did not provide an added value to products, it would not be chosen, given its higher price. Commodity viscose staple fibers (Commodity VSF) are used for both textile applications (spinning) and non-woven applications. Fibers for textile applications are purchased by spinners, whereas fibers for non-woven applications are in general sold to roll goods manufacturers. Note that cotton-type spinners need short staple lengths, whereas woollen-type spinners use longer fibers.

VISCOSITY = ВЯЗКОСТЬ (или ВНУТРЕННЕЕ ТРЕНИЕ) – Viscosity is a measurement of a fluid's resistance to flow. The common metric unit of absolute viscosity is the Poise, which is defined as the force in dynes required to move a surface one square centimeter in area past a parallel surface at a speed of one centimeter per second, with the surfaces separated by a fluid film one centimeter thick. In addition to kinematic viscosity, there are other methods for determining viscosity, including Saybolt Universal Viscosity (SUV), Saybolt Furol Viscosity, Engier Viscosity, and Redwood Viscosity. Since viscosity varies in inversely with temperature, its value is meaningless until the temperature at which it is determined is reported. See also Absolute Viscosity; Apparent Viscosity; Brookfield Viscosity; Dynamic Viscosity; High Temperature High Shear Viscosity; Kinematic Viscosity; SAE Viscosity; and Saybolt Universal Viscosity or Saybolt Universal Seconds. Viscosity is a measure of the internal friction of a fluid or its resistance to flow. Viscosity:- resistance of a fluid (liquid or gas) to a change in shape, or movement of neighbouring portions relative to one another. Viscosity denotes opposition to flow. The reciprocal of the viscosity is called the Fluidity, a measure of the ease of flow. Molasses, for example, has a greater viscosity than water. Because part of a fluid that is forced to move carries along to some extent adjacent parts, viscosity may be thought of as internal friction between the molecules; such friction opposes the development of velocity differences within a fluid. Viscosity is a major factor in determining the forces that must be overcome when fluids are used in lubrication and transported in pipelines. It controls the liquid flow in such processes as spraying, injection molding, and surface coating. For many fluids the tangential, or shearing, stress that causes flow is directly proportional to the rate of shear strain, or rate of deformation, that results. In other words, the shear stress divided by the rate of shear strain is constant for a given fluid at a fixed temperature. This constant is called the Dynamic, or Absolute, Viscosity and often simply the Viscosity. Fluids that behave in this way are called Newtonian Fluids in honour of Sir Isaac Newton, who first formulated this mathematical description of viscosity. The viscosity of liquids decreases rapidly with an increase in temperature; the viscosity of gases increases with an increase in temperature. Thus, upon heating, liquids flow more easily, whereas gases flow more sluggishly. The dimensions of dynamic viscosity are force times time divided by area. The unit of viscosity, accordingly, is Newton-second per square meter. For some applications the kinematic viscosity is more useful than the absolute, or dynamic, viscosity. Kinematic viscosity is the absolute viscosity of a fluid divided by its mass density. (Mass density is the mass of a substance divided by its volume.) The dimensions of kinematic viscosity are area divided by time; the appropriate units are meter squared per second. The unit of kinematic viscosity in the centimetre-gram-second (CGS) system, called the Stokes in Britain and the Stoke in the United States, is named for the British physicist Sir George Gabriel Stokes. The Stoke is defined as 1 cm squared per second. Viscosity is a property of liquids that indicates their resistance to flow. Viscosity is the property of a fluid that resists the force tending to cause the fluid to flow, or the measure of the extent to which a fluid possesses this property. Viscosity is a measure of a liquid's resistance to flow. There are a number of viscosity scales in current use. / Вязкость:- мера сопротивления жидкости течению. В настоящее время применяются несколько шкал определения вязкости. Смотрите также Абсолютная Вязкость (Absolute Viscosity); Кажущаяся Вязкость или Структурная Вязкость или Псевдопластичность (Apparent Viscosity); Вязкость По Брукфилду (Brookfield Viscosity); Динамическая Вязкость (Dynamic Viscosity); Высокая Температура Высокий Сдвиг (или Скалывание, или Срез) Вязкость (High Temperature High Shear Viscosity); Кинематическая Вязкость (Kinematic Viscosity); Вязкость По САИ (SAE Viscosity); и Вязкость По Сэйболту Универсалу или Секунд По Сэйболту Универсалу (Saybolt Universal Viscosity or Saybolt Universal Seconds). (1) Вязкость:- (1) свойство жидкостей и газов оказывать сопротивление перемещению одной их части относительно другой. При ламинарном течении вязкой жидкости в трубе скорость движения жидкости возрастает от нулевого значения у стенки трубы до максимального значения на оси. Между слоями, движущимися с разными скоростями, действуют касательные силы внутреннего трения:- слой, движущийся быстрее, увлекает за собой слой, движущийся медленнее, а тот в свою очередь тормозит первый. Напряжение трения (сила трения, отнесённая к единице площади поверхности слоя) согласно Закону Ньютчэна (или Закону Ньютона) пропорционально модулю градиента скорости в направлении, перпендикулярном рассматриваемому слою. Вязкость жидкостей в основном определяется силами молекулярного взаимодействия и увеличивается с понижением температуры. Вязкость газов в основном определяется тепловым движением молекул и увеличивается с ростом температуры. Другое название вязкости жидкостей и газов – Внутреннее Трение. Под Вязкостью или Внутренним Трением понимается свойство текучих тел (жидкостей и газов) оказывать сопротивление перемещению одной их части относительно другой. Вязкость твёрдых тел обладает рядом специфических особенностей и рассматривается обычно отдельно (смотрите Внутреннее Трение в твёрдых телах). Основной закон вязкого течения был установлен Айзэком Ньютчэном (или Исааком Ньютоном; Isaac Newton) (1687):- формула 1:- $F = \eta \times ((v_2 - v_1) / (z_2 - z_1)) \times S$, где F – тангенциальная (касательная) сила, вызывающая сдвиг слоёв жидкости (газа) относительно друг друга; S – площадь слоя, по которому происходит сдвиг; $(v_2 - v_1)/(z_2 - z_1)$ – градиент скорости течения (быстрота изменения её от слоя к слою), иначе – скорость сдвига. Коэффициент пропорциональности η называется Коэффициентом Динамической Вязкости или просто Вязкостью. Он количественно характеризует сопротивление жидкости (газа) смещению её слоёв. Величина, обратная вязкости, j = 1 / h, называется Текучестью. Согласно формуле (1), вязкость численно равна тангенциальной силе PS = F / S (на единицу площади), необходимой для поддержания разности скоростей, равной единице, между двумя

параллельными слоями жидкости (газа), расстояние между которыми равно единице. Из этого определения следует, что в Международной Системе Единиц единица вязкости имеет размер Ньютон·секунда на квадратный метр (Н·сек/м^2), а в СГС Системе Единиц – граммов на квадратный метр·секунда (г/(см^2·сек)) (Пуаз (Пз)). 1 пз = 0.1 Н·сек/м^2. Наряду с Динамической Вязкостью η часто рассматривают так называемую Кинематическую Вязкость n = h / r, где r – плотность жидкости или газа. Единицами Кинематической Вязкости служат, соответственно, квадратный метр в секунду (м^2/сек) и квадратный сантиметр в секунду (см^2/сек) (Стокс). Вязкость жидкостей и газов определяют Вискозиметрами. В условиях установившегося слоистого течения (смотрите Ламинарное Течение) при постоянной температуре вязкости газов и нормальных жидкостей (так называемых Ньютоновских Жидкостей) – постоянная величина, не зависящая от градиента скорости. В таблице приведены значения вязкости некоторых жидкостей и газов (Вещество – h при 20 °C, 10^{-3} Н·сек/м^2 или сПз):- Азот – 0.017 5, Водород – 0.008 8, Кислород – 0.020 2, Вода – 1.002, Глицерин ~1 500, Ртуть – 1.554, Этиловый Спирт – 1.200. Расплавленные металлы имеют вязкость того же порядка, что и обычные жидкости. Особыми вязкостными свойствами обладает жидкий гелий. При температуре 2.172 К он переходит в сверхтекучее состояние, в котором вязкость равна нулю (смотрите Гелий, Сверхтекучесть). Вязкость – важная физико-химическая характеристика веществ. Значение вязкости приходится учитывать при перекачивании жидкостей и газов по трубам (нефтепроводы, газопроводы). Вязкость расплавленных шлаков весьма существенна в доменном и мартеновском процессах. Вязкость расплавленного стекла определяет процесс его выработки. По вязкости во многих случаях судят о готовности или качестве продуктов или полупродуктов производства, поскольку вязкость тесно связана со структурой вещества и отражает те физико-химические изменения материала, которые происходят во время технологических процессов. Вязкость масел имеет большое значение для расчёта смазки машин и механизмов и так далее. Молекулярно-Кинетическая Теория объясняет вязкость движением и взаимодействием молекул. В газах расстояния между молекулами существенно больше радиуса действия молекулярных сил, поэтому вязкость газов определяется главным образом молекулярным движением. Между движущимися относительно друг друга слоями газа происходит постоянный обмен молекулами, обусловленный их непрерывным хаотическим (тепловым) движением. Переход молекул из одного слоя в соседний, движущийся с иной скоростью, приводит к переносу от слоя к слою определённого количества движения. В результате медленные слои ускоряются, а более быстрые замедляются. Работа внешней силы F, уравновешивающей вязкое сопротивление и поддерживающей установившееся течение, полностью переходит в теплоту. Вязкость газа не зависит от его плотности (давления), так как при сжатии газа общее количество молекул, переходящих из слоя в слой, увеличивается, но зато каждая молекула менее глубоко проникает в соседний слой и переносит меньшее количество движения (Закон Максвелла). Для вязкости идеальных газов в молекулярно-кинетической теории даётся следующее соотношение (формула 2):- η = (1 / 3)·m·n·ū·λ, где m – масса молекулы, n – число молекул в единице объёма, ū – средняя скорость молекул и λ – длина свободного пробега молекулы между двумя соударениями её с другими молекулами. Так как ū возрастает с повышением температуры T (несколько возрастает также и λ), то вязкость газов увеличивается при нагревании (пропорционально √T). Для очень разреженных газов понятие Вязкость теряет смысл. В жидкостях, где расстояния между молекулами много меньше, чем в газах, вязкость обусловлена в первую очередь межмолекулярным взаимодействием, ограничивающим подвижность молекул. В жидкости молекула может проникнуть в соседний слой лишь при образовании в нём полости, достаточной для перескакивания туда молекулы. На образование полости (на ‘рыхление’ жидкости) расходуется так называемая Энергия Активации Вязкого Течения. Энергия активации уменьшается с ростом температуры и понижением давления. В этом состоит одна из причин резкого снижения вязкости жидкостей с повышением температуры и роста её при высоких давлениях. При повышении давления до нескольких тысяч атмосфер η увеличивается в десятки и сотни раз. Строгая теория вязкости жидкостей, в связи с недостаточной разработанностью теории жидкого состояния, ещё не создана. На практике широко применяют ряд эмпирических и полуэмпирических формул вязкости, достаточно хорошо отражающих зависимость вязкости отдельных классов жидкостей и растворов от температуры, давления и химического состава. Вязкость жидкостей зависит от химической структуры их молекул. В рядах сходных химических соединений (насыщенные углеводороды, спирты, органические кислоты и так далее) вязкость изменяется закономерно – возрастает с возрастанием молекулярной массы. Высокая вязкость смазочных масел объясняется наличием в их молекулах циклов (смотрите Циклические Соединения, и Нафтены). Две жидкости различной вязкости, которые не реагируют друг с другом при смешивании, обладают в смеси средним значением вязкости. Если же при смешивании образуется химическое соединение, то вязкость смеси может быть в десятки раз больше, чем вязкость исходных жидкостей. На этом основано применение измерений вязкости в качестве метода физико-химического анализа. Возникновение в жидкостях (дисперсных системах или растворах полимеров) пространственных структур, образуемых сцеплением частиц или макромолекул, вызывает резкое повышение вязкости. При течении ‘структурированной’ жидкости работа внешней силы затрачивается не только на преодоление истинной (Ньютоновской) вязкости, но и на разрушение структуры (смотрите Реология). Для нормальных вязких жидкостей между количеством жидкости Q, протекающей в единицу времени через капилляр, и давлением p существует прямая пропорциональность (смотрите Закон Пуазёйля). Течение структурированных жидкостей не подчиняется этому закону, для них кривые зависимости Q от p выпуклы к оси давления, что объясняется непостоянством η. Аномальной вязкостью, характерной для структурированных жидких систем, обладают важнейшие биологические среды – цитоплазма и кровь. Вязкость биологических сред определяется в большинстве случаев структурной вязкостью. Вязкость жидкого содержимого клетки-цитоплазмы связана со структурой составляющих её биополимеров и субклеточных образований, что вызывает отклонения (характера Тиксотропии) вязкого течения от Ньютоновского Закона нормальных жидкостей. Методы измерения вязкости биологических сред – наблюдение скорости перемещения гранул при центрифугировании или железных опилок в магнитном поле, измерение среднего смещения Броуновских частиц (смотрите Броуновское Движение). Абсолютная вязкость цитоплазмы колеблется от 2 до 50 сПз (1 сПз = 10^{-3} Н·сек/м^2), она меняется в различных частях клетки и в разные периоды клеточного цикла. С понижением температуры ниже 12–15 °C и при повышении её свыше 40–50 °C вязкость цитоплазмы увеличивается. При воздействии облучения наблюдается сначала уменьшение вязкости, а затем, при увеличении дозы, – её возрастание. Вязкость ликвора, лимфы и плазмы крови достаточно точно описывается Ньютоновским Законом вязкого течения, она исследуется в капиллярных или цилиндрических вискозиметрах. Кровь – Неньютоновская Жидкость, так как содержит структурированные компоненты – белки и клетки крови, её вязкость у человека в норме 4–5 сПз, при патологии колеблется от 1.7 до 22.9 сПз, что отражается в реакции оседания эритроцитов (РОЭ).

(2) Viscosity is a measurement of a liquid’s resistance to flow. As temperature increases, viscosity decreases. Viscosity is the internal flow resistance of a fluid. See also Intrinsic Viscosity, and Relative Viscosity. What Is The Best Motor Oil Viscosity? There is no single best motor oil viscosity. As a rule of thumb always follow the car manufacturer’s recommendations. Older cars are usually ok with a 10W-30 oil, while newer cars usually like a lower viscosity oil, like 5W-30, 0W-30 or sometimes even 0W-20. It’s important to keep in mind that viscosity is not the only important property of the oil:- if there are some further specifications (e.g., API SN or GM Dexos 2) required by the car manufacturer then the oil should meet those specifications and should also have the correct viscosity in order to be used for that particular vehicle. American Petroleum Institute (API). Viscosity of oil is defined as the ability of the oil to flow. It is the property of the liquid which tends to prevent relative movement between adjacent parts within itself. Generally, thicker the fluid, higher

is its viscosity; whereas thinner liquids have lower viscosity. Viscosity is a method of measuring a given liquid's resistance to flow, usually decreasing with increasing temperatures. Material with higher viscosity is more resistant to flow. There are a number of viscosity scales in current use. Viscosity:- (Latin:- Viscum – Tenacity) Degree of resistance to flow in a fluid or semifluid for gas, caused by internal friction. Viscosity is the internal resistance of a liquid substance to flow. What is Oil Viscosity also known as (a.k.a.) Oil Weight? Viscosity is a fluid's resistance to flow. In case of lubricants the viscosity is very important because it affects the oil's ability to reduce friction and transfer heat. The viscosity is measured in mPa·s (milliPascal-seconds) or its equivalent cP (centiPoise) but in everyday life we don't use the actual measured viscosity, we use viscosity grades instead. In case of engine oils, these grades, also known as 'Weights' were set by the SAE (Society of Automotive Engineers) and in order for a fluid to fall in a given category it has to meet certain limits. These limits are listed in the following SAE J 300 table (Table of Engine Oil Viscosity Grades):-.

The numbers that have a W after them are the so-called Winter Viscosity Grades while the numbers that don't have a W are the so-called summer- or operating temperature viscosity grades. Several decades ago motor oils either fell in one of the winter viscosity grades or in one of the summer viscosity grades. These products were monograde oils and car owners had to change oil at least twice a year:- once for the winter and once for the summer. Thanks to the synthetic base oils and the viscosity modifier additives, nowadays most motor oils are so-called Multigrade Oils that don't change their viscosity with temperature that much, so they meet the limits of a winter and that of a summer viscosity grade at the same time. These oils can be used regardless of season. Monograde oils are still used for special purposes but usually not as engine lubricants. / Вязкость:- (2) величина, характеризующая вязкостные свойства жидкостей и газов, в том числе и смазочных масел. Различают:- (i) Динамическую Вязкость (Dynamic Viscosity) η (входит в виде коэффициента пропорциональности в формулу Закона Ньютона), единицей которой в Международной Системе Единиц, так называемой системе СИ (или SI по первым буквам первых двух слов полного Франкоязычного наименования Système International d'Unités; введена в действие в бывшем Союзе Советских Социалистических Республик (СССР) с 01 Января 1963 для предпочтительного применения) является Паскаль-секунда (Па·с), в Англоязычных странах для обозначения динамической вязкости и в Системах Единиц СГС (системы единиц физических величин lmt (где l – длина, m – масса, t – время), в которых приняты три основные единицы:- сантиметр (см) – единица длины, грамм (г) – единица массы и секунда (с) – единица времени; отсюда и название системы по первым буквам названий этих трёх единиц) использовалась устаревшая и более не подлежащая применению единица измерения Пуаз (П (P); на Французском Poise, от имени Французского физика и физиолога Жона Луи Мари Пуазёйя (или Пуазёйля; Jean Louis Marie Poiseuille; 1799–1869)). 1 П = 0.1 Па·с. Чаще использовалась дольная единица – сантиПуаз (сП); 1 сП = 1 мПа·с; и (ii) Кинематическую Вязкость (Kinematic Viscosity) ν (ν = η/ρ, где ρ – плотность жидкости или газа), единицей которой в системе СИ является квадратный метр на секунду ($м^2/с$), в Англоязычных странах до сих пор используется единица измерения Стокс (Ст (St или S); по имени Английского математика и физика Сэра Дьжёдьжа Гейбриэла Стокса (Sir George Gabriel Stokes; 1819–1903)), устаревшая и более не подлежащая применению в так называемых Системах Единиц СГС. 1 Ст = 10^{-4} $м^2/с$. Чаще использовалась дольная единица – сантиСтокс (сСт); 1 сСт = 1 $мм^2/с$. Чем гуще жидкость, тем выше её вязкость. Международные производители смазочных масел до сих пор используют в основном единицы измерений Пауз (П) и Стокс (Ст), несмотря на то, что в настоящее время все страны мира официально перешли на использование единиц измерений системы СИ. Под Вязкостью или Внутренним Трением понимается свойство газов или жидкостей, характеризующее сопротивление действию внешних сил, вызывающих их течение. Вязкость Масла:- свойство жидкости или газа оказывать сопротивление перемещению одной их части относительно другой. Чем выше вязкость, тем толще масляная плёнка и надёжнее смазывание; и тем больше потери мощности на преодоление трения внутри жидкости. Вязкость масла зависит от температуры. Степень зависимости вязкости масла от температуры характеризуется Индексом Вязкости (ИВ; Viscosity Index (VI)), который зависит от свойств базового масла и присадок к нему. Чем выше ИВ, тем меньше меняется вязкость при изменении температуры; надёжное смазывание легче обеспечить при высоких температурах, а хорошие пусковые качества – при низких. В настоящее время применяются несколько шкал вязкости. Вместе с любой единицей вязкости всегда указывается температура. Вязкость смазочных масел при повышении температуры существенно снижается, например, динамическая вязкость моторного масла, маркированного SAE 10W, при температуре –20 °C может составлять 2 000 сП (cP), но при нагреве до +100 °C кинематическая вязкость снижается до уровня приблизительно 5.2 сСт (cSt).

VISCOSITY GRADE = СОРТ ПО ВЯЗКОСТИ – Viscosity Grade:- any of a number of systems which characterize lubricants according to viscosity for particular applications, such as industrial oils, gear oils, automotive engine oils, automotive gear oils, and aircraft piston engine oils. See also ISO Viscosity Grade; and Viscosity. Viscosity Grade (VG) is a commercial rating of industrial lubricants. The grade numbers are approximately equal to the kinematic viscosity of the lubricant in centiStokes. The Cannon Instrument Company®

VISCOSITY INDEX = ИНДЕКС ПО ВЯЗКОСТИ (или ИНДЕКС ВЯЗКОСТИ) – Viscosity Index (VI) is a commonly used measure of a fluid's change of viscosity with temperature. The higher the viscosity index, the smaller the relative change in viscosity with temperature. Viscosity Index is a term which is mainly related to marine lubricating oils. It can be defined as the change in viscosity of the oil which takes place as a result of change of temperature. Higher the viscosity index of the lubricating oil better is the quality. This means that lubricating oil with higher viscosity index has only a small change as a result of large temperature difference. As a general practice, various additives are added in the oil to improve the viscosity index of the lubricating oil. Viscosity index is a dimensionless number. See also High Viscosity Index; Low Viscosity Index; and Viscosity. Viscosity Index:- the relationship between a fluid's viscosity and temperature. Fluids with a higher viscosity index change their viscosity to a lesser degree due to the change of temperature. What is the Viscosity Index (VI)? Viscosity (actual viscosity, not the viscosity grade) changes with temperature. The hotter the temperature gets the lower is the viscosity, the colder it gets the higher the viscosity. However, the degree of this temperature related change of viscosity is not the same in case of every oil. Some oils change their viscosity more when temperature changes some change less. Those that change less have a higher viscosity index, those that change more have a lower one. (Remember the discussion about the monograde and multigrade oils before? Monograde oils' viscosities change more as temperature changes multigrade oils' change less so multigrade oils have higher viscosity indices.) We like oils with higher viscosity indices more because it means that the oil is more stable viscosity-wise. For lubrication purposes there is an optimal viscosity for every engine and the less the oil deviates from this optimum, the better. Synthetic oils have higher viscosity indices making them superior to the mineral oils in this regard as well. / Степень зависимости вязкости масла от температуры характеризуется Индексом Вязкости (ИВ; Viscosity Index (VI)), который зависит от свойств базового масла и присадок к нему. Чем выше ИВ, тем меньше меняется вязкость при изменении температуры; надёжное смазывание легче обеспечить при высоких температурах, а хорошие пусковые качества – при низких. Индекс Вязкости (ИВ; Viscosity Index (VI)) безразмерный показатель, он характеризует зависимость вязкости масла от изменения температуры. Чем выше значение VI, тем меньше зависимость вязкости масла от изменения температуры. Индекс Вязкости (ИВ) характеризует свойства жидкости разжижаться при повышении температуры. Чем ниже значение ИВ, тем жидкость более подвижная. ИВ сезонных моторных масел находится в диапазоне 95 – 110, а ИВ всесезонных – даже более 200.

VISCOSITY INDEX IMPROVERS = УЛУЧШИТЕЛИ ИНДЕКСА ПО ВЯЗКОСТИ (или УЛУЧШИТЕЛИ ИНДЕКСА ВЯЗКОСТИ) – Viscosity Index Improvers are the additives that increase the viscosity of the fluid throughout its useful temperature range. Such additives are polymers that possess thickening power as a result of their high molecular weight and are necessary for formulation of multi-grade engine oils. See also Viscosity Index. / Присадки, понижающие температурную зависимость вязкости.

VISCOSITY MODIFIER = МОДИФИКАТОР ВЯЗКОСТИ – Viscosity Modifier is a lubricant additive, usually a high molecular weight polymer, that reduces the tendency of an oil's viscosity to change with temperature. See also Viscosity. Viscosity Modifier is a lubricant additive, usually a polymer that provides beneficial rheological properties to lubricating oils, such as reducing the tendency of an oil's viscosity to change with temperature. / Под Модификатором, от позднелатинского слова Modifico, означающее Видоизменяю или Меняю Форму, понимается вещество, малые дозы которого существенно изменяют структуру и свойства обработанного им материала.

VISCOSITY–TEMPERATURE RELATIONSHIP = ЗАВИСИМОСТЬ ВЯЗКОСТЬ–ТЕМПЕРАТУРА – Viscosity-Temperature Relationship:- the manner in which the viscosity of a given fluid varies inversely with temperature. Because of the mathematical relationship that exists between these two variables, it is possible to predict graphically the viscosity of a petroleum fluid at any temperature within a limited range if the viscosities at two other temperatures are known. The charts used for this purpose are the ASTM Standard Viscosity-Temperature Charts for liquid Petroleum Products, available in 6 ranges. If two know viscosity-temperature points of a fluid are located on the chart and a straight line drawn through them, other viscosity-temperature values of the fluid will fall on this line; however, values near or below the cloud point of the oil may deviate from the straight-line relationship. VISCOUS = ВЯЗКОВАТОЕ (или ВЯЗКОЕ, или ВЯЗКОСТНОЕ, или ТЯГУЧЕЕ) – Viscous:- possessing viscosity. Frequently used to imply high viscosity.

VISE = КЛЕЩИ (или ТИСКИ, или ВИЗА) – Vise:- also spelled Vice, device consisting of two parallel jaws for holding a workpiece; one of the jaws is fixed and the other movable by a screw, a lever, or a cam. When used for holding a workpiece during hand operations, such as filing, hammering, or sawing, the vise may be permanently bolted to a bench. In vises designed to hold metallic workpieces, the active faces of the jaws are hardened steel plates, often removable, with serrations that grip the workpiece; to prevent damage to soft parts, the permanent jaws can be covered with temporary jaws made from sheet copper or leather. Pipe vises have double V-shaped jaws that grip in four places instead of only two. Woodworking vises have smooth jaws, often of wood, and rely on friction alone rather than on serrations. For holding workpieces on the tables of machine tools, vises with smooth hardened-steel jaws and flat bases are used. These machine vises are portable but may be clamped to the machine table when in use; means may also be provided for swivelling the active part of the vise so that the workpiece can be held in a variety of positions relative to the base. For holding parts that cannot be clamped with flat jaws, special jaws can be provided. / Клещи, инструмент в виде рычажных щипцов для зажима, захвата материала или изделий при их обработке. В зависимости от назначения различают клещи для столярных, кузнечных, электромонтажных и других работ. Кузнечные клещи рычажного типа появились в начале железного века. Им предшествовали, вероятно, пинцетообразные клещи, применявшиеся металлургами в бронзовом веке (например, в Египте). Дифференциация кузнечного ремесла способствовала появлению клещей специального назначения, с фигурными губками и другим. Тиски, приспособление для установки и закрепления изделий в удобном для обработки положении, состоящее из корпуса и двух зажимных губок. Различают станочные тиски и слесарные тиски. Станочные Тиски, устанавливаемые на металлорежущих станках, используют при фрезеровании, сверлении, строгании и других операциях механической обработки. Слесарные Тиски устанавливают на верстаках и используют при различных слесарных работах:- стуловые – при рубке, правке и других видах обработки с ударными нагрузками; параллельные, неповоротные и поворотные, – при выполнении более сложных и тонких операций, не связанных с ударами по изделию (прочность губок невысока); ручные – для закрепления небольших изделий при сверлении, опиливании и тому подобному, если их неудобно или опасно держать руками; специальные – для определённых видов обработки, например, тиски с отогнутыми губками для снятия фасок. Сближение губок и зажим изделий в тисках обычно осуществляют вращением рукоятки винта. Наряду с этим применяют

клиновые, диафрагменные, эксцентриковые и другие механизмы; в некоторых конструкциях для перемещения и прижатия подвижной губки используют сжатый воздух (пневматические параллельные тиски). Размер тисков определяется шириной губок и их расхождением. У стуловых тисков эти размеры соответственно до 180 и 200 миллиметров (мм), у параллельных до 140 и 180 мм, у ручных 15–45 и 15–40 мм.

VISFATIN = ВИСФАТИН – Visfatin is a newly discovered adipocyte hormone with a direct relationship between plasma visfatin level and type 2 diabetes mellitus. Visfatin binds to the insulin receptor at a site distinct from that of insulin and causes hypoglycaemia by reducing glucose release from liver cells and stimulating glucose utilization in adipocytes and myocytes. Visfatin is upregulated by hypoxia, inflammation and hyperglycaemia and downregulated by insulin, somatostatin and statins. This hormone is found in the cytoplasm as well as the nucleus of cells and has been identified in many tissues and organs including the brain, kidney, lung, spleen and testis but preferentially expressed in visceral adipose tissue and upregulated in some animal models of obesity. Visceral adipose tissue is regarded to be more pernicious than subcutaneous adipose tissue. Visfatin is an endocrine, autocrine as well as paracrine peptide with many functions including enhancement of cell proliferation, biosynthesis of nicotinamide mono- and dinucleotide and hypoglycaemic effect. Visfatin, also known as a Pre-B Cell Colony-Enhancing Factor (PBEF), consists of 491 amino acids (aa) in human, chimpanzee, cattle, pig, rat and mouse, 490 aa in rhesus monkey, 285 aa in sheep, 587 in opossum and 588 aa in canines. Visfatin gene is well preserved during evolution. For example, the canine visfatin protein sequence is 96% and 94% identical to human and rodent visfatin, respectively. Since evidence of a direct link between visfatin genotype and human type 2 diabetes mellitus is still weak, more molecular, physiological and clinical studies are needed to determine the role of visfatin in the etiology and pathogenesis of type 2 diabetes mellitus. Visfatin is a protein discovered during 2004 by Iichiro Shimomura, which is secreted by visceral adipose cells, i.e. visceral fat tissue surrounding the body's organs. Scientists continue to debate the validity of a highly-cited, controversial 2004 Science paper about a new fat cell protein with insulin-mimetic properties. Last week, Osaka University, which hosted the research, demanded that the researchers retract the paper. In the contested study, Iichiro Shimomura and colleagues at Osaka University Graduate School of Medicine identified a new protein, visfatin, in fat cells and reported that it had insulin-mimetic properties. They found that Visfatin lowered blood glucose in vivo in mice and promoted glucose uptake in vitro. Visfatin, the researchers found, is present in visceral adipose tissue, and circulating levels of the protein correlated with fat mass in humans, which raised the possibility of this protein as a potential drug target for type 2 diabetes and other metabolic disorders, the authors wrote. But further research in humans has cast doubt on visfatin as a potential therapy. In the 2004 article, Shimomura and colleagues note that visfatin is genetically identical to a known growth factor for early-stage B-cells. The factor, called pre-B cell colony-enhancing factor (PBEF), is found in bone marrow, liver and muscle. Since 2004, studies have found visfatin/PBEF to be identical to yet another protein, nicotinamide phosphoribosyltransferase (Nampt), an enzyme involved in cellular redox reactions. How visfatin mediates its effects is unclear. In a recent review article, Shin-ichiro Imai, who also works on the same protein, at the Washington University School of Medicine in St. Louis, Mo., and colleagues proposed that the multiple effects of the protein, including its insulin-like properties, can be explained entirely by its ability to catalyze the biosynthesis of nicotinamide adenine dinucleotide (NAD), a classic coenzyme in cellular redox reactions. Imai's group is testing this proposal, and he declined to talk about unpublished results, but said he believes Shimomura's findings 'absolutely' are no longer valid. Imai said it is unclear whether visfatin truly mimics insulin, 'but we have made up our mind to deal with this issue purely scientifically', he told The Scientist in an Email. Using two human subjects, Shimomura's team did not find visfatin mRNA in subcutaneous tissue, but a 2005 Diabetes study found visfatin mRNA in both visceral and subcutaneous adipose tissues. That study did not find a link between plasma concentration of visfatin and insulin sensitivity. Herbert Tilg, of Innsbruck Medical University in Austria, said 'Of course I don't know (whether Shimomura's findings still stand), but the only thing that we can say is that visfatin has been detected repeatedly now in adipose tissue, in visceral adipose tissue and in subcutaneous tissue', he added. In June 2006, a committee was formed by Osaka University to investigate the findings when 'an accuser started to insist existence of fraud, like fabrication or falsification, in the papers of our group', Shimomura wrote to The Scientist in an Email. There was no evidence of fraud, according to Shimomura. Shimomura wrote that the University raised 'several criticisms', though he did not elaborate on what they were. 'We authors responded to each of them sincerely. In some aspects, the committee showed different opinions from us', he wrote. According to Science, the school has not accused the authors of misconduct, but raised 'numerous questions' about the paper, including leaving out data that affected the conclusions. One criticism, according to Science, was the exclusion of data from female knockout mice. The group had made mice heterozygous for a mutation in the visfatin gene and reported that male knockout mice had higher levels of plasma glucose relative to wild-types. The heterozygous female knockouts were left out because they were poor models, according to Shimomura. 'Maybe there is something that I missed, but I don't think that is a real problem', said Claudio Pagano of the University of Padua in Italy. 'When you make knockout mice, usually it's not news that you have different phenotypes in males and females'. Shimomura said the group is preparing 'adequate action' against the Osaka University. A representative from Osaka University declined to comment on the investigation. According to Donald Kennedy, editor-in-chief of Science, the journal is taking the investigation very seriously. 'We are aware that an investigation of scientific misconduct has been underway at the University of Osaka, and our editors have been in contact with the investigating committee. We have not yet been informed about whether the investigation has been fully concluded. We await the investigation's results and will take appropriate actions once that process has been completed', he said in a statement. Tilg said it's possible Shimomura's group is wrong about visfatin's potential as a therapeutic target, but in general 'he has been considered a high profile scientist. He has made major contributions'. The 2004 findings in Science have been cited 158 times, according to Web of Science. Shimomura retracted other findings, published in Nature Medicine in 2005, after his group was unable to reproduce data published in the paper. The paper, cited 13 times, found that that reducing activity of an enzyme (different from visfatin) could lead to weight loss and lower blood sugar levels in mice. Visfatin is a protein that is preferentially produced in visceral adipose tissue and both its tissue expression and secreted plasma levels increase in parallel with obesity. Although visfatin is preferentially produced in visceral adipose tissue, it can be found in skeletal muscle, liver, bone marrow and lymphocytes, where it was initially identified as pre-B-cell colony-enhancing factor (PBEF). Interestingly, PBEF expression is regulated by cytokines that promote insulin resistance, such as lipopolysaccharide, IL-1β, TNFα and IL-6. Its levels are also increased in acute lung inflammation and sepsis, which is accompanied by an insulin-resistant state. The biological properties of visfatin (PEBF) are similar to the growth-factor-like properties of some of these cytokines (i.e. it is anti-apoptotic and promotes cell proliferation). Visfatin is a newly discovered adipokine that is produced by the intra-abdominal adipose tissue, which simultaneously facilitates adipogenesis and has insulin-mimetic properties. It is currently unclear what would be its physiological role or relevance in the context of the metabolic syndrome. Visfatin might be part of the mechanisms that facilitate the accumulation of fat in the intra-abdominal depot, a feedback mechanism preventing the deleterious effects of the expansion of the intra-abdominal depot in insulin sensitivity or simply an epiphenomenon that might be useful as a surrogate marker of increased visceral fat mass and cardiovascular risk. Its paradoxical effects facilitating fat accumulation and promoting insulin sensitivity suggest that visfatin is either good news for diabetes treatment or bad news for obesity treatment. Visfatin is a protein present in several mammals, encoded by the NAMPT gene within humans, expressed to a high degree in visceral fat. It is also known as Nicotinamide Phosphoribosyltransferase, NAmPRTase, NAMPT, pre-B-cell colony-enhancing factor 1, PBEF1, NMN synthetase and NMN pyrophosphorylase. As the primary rate-limited enzyme in the Nicotinamide adenine dinucleotide biosynthesis process, it plays a key role in converting nicotinamide to nicotinomide mononucleotide.

As a rather recently discovered protein, it has become known to share a direct relationship with type 2 diabetes, potentially as a marker of predisposition, though this has come under question. There are experimental drugs such as APO866, that inhibits the enzyme, and P7C3 compounds that enhance it for the purposes of combating age-related neurodegeneration. Function:- Visfatin is an endocrine, autocrine as well as paracrine peptide with many functions. One includes the part it plays in the nicotinamide adenine dinucleotide biosynthesis process, catalyzing the nicotinamide with 5-phosphoribosyl-1-pyrophosphate to yield nicotinamide mononucleotide. It also plays a role in the biosynthesis of nicotinamide dinucleotide. Further functions also include the enhancement of cell proliferation, the process by which the number of cells in increased and the balance kept by mixture of cell death and differentiation, particularly in the promotion of vascular smooth muscle cell maturation and inhibition of neutrophil apoptosis. It also has a function within the hypoglycemic effect, causing insulin within the blood to quickly drop, by lowering blood glucose and improving insulin sensitivity as an insulin receptor activator. It is because of this latter function that it has become known primarily for it's link to type 2 diabetes, potentially as a genetic marker to help identify those who are predisposed to the condition. Mechanisms:- Though the insulin-mimetic functions of visfatin are under question, there have been proposed links between visfatin levels with several medical conditions. For one, It has anti-apoptotic effects on neutrophils in several models of sepsis. It is also useful as a marker of acute pulmonary lesion. One the other hand, it is diminished in people with steatohepatitis when compared to pure steatosis. Furthermore, increased visfatin levels correlated positively with portal inflammation, bearing a possible association of visfatin with inflammation. Negative correlation of visfatin with creatinine clearance and positive correlation with urinary albumin excretion has been demonstrated, suggesting visfatin circulating levels to be influenced by renal function. An inhibitor of visfatin (FK866) is being tested as a potential anti-tumor agent due to NAD depletion leading to apoptosis on highly metabolically active cells. Visfatin is important to insulin secretion, but its relationship with diabetes risk and progression is still unknown. Interactions:- The interactions of vistatin are still being studied closely, but it has been shown to have a relationship with other adipokines involved in insulin sensitivity, including adiponectin and omentin. There is also possible interaction with iron in gestational diabetes mellitus and interaction with resistin in the risk of colorectal adenoma. Structure:- It has been widely reported by several groups that Visfatin has a crystal structure, with all of them showing that the enztne is a dimeric type II phosphoribosyltransferase enzyme involved in NAD biosynthesis. / Хэрбат Тильхь (Herbert Tilg). Висфатин:- цитокинин, синтезирующийся в нутряном жире, уровень содержания которого в крови коррелирует со степенью ожирения. Висфатин был выделен в 2004 группой Японских исследователей как гормон, который продуцируется преимущественно висцеральной жировой тканью и обладает инсулиномиметическими свойствами. Целью этого исследования была идентификация новых адипоцитокинов именно висцеральной жировой ткани, с которой связано развитие метаболического синдрома. Ацунори Фукухара, Морихиро Мацуда, Масако Нищизава, Ичиро Щимомура и другие соавторы обнаружили, что ранее идентифицированный фактор роста предшественников В-лимфоцитов – PBEF (pre-B cell colony-enhancing factor), синтезируемый в костном мозге, печени и скелетных мышцах, высоко экспрессируется в висцеральной жировой ткани и обладает инсулиномиметическими свойствами. Это вещество получило название Висфатин. Висфатин – 52-кDa белок с кристаллической структурой, циркулирующий в кровотоке в виде мономерных и димерных форм и обладающий свойствами цитокина и фермента, участвующего в биосинтезе никотин амид-аденин-динуклеотида (НАД), вследствие чего ещё одно из названий этого вещества – никотинамид-фосфорибозил-трансфераза (Nampt). Концентрации висфатина в плазме относительно невысоки (нг/мл), и по отношению к циркулирующему инсулину составляют около 3–10%. На сегодняшний день нет единого представления о физиологической и патофизиологической роли висфатина, однако данные последних исследований позволяют предположить вовлечённость этого адипокина в патогенез развития связанных с ожирением метаболических нарушений. Количество работ, посвящённых исследованию клинической значимости этого адипокина у детей, ограничено. Ген висфатина – PBEF1 – статистически значимо выше экспрессируется в висцеральной жировой ткани, чем в подкожной жировой ткани ($p = 0.002$), при этом наиболее высокий уровень его экспрессии отмечается у детей в допубертатном периоде и снижается по мере полового созревания. Не обнаружено достоверных отличий содержания висфатина сыворотки крови у детей с нормальной массой тела и избытком веса, а также не выявлено корреляций с показателями ИМТ, SDS ИМТ и ОТ.

VISIBILITY = ВИДИМОСТЬ (или ВИДНОСТЬ) – Visibility:- the properties and behavior of light waves and objects interacting in the environment to produce light signals capable of evoking visual sensation. ICAO (short for the International Civil Aviation Organization (ICAO) or in French:- Organisation de l'Aviation Civile Internationale (OACI); headquartered in Montreal, Quebec, Canada) Annex 3 Meteorological Service for International Air Navigation contains the following definitions and note:- (a) the greatest distance at which a black object of suitable dimensions, situated near the ground, can be seen and recognized when observed against a bright background; (b) the greatest distance at which lights of 1 000 candelas can be seen and identified against an unlit background. (Note:- The two distances have different values in air of a given extinction coefficient, and the latter b) varies with the background illumination. The former (a) is represented by the meteorological optical range (MOR). Annex 3 also defines Runway Visual Range (RVR) as:- The range over which the pilot of an aircraft on the center line of a runway can see the runway surface markings or the lights delineating the runway or identifying its center line. In extremely clean air in Arctic or mountainous areas, the visibility can be up to 160 km (100 miles) where there are large markers such as mountains or high ridges. However, visibility is often reduced somewhat by air pollution and high humidity. Various weather stations report this as haze (dry) or mist (moist). Fog and smoke can reduce visibility to near zero, making driving extremely dangerous. The same can happen in a sandstorm in and near desert areas, or with forest fires. Heavy rain (such as from a thunderstorm) not only causes low visibility, but the inability to brake quickly due to hydroplaning. Blizzards and ground blizzards (blowing snow) are also defined in part by low visibility. Visibility of less than 100 meters (330 ft) is usually reported as zero. In these conditions, roads may be closed, or automatic warning lights and signs may be activated to warn drivers. These have been put in place in certain areas that are subject to repeatedly low visibility, particularly after traffic collisions or pile-ups involving multiple vehicles. / Видность (оптическая). Видимость, возможность зрительного восприятия удалённых от наблюдателя объектов. Характеризуется либо степенью видимости – различимостью (насколько отчётливо виден объект), либо дальностью видимости – расстоянием, на котором наблюдаемый объект становится не различим глазом. В зависимости от среды наблюдения разделяют на:- атмосферную видимость (в воздухе), подводную видимость (в воде) и видимость в твёрдых средах (например, в стекле). В общем случае различимость объекта зависит от его угловых размеров, уровня яркости, контраста между фоном и объектом, времени восприятия объекта, степени загрязнения среды и других технических и физиологических факторов. Определение видимости объекта – одна из основных задач инженерной психологии, связанная с развитием систем автоматического управления, включающих устройства отображения для наглядной и быстрой передачи информации человеку-оператору. Атмосферная Видимость, возможность различать зрением удалённые объекты, отделённые от наблюдателя слоем воздуха той или иной мутности. Различают дневную, сумеречную и ночную атмосферную видимость. Для ночной атмосферной видимости, кроме того, различают атмосферную видимость светящихся и несамосветящихся объектов. Атмосферная видимость характеризуется дальностью видимости, то есть расстоянием, на котором наблюдаемый объект (здание, гора и тому подобное) становится не различим глазом (при условии, что объект достаточно велик и не

скрывается за горизонтом, так что его видимость зависит только от мутности атмосферного воздуха). Атмосферная видимость зависит, в первую очередь, от наличия в воздухе частичек пыли, мельчайших капелек и кристалликов воды; они рассеивают свет и уменьшают дальность видимости до нескольких километров (км), а иногда до нескольких десятков метров (м) (при тумане, выпадении осадков, метели, пыльной буре). В атмосферной видимости несамосветящихся объектов основную роль играет контраст К между видимыми яркостями объекта и окружающего его фона, определяемый формулой:- K = D B/B, где D B – разность между видимыми яркостями объекта и фона и B – видимая яркость фона. Наименьшее значение К, при которой глаз может различить объект, называется Порогом Контрастной Чувствительности Глаза e. Для объектов, видимых под углом зрения a, превышающим 1°, при дневном освещении e мало зависит от угловых размеров объектов и освещённости. Видимость огней, которые обычно можно рассматривать как точечные источники света, определяется той освещённостью, которую они создают в месте наблюдения. Изучение атмосферной видимости имеет большое практическое значение для всех видов транспорта (видимость путевых знаков, посадочных площадок и тому подобного), для топографических работ (видимость триангуляционных знаков), для аэрофотосъёмки и для военного дела. Колебания атмосферной видимости тесно связаны с погодой. Поэтому на метеорологических станциях ведутся регулярные наблюдения над атмосферной видимостью и значение её даётся в прогнозах погоды. Для улучшения атмосферной видимости объектов, имеющих малые угловые размеры, можно пользоваться биноклем. Атмосферная видимость далей при отсутствии тумана и мглы может быть улучшена, если смотреть через красное стекло, не пропускающее синих лучей воздушной дымки, или фотографировать дали в инфракрасных лучах. Применяя радиолокацию, можно обнаруживать и фотографировать объекты в полной темноте и через плотные слои тумана и облаков.

VISIBLE = ВИДИМОЕ – Visible:- pertaining to that portion of the electromagnetic spectrum to which the eye is sensitive, approximately 390 to 710 nm in wavelength. / Под Видимым Излучением или Светом понимается оптическое излучение с длинами волн (в вакууме) от 380–400 нм до 760–780 нм, которое способно непосредственно вызывать зрительное ощущение.

VISIBLE FLUORESCENT PROTEIN = ВИДИМЫЙ ФЛУОРЕСЦЕНТНЫЙ БЕЛОК – A term Visible Fluorescent Protein refers to a number of proteins, many of them naturally present in some species of organisms, which visibly fluoresce when illuminated with light of relevant wavelength. Examples include green fluorescent protein (GFP), cyan fluorescent protein (CFP), yellow fluorescent protein (YFP), red fluorescent protein (RFP), kusabira orange, etc. / Видимый Флуоресцентный Белок:- белок, являющийся причиной визуального наблюдения процесса биолюминесценции.

VISIBLE IMPORTS AND EXPORTS = ВИДИМЫЕ ПРИВОЗЫ И ВЫВОЗЫ (или ВИДИМЫЙ ИМПОРТ И ЭКСПОРТ) – Visible Imports And Exports:- goods actually shipped or otherwise sold as opposed to invisible imports or exports which are services earning or costing foreign exchange, e.g., freight, insurance, etc.

VISIBLE ITEMS OF TRADE = ВИДИМЫЕ СТАТЬИ ТОРГОВЛИ – Visible Items Of Trade:- visible trade involves the exchange, or the import and export, of tangible goods. Examples of invisible trade include consulting, income from foreign investments, shipping services and tourism. Invisible trade represents an increasing percentage of world trade. / Видимые Статьи Торговли:- (1) часть торговли между странами, показанная в отчётности об операциях, относящихся к обмену осязаемыми, материальными предметами; (2) вывоз (или экспорт) и привоз (или импорт) предметов и драгоценных металлов. Сравните с Невидимыми Статьями Торговли (Invisible Items Of Trade).

VISIBLE LIGHT TRANSMITTANCE = ПЕРЕДАЧА ВИДИМОГО СВЕТА (или КОЭФФИЦИЕНТ ПРОПУСКАНИЯ ВИДИМОГО СВЕТА) – Visible Light Transmittance:- the ratio of visible light transmitted through a substance to the total visible light incident on its surface.

VISIBLES = ВИДИМЫЕ – Visibles:- the buying and selling of goods, rather than services, between countries:- Trade in assets far outweighs the visibles for the United States, though not for most small countries. / Видимые:- статьи платёжного баланса. Поступления от вывоза (или экспорта) и платежи за привоза (или импорт) товаров в отличие от поступлений от вывоза (или экспорта) и платежей за привоз (или импорт) услуг, например, банковских или страховых. Торговый Баланс (Balance of Trade) складывается из видимых статей и иногда называется Видимым Балансом (Visible Balance).

VISIBLE SEDIMENT = ВИДИМЫЙ ОСАДОК (или ВИДИМЫЙ ОТСТОЙ) – Visible Sediment:- solid particulate matter, both mineral and organic, which can be seen with the unaided eye that has been or is being transported by water, air, gravity, or ice from its site of origin. This does not normally include colloidal sized particles.

VISIBLE SUPPLY = ВИДИМОЕ ПРЕДЛОЖЕНИЕ – Visible Supply is the amount of a good that is currently being stored or transported. The visible supply is the amount of goods or commodities that are available to be bought or sold. This supply is important as it identifies a definite quantity of good available for purchase or delivery upon futures contracts. The price of a good is not completely influenced by the amount of visible supply. Because commodities, such as wheat, are often purchased through futures contracts long before delivery, prices are more likely to be influenced by future supply rather than what is available at that moment. In general, an increase in visible supply is considered to be a bearish signal, while a decrease is considered a bullish one. Usually refers to supplies of a commodity in licensed warehouses. Often includes floats and all other supplies 'in sight' in producing areas. See also Invisible Supply. Visible Supply is the amount of a good that is currently being stored or transported. Visible Supply is the amount of a good that is currently stored in warehouses or other accessible locations. The visible supply is the amount of the good which could be immediately accessed and used, if necessary.

(2) Visible Supply:- new muni bond issues scheduled to come to market within the next 30 days. / Видимое Предложение:- вновь выпущенные муниципальные облигации, поступающие на рынок в течение 30 дней со дня выпуска. Видимое Предложение (Visible Supply):- Долларовая стоимость муниципальных облигаций, которые должны быть выпущены на рынок в течение текущего месяца. Инвесторы, аналитики, торговцы и инвестиционные банкиры, имеющие дело с муниципальными облигациями, рассматривают показатель видимого предложения для того, чтобы определить, может ли текущий месяц дать хорошие возможности для продажи и покупки облигаций или выхода на рынок эмиссии новых облигаций. Новые эмиссии на большие суммы могут способствовать снижению цен на облигации и затруднять представление на рынок новой эмиссии. И наоборот, новые эмиссии на небольшие суммы могут способствовать росту цен и облегчать продажу новых облигаций. Видимое предложение известно также как Календарь или 30-Дневное Видимое Предложение (30-Day Visible Supply), составляемое The Bond Buyer.

VISIBLE TRADE = ВИДИМАЯ ТОРГОВЛЯ – Visible Trade:- in economics, exchange of physically tangible goods between countries, involving the export, import, and re-export of goods at various stages of production. It is distinguished from invisible trade, which involves the export and import of physically intangible items such as services. Countries lacking various raw materials will import needed substances such as coal or crude oil from nations able to export such materials. Sometimes raw materials will be partially processed or converted into producer goods within the country from which they originate. Goods may also be processed into consumer goods prior to export or import and prior to the ultimate purchase by the buyer. These consumer goods may be durable (consumed over a period of time), as are appliances or automobiles, or nondurable (consumed almost immediately), as is food. Visible trade also includes the export and import of goods used directly in the production of other goods and services (capital goods) such as industrial machinery and equipment. The relationship of visible trade exports to imports is reflected in a country's balance of trade or visible balance. A surplus in the balance of trade occurs when exports exceed imports and a deficit occurs when imports are greater than exports. The balance of trade is the major component of a country's balance of payments, which includes debits and credits resulting from invisible trade.

VISIBLE UNDEREMPLOYMENT = ВИДИМАЯ НЕДОЗАНЯТОСТЬ – Visible Underemployment includes individuals who are involuntarily working less than the normal duration of work determined for the activity, who are seeking or available for additional work during the reference period. Context:- visible underemployment can usually be measured in labour force surveys. (OECD Employment Outlook, July 1995, page 45). In the Resolution Concerning the measurement of underemployment and inadequate employment situations adopted by the 16th International Conference of Labour Statisticians in October 1998 recommendations concerning the measurement of underemployment are limited to time-related underemployment. See also Invisible Underemployment, Time Related Underemployment, and Underemployment.

VISION = ЗРЕНИЕ (или ВИДЕНИЕ) – Vision:- physiological process of distinguishing, usually by means of an organ such as the eye, the shapes and colors of objects. See also Eye; Photoreception; and Sense. Vision is:- (i) the act or power of sensing with the eyes; sight; or (ii) the special sense by which the qualities of an object (such as color, luminosity, shape, and size) constituting its appearance are perceived through a process in which light rays entering the eye are transformed by the retina into electrical signals that are transmitted to the brain via the optic nerve. / Зрение, восприятие организмом внешнего мира, то есть получение информации о нём, посредством улавливания специальными органами зрения отражаемого или излучаемого объектами света. Аппарат зрения включает периферический отдел, расположенный в глазе (сетчатка, содержащая фоторецепторы и нервные клетки), и связанные с ним центральные отделы (некоторые участки среднего и межуточного мозга, а также зрительная область коры больших полушарий). Зрение позволяет на основе анализа внешних ситуаций организовать целесообразное поведение. С помощью зрения организм получает сведения о направлении отдельных пучков света, их интенсивности и так далее. Свет поглощается фоторецепторами глаза, содержащими зрительный пигмент, преобразующий энергию квантов света в нервные сигналы; от спектра поглощения пигментов зависит диапазон воспринимаемого света. Человек воспринимает электромагнитные излучения в диапазоне длин волн 400–700 нм, некоторые Насекомые различают и ультрафиолетовые лучи (до 300 нм), некоторые Ящерицы – инфракрасный свет. В процессе эволюции животных зрение прошло сложное развитие:- от способности различать лишь степень освещённости (дождевой Червь) или направление на источник света (Улитка) до многообразного анализа изображения. Своеобразно устроены фасеточные глаза Ракообразных и Насекомых, дающие 'мозаичное' изображение и приспособленные к различению формы близлежащих объектов. Глаза ряда беспозвоночных способны различать плоскость поляризации света. Глаз позвоночных имеет преломляющую свет оптическую систему:- роговицу, хрусталик (линзу), стекловидное тело, а также радужную оболочку со зрачком. При помощи специальной мышцы кривизна хрусталика, а следовательно, и его преломляющая сила меняются (аккомодация глаза), что обеспечивает резкость изображения на глазном дне. Внутреннюю поверхность глазного яблока занимает световоспринимающая часть глаза – сетчатка. За фоторецепторами – палочковыми и колбочковыми клетками – следует система из нескольких этажей нервных клеток, анализирующих поступающие от фоторецепторов сигналы. Нервные клетки сетчатки генерируют биоэлектрические потенциалы, которые можно зарегистрировать в виде электроретинограммы (смотрите Электроретинография). Анализ электрической активности сетчатки и её отдельных элементов – один из важных приёмов изучения её функции и состояния. Наиболее тонко дифференцирующий участок сетчатки глаза человека – так называемое жёлтое пятно и особенно его центральная ямка (фовеа), плотность рецепторов (колбочек) в которой достигает $1.8 \cdot 10^5$ на 1 миллиметр (мм); обеспечивает высокую пространственную разрешающую способность глаза, или остроту зрения (у человека при оптимальном освещении она в среднем равна 1 угловой минуте (мин)). На периферии сетчатки преобладают палочки, большие группы которых связаны каждая с одной нервной клеткой; острота зрения здесь значительно ниже. Соответственно периферия поля зрения служит для общей ориентировки, а центр – для детального рассматривания объектов. Кроме человека и обезьян, фовеа имеется у птиц (у некоторых по 2 в каждом глазу). У человека, обезьян и рыб обнаружены колбочки с тремя разными кривыми спектральной чувствительности, максимумы которых у человека находятся в фиолетовой, зелёной и жёлтой областях спектра. Согласно Теории Юнга-Гельмгольца, трёхмерность цветового зрения объясняется тем, что свет разного спектрального состава вызывает в 3 видах колбочек реакции разной интенсивности; это и ведёт к ощущению того или иного цвета. При интенсивном раздражении всех фоторецепторов может получиться ощущение белого цвета (смотрите Цветовое Зрение). Трёхмерное или двухмерное цветовое зрение свойственно многим позвоночным, а также некоторым Насекомым. Важное свойство зрения – адаптация физиологическая – приспособление к функционированию в сильно меняющихся условиях освещения, что обеспечивает сохранение высокой контрастной чувствительности глаза, то есть его способности улавливать небольшие различия в яркости (у человека – на 1%) в широком диапазоне освещённостей. Известен ряд механизмов адаптации:- изменение диаметра зрачка (диафрагмирование), ретиномоторный эффект (экранирование рецепторов зёрнами светонепроницаемого пигмента), распад и восстановление зрительного пигмента в палочках, перестройка в нервных структурах сетчатки. В сумерках функционирует лишь более чувствительная палочковая система (поэтому отсутствует цветовое зрение и снижена острота зрения), при дневном освещении – колбочковая и палочковая. У ночных животных в сетчатке преобладают палочки, у дневных – сетчатка либо смешанная, либо в ней преобладают колбочки. Системы зрения разных животных различаются по инерционности, или временной разрешающей способности. Так, Лягушка воспринимает мелькания частотой до 15–20 Герц (Гц), Человек – до 50–60 Гц (при ярком освещении), некоторые Насекомые (например, Муха) – до 250–300 Гц. Различают монокулярное зрение (одним глазом) и бинокулярное, когда поля зрения двух глаз частично перекрываются. Благодаря разнице углов, под которыми рассматривается один и тот же объект обоими глазами, бинокулярность приводит к стереоскопичности восприятия, которая является одним из средств оценки объёмности предметов и расстояний до них. Большую роль в зрении, особенно у высших позвоночных, играют движения глаз, которые осуществляются глазными мышцами, управляемыми из среднего мозга. Движения бывают произвольными и непроизвольными. Последние разделяют на 3 типа:- медленный дрейф, высокочастотный тремор (80 Гц) и быстрые скачки. Объекты, изображение которых неподвижно относительно сетчатки, человеком не воспринимаются, поэтому без движений глаз зрение практически невозможно. Сигналы от глаза через зрительный нерв идут по двум основным путям:- в средний мозг,

который у рыб и земноводных служит высшей инстанцией, так как передний мозг у них развит слабо, и в получивший у млекопитающих очень большое развитие передний мозг (через боковое коленчатое тело в затылочную область коры больших полушарий). Переработка зрительных сигналов и анализ изображения осуществляются на всех этажах зрительной системы, в том числе и в сетчатке. У разных животных обнаружены волокна зрительного нерва (‘детекторы’), передающие в мозг сигналы о таких специфических свойствах объектов, как их движение, направление движения, наличие в поле зрения тёмного пятнышка или горизонтального края и другие. Сигналы детекторов сетчатки, вероятно, используются в среднем мозгу для организации простых, автоматизированных реакций, свойственных поведению низших, а отчасти и высших позвоночных (движения глаз и головы при опасности, при слежении за движущимся объектом и так далее). Анализ, осуществляющийся в коре больших полушарий, значительно многообразнее и тоньше. Существенное для анализа свойство зрения – его константность, благодаря чему особенности объектов (их окраска, размеры, форма) воспринимаются как постоянные, несмотря на колебания интенсивности и спектрального состава освещения, расстояния до объекта, угла зрения и других.

VISIT AND SEARCH = ВИЗИТ И ОБСЛЕДОВАНИЕ (или ПОСЕЩЕНИЕ И ДОСМОТР) – Visit And Search:- procedure adopted by a belligerent warship to ascertain whether a merchant vessel is liable to seizure. If an inspection of the papers shows the ship to be an enemy vessel or to be carrying contraband, breaking blockade, or engaging in unneutral service, it is immediately captured. More often there is merely suspicion of such activities, in which case the vessel may be searched. If the searchers are satisfied the vessel is innocent, it is allowed to proceed. If suspicion remains, it may be brought into port for a more thorough search. If it is finally declared innocent and a prize court considers there was no probable cause for capture, the court may order damages to be paid. As the size of modern ships makes it impossible to search them thoroughly on the high seas, the practice of taking them automatically into port for search was adopted by British warships in World War I. The United States, however, protested on the ground that international law did not permit diversion of the vessel unless search at sea showed probable cause for capture. As a result, the British adopted the navicert system in 1916. The navicert issued by the belligerent’s representative in a neutral country was tantamount to a ship’s passport, possession of which ensured, in the absence of suspicious circumstances, that the vessel would be allowed to proceed on its way. While the principle of freedom of the seas normally forbids visit and search of foreign merchant vessels on the high seas in time of peace, the practice has occasionally been extended to ‘pacific blockades’ instituted as measures of reprisal, usually by a large state against a small one. On October 23, 1962, for example, US President John Fitzgerald Kennedy (1917–1963) proclaimed a ‘Quarantine’ of Cuba, under which any vessel suspected of carrying prohibited materials, especially missiles, to Cuba would be intercepted within a designated zone around Cuba, stopped, visited, searched, and, if found to be carrying such materials, diverted. If it attempted to escape or resist, it would be shot at and perhaps sunk. A few Soviet vessels were diverted, but none were sunk, and the crisis was soon terminated. This procedure, which resembled pacific blockade, was criticized as contrary to the UN Charter, which prohibited the use or threat of force except in defense against armed attack. / 23 Октября 1962, например, Президент США Дьжон Фицдьжерэлд Кенэди (John Fitzgerald Kennedy (1917–1963)).

VISITOR CONSUMPTION = ПОТРЕБЛЕНИЕ СО СТОРОНЫ ПОСЕТИТЕЛЕЙ – Visitor Consumption is the basic concept measuring tourism activity and refers to total consumption of or on behalf of visitors and could, consequently, also be termed as Visitor Demand. Context:- in visitor consumption concepts, visitor final consumption expenditure in cash (its main component), corresponds to the term Visitor Expenditure, traditionally used in the analysis of tourism. Visitor consumption exceeds visitor purchases on a trip. It encompasses these purchases as well as all expenditure on goods and services by all other institutional units on behalf of visitors. If cash or financial assets are transferred to the visitor to finance his/her trip, the purchases funded by these are included in visitor consumption. Along with this are all forms of transfers in kind and other transactions benefiting visitors where it is not cash or financial assets which is provided to the visitors but the goods and services themselves – thus the consumption of individual non-market services is included. Essentially all transactions where there is a direct link between the visitor and the producer/provider of the good or service are within scope.

VISITOR DEMAND = СПРОС СО СТОРОНЫ ПОСЕТИТЕЛЕЙ – Visitor Demand:- visitor consumption is the basic concept measuring tourism activity and refers to total consumption of or on behalf of visitors and could, consequently, also be termed as Visitor Demand. Essentially all transactions where there is a direct link between the visitor and the producer/provider of the good or service are within scope. (World Tourism Organization 2005a). See also Visitor Consumption.

VISITORIAL POWERS = ПОСЕТИТЕЛЬСКИЕ ПОЛНОМОЧИЯ – A term Visitorial Powers refers to the power of a regulator or superintendent to inspect, examine, supervise, and regulate the affairs of an entity. Visitorial Power is a power to control and arrest abuses and enforce due observance of the statutes. / Право Инспекции.

VISITORS = ПОСЕТИТЕЛИ (или ГОСТИ) – (1) Visitors:- the persons referred to in the definition of tourism are termed ‘Visitors’:- ‘Any person travelling to a place other than that of his/her usual environment for less than 12 months and whose main purpose of trip is other than the exercise of an activity remunerated from within the place visited’.

(2) Visitors (from abroad to the country) are persons who do not reside in the country of arrival and who are admitted for short stays for purposes of leisure, recreation, holidays; visits to friends or relatives; business or professional activities not remunerated from within the receiving country; health treatment; or religious pilgrimages. Visitors include excursionists, tourists and business travellers.

VISITT = VENDOR INFORMATION SYSTEM FOR INNOVATIVE TREATMENT TECHNOLOGIES

VIS MAJOR = ВИС МАЙОР (или НЕПРЕОДОЛИМАЯ СИЛА) – Vis Major (in Latin):- literally, Greater Force – an overwhelming force, greater or superior force-events over which no humans have control, and so cannot be held responsible. Also an Act of God. In law, the more common term is the French phrase ‘Force Majeure’. Vis Major:- irresistible force (act of God). / Смотрите также Действие Бога (Act Of God), и Форс Мажор (Force Majeure). Форс-Мажор (от Французского слова Force Majeure). Смотрите Непреодолимая Сила. Непреодолимая Сила (на Латинском языке Vis Major, на Французском языке Force Majeure), в гражданском праве – обстоятельство, освобождающее от ответственности. Под непреодолимой силой понимается чрезвычайное событие, вредные последствия которого не могло предотвратить лицо, обязанное это сделать. К таким событиям относятся стихийные бедствия (например, землетрясения, наводнения), общественные явления (например, война). Будучи непредотвратимой, непреодолимая сила обладает тем не менее относительным характером:- событие, непреодолимое в одних условиях, может стать преодолимым в других. Как правило, непреодолимая сила освобождает от имущественной ответственности, если именно непреодолимая сила – причина правонарушения и отсутствует вина обязанного

лица. В некоторых случаях правонарушитель несёт имущественную ответственность даже при наличии непреодолимой силы (например, согласно Статьи 101 Воздушного Кодекса СССР). Непреодолимая сила является также основанием приостановления срока течения исковой давности.

VISOR = КОЗЫРЁК (или ЗАТЕМНЯЮЩЕЕ ОБРАМЛЕНИЕ, или СМОТРОВОЕ ОТВЕРСТИЕ, или СМОТРОВОЙ ТАМБУР, или ЗАБРАЛО, или ВИЗИР, или ЩИТОК) – Visor is the front piece of a helmet, especially a movable upper piece; a projecting front of a cap for shading the eyes. Visor is an eyeshade with a deep front brim attached to an elastic or buckled head strap. / к эластичной или xx xx стропе. Под Визиром, от Немецкого слова Visier, в фотографии, понимается редко употребляемое название видоискателя.

VISTA = ВИСТА (или XX) – (1) Vista:- employee ID No. data entry at parklawn computer. Vista usually refers to a distant view. Borrowed from Italian Vista (View, Sight), from Visto, past participle of Vedere (To See), from Latin Vidēre, present active infinitive of Videō (I See).

(2) Windows Vista is an operating system by Microsoft for use on personal computers, including home and business desktops, laptops, tablet PCs and media center PCs. Initial release date:- November 2006.

VISTTA = VISIBILITY IMPAIRMENT FROM SULFUR TRANSFORMATION AND TRANSPORT IN THE ATMOSPHERE

VISUAL ANALYSIS = ВИЗУАЛЬНЫЙ АНАЛИЗ – Visual Analysis is an observation of the obvious, external features (usually without the aid of an instrument) to arrive at a general estimate. Also called Visual Inspection. Visual Analysis is a form of analysis that utilizes charts and market indicators to determine market direction. / Вид анализа, использующий графики и рыночные индикаторы для предопределения направления движения цен на рынке.

VISUAL BASIC = ВИЗУАЛЬНЫЙ БЭЙСИК – Visual Basic is a programming language and development environment created by Microsoft. It is an extension of the BASIC (short for the Beginner's All-purpose Symbolic Instruction Code) programming language that combines BASIC functions and commands with visual controls. Visual Basic provides a graphical user interface GUI (short for the Graphical User Interface) that allows the developer to drag and drop objects into the program as well as manually write program code. Visual Basic, also referred to as 'VB', is designed to make software development easy and efficient, while still being powerful enough to create advanced programs. For example, the Visual Basic language is designed to be 'human readable', which means the source code can be understood without requiring lots of comments. The Visual Basic program also includes features like 'IntelliSense' and 'Code Snippets', which automatically generate code for visual objects added by the programmer. Another feature, called 'AutoCorrect', can debug the code while the program is running. Programs created with Visual Basic can be designed to run on Windows, on the Web, within Office applications, or on mobile devices. Visual Studio, the most comprehensive VB development environment, or IDE (short for both the Integrated Device Electronics and the Integrated Development Environment), can be used to create programs for all these mediums. Visual Studio .NET provides development tools to create programs based on the .NET framework, such as ASP.NET applications, which are often deployed on the Web. Finally, Visual Basic is available as a streamlined application that is used primarily by beginning developers and for educational purposes. / Visual Basic – язык программирования высокого уровня, разработанный корпорацией Майкрософт (Microsoft).

VISUAL COLORIMETER = ВИЗУАЛЬНЫЙ КОЛОРИМЕТР – Visual Colorimeter is an instrument using the eye as detector that measures color stimuli produced by mixing one or more of at least three primary colors.

VISUAL EXAMINATION = ВИЗУАЛЬНЫЙ ДОСМОТР – (1) The Visual Examination is the starting point of the examinations for every damage analysis and condition assessment. Damage attributes can often already be identified by visual inspection and, based on the results; further targeted tests are carried out. In addition, visual inspection is an important tool in the inspection and evaluation of welding seams and of cast parts and forged parts. See also Visual Inspection.

(2) Visual Examination is the physical examination of plants, plant products, or other regulated articles using the unaided eye, lens, stereoscope or microscope to detect pests or contaminants without testing or processing. / Визуальный Досмотр или Визуальная Проверка – физический досмотр растений, растительных продуктов или других подкарантинных материалов невооружённым глазом, с помощью лупы, бинокуляра или микроскопа с целью выявления вредных или засоряющих вредных организмов без проведения испытаний или переработки.

(3) Visual Examination encompasses non-sampling examination methods for support and media, surface and underlying layers, by direct or magnified observation using a variety of illumination sources and techniques.

VISUAL–FIT METHOD = МЕТОД ВИЗУАЛЬНОЙ ПОСАДКИ – Visual-Fit Method is a cost estimation method where an analyst examines a cost by plotting points on a graph (called a Scatter Diagram) and places a line through the points to yield a cost function. This method is more objective than the account-classification method, but it is still lacking because two cost analysts could (and likely would) visually fit different lines. Such an approach is useful, though, because it helps spot non-representative data points, or outliers.

VISUAL FLIGHT RULES = ПРАВИЛА ВИЗУАЛЬНОГО ПОЛЁТА – Visual Flight Rules (VFR) are the rules that govern the procedures for conducting flight under visual conditions. The term (VFR) is also used in the United States to indicate weather conditions that are equal to or greater than minimum Visual Flight Rules (VFR) requirements. In addition, it is used by pilots and controllers to indicate type of flight plan. / Визуальный Полёт – полёт, когда пространственное положение воздушного судна и его местонахождение определяются экипажем визуально по естественному горизонту, земным ориентирам, а также относительно других материальных объектов и сооружений. Полётный Лист или Задание На Полёт – документ установленной формы, разрешающий командиру воздушного судна выполнение полёта. Аэродромные полёты по утверждённой плановой таблице могут выполняться без полётных листов.

VISUAL FLIGHT RULES CONDITIONS = УСЛОВИЯ ПРАВИЛ ВИЗУАЛЬНОГО ПОЛЁТА – Visual Flight Rules (VFR) Conditions are the weather conditions equal to or better than the minimum for flight under visual flight rules.

VISUAL FLIGHT RULES FLIGHT = ПОЛЁТ ПО ПРАВИЛАМ ВИЗУАЛЬНОГО ПОЛЁТА – Visual Flight Rules (VFR) Flight is a flight conducted in accordance with Visual Flight Rules.

VISUAL FLIGHT RULES OVER–THE–TOP = ПРАВИЛА ВИЗУАЛЬНОГО ПОЛЁТА ЗА ГРАНЬЮ (или XX) – Visual Flight Rules (VFR) Over-The-Top:- with respect to the operation of aircraft, means the operation of an aircraft over-the-top under Visual Flight Rules (VFR) when it is not being operated on an Instrument Flight Rules (IFR) flight plan.

VISUAL FLIGHT RULES TERMINAL AREA CHARTS = ГРАФИКИ ДИСПЕТЧЕРСКОЙ ЗОНЫ ПРАВИЛ ВИЗУАЛЬНОГО ПОЛЁТА (или XX) – Visual Flight Rules (VFR) Terminal Area Charts:- depict Class B airspace which provides for the control of

segregation of all the aircraft within Class B airspace. The chart depicts topographic information and aeronautical information which includes visual and radio aids to navigation, airports, controlled airspace, restricted areas, obstructed and related data.

VISUAL FLIGHT RULES TOWER = БАШНЯ ДЛЯ ПРАВИЛ ВИЗУАЛЬНОГО ПОЛЁТА (или ДИСПЕТЧЕРСКАЯ ДЛЯ ПРАВИЛ ВИЗУАЛЬНОГО ПОЛЁТА) – Visual Flight Rules (VFR) Tower is an airport traffic control tower providing takeoff and landing services only. It does not provide approach control services.

VISUAL INSPECTION = ВИЗУАЛЬНАЯ ИНСПЕКЦИЯ (или ВИЗУАЛЬНЫЙ ОСМОТР) – Visual Inspection is a nondestructive testing technique that provides a means of detecting and examining a variety of surface flaws, such as corrosion, contamination, surface finish, and surface discontinuities on joints (for example, welds, seals, solder connections, and adhesive bonds). Visual inspection is also the most widely used method for detecting and examining surface cracks, which are particularly important because of their relationship to structural failure mechanisms. Even when other nondestructive techniques are used to detect surface cracks, visual inspection often provides a useful supplement. For example, when the eddy current examination of process tubing is performed, visual inspection is often performed to verify and more closely examine the surface disturbance. Given the wide variety of surface flaws that may be detectable by visual examination, the use of visual inspection may encompass different techniques, depending on the product and the type of surface flaw being monitored. This article focuses on some equipment used to aid the process of visual inspection. The techniques and applicability of visual inspection for some products are considered in the Selected References in this article and in the Section 'Nondestructive Inspection of Specific Products' in this Volume. The methods of visual inspection involve a wide variety of equipment, ranging from examination with the naked eye to the use of interference microscopes for measuring the depth of scratches in the finish of finely polished or lapped surfaces. Some of the equipment used to aid visual inspection includes:- Flexible or rigid borescopes for illuminating and observing internal, closed or otherwise inaccessible areas Image sensors for remote sensing or for the development of permanent visual records in the form of photographs, videotapes, or computer-enhanced images Magnifying systems for evaluating surface finish, surface shapes (profile and contour gaging), and surface microstructures Dye and fluorescent penetrants and magnetic particles for enhancing the observation of surface cracks (and sometimes near-surface conditions in the case of magnetic particle inspection). This article will review the use of the equipment listed above in visual inspection, except for dye penetrants and magnetic particles, which are discussed in the articles 'Liquid Penetrant Inspection' and 'Magnetic Particle Inspection', respectively, in this Volume. See also Visual Examination.

VISUALLY STRESS–GRADED LUMBER = ПИЛОМАТЕРИАЛ ВИЗУАЛЬНОЙ СОРТИРОВКИ – Visually Stress-Graded Lumber is a lumber that has been graded for strength based on visual appearance, as opposed to Machine Stress-Rated (MSR) Lumber which is evaluated mechanically and checked visually. / Пиломатериалы, отсортированные путём внешнего осмотра, основанного на учёте размеров, количества, характера и местоположения пороков.

VISUAL METEOROLOGICAL CONDITIONS = ВИЗУАЛЬНЫЕ МЕТЕОРОЛОГИЧЕСКИЕ УСЛОВИЯ – Visual Meteorological Conditions (VMC) are the meteorological conditions expressed in terms of visibility, distance from cloud, and ceiling equal to or better than the specified minima. / Визуальные Метеорологические Условия – метеорологические условия, выраженные в величинах дальности видимости, высоты нижней границы облаков и расстояния до облаков, при которых полёт выполняется по правилам визуальных полётов.

VISUAL PERCEPTION = ВИЗУАЛЬНОЕ ВОСПРИЯТИЕ (или ЗРИТЕЛЬНОЕ ВОСПРИЯТИЕ) – Visual Perception is the the visual experience resulting from stimulation of the retina and the resulting activity of associated neural systems.

VISUAL PIGMENT = ЗРИТЕЛЬНЫЙ ПИГМЕНТ (или ВИЗУАЛЬНЫЙ ПИГМЕНТ) – Visual Pigment:- any of a number of related substances that function in light reception by animals by transforming light energy into electrical (nerve) potentials. It is believed that all animals employ the same basic pigment structure, consisting of a colored molecule, or chromophore (the carotenoid retinal, sometimes called Retinene), and a protein, or opsin, of moderate size. Retinal$_1$ is derived from vitamin A$_1$; Retinal$_2$ is derived from vitamin A$_2$. Many vertebrate animals have two or more visual pigments. Scotopsin pigments are associated with vision in dim light and, in vertebrates, are found in the rod cells of the retina; the retinal$_1$ forms are called Rhodopsins, and the retinal$_2$ forms porphyropsins. Photopsin pigments operate in brighter light than scotopsins and occur in the vertebrate cone cells; they differ from the scotopsins only in the characteristics of the opsin fraction. The retinal$_1$ forms are called Iodopsins; the retinal$_2$ forms Cyanopsins. / Зрительный Пигмент, структурно-функциональная единица светочувствительной мембраны фоторецепторов сетчатки глаза – палочек и колбочек. В зрительном пигменте осуществляется первый этап зрительного восприятия – поглощение квантов видимого света. Молекула зрительного пигмента (молярная масса около 40 000) состоит из хромофора, поглощающего свет, и опсина – комплекса белка и фосфолипидов. Хромофором всех зрительных пигментов служит альдегид витамина A$_1$ или A$_2$ – ретиналь или 3-дегидроретиналь. Два вида опсина (палочковый и колбочковый) и два вида ретиналя, соединяясь попарно, образуют 4 вида зрительного пигмента, различающихся по спектру поглощения:- родопсин (самый распространённый палочковый зрительный пигмент), или зрительный пурпур (максимум поглощения 500 нм), иодопсин (562 нм), порфиропсин (522 нм) и цианопсин (620 нм). Первичное фотохимическое звено в механизме зрения состоит в фотоизомеризации ретиналя, который под действием света меняет изогнутую конфигурацию на плоскую. За этой реакцией следует цепь темновых процессов, приводящих к возникновению зрительного рецепторного сигнала, который затем синаптически передаётся следующим нервным элементам сетчатки – биполярным и горизонтальным клеткам.

VISUAL RUNWAY = ВИЗУАЛЬНАЯ ВЗЛЁТНО–ПОСАДОЧНАЯ ПОЛОСА – Visual Runway is a runway without an existing or planned straight in instrument approach procedure. Visual Runway means a runway intended solely for the operation of aircraft using visual approach procedures, with no straight-in instrument approach procedure and no instrument designation indicated on an FAA-approved (Federal Aviation Administration) airport layout plan, a military service approved military airport layout plan, or by any planning document submitted to the FAA by competent authority. / Взлётно-Посадочная Полоса (ВПП) – часть аэродрома, предназначенная для разбега при взлёте и пробега после посадки воздушных судов. Видимость на ВПП или Дальность Видимости на ВПП – максимальное расстояние, в пределах которого пилот воздушного судна, находящегося на осевой линии ВПП, может видеть маркировку её покрытия или световые ориентиры. За видимость на ВПП ночью принимается видимость световых ориентиров. Визуальный Заход На Посадку – заход на посадку, когда пространственное положение воздушного судна и его местонахождение определяются экипажем визуально по естественному горизонту, земным ориентирам, а также относительно других материальных объектов и сооружений.

VITAFOODS = ВИТАФУДЗ (или ЖИЗНЕННЫЕ ПРОДУКТЫ) – Vitafoods are the foods designed to meet the needs of health conscious consumers which enhance physical or mental quality of life and may increase health status. See also Nutraceuticals. / Витафудз:- .

VITAL EVENT = ЖИЗНЕННОЕ СОБЫТИЕ (или ДЕМОГРАФИЧЕСКОЕ СОБЫТИЕ) – A Vital Event refers to the live birth, death, foetal death, marriage, divorce, adoption, legitimation, recognition of parenthood, annulment of marriage, or legal separation.

VITAL EVENT RECORD = ЗАПИСЬ О ЖИЗНЕННОМ СОБЫТИИ (или ЗАПИСЬ О ДЕМОГРАФИЧЕСКОМ СОБЫТИИ) – A Vital Event Record is a legal document entered in the civil register which attests to the occurrence and characteristics of a vital event.

VITAL RATES = СТАВКИ НАРОДОНАСЕЛЕНИЯ (или ДЕМОГРАФИЧЕСКИЕ ПОКАЗАТЕЛИ) – Vital Rates:- relative frequencies of vital occurrences that affect changes in the size and composition of a population. When calculated per 1 000 inhabitants – as is conventional in vital-statistics publications – they are referred to as Crude Rates. More refined rates often must be used in the more meaningful analysis of population change. Principal among vital rates are the crude birth rate and the crude death rate; i.e. annual numbers of births or of deaths per 1 000 population, based on the midyear population estimate. The difference between these two rates is the rate of natural increase (or decrease, if deaths exceed births). Rates of natural increase are a net result of fertility trends, health conditions, and variations in the age composition of the population. They approximate rates of population growth, a result of natural increase and the balance of migration (immigrants minus emigrants), when the latter is comparatively small. The marriage rate records the annual number of marriages per 1 000 inhabitants. It is a crude measure, since, aside from the effects of age composition and preferred ages at marriage, it also is influenced by remarriages of previously widowed or divorced persons. More importantly, it does not include marriage unions that are not legally formalized, and there are differences in the definition of legal marriage. Some countries, for example, recognize common-law marriages as legal, while others do not; and in some Latin-American countries, marriages performed under indigenous tribal rites are not recorded as legal. Divorce rates and the infant mortality rate complete the set of most widely published vital rates. The infant mortality rate is calculated as the number of infant deaths (deaths of children under 12 months of age) occurring in a given year per 1 000 live births occurring in the same year. These vital rates are widely used and facilitate much useful comparison of time trends and of local variations within or among countries. Being summary measures, they do not reveal many factors that may have a distorting effect for purposes of more specialized comparison. Chief among these factors is the variable age composition of the population. Thus, the crude birth rates are somewhat distorted measures of reproductivity, because the percentage of total population at reproductive ages is not taken into account. The crude death rates distort the comparison of mortality conditions to an even greater extent. Even under the best health conditions, mortality is at least relatively high at advanced ages; therefore, the proportion of aged persons in the population – e.g., those aged 65 and over – has a large effect. See also Mortality.

VITAL STATISTICAL RECORD = СТАТИСТИЧЕСКАЯ ЗАПИСЬ НАРОДОНАСЕЛЕНИЯ (или XX) – A Vital Statistical Record is a document or form, containing the items of information concerning an individual vital event or a number of vital events of the same type, filled in at the time of registration, to meet the needs of vital statistics compilation.

VITAL STATISTICS = СТАТИСТИКА НАРОДОНАСЕЛЕНИЯ (или СТАТИСТИКА НАСЕЛЕНИЯ, или ДЕМОГРАФИЧЕСКАЯ СТАТИСТИКА, или ЖИЗНЕННАЯ СТАТИСТИКА) – Vital Statistics:- quantitative data concerning the population, such as the number of births, marriages, and deaths. The statistics concerning human life or the conditions affecting human life and the maintenance of population. Vital Statistics are information systematically collected and compiled in numerical form, relating to or derived from vital event records. / Статистика Естественного Движения Населения:- статистика населения страны или региона, включающая в себя статистику рождаемости, смертности, браков и так далее.

VITAMER = ВИТАМЕР – A Vitamer of a particular vitamin is any of a number of chemical compounds, generally having a similar molecular structure, each of which shows vitamin-activity in a vitamin-deficient biological system. / Витамер (Vitamer):- одна из нескольких химических форм витамина.

VITAMIN = ВИТАМИН – Vitamin is any of several organic substances that usually are separated into water-soluble (e.g., the B vitamins, vitamin C) and fat-soluble (e.g., vitamins A, D, E, K) groups; small quantities (from 0.000 02 percent to 0.005 percent of a diet) are necessary for normal health and growth in higher forms of animal life. The substances commonly known as Vitamins are diverse in chemical structure and function. Originally defined as organic compounds obtainable in a normal diet and capable of maintaining life and promoting growth, vitamins are distinct from carbohydrates, fats, and proteins in function, as well as in the quantities in which organisms require them. A number of compounds (e.g., choline, carnitine) once grouped with vitamins no longer are considered vitamins (see below Vitamin-Like Substances). If a vitamin is absent from the diet or is not properly absorbed by an organism, a specific deficiency disease may develop. The term Vitamin originated from ‘Vitamine’, a word first used in 1911 to designate a group of compounds considered vital for life; each was thought to have a nitrogen-containing component known as an Amine. The final e of vitamine was dropped when it was discovered that not all of the vitamins contain nitrogen, and, therefore, not all are amines. The term Accessory Food Factor sometimes is used instead of vitamin to refer to these substances. Since they generally cannot be synthesized by an animal (or, if synthesized, the amounts are insufficient to meet body needs) and must be obtained from the diet or from some synthetic source, vitamins are called Essential Nutrients. The requirements for some of the B vitamins may be met in part by bacterial synthesis in the intestines of some mammals. The amino acid tryptophan can be converted to nicotinic acid (or niacin, a water-soluble vitamin) and thus can serve as a source for part of the nicotinic acid required by an animal. Vitamin C (also a water-soluble vitamin) can be synthesized by some organisms in sufficient amounts so that the dietary requirement is eliminated; vitamin C usually is considered a vitamin, however, because it must be included in the diet of man. Vitamins are distinct from many other compounds, which, although indispensable for proper animal functions, can be synthesized in adequate quantities. General Characteristics:- a provitamin is similar in structure to a specific vitamin and can be converted to it by a few metabolic reactions (e.g., beta-carotene can be converted to vitamin A; 7-dehydrocholesterol can be converted to vitamin D_3). The amino acid tryptophan is called a Precursor of the vitamin nicotinic acid because the conversion pathway is less direct than that of a provitamin. Antivitamins are compounds that prevent the normal function of certain vitamins. Antivitamins may act by binding a vitamin (e.g., the antivitamin avidin binds the vitamin biotin), by destroying a vitamin (e.g., the antivitamin thiaminase destroys thiamine), or by inhibiting the coenzyme function of a vitamin. A coenzyme is, as noted previously, a heat stable compound that combines with the protein component of an enzyme (i.e. an organic catalyst) to form an active enzyme. Antivitamins that act by inhibiting the coenzyme function of a vitamin usually are known as antagonists or antimetabolites. Letters originally were assigned to the vitamins, which were differentiated according to physiological function. As chemical structures of the vitamins became known, however, they were also given names and now are commonly known either by letter or by name. Currently accepted names for the vitamins, established by international agreement, are given in Tables 1 and 2. Biological Significance:- Regulatory Role:- the vitamins regulate reactions that occur in metabolism, in contrast to other dietary components known as Macronutrients (e.g., fats, carbohydrates, proteins), which are the compounds utilized in the reactions regulated by the vitamins. Absence of a vitamin blocks one or more specific metabolic reactions in a cell and eventually may disrupt the metabolic balance within a cell and in the entire plant or animal as well. With the exception of vitamin C (ascorbic acid), all of the water-soluble vitamins have a catalytic function; i.e. they act as coenzymes of enzymes that function in energy transfer or in the metabolism of fats, carbohydrates, and proteins. The metabolic importance of the water-soluble vitamins is reflected by their presence in most plant and animal tissues involved in metabolism. Some of the fat-soluble vitamins form part of the structure of biological membranes or assist in maintaining the integrity (and therefore, indirectly, the function) of membranes. Some fat-soluble vitamins also may function at the genetic level by controlling the synthesis of certain enzymes. The roles of the fat-

soluble vitamins have not yet been established with certainty. Unlike the water-soluble ones, fat-soluble vitamins are necessary for specific functions in highly differentiated and specialized tissues; therefore, their distribution in nature tends to be more selective than that of the water-soluble vitamins. Sources:- vitamins, which are found in all living organisms either because they are synthesized in the organism or are acquired from the environment, are not distributed equally throughout nature. Some are absent from certain tissues or species; for example, beta-carotene (provitamin A) is synthesized in plant tissues but not in animal tissues. On the other hand, vitamins A and D_3 occur only in animal tissues. Both plants and animals are important natural vitamin sources for man. Since vitamins are not distributed equally in foodstuffs, the more restricted the diet of an animal (man, for example), the more likely it is that he will lack adequate amounts of one or more vitamins. Food sources of vitamin D are limited, but it can be synthesized in the skin through ultraviolet radiation (from the Sun) on the provitamin, 7-dehydrocholesterol; therefore, with adequate exposure to sunlight, the dietary intake of vitamin D is of little significance. All vitamins either can be synthesized or produced commercially from food sources and are available for human consumption in pharmaceutical preparations. Commercial processing of food (e.g., milling of grains) frequently destroys (or removes) considerable amounts of vitamins. In most such instances, however, the vitamins are replaced by chemical methods. Some foods are 'fortified' with vitamins not normally present in them (e.g., vitamin D is added to milk). Loss of vitamins may also occur when food is cooked (e.g., heat destroys vitamin A, water-soluble vitamins may be extracted from food to water and lost). Certain vitamins (e.g., B vitamins, vitamin K) can be synthesized by microorganisms normally present in the intestines of some animals; however, the microorganisms usually do not supply the host animal with an adequate quantity of a vitamin. Requirements Of Living Things:- the vitamins required by most organisms are fairly well established. Vitamin requirements vary according to species and the amount of a vitamin required by a specific organism is difficult to determine because of the numerous factors involved (e.g., genetic variation; presence of specific disease states; therapeutic use of certain drugs that also may act as vitamin antagonists; infestation with parasites; relative proportions of other dietary constituents, food additives, or contaminants; environmental stresses; and stimulation of growth rate, as in animal husbandry). There is not uniform agreement concerning the vitamin requirements for man. Differences in opinion arise mainly from different ways by which requirements can be determined and from the scanty data available for the requirements for some of the vitamins. Recommended daily vitamin allowances, however, are sufficiently high to account for individual variation and normal environmental stresses. For detailed information on vitamin requirements in man, see Nutrition, Human. A number of interrelationships exist among vitamins and between vitamins and other dietary constituents. The interactions may be synergistic (i.e. cooperative) or antagonistic, reflecting, for example, overlapping metabolic roles (of the B vitamins in particular), protective roles (e.g., vitamins A and E), or structural dependency (e.g., cobalt in the vitamin B_{12} molecule). Results Of Deficiencies:- an inadequate intake of a specific vitamin results in a characteristic deficiency disease (or hypovitaminosis); the severity of the disease depends upon the degree of vitamin deprivation. Symptoms may be specific (e.g., functional night blindness of vitamin A deficiency) or nonspecific (e.g., loss of appetite, failure to grow). All symptoms for a specific deficiency disease may not appear; in addition, the nature of the symptoms may vary with the species. Some effects of vitamin deficiencies cannot be reversed by adding the vitamin to the diet, especially if damage to nonregenerative tissue (e.g., cornea of the eye, nerve tissue, calcified bone) has occurred. A vitamin deficiency may be 'primary' (or dietary), in which case the dietary intake is lower than the normal requirement of the vitamin. A 'secondary' (or conditioned) deficiency may occur (even though the dietary intake is adequate) if a pre-existing disease or state of stress is present (e.g., malabsorption of food from the intestine, chronic alcoholism, repeated pregnancies and lactation). For more details on vitamin deficiencies in man, see Nutritional Disease:- Diet And Diseases. Evolution Of Vitamin-Dependent Organisms:- evolution of metabolic processes in primitive forms of life required the development of enzyme systems to catalyze the complex sequences of chemical reactions involved in metabolism. In the beginning, the environment presumably could supply all the necessary compounds (including the vitamin coenzymes); eventually, these compounds were synthesized within an organism. As higher forms of life evolved, however, the ability to synthesize certain of these vitamin coenzymes was gradually lost. Since higher plants show no requirements for vitamins or other growth factors, it is assumed that they retain the ability to synthesize them. Among insects, however, nicotinic acid; vitamins B_1, B_2, B_6, and C; and pantothenic acid are required by a few groups. All vertebrates, including man, require dietary sources of vitamins A, D, B_1, B_2, B_6, and pantothenic acid; some vertebrates, particularly the more highly evolved ones, have additional requirements for other vitamins. The inability of man and a few other primates to synthesize vitamin C, however, may be a genetic disease (i.e. an inborn error of metabolism), rather than the result of a true evolutionary process. For more details on the evolution of primitive forms, see Life. Methods Used In Vitamin Research:- Determination Of Vitamin Requirements:- if a specific factor in food is suspected of being essential for the growth of an organism (either by growth failure or some other clinical symptoms that are alleviated by adding a specific food to the diet) a systematic series of procedures (described below) is used to characterize the factor. The active factor (or principle) is isolated from specific foods and purified; then its chemical structure is determined, and it is synthesized in the laboratory. Structural determination and synthesis, which may be achieved only after long and intensive research, must be completed before the function and the quantitative requirements of the factor can be established accurately. Established organic and analytical chemical procedures are used to determine the structure of the factor and to synthesize it. Biological studies may be performed to determine functions, effects of deprivation, and quantitative requirements of the factor in various organisms. The development in an organism of a deficiency either by dietary deprivation of the vitamin or by administration of a specific antagonist or antivitamin often is the method used. The obvious effects (e.g., night blindness, anemia, dermatitis) of the deficiency are noted. Less obvious effects may be discovered after microscopic examination of tissue and bone structures. Changes in concentrations of metabolites or in enzymatic activity in tissues, blood, or excretory products are examined by numerous biochemical techniques (including the use of radioisotopes). The response of an animal to a specific vitamin of which it has been deprived usually confirms the deficiency symptoms for that vitamin. Effects of deprivation of a vitamin sometimes indicate its general physiological function, as well as its function at the cellular level. Biochemical function often is studied by observing the response of tissue enzymes (removed from a deficient host animal) after a purified vitamin preparation is added. The functions of most of the known vitamins have been reasonably well defined; however, the mechanism of action has not yet been established for some of them (e.g., vitamins A, E, C.) The procedure for determining the amount of a vitamin required by an organism is less difficult for microorganisms than for higher forms; in microorganisms, the aim is to establish the smallest amount of a vitamin that produces maximal growth (i.e. maximal rate of multiplication) of the organisms when it is added to the culture medium. Among vertebrates, particularly man, a number of procedures are used together to provide estimates of the vitamin requirement. These procedures include determinations of: the amount of a vitamin required to cure a deficiency that has been developed under controlled, standard conditions; the smallest amount required to prevent the appearance of clinical or biochemical symptoms of the deficiency; the amount required to saturate body tissues (i.e. to cause 'spillover' of the vitamin in the urine; valid only with the water-soluble vitamins); the amount necessary to produce maximum blood levels of the vitamin plus some tissue storage (applicable only to the fat-soluble vitamins, particularly vitamin A); the amount required to produce maximum activity of an enzyme system if the vitamin has a coenzyme function; the actual rate of utilization, and hence the requirement, in healthy individuals (as indicated by measuring the excreted breakdown products of radioisotope-labelled vitamins). The above procedures are practical only with small groups of animals or human subjects and thus are not entirely representative of larger populations of a particular species. A less precise (but more representative) method used among human populations involves comparing levels of dietary intake of a vitamin in a population that shows no deficiency symptoms with levels of intake of the vitamin in a population that reveals clinical or

biochemical symptoms. The data for dietary intakes and incidence of deficiency symptoms are obtained by surveys of representative segments of a population. Determination Of Vitamin Sources:- a quantitative analysis of the vitamin content of foodstuffs is important in order to identify dietary sources of specific vitamins (and other nutrients as well). Three methods commonly used to determine vitamin content are described below. Physicochemical Methods:- the amount of vitamin in a foodstuff can be established by studying the physical or chemical characteristics of the vitamin; e.g., a chemically reactive group on the vitamin molecule, fluorescence (for thiamin, riboflavin, vitamin A), absorption of light at a wavelength characteristic of the vitamin (for most vitamins), radioisotope dilution techniques (for vitamin B_{12}). These methods are accurate and can detect very small amounts of the vitamin. Biologically inactive derivatives of several vitamins have been found, however, and may interfere with such determinations; in addition, these procedures also may not distinguish between bound (i.e. unavailable) and available forms of a vitamin in a food. Microbiological Assay:- microbiological assay is applicable only to the B vitamins. The rate of growth of a species of microorganism that requires a vitamin is measured in growth media that contain various known quantities of a foodstuff preparation containing unknown amounts of the vitamin. The response (measured as rate of growth) to the unknown amounts of vitamin is compared with that obtained from a known quantity of the pure vitamin. Depending on the way in which the food sample was prepared, the procedure may indicate the availability of the vitamin in the food sample to the microorganism. Animal Assay:- all of the vitamins, with the exception of vitamin B_{12}, can be estimated by the animal-assay technique. One advantage of this method is that animals respond only to the biologically active forms of the vitamins. On the other hand, many other interfering and complicating factors may arise; therefore, experiments must be rigidly standardized and controlled. Simultaneous estimates usually are made using a pure standard vitamin preparation (as a reference) and the unknown food (whose vitamin content is being sought); each test is repeated using two or more different amounts of both standard and unknown in the assays listed below (i.e. growth, reaction time, graded response, all-or-none). In a growth assay, the rat, chick, dog (used specifically for niacin), and guinea pig (used specifically for vitamin C) usually are used. One criterion used in a vitamin assay is increase in body weight in response to different amounts of a specific vitamin in the diet. There are two types of growth assay. In a prophylactic growth assay, the increase in weight of young animals given different amounts of the vitamin is measured. In a curative growth assay, weight increase is measured in animals first deprived of a vitamin and then given various quantities of it. The curative growth assay tends to provide more consistent results than the prophylactic technique. In a reaction time assay, an animal is first deprived of a vitamin until a specific deficiency symptom appears; then the animal is given a known amount of a food extract containing the vitamin, and the deficiency symptom disappears within a day or two. The time required for the reappearance of the specific symptoms when the animal again is deprived of the vitamin provides a measure of the amount of vitamin given originally. The graded response assay, which may be prophylactic or curative, depends on a characteristic response that varies in degree with the vitamin dosage. An example of the use of this technique is an assay for vitamin D in which the measured ash content of a leg bone of a rat or chick is used to reflect the amount of bone calcification that occurred as a result of administration of a specific amount of vitamin D. In an all-or-none assay, the degree of response cannot be measured; an arbitrary level is selected to separate positive responses from negative ones. The percent of positively reacting animals provides a measure of response; i.e. vitamin E can be measured by obtaining the percent of fertility in successfully mated female rats. Biochemistry Of The Water-Soluble Vitamins:- Basic properties:- although the vitamins included in this classification are all water-soluble, the degree to which they dissolve in water is variable. This property influences the route of absorption, their excretion, and their degree of tissue storage and distinguishes them from fat-soluble vitamins, which are handled and stored differently by the body. The water-soluble vitamins (excluding vitamin C) popularly are termed the B-vitamins; these include B_1 (thiamine), B_2 (riboflavin), B_6 (pyridoxine), niacin (nicotinic acid), B_{12} (cyanocobalamin), folic acid, pantothenic acid, and biotin. These relatively simple molecules contain the elements carbon, hydrogen, and oxygen; some also contain nitrogen, sulfur, or cobalt. The water-soluble vitamins, inactive in their so-called Free States, must be activated to their coenzyme forms; addition of phosphate groups occurs in the activation of vitamins B_1, B_2, and B_6; a shift in structure activates biotin, and formation of a complex between the free vitamin and parts of other molecules is involved in the activation of nicotinic acid, pantothenic acid, folic acid, and vitamin B_{12}. After an active coenzyme is formed, it must combine with the proper protein component (called an Apoenzyme) before enzyme-catalyzed reactions can occur. Vitamin antagonists (or antimetabolites) function by:- (1) preventing coenzyme formation, (2) competing with the vitamin coenzyme for a site on the protein portion of the enzyme, (3) competing with a compound (whose transformation is catalyzed by the enzyme) for the active center on the enzyme, or (4) inactivating an already formed coenzyme. Functions:- the B-vitamin coenzymes function in enzyme systems that transfer certain groups between molecules; as a result, specific proteins, fats, and carbohydrates are formed and may be utilized to produce body tissues (including blood cells) or to store or release energy. The pantothenic acid coenzyme functions in the Krebs tricarboxylic acid (or citric acid) cycle, which interconnects carbohydrate, fat, and protein metabolism; this coenzyme (coenzyme A) acts at the hub of these reactions and thus is an important molecule in controlling the interconversion of fats, proteins, and carbohydrates and their conversion into metabolic energy. Thiamine (B_1) and pyridoxine (B_6) coenzymes control the conversion of carbohydrates and proteins respectively into metabolic energy during the citric acid cycle. Nicotinic acid (niacin) and riboflavin (B_2) coenzymes facilitate the transfer of hydrogen ions or electrons (negatively charged particles), which occurs during the reactions of the citric acid cycle. All of these coenzymes also function in transfer reactions that are involved in the synthesis of structural compounds; these reactions are not part of the citric acid cycle. Although vitamin C (ascorbic acid) participates in some enzyme-catalyzed reactions, it has not yet been established that the vitamin is a coenzyme. Its function probably is related to its properties as a strong reducing agent (i.e. it readily gives electrons to other molecules). Metabolism:- the water-soluble vitamins are absorbed in the animal intestine, pass directly to the blood, and are carried to the tissues in which they will be utilized. Vitamin B_{12} requires a substance known as Intrinsic Factor For Absorption. Some of the B vitamins can occur in forms that cannot be used by an animal. Most of the nicotinic acid in some cereal grains (Wheat, Corn, Rice, Barley, Bran), for example, is bound to another substance, and the complex is called Niacytin; this compound is not absorbed in the animal intestine. Biotin can be bound by avidin, which is found in raw egg white; this complex cannot be absorbed or broken down by digestive-tract enzymes, and thus the biotin cannot be utilized. In animal products (e.g., meat), biotin, vitamin B_6, and folic acid are bound to other molecules to form complexes or conjugated molecules; although none is active in the complex form, the three vitamins normally are released from the bound forms by the enzymes of the intestinal tract (for biotin and vitamin B_6) or in the tissues (for folic acid) and thus can be utilized. The B vitamins are distributed in most metabolizing tissues of plants and animals. Water-soluble vitamins usually are excreted in the urine of man. Thiamine (B_1), riboflavin (B_2), pyridoxine (B_6), ascorbic acid (C), pantothenic acid, and biotin appear in urine as free vitamins (rather than as coenzymes); however, little free nicotinic acid is excreted in the urine. Products (also called Metabolites) that are formed during the metabolism of thiamine, nicotinic acid, and pyridoxine also appear in the urine. Urinary metabolites of biotin, riboflavin, and pantothenic acid also are formed, although they have not yet been characterized. Excretion of these vitamins (or their metabolites) is low when intake is just sufficient for proper body function. If intake begins to exceed minimal requirements, excess vitamins are stored in the tissues. Tissue storage capacity is limited, however, and, as the tissues become saturated, the rate of excretion increases sharply. This knowledge is valuable in establishing the nutritional status of an individual with respect to the vitamins. Unlike the other water-soluble vitamins, however, vitamin B_{12} is excreted solely in the feces. Some folic acid and biotin also are normally excreted in this way. Although fecal excretion of water-soluble vitamins (other than vitamin B_{12}, folic acid, and biotin) occurs, their source probably is the intestinal bacteria (which synthesize the vitamins), rather than vitamins that have been

eaten and utilized by an animal. The water-soluble vitamins generally are not considered toxic if taken in excessive amounts. There is, however, one exception in man; large amounts (50–100 milligrams) of nicotinic acid produce dilation of blood vessels; in larger amounts, the effects are more serious and may result in impaired liver function. Thiamine given to animals in amounts 100 times the requirement (i.e. about 100 milligrams) can cause death from respiratory failure. Therapeutic doses (100–500 milligrams) of thiamine have no known toxic effects in man (except rare instances of anaphylactic shock in sensitive individuals). There is no known toxicity for any other B vitamins. Biochemistry Of Fat-Soluble Vitamin Groups:- the four fat (lipid) soluble vitamin groups are A, D, E, and K; they are related structurally in that all have as a basic structural unit of the molecule a five-carbon isoprene segment. Each of the lipid-soluble vitamin groups contains several related compounds that have biological activity. The active forms and the accepted nomenclature of individual vitamins in each vitamin group are given in Table 2. The potency of the active forms in each vitamin group varies, and not all of the active forms now known are available from dietary sources; i.e. some are produced synthetically. The characteristics of each lipid-soluble vitamin group are discussed below. Principal Characteristics:- Active Forms Of Biological Importance:- Vitamin A Group:- ten carotenes, colored molecules synthesized only in plants, show vitamin A activity (i.e. function like vitamin A); however, only the alpha- and beta-carotenes and cryptoxanthin are important to man, and beta-carotene is the most active. Retinol (vitamin A alcohol) is considered the primary active form of the vitamin, although retinal, or vitamin A aldehyde, is the form involved in the visual process in the retina of the eye. A metabolite of retinol with high biological activity may be an even more direct active form than retinol. The ester form of retinol is the storage form of vitamin A; presumably, it must be converted to retinol before it is utilized. Retinoic acid is a short-lived product of retinol; only retinoic acid of the vitamin A group is not supplied by the diet. Vitamin D Group:- although about 10 compounds have vitamin D activity, the two most important ones are vitamins D_2 (or ergocalciferol) and D_3 (or cholecalciferol). Vitamin D_3 represents the dietary source, while vitamin D_2 occurs in yeasts and fungi. Both can be formed from their respective provitamins by ultraviolet irradiation; in man and other animals the provitamin (7-dehydrocholesterol), which is found in skin, can be converted by sunlight to vitamin D_3 and thus is an important source of the vitamin. Both vitamins D_2 and D_3 can be utilized by the rat and man; however, chicks cannot use vitamin D_2 effectively. The form of the vitamin probably active in man is 1, 25-di-hydroxycholecalciferol. Vitamin E Group:- the tocopherols are a closely related group of biologically active compounds that vary only in number and position of methyl (i.e. $-CH_3$) groups in the molecule; however, these structural differences influence the biological activity of the various molecules. The active tocopherols are named in order of their potency; i.e. alpha-tocopherol is the most active. Some metabolites of alpha-tocopherol (e.g., alpha-tocopherolquinone, alphatocopheronolactone) have activity in some mammals (e.g., rats, rabbits); however, these metabolites do not support all the functions attributed to vitamin E. Vitamin K Group:- Vitamin K_1 (20) is synthesized by plants; the members of the vitamin K_2 (30) series are of microbial origin. Vitamin K_2 (20) is the important form in mammalian tissue; all other forms are converted to K_2 (20) from vitamin K_3. Since vitamin K_3 does not accumulate in tissue, it does not furnish any dietary vitamin K. Vitamins K_4, K_5, K_6, and K_7 have been synthesized and have vitamin K activity, but they are not found in nature. Units Of Activity:- for many years, the unit of measurement for the activity of vitamins A, D, and E has been the International Unit (IU); this is analogous with the United States Pharmocopeia unit (USP), which is based on a measured biological activity. The weight equivalents of these vitamins are found in Table 3. Vitamin K activity is expressed only in micrograms. The activity of fat-soluble vitamins now is given on a weight basis (as is that of water-soluble vitamins) because pure vitamin preparations are available for use as references. Functions:- the vitamin A group has at least one known function. In the retina of the eye, retinal is combined with a protein called Opsin; the complex molecules formed as a result of this combination and known as Rhodopsin (or Visual Purple) are involved in dark vision. Other metabolic functions of vitamin A have not yet been defined with certainty. The vitamin D group is required for growth (especially bone growth or calcification). The vitamin E group also is necessary for normal animal growth; without these tocopherols, animals are not fertile and develop abnormalities of the central nervous system, muscles, and organs (especially the liver). The vitamin K group is required for normal metabolism, including the conversion of food into cellular energy in certain biological membranes; vitamin K also is necessary for the proper clotting of blood. Knowledge concerning the functions of the fat-soluble vitamins is not yet so extensive as that for the water-soluble ones. It appears, however, that most vitamins may be concerned with proper enzyme function. Metabolism:- the fat-soluble vitamins are transported primarily by lymph from the intestines to the circulating blood. Bile salts are required for efficient absorption of fat-soluble metabolites in the intestine; anything that interferes with fat absorption, therefore, also inhibits absorption of the fat-soluble vitamins. Since a fatty acid (preferentially palmitic acid) is added to the vitamin A alcohol (retinol) molecule before it is transported by the lymph, this ester form predominates in the bloodstream during digestion. Vitamins D, E, and K do not require the addition of a fatty acid molecule for absorption. Small amounts of vitamin A alcohol (and possibly vitamin K) may be absorbed directly into the bloodstream; however, both vitamins A and D are bound to a protein during transport in the bloodstream. Larger quantities of the fat-soluble vitamins than of water-soluble ones can be stored in the body. Vitamins A, D, and K are stored chiefly in the liver, with smaller amounts stored in other soft body tissues; however, most of the stored vitamin E is found in body fat, although large amounts also occur in the uterus of females and testis of males. The various forms of vitamin E are stored in tissues in different amounts; alpha-tocopherol is stored in higher concentrations than are the other forms. More vitamin A is stored (in ester form) than any other fat-soluble vitamin. Before its release in the bloodstream, the ester form of vitamin A is converted to retinol. In animals in the postabsorptive stage, retinol is the predominant form in the blood. Excessive intakes of both vitamins A and D may produce toxicity (or hypervitaminosis A or D). Among natural foods, only seal liver and polar bear liver are known to contain sufficiently high concentrations of vitamin A to produce toxic effects. Toxicity of both vitamin A and vitamin D can easily occur, however, if pharmaceutical vitamin preparations are used in excess. Toxic levels of vitamin A exceed the normal requirement by 100 times; i.e. about 500 000 IU each day for a period of several months. Toxicity in infants may occur with doses of 18 000 to 60 000 IU per day. Excessive doses of the natural vitamins K_1 and K_2 have no obvious effects except that resistance may develop to therapy with dicumarol compounds (anticoagulants); however, vitamin K_3 is toxic to newborn infants if given in large doses. Vitamin E, even if given in large excess of the normal requirement, has no apparent obvious adverse effects. Vitamin groups E and K belong to a class of organic compounds called Quinones. These substances are changed to sugar-like substances known as Alpha-Lactones, which are excreted in the urine (probably as carbohydrates called Glucuronides). Some vitamin K_1 also is excreted in the bile and thus appears in the feces. Vitamin A is broken down and excreted as a glucuronide and a number of compounds in bile (and, therefore, feces) and urine. Vitamin D and its breakdown products are excreted only in the feces. Vitamin-Like Substances:- there are a number of organic compounds that, although related to the vitamins in activity, cannot be defined as true vitamins; normally they can be synthesized by man in adequate amounts and therefore are not required in the diet. These substances usually are classified with the B vitamins, however, because of similarities in biological function or distribution in foods. Choline:- choline appears to be an essential nutrient for a number of animals (including some birds) and microorganisms that cannot synthesize adequate quantities to satisfy their requirements. Choline is a constituent of an important class of lipids called Phospholipids, which form structural elements of cell membranes; choline is a component of the acetylcholine molecule, which is important in nerve function. Choline also serves as a source of methyl groups ($-CH_3$ groups) that are required in various metabolic processes. The effects of a dietary deficiency of choline itself can be alleviated by other dietary compounds that can be changed into choline. Choline also functions in the transport of fats from the liver; for this reason, choline may be called a Lipotropic Factor. A deficiency of choline in the rat results in an accumulation of fat in the liver. Choline deficiency symptoms vary among species; it is not yet known if choline is an essential nutrient for man since a dietary deficiency has

not been demonstrated. Myoinositol:- the biological significance of myoinositol (also previously known as Meso-Inositol) has not yet been established with certainty. It is present in large amounts (principally as a constituent of phospholipids) in man. Inositol is a carbohydrate that closely resembles glucose in structure; inositol can be converted to phytic acid, which is found in grains and forms an insoluble (and thus unabsorbable) calcium salt in the intestines of mammals. Inositol has not yet been established as an essential nutrient for man; however, it is a required factor for the growth of some yeasts and fungi. Para-Aminobenzoic Acid:- para-aminobenzoic acid (abbreviated to PABA) is required for the growth of several types of microorganisms; however, a dietary requirement by vertebrates has not yet been shown. The antimicrobial sulfa drugs (sulfanilamide and related compounds) inhibit the growth of bacteria by competing with PABA for a position in a coenzyme that is necessary for bacterial reproduction. Although a structural unit of folic acid, PABA is not considered a vitamin. Carnitine:- carnitine (originally called Vitamin B_T) is essential for the growth of mealworms. The role of carnitine in all organisms is associated with the transfer of fatty substances (e.g., fatty acids) from the bloodstream to active sites of fatty acid oxidation within muscle cells. Carnitine, therefore, regulates the rate of oxidation of these acids; this function may afford means by which a cell can rapidly shift its metabolic patterns (e.g., from fat synthesis to fat breakdown). Synthesis of carnitine occurs in insects and in higher animals; therefore, it probably should not be considered a true vitamin. Lipoic Acid:- lipoic acid has a coenzyme function similar to that of thiamine. Although it is apparently an essential nutrient for some microorganisms, no deficiency in mammals has yet been observed; therefore, lipoic acid is not considered a true vitamin. Bioflavinoids:- the bioflavinoids once were thought to prevent scurvy and were designated as vitamin Pc, but additional evidence refuted this claim. Vitamin:- the modern term that is descended from the original phrase ‘Vital Amine’ (or ‘Vitamine’), which was coined by a Polish biochemist Casimir Funk (1884–1967) in 1912. Most vitamins are actually ‘families’ of chemically-related isomers (i.e. vitamers) which cause same or similar metabolic impact (benefit) in most animals (including humans) that consume those vitamins. Some compounds are vitamins for certain species of animals, but are not for certain other species. In general, a vitamin is an organic compound required in tiny amounts (for the optimal growth, proper biological functioning and maintenance of health of an organism). Vitamins are commonly classified into two categories, the fat soluble and the water soluble. Vitamins A, D, E, and K are fat soluble whereas vitamin C (ascorbic acid) and members of the vitamin B complex group are water soluble. In general, the vitamins play catalytic and regulatory roles in the body’s metabolism. Among the water-soluble vitamins, the B vitamins apparently function as coenzymes (nonprotein parts of enzymes). Vitamin C’s coenzyme role, if any, has not been established. Part of the importance of vitamin C to the body may arise from its strong antioxidant action. The functions of the fat-soluble vitamins are less well understood. Some of them, too, may contribute to enzyme activity; and others are essential to the functioning of cellular membranes (on surface of cells). / Польский биохимик Кашимир Функ (Casimir Funk; 1884–1967) в 1912. Витамин:- органическое вещество, образующееся в животном организме или поступающее с пищей в очень незначительных количествах, но абсолютно необходимое для нормального обмена веществ и жизнедеятельности. Под Витаминами, от Латинского слова Vita, означающее Жизнь, понимается группа органических соединений разнообразной химической природы, необходимых для питания человека, животных и других организмов в ничтожных количествах по сравнению с основными питательными веществами (белками, жирами, углеводами и солями), но имеющих огромное значение для нормального обмена веществ и жизнедеятельности. Первоисточником витаминов служат главным образом растения (смотрите Витаминоносные Растения). Человек и животные получают витамины непосредственно с растительной пищей или косвенно – через продукты животного происхождения. Важная роль в образовании витаминов принадлежит также микроорганизмам. Например, микрофлора, обитающая в пищеварительном тракте жвачных животных, обеспечивает их витаминами группы В. Витамины поступают в организм животных и человека с пищей, через стенку желудочно-кишечного тракта, и образуют многочисленные производные (например, эфирные, амидные, нуклеотидные и другие), которые, как правило, соединяются со специфическими белками и образуют многие ферменты, принимающие участие в обмене веществ. Наряду с ассимиляцией в организме непрерывно совершается диссимиляция витаминов, причём продукты их распада (а иногда и малоизменённые молекулы витаминов) выделяются наружу. Недостаточность снабжения организма витаминами ведёт к его ослаблению (смотрите Витаминная Недостаточность), резкий недостаток витаминов – к нарушению обмена веществ и заболеваниям – авитаминозам, которые могут окончиться гибелью организма. Авитаминозы могут возникать не только от недостаточного поступления витаминов, но и от нарушения процессов их усвоения и использования в организме. Основоположник учения о витаминах Русский врач педиатр Николай Иванович Лунин (1853–1937) установил в 1880, что при кормлении белых мышей только искусственным молоком, состоящим из казеина, жира, молочного сахара и солей, животные погибают. Следовательно, в натуральном молоке содержатся и другие вещества, незаменимые для питания. В 1912 Польский биохимик, врач Кашимир Функ (1884–1967), предложивший само название Витамин, обобщил накопленные к тому времени экспериментальные и клинические данные и пришёл к выводу, что такие заболевания, как цинга, рахит, пеллагра, бери-бери, – болезни пищевой недостаточности, или авитаминозы. С этого времени наука о витаминах (Витаминология) начала интенсивно развиваться, что объясняется значением витаминов не только для борьбы со многими заболеваниями, но и для познания сущности ряда жизненных явлений. Метод обнаружения витаминов, применённый Луниным (содержание животных на специальной диете – вызывание экспериментальных авитаминозов), был положен в основу исследований. Было выяснено, что не все животные нуждаются в полном комплексе витаминов, отдельные виды животных могут самостоятельно синтезировать те или иные витамины. В то же время многие плесневые и дрожжевые Грибы и различные Бактерии развиваются на искусственных питательных средах только при добавлении к этим средам вытяжек из растительных или животных тканей, содержащих витамины. Таким образом, витамины необходимы для всех живых организмов. Изучение витаминов не ограничивается обнаружением их в естественных продуктах с помощью биологических тестов и другими методами. Из этих продуктов получают активные препараты витаминов, изучают их строение и, наконец, получают синтетически. Исследована химическая природа всех известных витаминов. Оказалось, что многие из них встречаются группами по 3–5 и более родственных соединений, различающихся деталями строения и степенью физиологической активности. Было синтезировано большое число искусственных аналогов витаминов с целью выяснения роли функциональных групп. Это способствовало пониманию действия витаминов. Так, некоторые производные витамины с замещёнными функциональными группами оказывают на организм противоположное действие, по сравнению с витаминами, вступая с ними в конкурентные отношения за связь со специфическими белками при образовании ферментов или с субстратами воздействия последних (смотрите Антивитамины). Витамины имеют буквенные обозначения, химические названия или названия, характеризующие их по физиологическому действию. В 1956 принята единая классификация витаминов, которая стала общеупотребительной. Наличие химически чистых витаминов дало возможность подойти к выяснению их роли в обмене веществ организма. Витамины либо входят в состав ферментов, либо являются компонентами ферментативных реакций. При отсутствии витаминов в организме нарушается деятельность ферментных систем, в которых они участвуют, а следовательно, – и обмен веществ. Известно несколько сот ферментов, в состав которых входят витамины, и огромное количество катализируемых ими реакций. Многие витамины – преимущественно участники процессов распада пищевых веществ и освобождения заключённой в них энергии (витамины B_1, B_2, PP и другие). Участвуют они и в процессах синтеза:- B_6 и B_{12} – в синтезе аминокислот и белковом обмене, B_3 (пантотеновая кислота) – в синтезе жирных кислот и обмене жиров, B_c (фолиевая кислота) – в синтезе пуриновых и пиримидиновых оснований и многих физиологически важных

соединений – ацетилхолина, глутатиона, стероидов и других Менее изучено действие жирорастворимых витаминов, однако несомненно их участие в построении структур организма, например, в образовании костей (витамин D), развитии покровных тканей (витамин A), нормальном развитии эмбриона (витамин E и другие). Таким образом, витамины имеют огромное физиологическое значение. Выяснение физиологической роли витаминов позволило использовать их для витаминизации продуктов питания, в лечебной практике и в животноводстве. Особенно широко стали применяться витамины после освоения их промышленного синтеза. Смотрите также Витаминные Препараты. Получение Витаминов:- Витамины получают главным образом синтетически и лишь в некоторых случаях отдельные стадии в цепи синтеза выполняются биологическими способами. Производство концентратов витаминов из продуктов растительного или животного происхождения почти полностью потеряло своё значение. Получение витаминов относится к тонкому органическому многостадийному синтезу. Химическими методами синтезируют следующие витамины:- A, B_1, B_2, B_3, B_6, B_c, C, D_2, D_3, E, K, PP, а B_{12} – ферментативными методами микробиологического синтеза. Ферментацией пользуются также на одной из стадий синтеза витамина C. Этот витамин в виде индивидуального кристаллического вещества высокой степени чистоты образуется при восстановлении D-глюкозы в D-сорбит. Последний ферментативно окисляют в L-сорбозу, которую после ряда операций превращают в витамин C (I). Витамин A (ретинол) синтезируют, исходя из псевдоионона (II), который циклизуют в b-ионон и затем через ряд сложных операций превращают в ретинол (III). Псевдоионон служит также исходным сырьём для многостадийного синтеза изофитола, используемого при получении чистого витамина E (a-токоферилацетата, IV). Витамин K_3 (2-метил-1,4-нафтохинон) получают окислением 2-метилнафталина. Витамином K_3 пользуются в медицинской практике в виде растворимой в воде натриевой соли бисульфитного производного (V). Производство витамина B_1 (тиамина, VI) основано на конденсации 2-метил-4-амино-5-хлор (бром) метилпиримидина с 4-метил-5-b-оксиэтилтиазолом. Кофермент витамина B_1 – кокарбоксилаза (VII), или дифосфорный эфир тиамина, применяемый для лечения заболеваний сердца, получают фосфорилированием тиамина с последующей очисткой на ионообменных смолах и кристаллизацией. Витамин B_2 (рибофлавин, VIII) образуется при культивировании Eremothecium Ashbyii и других микроорганизмов без выделения в виде сухой биомассы (с использованием только для кормления сельскохозяйственных животных), а синтетический рибофлавин (применяемый в медицине) получают в виде кристаллического продукта деструктивным окислением D-глюкозы (из кукурузного крахмала) в D-арабоновую кислоту и рядом других операций превращают в конечный продукт – жёлто-оранжевые кристаллы высокой степени чистоты. Важное производное рибофлавина – его кофермент рибофлавин-5”-фосфат натрия (IX, R = Na), применяемый для инъекций, получают фосфорилированием рибофлавина, а другой кофермент – ФАД (IX, R – остаток аденозин-5”-фосфата) получают конденсацией рибофлавина-фосфата и аденозин-5”-фосфата. Витамин B_6 (пиридоксин, X, а) синтезируют, конденсируя метоксиацетил-ацетон с цианоксусным эфиром в присутствии аммиака в 2-метил-4-метоксиметил-5-циан-6-оксипиридин, который подвергают нитрованию, затем рядом операций превращают в пиридоксин. Известен также и другой способ получения пиридоксина – через 4-метил-5-пропоксиоксазол диеновым синтезом с формалем бутен-2-диола-1,4. Другими формами B_6 являются пиридоксол (X, б) и пиридоксамин (X, в). Витамин B_c (фолиевую кислоту, XI) синтезируют одностадийной конденсацией 2,4,5-триамино-6-оксипиримидина, 1,1,3-трихлорацетона и n-аминобензоил-L-глутаминовой кислоты. Витамин PP (никотиновую кислоту, XII) получают окислением b-пиколина (выделяемого из каменноугольного дёгтя), ресурсы которого ограниченны, а также окислением хинолина или 2-метил-5-этилпиридина. Для медицинских целей пользуются, кроме никотиновой кислоты, никотинамидом (XIII). Витамин B_3, оптически активная D-пантотеновая кислота $HOCH_2C\ (CH_3)_2CH\ (OH)\ CONH\ (CH_2)_2COOH$, для медицинских целей применяется в виде кальциевой соли. Для нужд животноводства нет необходимости в разделении на промежуточных ступенях синтеза рацемата пантолактона на оптические антиподы. Синтез рацемического пантотената кальция состоит в альдольной конденсации изобутираля и формальдегида с последующим превращением в пантолактон, затем в его конденсации с b-аланином, приводящей к образованию конечного продукта. Витамин B_{12} (цианкобаламин), вещество весьма сложного строения, получают с помощью микробиологического синтеза с Propionbacterium Shermanii на углеводо-белковых средах – отходах свёклосахарного производства (мелассе). Культивирование проводят в присутствии 5,6-диметил-бензимидазола. Витамин выделяют в кристаллическом виде. Имеет значение также технология брожения термофильными метанобразующими Бактериями при 55–57 °C барды ацетоновых и спиртовых заводов, работающих на мелассе. Витамин D_2 (эргокальциферол), имеющий также весьма сложное строение, выделяют из пекарских дрожжей в виде эргостерина, который затем подвергают фотоизомеризации. Для медицинских целей эргокальциферол очищают от побочных веществ, образующихся при фотоизомеризации. Витамин D_3 (холекаль-циферол) получают из холестерина – продукта мясной промышленности. Его бензоилируют, затем подвергают бромированию и другим операциям (смотрите также Витаминные Препараты и Витаминная Промышленность). Витамины В Животноводстве:- Значение витаминов в кормлении сельскохозяйственных животных велико. При их недостатке или отсутствии задерживается рост и развитие молодняка, снижается сопротивляемость организма различным заболеваниям, уменьшается продуктивность. С недостаточным витаминным питанием у сельскохозяйственных животных нередко связаны яловость, аборты, низкая плодовитость. Потребность в витаминах зависит от вида животных, возраста, физиологического состояния, продуктивности, условий кормления и содержания, а также от запаса витаминов в организме. Особенно велика эта потребность у молодняка, беременных и лактирующих самок, высокопродуктивных и племенных животных. Каротина требуется (милиграммов (мг) на 100 килограммов (кг) живой массы в сутки):- коровам стельным 60–80, лактирующим 50–60, быкам-производителям 70–100, овцам суягным и подсосным 20–40, баранам 40–60, свиноматкам супоросным и подсосным 20–30, хрякам 50–60, рабочим лошадям 20–25, племенным 40–50; витамина D_2 или D_3 (ИЕ на 100 кг живой массы в сутки):- крупному рогатому скоту 1 000–1 500, овцам 1 000, свиньям 1 000. Витамины группы В жвачным животным не нормируют, так как они почти полностью покрывают свою потребность в витаминах этой группы благодаря способности Бактерий рубца синтезировать их. В рационе свиней нормируют (мг на 100 кг живой массы) витамина B_2 – 10, B_{12} – 0.04, PP – 50–75. Потребность в витаминах для птицы рассчитывается на тонну (т) концентратов:- витамина A – 4.5 г, D_2 – 30 миллионов ИЕ, D_3 – 1 миллион ИЕ, B_{12} – 12 мг, PP – 15 мг, B_2 – 4 мг, пантотеновой кислоты – 10 г, холин-хлорида – 1 000 г. Основной источник витаминов для животных – корма. Поэтому для правильной организации кормления необходимо знать наряду с потребностью в витаминах содержание их в кормах. Нормирование витаминного питания животных осуществляют подбором кормов, обогащением рационов витаминными кормами или концентратами витаминов, выпускаемыми промышленностью. В состав комбикормов, выпускаемых промышленностью, включают все необходимые витамины.

VITAMIN E = ВИТАМИН E (или ВИТАМИН И.) – A term Vitamin E refers to a group of related, naturally-occurring compounds consisting of Tocopherol and Tocotrienol ‘families’. It is a fat-soluble vitamin with antioxidant properties (i.e. helps prevent lipids in body from breaking-down). Vitamin E is especially effective at preventing oxidation of low-density lipoproteins (so-called ‘Bad Cholesterol’), whose oxidation products (e.g., beta hydroxycholesterol) can be deposited onto the interior walls of blood vessels (e.g., arteries) in the form of plaque.

VITELLINE = ВИТЕЛЛИН – Vitelline:- resembling the yolk (or yolk sac) of an egg or embryo, or to yolk-producing organs, especially in yellow color. From Latin Vitellus. / , от Латинского слова Vitellus, означающее Желток. Вителлин белковое вещество,

содержащее фосфор и относящееся к группе нуклео-альбуминов. Вителлин открыт впервые Дени, извлекается чаще всего из желтка птичьих яиц, пресмыкающихся и рыб. Их характеристической реакцией служит их расщепление под влиянием горячей воды, пищеварения и кислот и так далее на альбуминоидные вещества и лецитины. Растительный вителлин относится к группе глобуминов, то есть белковых веществ, не растворимых в воде, но растворимых в водных растворах поваренной соли или хлористого аммония. Лучшим объектом для получения растительного вителлина служат семена жёлтого лупина. Мелко измельчённые семена обливаются 10-процентным раствором одной из названных солей и через сутки фильтруются. Густой фильтрат подвергается диализу. Через 2–3 дня вителлин осаждается внутри диализатора в виде очень клейкой, тягучей массы, дающей все реакции на белковые вещества.

VITICULTURE = ВИТИКУЛЬТУРА (или ВИНОГРАДАРСТВО) – Viticulture is the scientific study of grapes and is practiced nearly everywhere in the world. The common grape, vitis vinifera, is highly adaptable to a wide variety of environments, so grapes grow on nearly every continent. The viticulturist helps maximize yield and quality by monitoring pests and diseases, irrigation, fertilization, and canopy management. Viticulture holds such prominence because proper vineyard management provides the basis for which wine making can begin. Viticulturists work closely with winemakers developing and selecting new varieties, deciding when to prune during the winter months, and even harvesting the grapes. The history of viticulture closely follows the history of wine making and has been performed for at least 7 000 years. Viticulture practices were developed as early as the Phoenicians and later used in Carthage. The first major text outlining the techniques and science of viticulture was a two-volume book appearing around 500 BC. Such was the Roman love for wine and the respect for viticulture that they produced a twelve-volume text about the science around 65 AD. Early viticulturists domesticated grapes and developed pruning and cultivating techniques to maximize yield and enhance the flavor. They also developed the staking or trellis systems for growing grapes that are still in use today. By the Middle Ages, Catholic monks took over the practice and were highly respected for their knowledge of viticulture at that time. They were instrumental in breeding and selecting grape varieties that could thrive in the cold, damp environment of northern Europe. Modern viticulturists still utilize these early techniques and still play an extensive role in the wine making process. Viticulture is the science and practice of growing grapes. Viticulture is the cultivation or culture of grapes especially for wine making. / Под Витикультурой, от Латинских слов Vitis, означающее Лоза, и Cultura, означающее Возделывание, понимается виноградарство, разведение Винограда. Виноградарство:- (1) отрасль сельского хозяйства, возделывание Винограда. Виноградарство обеспечивает население свежим и сушёным (смотрите Изюм, Кишмиш, Коринка) Виноградом, а винодельчество (смотрите Виноделие) и консервную промышленность сырьём. В соответствии с этим виноградарство имеет четыре производственных направления:- (i) Столовое Виноградарство – производство свежего Винограда для местного потребления, вывоза и хранения. (ii) Виноградарство как сырьевая база производства сушёного Винограда – выращивание кишмишно-изюмных сортов. (iii) Виноградарство как сырьевая база винодельческой промышленности – возделывание винных сортов Винограда для обеспечения сырьём заводов, специализированных на производстве разных типов вина, шампанских и коньячных виноматериалов. (iv) Виноградарство как сырьевая база консервной промышленности – производство сырья для соков (в том числе бекмеса), компотов, варенья, маринада и других безалкогольных продуктов. Виноградарство отличается интенсивностью хозяйства, требует больших капиталовложений и значительных затрат труда (например, в бывшем Союзе Советских Социалистических Республик (СССР) на 1 гектар (га) плодоносящего виноградника затрачивается от 200 до 300 человеко-дней в год). Виноградарство – доходная отрасль. В ряде хозяйств СССР, где виноградники занимают всего лишь 10–15% общей земельной площади, доход от виноградарства составляет 50–80% общего дохода хозяйства. Виноград можно возделывать на землях, непригодных под другие культуры, например, на каменистых почвах и известняках, на песках и слабо засолённых почвах, на крутых склонах (на песках он выполняет роль мелиоративной культуры). Виноградарство зародилось в древности. В энеолите и бронзовом веке в культуру был введён Дикий Европейский Виноград. На территории Закавказья, Средней Азии и прилегающих районов Передней Азии виноградарство было известно за несколько тысячелетий до Нашей Эры. В 1968 мировая площадь под виноградниками составляла около 10 миллионов га. В СССР в 1969 площадь виноградных насаждений составила 1 079 тысяч га, валовой сбор Винограда 4 181 тысяч тонн (т). Основные районы виноградарства в СССР (1969, тысяч га):- Украинская ССР – 303, Молдавская ССР – 239, РСФСР – 163, Азербайджанская ССР – 119, Грузинская ССР – 113, Узбекская ССР – 55, Армянская ССР – 37, Казахская ССР – 18, Таджикская ССР – 17, Туркменская ССР – 9, Киргизская ССР – 6. Промышленное виноградарство в основном развито в Южных районах страны. Северная граница его проходит через Киев, Саратов, Семипалатинск, Уссурийск. Приусадебное виноградарство проникает значительно севернее (Москва, Козьмодемьянск, Барнаул). Лучшими районами виноградарства в СССР по качеству производимых столового винограда и вин считаются Юг Украинской ССР (Крымская Область), Молдавская ССР, РСФСР (Северный Кавказ), республики Закавказья и Средней Азии. В СССР различают виноградарство:- укрывное (42%, по данным на 1968) и неукрывное (58%), орошаемое (30%) и неорошаемое, или богарное (70%), корнесобственное (55%) и привитое на морозоустойчивых и филлоксероустойчивых (45%) подвоях. Виноградарство развито в совхозах и других государственных хозяйствах (47% на 1969), колхозах (40%) и на приусадебных участках (13%). Большое значение для получения продукции отличного качества при разных типах виноградо-винодельческого производства имеет специализация районов виноградарства. В СССР около 85% общей площади виноградников занимают винные сорта Винограда, в том числе 13% – гибриды прямые производители (сорта, полученные путём межвидовой гибридизации Американских Видов и Европейского Винограда), 12% – столовые сорта и 3% – кишмишно-изюмные. Всего известно около 4 000 сортов Европейского Винограда, в СССР – около 2 000, из них более 1 500 местных. При правильной организации специализированных хозяйств виноградарство успешно сочетается с другими отраслями. В виноградарстве применяется механизация многих трудоёмких работ:- террасирования, плантажа, посадки, рыхления междурядий, внесения удобрений, укрывания и открывания кустов, установки шпалер (искусственных опор), сбора лозы, борьбы с вредителями и болезнями винограда и другие. Виноградарские специализированные совхозы и колхозы представляют собой крупные (до 3 000 га виноградников) механизированные социалистические хозяйства. Механизация позволяет значительно снизить себестоимость продукции и увеличить рентабельность культуры Винограда. В основных районах виноградарства СССР виноградарские совхозы находятся в ведении республиканских министерств сельского хозяйства и пищевой промышленности. (2) Виноградарство:- наука (раздел растениеводства) о биологических особенностях Винограда и способах его возделывания. Состоит из следующих разделов:- (i) общее виноградарство, изучающее вопросы биологии, экологии и агротехники винограда; и (ii) частное виноградарство, разрабатывающее агротехнику Винограда в различных почвенно-климатических условиях, для разных производственных направлений, а также при выращивании Винограда в теплицах; ампелография (наука о сортах и видах Винограда); селекция Винограда (выведение новых сортов). Научно-исследовательскую работу по виноградарству и виноделию проводят Всесоюзный Научно-Исследовательский Институт Виноделия и Виноградарства ‘Магарач’, Украинский Научно-Исследовательский Институт Виноградарства и Виноделия, Всероссийский Научно-Исследовательский Институт Виноградарства и Виноделия, республиканские и зональные научно-исследовательские институты садоводства и виноградарства с сетью опытных станций и опорных пунктов, а также Всесоюзный Научно-Исследовательский Институт Растениеводства имени Николая Ивановича Вавилова (ВИР), кафедры сельскохозяйственных и пищевых институтов. Научно-исследовательскую работу по борьбе с вредителями и болезнями

Винограда ведут специальные отделы при научно-исследовательских учреждениях по виноградарству, станции по защите растений, а также Всесоюзная Научно-Исследовательская Противофиллоксерная Станция, Всесоюзный Научно-Исследовательский Институт Защиты Растений (ВИЗР). Агрономов-виноградарей выпускают сельскохозяйственные институты, специалистов средней квалификации – техникумы и училища по виноградарству и виноделию. Имеются школы, готовящие техников виноградарства и виноделия. За годы Советской власти виноградарство достигло больших успехов. Важнейшей работой, выполненной ампелографами страны под руководством института Магарач, является создание 10-томного труда Ампелография СССР (1946–70), в котором описано 2 600 сортов Винограда. Селекционеры вывели много сортов Винограда, из которых свыше 30 районированы по Советскому Союзу (Мускат Узбекистанский, Октябрьский, Победа, Первомайский и другие – сорта селекции ВИР; Армения, Арагаци, Токун и другие – сорта Армянского Научно-Исследовательского Института Виноградарства, Виноделия и Плодоводства; Фиолетовый ранний, Саперави Северный и другие – сорта Всероссийского Научно-Исследовательского Института Виноградарства и Виноделия; Рубиновый Магарача, Ранний Магарача – сорта Всесоюзного Научно-Исследовательского Института Виноделия и Виноградарства Магарач, и другие). В ряде научно-исследовательских учреждений ведут работу по выведению морозоустойчивых, стойких к разным заболеваниям и вредителям сортов, отличающихся высокой транспортабельностью, лёжкостью, технологическими свойствами и так далее. Разработаны рекомендации по особенностям агротехники отдельных сортов применительно к различным районам возделывания Винограда. Издаются журналы Виноделие И Виноградарство СССР (с 1939), Садоводство, Виноградарство И Виноделие Молдавии (с 1946). Существует Международное Бюро Винограда И Вина, основанное в 1924 и объединяет 25 стран (в том числе СССР); проводит конгрессы, сессии, издаёт бюллетень.

VITIS VINIFERA = ВИТИС ВИНИФЭРА (или ВИНОГРАД НАСТОЯЩИЙ) – Vitis Vinifera:- in the context of wine grape vine species, Vitis Vinifers is a native grape vine of temperate growing regions in the Northern Hemisphere and a member of the family Vitaceae. There are between 5 000 to 10 000 different varietals of Vitis Vinifera, although not all are widely cultivated or used for wine production. Varietals of Vitis Vinifera account for the majority of commercially planted grapes more so than any other species. Vitis Vinfera varietals are used for wine, food (raisins), juice and for use in other foods. Vitis Vinifera is one of the oldest fruit crops, with seed evidence dating back to 4500 BC. Grapes from Vitis Vinifera were used to make wine as early as 2500 BC, although there is no detail of when or where the vine was first domesticated. The Vitis Vinifera vine is an active climber and can grow up to 60 feet if not pruned or trained. Vitis Vinifera produces both red and white varietal grapes that contain high amounts of sugar, tartaric and malic acids, with soft juicy flesh and high acid, making them excellent for wine production. Popular wine grape varietals of Vitis Vinifera include:- (a) Red Varietals:- (i) Pinot Noir; (ii) Cabernet Franc; and (iii) Cabernet Sauvignon. (b) White Varietals:- (i) Chardonnay; (ii) Riesling; and (iii) Pinot Gris for white varietals. See also Vinifera. Vitis Vinifera is common European Grape cultivated in many varieties; chief source of Old World wine and table grapes. Vitis Vinifera, the common grape vine, is a Species of Vitis, native to the Mediterranean region, central Europe, and Southwestern Asia, from Morocco and Portugal North to Southern Germany and East to Northern Iran. There are currently between 5 000 and 10 000 varieties of Vitis Vinifera grapes though only a few are of commercial significance for wine and table grape production. It is a liana growing to 35 yards (32 meters) in length, with flaky bark. The leaves are alternate, palmately lobed, 5–20 cm (2.0–7.9 in) long and broad. The fruit is a berry, known as a Grape; in the wild species it is 6 mm (0.24 in) diameter and ripens dark purple to blackish with a pale wax bloom; in cultivated plants it is usually much larger, up to 3 cm (1.2 in) long, and can be green, red, or purple (black). The species typically occurs in humid forests and streamsides. The wild grape is often classified as Vitis Vinifera Subsp. Sylvestris (in some classifications considered Vitis Sylvestris), with Vitis Vinifera Subsp. Vinifera restricted to cultivated forms. Domesticated vines have hermaphrodite flowers, but Subsp. Sylvestris is dioecious (male and female flowers on separate plants) and pollination is required for fruit to develop. The grape is eaten fresh, processed to make wine or juice, or dried to produce raisins. Cultivars of Vitis Vinifera form the basis of the majority of wines produced around the world. All of the familiar wine varieties belong to Vitis Vinifera, which is cultivated on every continent except for Antarctica, and in all the major wine regions of the world. / Европейско-Азиатский Вид Винограда (Vitis Vinifera L., Витис Винифэра – Виноград, Дающий Вино (в переводе с Латинского языка)), Вид Рода Vitis Европейского, Западноазиатского и Североафриканского происхождения. Подразделяется на два Подвида – Виноград Культурный (Vitis Vinifera Subsp. Sativa D.C.) и на Дикий Виноград (Vitis Vinifera L. Subsp. Silvestris Gmel.). Виноград Культурный – самый распространённый в мире, насчитывает десятки тысяч сортов, которые произрастают во всех регионах выращивания Винограда. Иногда, Виноград Культурный делят на 3 Группы:- Группу Западноевропейских сортов, Группу сортов бассейна Чёрного Моря и Группу Восточных сортов Винограда. Сорта Vitis Vinifera и их внутривидовые гибриды дают лучшее вино и самый качественный столовый Виноград. Среди лучших представителей винных сортов:- Каберне-Совиньон, Рислинг, Шардоне, Пино Нуар; столовых:- Карабурну, Паркент, Ред Глоуб, Халили, Хусайне, Ризамат. Но эти сорта неустойчивы к грибным заболеваниям, повреждаются вредителями и слабо устойчивы к морозам. Поэтому, одна из задач селекции Винограда:- выведение межвидовых гибридов, сочетающих качество плодов и одновременную устойчивость к неблагоприятным факторам, где сорта Европейско-Азиатского вида используются как носители качества. Виноград Дикий – естественно растёт во многих странах Европы (в поймах рек, в странах граничащих с Чёрным и Средиземным морями), в Закавказье, Средней Азии, Западной части Азии, Ближнем Востоке, Северной Африке. Мощная лиана, оплетающая кроны деревьев, грозди и ягоды мелкие, кисло-сладкие, чёрные. Качество плодов выше, чем у Американских Видов Винограда. Растения двудомные – цветки или мужские или функционально-женские. От Дикого Винограда произошёл Культурный Виноград. Виноград Дикий является исчезающим Видом. Витис Винифера (Vitis Vinifera) или Виноград Настоящий:- из Семейства Виноградных. Многолетняя лиана длиной 30–40 метров (м), однолетние побеги до 3–5 м. Побеги тонкие, сочленённого строения, в каждом узле развиваются листья, в пазухах – пасынковые и зимующие почки. Листья цельные, трёх-, пятилопастные, пильчатые, тёмно-зелёные. Цветки мелкие, зеленоватые, собраны в рыхлую метелку. Плоды – сочные ягоды, которые собраны в грозди. Культивируется на Черноморском побережье Кавказа, в Краснодарском и Ставропольском краях, в Ростовской Области, в Дагестане, в Крыму, Молдове, в Средней Азии. С лечебной целью используются плоды и листья Винограда. Плоды содержат сахар (глюкозу и фруктозу), флобафен, галловую кислоту, кверцитин, эним, гликозиды (монодельфинидин, дидельфинидин), кислоты (яблочную, кремневую, салициловую, фосфорную, винно-каменную, лимонную, янтарную, муравьиную и следы щавелевой), пектины, дубильные вещества, соли калия, магния, кальция, марганца, кобальта, железа, витамины B_1, B_2, B_6, B_{12}, A, C, PP, фолиевую кислоту, витамин K. В кожице виноградин – красящие и дубильные вещества, эфирное масло. В семенах обнаружены дубильные вещества, флобофен, лецитин, ванилин, жирное масло. В листьях Винограда содержится сахар, кверцитин, инозит, дубильные вещества, каротин, бетаин, органические кислоты, минеральные соли. Настой листьев Винограда (1 столовая ложка (ст л) сухих листьев на 1 стакан кипятка, настоять, процедить, принимать по 100 миллилитров (мл) 2–3 раза в день) используется в народной медицине при гипертонической болезни, поносе, нарушениях обмена веществ (щавелевой кислоты). Настоем листьев обмывают кожу при экземе, лишаях, полощут горло при ангине. Ягоды (Виноград) используются как диетический продукт, а также как лечебное средство при начальных формах туберкулеза, при малокровии, мочекислом диатезе. Сок незрелого Винограда применяется как жаропонижающее, а также при ангинах, стоматите. Сушёные ягоды (изюм) употребляют при кашле, ангинах, болезнях мочевого пузыря, при аритмиях сердца и как лёгкое слабительное при геморрое. Молодые листья и веточки Винограда,

собранные в Мае, применяют при лечении гипертонической болезни, диареи, сахарного диабета. Усики Винограда обладают антиспастическим действием. Виноградное вино, потребляемое в незначительных дозах, тонизирует сердечно-сосудистую систему, способствует снижению уровня холестерина в крови, улучшает настроение и общее самочувствие, обезвреживает токсины и болезнетворные микробы. Экстракт из семян Винограда применяется для предупреждения кариеса зубов, с целью предупреждения ретинопатии и защиты от воздействия радиации. Виноград не рекомендуется принимать при ожирении, сахарном диабете, язвенной болезни желудка и двенадцатипёрстной кишки, при поносах, дизентерии. Виноград, попадая на кариозные зубы, усиливает их разрушение. В гомеопатии используется подобно Дикому Винограду Ампелопсис. Эссенция готовится из свежих побегов и внутренней коры. Употребляемые разведения:- 3х, 3 и более высокие. Гомеопатические разведения применяются при хронических кожных сыпях и язвах, при охриплости, диарее.

VITREOUS = СТЕКЛОВАТОЕ (или СТЕКЛОВИДНОЕ, или СТЕКЛООБРАЗНОЕ) – Vitreous:- translucent. / .

VITRIFICATION = ВИТРИФИКАЦИЯ – Vitrification is an alternative approach to cryopreservation that enables hydrated living cells to be cooled to cryogenic temperatures in the absence of ice. Vitrification simplifies and frequently improves cryopreservation because it eliminates mechanical injury from ice, eliminates the need to find optimal cooling and warming rates, eliminates the importance of differing optimal cooling and warming rates for cells in mixed cell type populations, eliminates the need to find a frequently imperfect compromise between solution effects injury and intracellular ice formation, and enables cooling to be rapid enough to 'outrun' chilling injury, but it complicates the osmotic effects of adding and removing cryoprotective agents and introduces a greater risk of cryoprotectant toxicity during the addition and removal of cryoprotectants. Fortunately, a large number of remedies for the latter problem have been discovered over the past 30+ years, and the former problem can in most cases be eliminated or adequately controlled by careful attention to technique. Vitrification is therefore beginning to realize its potential for enabling the superior and convenient cryopreservation of most types of biological systems (including molecules, cells, tissues, organs, and even some whole organisms), and vitrification is even beginning to be recognized as a successful strategy of nature for surviving harsh environmental conditions. However, many investigators who employ vitrification or what they incorrectly imagine to be vitrification have only a rudimentary understanding of the basic principles of this relatively new and emerging approach to cryopreservation, and this often limits the practical results that can be achieved. A better understanding may therefore help to improve present results while pointing the way to new strategies that may be yet more successful in the future. To assist this understanding, this chapter describes the basic principles of vitrification and indicates the broad potential biological relevance of vitrification. Vitrification:- (1) act or process of vitrifying; state of being vitrified; and (2) something vitrified. Vitrification (from Latin Vitreum, Glass via French Vitrifier) is the transformation of a substance into a glass, that is to say a non-crystalline amorphous solid. In the production of ceramics, vitrification is responsible for its impermeability to water. Vitrification is usually achieved by heating materials until they liquidize, then cooling the liquid, often rapidly, so that it passes through the glass transition to form a vitrified solid. Certain chemical reactions also result in glasses. In a wider sense, the embedding of material in a glassy matrix is also called Vitrification. An important application is the vitrification of radioactive waste to obtain a stable compound that is suitable for ultimate disposal. In terms of chemistry, vitrification is characteristic for amorphous materials or disordered systems and occurs when bonding between elementary particles (atoms, molecules, forming blocks) becomes higher than a certain threshold value. Thermal fluctuations break the bonds; therefore, the lower the temperature, the higher the degree of connectivity. Because of that, amorphous materials have a characteristic threshold temperature termed glass transition temperature (Tg):- below Tg amorphous materials are glassy whereas above Tg they are molten. The most common applications are in the making of pottery, glass, and some types of food, but there are many others, such as the vitrification of an antifreeze-like liquid in cryopreservation. Vitrification can be defined as the transition of water directly from the liquid phase into an amorphous phase or glass, while avoiding the formation of crystalline ice. / Под Витрификацией, от Латинских слов Vitrum, означающее Стекло, и Facio, означающее Делаю или Превращаю, понимается переход жидкости при понижении температуры в стеклообразное состояние. У растений и животных, а также в их изолированных органах и тканях витрификация наступает при резком охлаждении (ниже – 20 °C). Застывшая при этом в виде аморфной стекловидной массы ткань долго сохраняет жизнеспособность; при осторожном размораживании жизнедеятельность тканей и целых организмов восстанавливается (смотрите Анабиоз).

VITRIOL = ВИТРИОЛ (или СЕРНАЯ КИСЛОТА, или КУПОРОС) – Vitriol:- any of certain hydrated sulfates or sulfuric acid. Most of the vitriols have important and varied industrial uses. Blue, or roman, vitriol is copper(II) sulfate pentahydrate; green vitriol – also called Copperas, a name formerly applied to all the vitriols – is iron(II) sulfate. White vitriol is zinc sulfate; red, or rose, vitriol is cobalt sulfate; and uranvitriol is a native uranium sulfate. Oil of vitriol is concentrated Sulfuric Acid.

VITTATA = УКРАШЕННОЕ СВЯЩЕННЫМИ ПОВЯЗКАМИ (или УКРАШЕННОЕ СВЯЩЕННЫМИ ЛЕНТАМИ) – Vittata:- with lengthwise stripes.

ViTS = VIDEO TELECOMMUNICATIONS SYSTEM

VIVA VOCE = ВИВА ВОЧЭ (или ЖИВЫМ ГОЛОСОМ) – Viva Voce (in Latin):- (especially of an examination) oral rather than written. Viva Voce:- by word of mouth (oral testimony). Viva Voce is a Latin phrase literally meaning 'With Living Voice' but most often translated as 'By Word Of Mouth'. It may refer to:- word of mouth; a voice vote in a deliberative assembly; an oral exam, especially in a thesis defense in academia; and spoken evidence in law.

VIVIPARITY = ВИВИПАРИЯ (или ЖИВОРОЖДЕНИЕ) – Viviparity:- retention and growth of the fertilized egg within the maternal body until the young animal, as a larva or newborn, is capable of independent existence. The growing embryo derives continuous nourishment from the mother, usually through a placenta or similar structure. This is the case in most mammals, many reptiles, and a few lower organisms. A more primitive condition, known as Ovoviviparity and found in certain snakes, is the simple retention of the egg until it hatches. In this case the embryo derives food from the yolk present in the egg and is not dependent on the mother except for physical protection. Compare Oviparity. / Под Вивипарией, от Латинского слова Viviparus, означающее Живородящий, от слов Vivus, означающее Живой, и Pario, означающее Рожаю), понимается то же, что живорождение. Вивипария у растений – смотрите Живородящие Растения. Живорождение или Вивипария, способ воспроизведения потомства, при котором зародыш развивается в материнском организме, питается непосредственно от матери через плаценту и рождается в виде более или менее развитого детёныша, свободного от яйцевых оболочек. Живорождение противопоставляется яйцерождению, при котором развитие зародыша и освобождение его от яйцевых оболочек происходит вне материнского организма (после откладки яиц). Историческая связь живорождения и яйцерождения доказывается нередкими случаями яйцеживорождения, при котором зародыш развивается из яйца, находящегося в теле матери, питается главным образом за счёт веществ, запасённых в самом яйце, а также выделяемых материнским организмом, и освобождается от яйцевых оболочек обычно после откладки яиц. Среди беспозвоночных животных живорождение характерно для некоторых Кишечнополостных, Членистоногих, Моллюсков, Червей, Иглокожих и других; среди Хордовых – для Сальп, многих Акул и Скатов, некоторых Карпозубых, Жаб, Червяг, Саламандр, Черепах, Ящериц и Змей, для большинства Млекопитающих (исключая Клоачных – Ехидну, Проехидну и Утконоса), в том числе и Человека. Развитие зародыша при живорождении может происходить в яичнике, яйцеводах или их

расширениях, преобразованных в матку, а также во влагалище. У многих живородящих животных вокруг зародыша образуются зародышевые оболочки. О живорождении у растений смотрите Живородящие Растения.

VIVIPAROUS = ВИВИПАРНОЕ (или ЖИВОРОДЯЩЕЕ) – Viviparous:- germinating or spouting from a seed, bulbil or bud while still attached to the parent plant. / Вивипарное или Живородящее:- зарождающееся или происходящее из семени, луковички или почки, пока остаётся прикреплённым к родительскому (исходному) растению. Под Вивипарией, от Латинских слов Vivus, означающее Живой, и Parsio, означающее Рожаю, понимается то же, что Живорождение.

VIX® = VOLATILITY INDEX

VIX® = ВИ.АЙ.ЭКС.® – Volatility Index (VIX®) is a contrarian sentiment indicator that helps to determine when there is too much optimism or fear in the market. When sentiment reaches one extreme or the other, the market typically reverses course. How It Works (Example):- the VIX® is based on data collected by the Chicago Board Options Exchange (CBOE®). Each day the CBOE® calculates a figure for a 'synthetic option' based on prices paid for puts and calls. The computation of the VIX® was changed in 2003 and is based on the S&P 500 option series. The key question the Volatility Index answers is 'What is the 'implied', or expected, volatility of the synthetic option on which the index is based'? We already know the following variables:- (i) The market price of the S&P 500; (ii) The prevailing interest rate; (iii) The number of days to expiration of the option series; and (iv) The strike prices of those options contracts. What the equation solves is the 'implied', or expected, volatility. What is volatility? One definition describes volatility as 'the rate and magnitude of changes in price'. In simple English, volatility is how fast prices move. When the market is calm and moving in a trading range or even has a mild upside bias, volatility is typically low. On these kinds of days, call option buying (a bet that the market will move higher) generally outnumbers put option buying (a bet that the market will go down). This kind of market typically reflects complacency, or a lack of fear. Conversely, when the market sells off strongly, anxiety among investors tends to rise. Traders rush to buy puts, which in turn pushes the price of these options higher. This increased amount investors are willing to pay for put options shows up in higher readings on the VIX®. High readings typically represent a fearful marketplace. Paradoxically, an oversold market that is filled with fear is apt to turn and head higher. Why It Matters:- the Volatility Index works well in conjunction with other 'overall market indicators'. By studying its message, traders will have a better understanding of investor sentiment, and thus possible reversals in the market. See also Volatility Index. VIX® is the ticker symbol for CBOE Volatility Index. The index, calculated by Chicago Board Options Exchange (CBOE®), measures expected volatility of S&P 500 stock index in the next 30 days. The exact definition of VIX® is:- implied volatility of a hypothetical S&P 500 option with 30 days to expiration. The VIX® Index is calculated from prices and implied volatility of a broad range of near term options on S&P 500. To keep the time period of the implied volatility constant 30 days, options with different time to expiration are weighted accordingly. The VIX® Index has active derivative markets – VIX® options and VIX® futures. The index and its derivatives have several specific characteristics with important implications for trading. The VIX® is a highly touted index on CNBC and in financial circles, but what is it and what does it represent? You may hear it called the 'Fear Index', but that too is a misnomer and not an accurate representation of what it is. Certainly there are times based on the price of this index that it construes fear, but other times it may reflect complacency. What is it? The VIX® is a number derived from the prices of options premium in the S&P 500 index (which is an index comprising 500 large cap stocks). It is a good indicator of the expectation of market volatility, note I said 'expectation', it is not representative of the actual volatility or what will happen. This is a very important point; it is just a general assumption based on the premiums investors are willing to pay for the right to buy or sell stock. This premium in options can be loosely defined as risk. Just like other forms of insurance, the greater the risk the higher the premiums, and the lower the risk the lower the premiums. When the options premium fall the VIX falls and when premiums rise the VIX® rises. The VIX® is not set by any one person, but rather the results of millions of transactions by millions of traders from around the world. The buyers and sellers move the option prices, more buyers and the premiums go up, more sellers and the premiums go down. The VIX® takes a weighted average of all these options prices in the S&P 500 index and derives a single number that is called the VIX®. This one VIX® number gives us a general idea if investors are paying more or less for the right to buy or sell the S&P 500 index. What does the number mean? For those interested in what the number mathematically represents, here it is in the most simple of terms. The VIX® represents the S&P 500 index ± percentage move, annualized for one standard deviation. Example, if the VIX® is currently at 15. That means, based on the option premiums in the S&P 500 index, the S&P is expected to stay with in a ±15% range over 1 year, 68% of the time (which represents one standard deviation). VIX®:- the implied volatility on the S&P 100 (OEX) option. This volatility is meant to be a forward looking volatility. It is calculated from both calls and puts that are near the money. The VIX® is a popular measure of market risk. VIX® is the CBOE Volatility Index. VIX® is the ticker symbol for the Chicago Board Options Exchange (CBOE®) Volatility Index, which shows the market's expectation of 30-day volatility. It is constructed using the implied volatilities of a wide range of S&P 500 index options. This volatility is meant to be forward looking, is calculated from both calls and puts, and is a widely used measure of market risk, often referred to as the 'Investor Fear Gauge'. The CBOE® designed the VIX to create various volatility products. Following the CBOE's lead, two other variations of volatility indexes have since been created:- the VXN, which tracks the NASDAQ 100; and the VXD, which tracks the Dow Jones Industrial Average (DJIA). The VIX®, however, was the first successful attempt at creating and implementing a volatility index. Introduced in 1993, it was originally a weighted measure of the implied volatility of eight S&P 100 at-the-money put and call options. Ten years later, in 2004, it expanded to use options based on a broader index, the S&P 500, which allows for a more accurate view of investors' expectations on future market volatility. VIX® values greater than 30 are generally associated with a large amount of volatility as a result of investor fear or uncertainty, while values below 20 generally correspond to less stressful, even complacent, times in the markets. How the VIX's Value Is Established:- the VIX® is a computed index, much like the S&P 500 itself, although it is not derived based on stock prices. Instead, it uses the price of options on the S&P 500, and then estimates how volatile those options will be between the current date and the option's expiration date. The CBOE® combines the price of multiple options and derives an aggregate value of volatility, which the index tracks. While there is not a way to directly trade the VIX®, the CBOE® does offer VIX® options, which have a value based on VIX® futures and not the VIX® itself. Additionally, there are 24 other volatility exchange-traded products (ETPs) for the VIX®, bringing the total number to 25. An Example of the VIX®:- movements of the VIX® are largely dependent on market reactions. For example, on June 13, 2016, the VIX® surged by more than 23%, closing at a high of 20.97, which represented its highest level in over three months. The spike in the VIX® came about due to a global sell-off of US equities. This means global investors saw uncertainty in the market and decided to take gains or realize losses, which caused a higher aggregate equity supply and lower demand, increasing market volatility. / СИБО® (CBOE®). VIYELLA = ВАЙЭЛА – Viyella:- a blend of 55% wool and 45% cotton. Twill weave. Has the appearance of very fine flannel. It is soft, fine, and warm. Holds a good pleat. Washable by machine. If made up in a slim skirt for women, should be underlined, as it has not much body. Excellent for all kinds of children's and baby's wear, sportswear, men's and women's tailored shirts and dresses. Viyella was a blend of wool and cotton first woven in 1893 in England, and soon to be the 'first branded fabric in the world'. It was made of 55 percent merino wool and 45 percent cotton in a twill weave, developed by James and Robert Sissons of William Hollins & Company, spinners and hosiers. The brand name, first registered as a trademark in 1894, and registered in the United States in 1907, soon

covered not only the original fabric, to be sold by the yard (piece goods), but also clothing. At first this was made by separate businesses, but it was not long before Hollins started producing their own clothes and offering franchises to manufacturers who would use the Viyella label. Following increasing emphasis on garment manufacture over the years, Viyella is now a fashion brand for clothes and home furnishings made of a variety of fabrics. The original wool/cotton blend is no longer on sale. The Fabric:- Viyella was a soft dress-weight fabric that was more resistant to shrinkage than any comparable pure wool alternative (challis, for example). In its early years it was marketed as a fabric which combined lightness and fashion with warmth and durability. One 1920s advertisement called it a 'guaranteed unshrinkable fine wool flannel' for women who wanted both 'daintiness' and 'protectiveness'. By the early XX century it came in various weights and widths, some rather narrow by today's standards, and in both plain colours and woven or printed patterns, and was exported from the United Kingdom to other English-speaking countries. Towards the end of the XX century it was woven in 150 cm wide lengths suitable for modern garment design and production. The first ready-made garments using Viyella were shirts and nightgowns, and soon came dresses, slips and other clothing, much of it produced under franchise arrangements using the Viyella trademark. It was also made into sheets, and at one time Viyella yarn was available for home knitting. In the mid-XX century the fabric was popular for children's clothes – from babies' nightgowns to winter shirts for British schoolchildren – and for pyjamas, shirts and dresses; it became associated with sensible, cosy clothing. Officers in the British and other Commonwealth armies purchased their uniforms during the Second World War, and Viyella shirts were a desirable option for them. In the late XX century it was 're-invented' as fashionable fabric. In 1987 The Times said it was used by designers interested in 'vintage' style, like Laura Ashley, and creators of 'modern classics'. Clydella was a cheaper, less soft alternative made with 81 per cent cotton, produced at factories in the Clydeside area, including Glasgow and Hamilton, where many yards of Viyella were also woven. Hollins also produced the related Dayella cloth used especially for babies' clothes. The Companies:- the name Viyella is based on the unusually-named valley road, Via Gellia, (the A5012 Road is a main road in the south of the English county of Derbyshire) near Matlock, where in 1890 Hollins & Co acquired a mill used for the early production of Viyella. Hollins had started business in 1784 in Pleasley, about 20 miles away on the Derbyshire/Nottinghamshire border. Later their offices were at Viyella House in Nottingham. After a merger in 1961, Hollins became Viyella International, led by Joe Hyman, who in the next few years acquired a series of related companies, with Viyella growing to be one of the biggest textile businesses in the UK, owning 40 factories across the country. After a few years as Carrington Viyella and then Vantona Viyella, the company owning the brand became Coats Viyella (Coats Paton, now Coats plc), who in the 1980s built a new mill to produce Viyella cloth in Barrowford, Lancashire, but this was demolished in 1999. In the XXI century much of Coats manufacturing (now specializing in thread) has been moved abroad and it is no longer possible to buy Viyella fabric. Coats underwent major restructuring in 2002 and sold off its Viyella fashion retail business (and Jaeger) to entrepreneur Richard Thompson in 2003 for £1, who re-sold Viyella weeks later to venture capitalist Harris Watson. Viyella Ladieswear has since added home furnishings to its range of goods. The fashion chain entered Administration on 07 January 2009 citing 'an assessment of the current economic situation and the prospects for the future' as the cause. In 2009, the upmarket retailer Austin Reed agreed to buy Viyella for an undisclosed sum. In late 2011, Viyella opened its flagship store next to Austin Reed at 92 Regent Street, London. / Вайэла – торговое название полушерстяной меланжевой ткани. VIZ. = VIDELICET

VIZ. = ВИЗ. – Viz. is an abbreviation of Videlicet, which itself is a contraction from Latin of 'Videre Licet' meaning 'It Is Permitted To See'. Both forms introduce a specification or description of something stated earlier; this is often a list preceded by a colon (:). Although both forms survive in English, viz. is far more common than videlicet. A similar expression is scilicet, abbreviated as sc., which is Latin for 'it is permitted to know'. Viz. is usually used to elaborate or detail text which precedes it, while sc. provides a parenthetic clarification, removes an ambiguity, or supplies a word omitted in preceding text. In legal usage, scilicet appears abbreviated as ss. or, in a caption, as §, where it provides a statement of venue and is read as 'to wit'. Viz.:- namely. Used in tariffs to specify commodities. Viz. (also rendered viz without a full stop) and the adverb videlicet are used as synonyms for 'Namely', 'That Is To Say', and 'As Follows'. / Видэличэт (Videlicet) (Виз (Viz.)), Видэрэ Личэт (Videre Licet).

VOCATIONAL EDUCATION = ПРОФЕССИОНАЛЬНОЕ ОБРАЗОВАНИЕ – Vocational Education:- instruction intended to equip persons for industrial or commercial occupations. It may be obtained either formally in trade schools, technical secondary schools, or in on-the-job training programs or, more informally, by picking up the necessary skills on the job. Vocational education in schools is a relatively modern development. Until the XIX century such education, except for the professions, was provided only by apprenticeship. This situation was partly due to the low social status associated with such instruction as opposed to a classical curriculum, which was considered 'necessary for a gentleman'. With the growth of industrialization during the XIX century, however, several European countries, notably Germany, began introducing vocational education in elementary and secondary schools. In Great Britain, however, opposition to vocational education persisted into the XX century, although a few trade and junior technical schools were established by local authorities before World War II. By the late XIX century public (common) school vocational education in the United States consisted of manual training and practical arts. These programs were gradually expanded until 1917 when federal aid was provided to public schools for trade and industrial, agricultural, and homemaking courses. After World War II the demand for trained paraprofessionals in the relatively new fields of computer science, electronics, and medical services led to an increased interest in short-term postsecondary specialized training programs in these areas as an alternative to a traditional college education. / Профессиональное Образование, образование, получаемое в процессе обучения в высших, средних специальных и профессионально-технических учебных заведениях, а также на специальных курсах. VOCATIONAL PROGRAMMES = ПРОФЕССИОНАЛЬНЫЕ ПРОГРАММЫ – Vocational Programmes:- vocational education prepares participants for direct entry, without further training, into specific occupations. Successful completion of such programmes leads to a labour-market relevant vocational qualification. Some indicators divide vocational programmes into school-based programmes and combined school and work-based programmes on the basis of the amount of training that is provided in school as opposed to training in the workplace.

VOCATIONAL REHABILITATION = ПРОФЕССИОНАЛЬНАЯ РЕАБИЛИТАЦИЯ – Vocational Rehabilitation includes ability testing, work adjustment measures and training other than ordinary labour market training.

VOCATIONAL TRAINING = ПРОФЕССИОНАЛЬНАЯ ПОДГОТОВКА (или ПРОФЕССИОНАЛЬНОЕ ОБУЧЕНИЕ) – Vocational Training is a training that emphasizes skills and knowledge required for a particular job function (such as typing or data entry) or a trade (such as carpentry or welding). Vocational Training is training for a specific career or trade, excluding the professions. Vocational training focuses on practical applications of skills learned, and is generally unconcerned with theory or traditional academic skills. A large part of the education in vocational schools is hands-on training. Vocational training thus provides a link between education and the working world. It is usually provided either at the high school level or in a postsecondary trade school. Why is Vocational Training Worth Considering? Vocational training offers training for specific jobs. Since vocational training often begins in high school, students can graduate prepared to take a high-paying, skilled job immediately. Graduates of trade or vocational schools have an advantage over informally trained job-seekers because an independent organization certifies that they have the skills needed to successfully perform a specific, skilled occupation. Traditional Venues for Vocational Training:- Secondary School:- most high schools offer some form of vocational training program, increasingly called Career And Technical Education. The expanded concept of career and technical education provides for a planned program of courses and learning experiences that allow students to explore career options, develop academic skills, achieve high academic standards, and prepare for industry-defined work or advanced education. For example, the Tech Center at Yorktown, New York, offers twenty-nine vocational specialties, not only to prepare students for the construction and manufacturing industries (traditional specialties of vocational education), but also for jobs in business, human services, health services, and natural and agricultural science. Specialties are as diverse as advertising art and design, television production, computer graphics, cosmetology, business and computer technology, auto mechanics, carpentry, masonry, small engine technology, practical nursing, floral design, and urban forestry. Public schools in some states have separate vocational schools where students attend part time, either as part of the school day or in the evening, for specialized programs in addition to academic courses. These programs usually include a sequence of courses as well as work-based learning experiences. Large communities and cities often have separate public schools that students attend full time that provide both academic instruction and vocational training to high school students. These schools commonly use the cooperative training technique, in which students work part time in the job for which they are preparing. The traditional focus of these schools is changing; no longer do students simply train for a vocation, but they are also required to work

toward a high school diploma or a GED. Additionally, students are encouraged to consider going on to some form of postsecondary education. The 2004 National Assessment of Vocational Education, published by the US Department of Education, reports that nearly one-half of all high school students in that year were involved in some form of vocational training, even if just one course. The report found that vocational training at the high school level had positive effects on short- and medium-range earnings. It also found that high school students who participated in vocational programs also increased their academic course taking and achievement, as well. Despite these positive findings, however, career and technical education in secondary schools is on the decline in the XXI century. One reason is that traditional vocational training prepared students for manufacturing jobs, such as mechanics and repair and precision production, but the manufacturing industry in the United States is in decline. Instead, the economy is becoming more service- and information-based. The National Center for Education Statistics notes that this change is partly responsible for a trend toward a greater emphasis on academics in vocational training, as workers in a service- and information-based economy have a greater need for critical thinking and social skills. The greater academic emphasis also results from toughening requirements for graduation from high school nationwide. The focus on academics has led to fewer high school graduates taking any specific labor market preparation courses, and an even bigger decrease in the number of students concentrating in the vocational curriculum. Another reason vocational training at the secondary school level is declining is that low-achieving students were often 'dumped' into the programs, undermining program quality and rigor. Traditionally, high school students in vocational programs have not been expected to go to college. While considerable federal effort and funds have been allocated to change that, there is evidence that those who participate in vocational programs at the high school level are more likely to get an associate's degree or postsecondary certificate than they are to go on to and complete a four-year college degree. Public high schools implemented some vocational education – related reforms in the late 1990s, including greater integration of academic and vocational education and less 'block scheduling' of vocational courses. However, these reforms have not yet produced increased achievement or college attendance for those who select vocational training. The administration of President George Walker Bush proposed to eliminate all federal funding for high school vocational education in fiscal year 2006. While some funds would still be available through a new program known as the High School Intervention Initiative, wide local discretion on how those funds might be used, coupled with an expansion of required high school assessments, would lead many local educational agencies to pursue interventions other than vocational education. It seems probable that vocational education options available to high school students will be significantly reduced during the next decade. Tech Prep Education:- the Carl D. Perkins Vocational and Technical Education Act of 1998, in addition to providing funds to postsecondary institutions, provided funding to programs known as Tech Prep programs. Tech Prep programs are based on a collaboration between secondary schools and postsecondary institutions to help prepare students for high tech careers in areas such as engineering, technology, applied science, health, and applied economics, and to improve the academic success of vocational students. Tech Prep is a sequenced program of study that combines at least two years of secondary and two years of postsecondary education. It is designed to help students gain both academic knowledge and technical skills. These programs typically lead to either a certificate or an associate's degree in a specific career field. Almost one half of the country's high schools offer some type of Tech Prep program. In fiscal year 2005 USD106 million was appropriated for the program, although because of proposed budget cuts, its future is uncertain. The effectiveness of Tech Prep programs is up for debate. Evaluations in Texas and New York found evidence that students enrolled in these programs were less likely to drop out of high school or have a chronic absenteeism problem and were more likely to enroll in postsecondary school. However, academic achievement and labor market outcomes were not demonstrably improved. This may be because Tech Prep programs are not always implemented as envisioned in the legislation, but instead are often implemented piecemeal or with a focus on improving only academics. Postsecondary Trade School:- the 2004 National Assessment of Vocational Education reported that about one-third of college students were involved in vocational programs as a major part of their studies. Postsecondary vocational schools, also called Trade Schools, provide an educational option other than community colleges and four-year colleges. They also help older students who want to advance or change their careers. Often these schools cater to the needs of working adults by offering classes at night or online. Trade schools offer both degree programs and vocational certificates. There are many occupations that require a trade school education, including hairdressing, massage therapy, auto mechanics, plumbing, and carpentry. Trade schools also teach students technological, culinary, and health care skills. Some trade schools offer apprenticeships as well. Recognizing the need for more skilled workers in the information-based economy, the Carl D. Perkins Vocational and Technical Education Act of 1998 granted money to postsecondary schools to develop and enhance vocational programs. The Act focused federal investment in high quality vocational and technical educational programs that integrate academic and vocational education, promote student attainment of high vocational and technical standards, provide students with strong experience and understanding of an industry, and develop, improve, and expand the use of technology. Postsecondary institutions that receive the funds have the flexibility to design services to meet the needs of their students. School guidance offices have information on trade schools. Two comprehensive online resources, http://www.trade-schools.net and http://www.trade-school.org, also list trade schools and the courses they offer. Institutions listed include mechanical and automotive schools, business schools, culinary schools, art and design schools, diving schools, cosmetology schools, education programs, health care schools, legal and criminal justice schools, schools focusing on occupations in the media, real estate schools, technology schools, and travel and tourism schools. These trade schools offer diplomas or certificates that employers nationwide will accept. They also provide their students with assistance in meeting necessary licensing requirements. Vocational Training is a training for a specific vocation in industry or agriculture or trade. Vocational Training is used to prepare for a certain trade or craft. Decades ago, it used to refer solely to such fields are welding and automotive service, but today it can range from hand trades to retail to tourism management. Vocational training is education only in the type of trade a person wants to pursue, forgoing traditional academics. Vocational training, also known as Vocational Education and Training (VET) and Career and Technical Education (CTE), provides job-specific technical training for trades, such as auto repair, plumbing and retail. These programs generally focus on providing students with hands-on instruction, and can lead to certification, a diploma or certificate. Vocational training can also give applicants an edge in job searches, since they already have the certifiable knowledge they need to enter the field. A student can receive vocational training either in high school, a community college or at trade schools for adults. In High School:- some vocational training is found in the form of high school CTE programs that include academic study as well as a variety of courses and work experiences designed to introduce students to trades ranging from construction, business and health services to art and design, agriculture and information technology. This form of education can be offered at high school campuses or separate vocational training centers. The ultimate goal of these programs is to prepare students for the job field and help them complete their high school education. After High School:- community colleges and technical schools also offer a variety of vocational courses and programs. This form of instruction includes hands-on training without the added emphasis on standard subjects like math and English. Instead, students take specific classes related to the job they're training for. Vocational schools typically utilize cooperative training techniques, where students are able to work in the job they're studying for and attend classes. Most vocational training programs can be completed within six months to two years. Vocational Training is a training you undertake to obtain National Vocational Qualifications or Scottish Vocational Qualifications, under certain full time courses lasting for at least four weeks. / Дьюдьж Вокё Бош (George Walker Bush; 1946–). Карл Ди. Пёкинз (Carl D. Perkins). Профессиональное Обучение:- обучение профессии или коммерции. В Великобритании в 1983 был создан Совет Делового и Технического Обучения, который разрабатывает национальную систему профессионального обучения, а в 1991 введена

система Национальная Профессиональная Квалификация, состоящая из черырёх уровней. Профессиональная Подготовка, совокупность специальных знаний, умений и навыков, позволяющих выполнять работу в определённой области деятельности. В зависимости от квалификации различают 4 основных уровня профессиональной подготовки, требующих соответствующего профессионального образования:- высшего, среднего специального, профессионально-технического и элементарного (подготовка работников низшей квалификации на профессиональных курсах, путём бригадно-индивидуального обучения на производстве и других). Профессиональная подготовка совершенствуется в процессе трудовой деятельности, в системе повышения квалификации, путём самообразования.

VOCC = VESSEL OPERATING COMMON CARRIER

VOCC = VICTIMS OF CRIME COORDINATOR

VOICE AUTHORIZATION = ГОЛОСОВАЯ АВТОРИЗАЦИЯ (или АВТОРИЗАЦИЯ ГОЛОСОМ) – Voice Authorization:- an approval response that is obtained through interactive communication between an issuer and an acquirer, their authorizing processors or stand-in processing or through telephone, facsimile or telex communications. / Голосовая Авторизация (в расчётах по картам):- применяется, когда нет подходящего устройства для проведения авторизации, например, POS-терминала.

VOICE IDENTIFICATION = ИДЕНТИФИКАЦИЯ ГОЛОСА (или РАСПОЗНАВАНИЕ ГОЛОСА) – Voice Identification:- police technique for identifying individuals by the time, frequency, and intensity of their speech-sound waves. A sound spectrograph is employed to record these waves in the form of a graph that may be compared to graphs of other individuals and differentiated. Though voice graphs (or voiceprints) have been used in courtroom proceedings, the accuracy of this technique in identifying individuals is a subject of controversy among speech scientists.

VOICEPRINT = ПЕЧАТЬ С ГОЛОСА (или ОБРАЗЕЦ ГОЛОСА, или ХХ) – A Voiceprint is a set of measurable characteristics of a human voice that uniquely identifies an individual. These characteristics, which are based on the physical configuration of a speaker's mouth and throat, can be expressed as a mathematical formula. The term applies to a vocal sample recorded for that purpose, the derived mathematical formula, and its graphical representation. Voiceprints are used in voice ID systems for user authentication. Voiceprint:- a stored digital model of an individual's voice, used for identification purposes. Voiceprint can refer to the spectrogram of a voice. More specific uses include:- (i) VoicePrint, as of March 2012 now AMI-audio, Canada's broadcast reading service; (ii) Voiceprint Records, an English record label; (iii) the stored template used to identify a person via their voice in speaker recognition. / , использованная с целью идентификации.

VOID = АННУЛИРОВАННОЕ (или НИЧТОЖНОЕ, или НЕДЕЙСТВИТЕЛЬНОЕ, или НЕ ИМЕЮЩЕЕ СИЛЫ) – Void means empty or useless or having no legal force. For example:- (i) an example of void is living a life of constant complaints and misery; or (ii) an example of void is a cancelled check. Void:- not valid or legally binding. Void:- absolutely null, without legal force and legal effect, such as an agreement for an immoral consideration. Not to be confused with voidable which indicates unenforceability of a valid agreement. Void:- in law, having no legal force or effect; not legally binding or enforceable. / Ничтожное или Недействительное:- лишённое законной силы или влияния, например, недействительный контракт (contract). Не Имеющий Силы (Void):- то, что не имеет законной силы. Void:- отказ покупателя от оплаты после того, как успешно прошла авторизация, принадлежащей ему карты. Транзакции, помеченные как Void, не включаются в Партию (Batch) и не предъявляются к дальнейшей оплате. Ничтожное:- (1) очень малое, незначительное по количеству, например, ничтожные средства; или (2) совершенно незначительное по роли, внутреннему содержанию; не внушающее к себе уважения, мелкое, например, ничтожная роль или ничтожная личность. Аннулированное – объявленное нежействительным, отменённым, например, аннулированный договор.

VOIDABLE = АННУЛИРУЕМОЕ (или ОСПОРИМОЕ, или ОСПАРИВАЕМОЕ) – Voidable:- capable of being set aside by a court or rescinded at the option of one of the involved parties. Voidable:- that which is not absolutely void, but may be avoided. Voidable:- valid until annulled, such as a resolution. / Оспоримый:- не имеющий (юридической) силы. Соглашение, которое может быть аннулировано любой из сторон в случае подлога, некомпетентности или нарушения закона, или вследствие возможности применения права на отказ (right of rescission).

VOIDABLE CONTRACT = АННУЛИРУЕМЫЙ ДОГОВОР (или ОСПОРИМЫЙ КОНТРАКТ, или ОСПАРИВАЕМЫЙ ДОГОВОР, или НИЧТОЖНЫЙ ДОГОВОР) – Voidable Contract is a contract which may be voided at the option of either party. For example, an insurer may avoid a policy from inception for the misrepresentation or non-disclosure of material facts during the negotiation of the placement, renewal or alteration of cover. An insurer may also avoid a policy from the date of the presentation of a fraudulent claim.

VOIDABLE POLICY = АННУЛИРУЕМЫЙ ПОЛИС (или ОСПОРИМЫЙ ПОЛИС, или ОСПАРИВАЕМЫЙ ПОЛИС, или НИЧТОЖНЫЙ ПОЛИС) – Voidable Policy is a policy in respect of which the underwriter is entitled to avoid liability. See also Avoidance. Voidable Policy is a contract which may be voided at the option of either party. For example, an insurer may avoid a policy from inception for the misrepresentation or non-disclosure of material facts during the negotiation of the placement, renewal or alteration of cover. An insurer may also avoid a policy from the date of the presentation of a fraudulent claim.

VOIDED BILL OF LADING = АННУЛИРОВАННЫЙ КОНОСАМЕНТ (или НИЧТОЖНЫЙ КОНОСАМЕНТ, или НЕ ИМЕЮЩИЙ ЮРИДИЧЕСКОЙ СИЛЫ КОНОСАМЕНТ, или НЕДЕЙСТВИТЕЛЬНЫЙ КОНОСАМЕНТ) – Voided Bill Of Lading:- related to consolidated bill of lading (B/L); those B/L's absorbed in the combining process. Different from Canceled Bill of Lading. B/L 'absorbed' in a consolidated bill of lading. In the process of shipping products, goods or some other type of item, a shipper generates a Bill of Lading (B/L), whether arriving via ship, train or truck. A bill of lading is documentation stating the terms of the agreement between the shipper and delivery company. It specifies the terms, agreements and condition of the carriage. Additionally, it indicates the quantity, weight and nature of the content or cargo. It even serves has a document of title of the specified goods. A canceled bill of lading is documentation that cancels a bill of lading in process. A canceled bill of lading is not the same as a Voided Bill of Lading, which usually consists of combining at least two more bill of lading to an existing order in process. / Относящийся к Консолидированному/Сводному Коносаменту; эти коносаменты поглощаются при комбинированном процессе перевозки груза. Отличается от Отменённого/Аннулированного Коносамента (Canceled Bill of Lading).

VOIDED CHECK = АННУЛИРОВАННЫЙ ЧЕК (или НИЧТОЖНЫЙ ЧЕК, или НЕДЕЙСТВИТЕЛЬНЫЙ ЧЕК) – A Voided Check is a check that has been cancelled. Once it has been appropriately voided, a check cannot be used. There are several possible reasons for a voided check, including the following:- (i) there was a mistake in filling out the check; (ii) the check was issued in error; and (iii) the check was submitted by an employee to an employer for use in setting up a direct deposit payroll account. In all of these cases, the voided check is not cashed. A voided check may be perforated with a 'Void' stamp, or crossed out, or have 'Void' written across it, be shredded, or simply be stored in a voided checks file. It is best to permanently deface or destroy a voided check, so that no one can present it to a bank at a later date and expect to be paid for it. If the check is not currently in the company's possession, then contact the bank and authorize a stop payment on the check (for which the bank will charge a fee). In the accounting system, the check would

have been recorded when it was originally created, so a reversing entry must be made that debits (increases) cash and credits (decreases) the account to which the payment applies. Thus, if the payment had been for an expense, the credit would be to the related expense account; if the payment had been to acquire an asset, the credit would be to the related asset account. If there is a check register, the reversing entry is needed in order to record the elimination of the accounting transaction associated with the check number that is printed on the check. In a computerized accounting system, there is usually a menu option for voiding a check, since this is a sufficiently common activity to warrant having its own routine.

VOID POLICY = АННУЛИРОВАННЫЙ ПОЛИС (или НИЧТОЖНЫЙ ПОЛИС, или НЕ ИМЕЮЩИЙ ЮРИДИЧЕСКОЙ СИЛЫ ПОЛИС, или НЕДЕЙСТВИТЕЛЬНЫЙ ПОЛИС) – Void Policy is a contract which has no legal effect and is therefore unenforceable in a court of law. For example, an insurance contract where the policyholder does not have an insurable interest. Void Policy:- policy which is inadmissible as evidence in a court of law, e.g., Policy Proof of Interest Policy (P.P.I. Policy). Void Policy:- a policy which is not acceptable to a court of law as a valid legal document. Examples expressed in the Marine Insurance Act (MIA) 1906, are a gaming and wagering contract, a contract entered into where the assured had no insurable interest and no expectation of acquiring such interest, a policy which states 'interest or not interest', a Policy Proof of Interest (PPI) policy and a policy which contains terms whereby the underwriter waives any benefit of salvage to the insurer, or any similar term. / Под Страховым Полисом, от Французского слова Police, от Итальянского слова Polizza, означающее Квитанция или Расписка, понимается документ (как правило, именной), удостоверяющий заключение договоров личного или имущественного страхования, а также отношения по государственному обязательному страхованию. В бывшем Союзе Советских Социалистических Республик (СССР) при добровольном страховании страховой полис вручался страхователю (гражданину или организации, в интересах которых осуществлялось страхование) вслед за уплатой им первого страхового взноса. При обязательном страховании страховой полис выдавался после определения органами Госстраха состава имущества, подлежащего страхованию, его оценки, исчисления размера страховых платежей. В страховом полисе фиксировались основные условия страхования:- вид, объект, начало и конец действия страхования, размер страховой суммы, сведения о страхователе, страховщике и другое.

VOILE = ВУАЛЬ – Voile is a sheer, transparent, low-count, crisp or soft, lightweight, plain-weave muslin with a thready feel, made of highly twisted yarns. It can be comprised of wool, cotton, silk, rayon, polyester, or other man-made fibers. Voile is especially popular when made of cotton or blends for summer wear and is often printed to match heavier fabrics. Voile is used for clothing, especially for blouses and summer dresses, and for curtains and similar items. Voile Fabric is a sheer spun cloth that is lightweight and soft. It is usually made with cylindrical, combed yarn. Voile is used for blouses, children's wear, draperies, bedspreads, etc. Voile is a lightweight, sheer fabric used for clothing and curtains. Voile is the French word for veil and the well-draping fabric can be, and has been, used to make wedding veils. Silk, rayon and cotton are the three main varieties of voile, but voile lace also exists. Voile lace is a hand cut lace that may be white or beige or dyed in many different colors. Hand cut voile lace has open spaces cut out in between the lace fabric. Voile lace is a type of cotton voile that is popular for table cloths and fabrics sold by the bolt. Voile lace, some with rich embroidery accents, is often imported from Africa. Cotton voile is used to make lingerie, baby clothes, blouses and skirts. It is also popular for making romantic sheer drapes that pool on the floor. It looks very much like gauze and is summer weight and breezy. Some cotton voile tops such as some poet's blouses feature voile lace as decorative accents. Silk voile is the most difficult type of voile to cut and work with as it is slippery in texture. It is also very luxurious and is also known as Silk Chiffon. A sheer floral print jacket to wear over a sleeveless top or dress is a classic and popular piece of clothing to sew from silk voile. Rayon voile is very different from silk voile as it has a crêpe-like texture. Crinkled rayon voile is a popular and practical choice for sewing a travel wardrobe. Sarongs and pareos, or rectangular pieces of fabric gathered at the waist for swimsuit cover-ups, are common travel uses for rayon voile. Sometimes polyester is added to voile such as for some types of curtains. Most voile curtains are either pure cotton voile or a cotton polyester voile blend. No matter what type of voile is used for clothing or for table cloths or curtains, it still always drapes well. Voile is a crisp, lightweight, plain weave cotton-like fabric, made with high twist yarns in a high yarn count construction. Similar in appearance to organdy and organza. Used in blouses dresses and curtains. Voile is a fine soft sheer fabric used especially for women's summer clothing or curtains. Sheer and very light weight. Usually made with cylindrical combed yarns. To obtain a top quality fabric, very highly twisted yarns are used. Voile drapes and gathers very well. The clear surface is obtained by singeing away any fuzzy yarns. Has a hard finish and crisp, sometimes wiry hand. 'Voile de Laine' is wool voile. Voile is a lightweight, woven fabric, generally made of 100% cotton or cotton blends, including linen or polyester. Often used to make curtains, blouses and dresses. Cotton Voiles:- Until within the past few years, voile fabrics were made and sold in quite large quantities, considering the material from which they were made, but inasmuch as they were composed of worsted yarn, they were high in price and not especially desirable to the large majority of consumers. Possibly four or five years ago, voiles began to be made of cotton yarn, and while they are not so desirable in some ways as fabrics composed of worsted yarn, nevertheless they are very attractive, and for ordinary users show a much larger value than when made from worsted. Gradually the style for such fabrics developed and for the past two years there has been possibly a greater sale for them than there has been for any other material manufactured in fancy cotton mills or for cotton fabrics which come under a fancy classification. The smoothness of the cotton yarns adds a great deal to the general cloth effect and has without doubt created a field which will show a greater or less demand continually. It is not likely that the sale will be as large as it is now or has been recently, but these fabrics show such a large amount of desirability that they cannot be dropped from the ordinary range of fancy fabrics to a great a degree as some others have been in the past. Naturally, the variety of fabrics produced from cotton yarns shows a much wider range of style and construction than they did from worsted, because cotton mills are better equipped to make a variety of combinations in yarn sizes, and also through the addition of other materials, such as silk, artificial silk and other fibres, to give certain effects. When voile fabrics were first made in cotton, the large majority of them were produced from two-ply yarn, and, naturally, much of this yarn was made from combed stock, because one of the main features of the fabric is to have as clear an effect as possible, or one in which there are as few fibres projecting from the yarn as possible. The twisting operation aids perceptibly in making yarn smooth, and for this reason it is used extensively. To give crispness and also to aid in making the yarn round, it is given a much greater amount of twist than ordinary two-ply yarn, and regarding this situation, we will give a more extensive description later. There are also a good many voile fabrics which have been produced from single yarns, but, of course, they are not as serviceable nor as desirable as the two-ply fabric, although they do offer opportunities in purchasing at a reduction in price As a general statement, it can be said that voile fabrics have a very low count in comparison with most other fabrics. This is done in order that it may aid in giving the open effect which is so desirable in the fabric, for it must be remembered that when a voile fabric is used for a dress or for most other uses, it is necessary to wear underneath an other dress or fabric to make the garment opaque and aid in creating a desirable effect, for combinations in colors between over-dress and underdress are often used. One of the great problems in the making of any voile cloth is to have the construction of the cloth just right, that is, so that the threads will not slip badly and still not be so close as to detract especially from the openwork effect. Voiles have often been sold in which the construction was too high, and which might have been lowered with a distinct saving in cost and a resulting better effect, and it is also true that voiles have been sold in which the construction was too low, for the threads slip badly and often create a wavy appearance. It is probable that the low constructions are much more frequent than the high constructions, because buyers are likely to cut the costs everywhere possible whenever an opportunity is presented. Because there

has been a low count used in these cloths, in the large majority of instances, the body of the fabric at least is composed of plain weave. Unless this is done a higher count is necessary for any size of yarn, and when the cloth count is increased the voile effect is lost. Some variation in count will be noted through the use of different staple lengths of cotton; that is, when a long cotton is used a smooth yarn is likely to be produced and the smoother a yarn is, the more it is likely to slip when woven. It is also true that it is not necessary to use as much twist when a long cotton is used as when a short one is being spun. Through the low construction, or small number of picks per inch, the production in yards on voile fabrics is much greater than it has been on the majority of fabrics which fancy mills are accustomed to produce, even though the percentage of production has not been as high as it has been on other fabrics. Each mill is likely to use a somewhat different amount of twist in its yarns, due to somewhat different manufacturing conditions under which each operates, but as a general thing, it can be said that the cotton which is used in any kind of voile yarn is that which is ordinarily used in the yarn of the same size which would be used in a fancy fabric. In combed yarn fabrics, it is seldom that cotton shorter than this, 1-1/8 inches, is used, because cotton shorter than this is seldom combed. It is a general mill policy to use just as short staple for any size of yarn as can be handled successfully, and it is not a good policy to use cotton which costs an extra cent or two when the advantage gained only amounts to a small portion of a cent. Inasmuch as the making of voile fabrics depends so much on the yarns used, it may be well to give some information regarding their construction and making. These ply yarns are both made from grey single yarns and also from dyed and bleached single yarns, but by far the largest majority are made in the grey state. Inasmuch as they are two-ply or more than two-ply, it is readily recognized that a twisting operation is necessary before they are completed. Of course, when the yarns are made in the dyed or oleached state before weaving, It makes little difference regarding the cost, because practically the same number of processes have to be used, no matter what method is pursued, but this is not true when grey yarns are being considered. In the first place, in making grey ply yarns, if they be taken and placed on the twister and twisted, they must also be handled by other succeeding processes, that is, the warp be spooled, warped and slashed just the same as any other warp yarn. The slashing operation sets the twist on the warp, so that it does not curl up and create any great trouble, but the filling cannot be quilled after twisting, but must be made up into a long chain warp and then sized and quilled before it can be woven. Unless this is done, the hard twist in the yarn is likely to make loops which appear in the cloth and make seconds. It has been found that so far as twisting the filling is concerned, it is much better to twist the two-ply on a spinning frame. This can be done by using filling bobbins which have been enamelled so as to stand a steaming process. When the filling yarn has been twisted or spun onto these bobbins, it can be taken directly from the spinning frame to a steaming chest, which sets the twist and makes the yarn in a condition ready for weaving. As will be readily seen, this method of making hard twist two-ply grey filling yarn is more desirable than when twisted on a twisting frame, because it eliminates a number of processes and results in a cheaper yarn cost. This operation cannot always be accomplished on a spinning frame, because they are sometimes not available, but it is a distinct advantage when it can be accomplished. When single yarns are being used in making a voile cloth, it is customary to use in some cases an ordinary warp yarn and in others a warp yarn in which there is only a slight excess of twist, while the filling yarn contains the extra hard twist. In making single yarn voiles it Is necessary to use enameled bobbins for the filling, so that it can be steamed as above described on the two-ply yarn. For ordinary warp yarn the standard of twist is from 4-1/4 to 4-3/4 times the square root of the yarn size, whereas in hard twist yarn, such as is used in voiles, the standard of twist is likely to be from 7 to 8-1/2 times the square root of the yarn size. This holds true for both warp and filling and for both single and two-ply yarn, with the single exception of warp yarn used in single yarn voiles. In making the single yarn, which is used before twisting, the standards of twist are almost always exactly the same as if ordinary warp yarn were being produced; that is, ordinary warp yarn can be taken and hard twisted, and then it is suitable for use in voiles. Thus it will be seen that the production of a voile yarn is likely to be only about half that noted on an ordinary yarn, and for this reason the cost of production is likely to be about twice as much as it is on an ordinary single or two-ply yarn of the same size. The twist in the two-ply yarn voiles for both warp and filling is practically always identical if the same size of yarn be used for warp and filling. Analysis No. 1:- (i) Width of the warp in reed 28-3/4 inches; (ii) Width of the fabric grey 27 inches; (iii) Width of the fabric finished 26 inches; (iv) Ends per inch in the reed 34; (v) Ends per inch finished 38; (vi) Reed (1 end per dent) 34; (vii) Ends in the warp 2/12 966 2/12 = 1 014 total ends; (viii) Warp yarn size 45/2; (ix) Warp take-up 6%; (x) Warp weight 0.058 3; (xi) Filling size 45/2; (xii) Picks per inch 34; (xiii) Filling weight 0.052 8; (xiv) Total weight per yard 0.111 1; (xv) Yards per pound (grey) 9. The above fabric is the one ordinarily known as 38x34, and has been sold in quite large quantities not only in the plain material but also in various dobby and striped patterns. The ply yarn in this fabric is made of 45-1 single yarn, and in the twisting operation there is a certain amount of contraction, and instead of this yarn containing 18 900 yards per pound, we have used as a basis 18 500 yards, a figure which allows for shrinkage in possibly an average number of instances. With a very high standard of twist, the yarn will shrink more, while if the standard is lower there will be less contraction. Two-ply hard twisted yarns are usually made from single yarns of a certain size, and the two-ply result is likely to be coarser in size than the single yarns used would indicate. When single hard twisted yarns are being made, it is customary to change the gears so that the yarn spun is a certain size. Analysis No. 2:- (i) Width of the warp in the reed 29 inches; (ii) Width of the fabric in the grey 27 inches; (iii) Width of the fabric finished 26 inches; (iv) Ends per inch in the reed 46; (v) Ends per inch finished 49; (vi) Reed (1 end per dent) 46; (vii) Ends in the warp 24 1 310 24 = 1 358 total ends; (viii) Warp yarn size 60/2; (ix) Warp take-up 7%; (x) Warp weight 0.062 8; (xi) Filling size 60/2; (xii) Picks per inch 46; (xiii) Filling weight 0.057 4; (xiv) Total weight per yard 0.120 2; (xv) Yards per pound (grey) 8.32. This above cloth is another one which is manufactured extensively, and is known as 49x46 with 60-2 hard twist warp and filling. The twisted yarn is made from 60-1 warp yarn and due to contraction in twist, it contains only 23 250 yards per pound, instead of 25 200. There is also a single yarn voile, which is made from carded and also from combed yarn with counts about 50x48, and – contains yarns in the vicinity of 30-1, the cloth being somewhat similar in weight to the one given in analysis No. 2, except that there is a difference in appearance and cost which would be noted between a single and two-ply fabric. Then there are many fabrics made of fine two-ply yarns, and a large portion of the imported voiles are made from yarns up to and even higher than 120-2. The count on such fabrics is seldom higher than 64x64, that is, unless the yarn is of extremely fine size. In order to increase the smoothness of the ply yarn it is often customary to use a gassing process after the yarn is twisted, which burns off the fibres of cotton projecting and which, although adding to the expense of production, is sometimes the means of returning a higher profit to the manufacturer because of added attractiveness. Weaving:- Practically all of the voile fabrics which have been sold have been woven on ordinary or fancy looms, even though some of them have been entirely of plain weave. This has been because mispicks and breakages cause secpnds to be made much quicker than would be noted on a cheaper class of fabrics and also because the fancy mills which are able to produce the right kind of yarns have not had automatic looms to use even had they so desired. Without doubt, the use of stripes made in various methods out of cotton or silk has added much to the attractiveness of voile fabrics and has been responsible for a portion of the large sale. When silk stripes have been used, fancy weaves have been employed on the stripes in many instances, and this is very desirable. The addition of a comparatively small amount of silk yarn is usually warranted through the higher selling price obtained and the higher rate of profit which a mill can obtain through this method of manufacturing. Generally, the weaving process causes very little difficulty, for the yarns are strong, even though they are hard twisted, and, due to the low cloth count, there are only a comparatively few warp threads to be looked after by a weaver, that is, unless there are crowded silk or cotton stripes. Probably, the large use of voiles has been the means of introducing to consumers in a large way the use of artificial silk. On fine fabrics, which are woven with a fine reed, there is a good deal of friction, which causes artificial silk wrarp threads to rub and fray out and be rather unsatisfactory in weaving, which fact has

curtailed their use to a certain extent in the past, but the coarse count of voile fabrics and the comparatively small amount of rubbing in weaving has made the use of this silk entirely satisfactory and much more of it is being noted, especially in the imported lines. Consumers have found that the use of this silk is not undesirable, and that there has been a change of sentiment, as shown by the fact that retailers to-day designate that such material has been used in making the cloth when they are showing the goods, while even one year ago it was very hard to find a case where such use was brought to a consumer's attention, although the material was used quite extensively at that time. Finishing:- For the fabric which is woven from dyed and bleached yarns there is no great necessity for any extra finishing processes after the cloth comes from the loom, and when it has been examined, washed, ironed and folded, it is ready for sale; in other words, the treatment of such cloth is very similar to other dyed yarn fabrics. The cloth which is woven from grey yarn is treated in an entirely different manner, and the results obtained may be of widely different character, even though the same grey cloth is used as a basis. In the first place, the grey fabric is bleached, and this process is likely to vary, depending upon the materials which have been used in the cloth. For an ordinary all cotton voile, the ordinary bleaching process may be used, but when silk is used in combination for stripes or checks, it must be bleached by a method which will not harm either material, and possibly sodium peroxide is more extensively used than any other material or bleaching such combination fabrics. After the voile fabric is bleached, it may be dyed a solid color or left white if the cloth is plain weave, or it may be printed in allover patterns or with various styles of borders, such as are being used and which have been popular since voiles have been selling well. Then it is also true that many of the finer and more expensive fabrics are treated to a mercerization process, as this seems to make the threads rounder and the voile effect better. The process acts, so far as results are concerned, much the same as if the ply yarn composing the fabrics had been treated to a gassing operation before being woven. Such a process is even being applied to many of the ordinary voiles, especially since the large use of mercerization has made the cost of doing it much less, and which does not make the fabric prohibitive in price. On fancy fabrics which contain silk there are other results besides the foregoing possible, for, besides being mercerized and sold in the white state or dyed solid colors or printed, the cloths can be dyed with certain colors, which is called cross dyeing, so that the silk yarn appears as one color, while the cotton is another, and it is also noted that many of the fabrics have the silk yarn with the cotton yarn in the color desired. On the cheap voiles which are only printed, the cost of finishing may be as low as 1-1/4 cents a yard, or if sold in the white state even less than this amount, while on the high-priced fabrics the cost may be much higher, and it is probable that most of the better fabrics being offered by the retailers cost from 3 cents to 3-1/2 cents to finish, that is, it costs the converter who handles the goods this amount to have it done. Carding And Spinning:- The yarns which are used in the making of voiles are varied, but in general the foundation yarns are much the same as those which would be used for the same kinds of cloth in a fancy cotton mill. For fine yarn longer cotton is used than for coarse yarn, but for the 45-2 yarn in the fabric, for which an analysis is given, the cotton staple length would be about 1-3/16 inches, while for the 60-2 fabric the cotton length would be about 1-1/4 inches, and if 100-2 were to be used, the cotton length would be about l-1/2 inches. Tn combing cotton for medium or coarse yarn sizes, the percentage of waste removed is less than when fine yarns are to be made, the amount of waste removed depending upon circumstances. There should be a good mixing of cotton before it is run through the pickers, as this is one of the features which results in even yarn which is so necessary in the production of voiles, while the weights of sliver will depend a good deal on the mill organization and also on the kind and size of comber being employed. The spacing of the rolls on the various machines should be wide enough, so that in no case will the cotton fibres be broken, and the amount will vary on the different machines from one-eighth inch to one-quarter inch more than the cotton staple length. Assuming that a finished drawing sliver is being produced of a weight of 40 grains and that three processes of fly frames are to be used, a lay-out for one yard of 45-1 yarn would be about as follows:- (i) 0.185 2 grain; 0.98 2% contraction in spinning; (ii) 0.181 5; 10.58 spinning draft; (iii) 1.92 ÷ 2 ends = 96 = 8.67 hank roving; 6.4 fine frame draft; (iv) 6.16 ÷ 2 ends = 3.08 = 2.70 hank roving; 5.65 intermediate frame draft; (v) 17.4 ÷ 2 ends = 8.70 = 0.96 hank roving; 4.6 slubber frame draft; (vi) 40.00 grains finisher drawing weight. If four processes of fly frames are to be used in producing 45-1 yarn, it probably would be better to use a heavier finished drawing sliver, and through the greater opportunity for drawing, due to the extra process, the right size of yarn can be obtained. It is a very good policy not to have the spinning draft much over 10-1/2, although there are mills where this is exceeded somewhat. Conservative drafts and speeds will usually be of ultimate advantage in manufacture, for it not only is likely to result in a greater yarn production, but it is likely to make fewer seconds in the cloth room, a higher percentage of production on the loom, with a corresponding lower cost, and also a better fabric, which will command a higher price because of the better yarn composing it. What would be a good layout for one mill would not be so good for another, but this statement does not mean that there rre mills which could not improve their yarn layout, either by changing the drafts or changing the speeds or even adding a few machines so as to give a greater amount of flexibility to the organization. There is such a wide range of up-to-dateness in the machinery in the various mills that one mill can operate to advantage with cotton of 1-1/8 inches in length, while another for the same size of yarn may have to use 1-1/4-inch stock. The problem is an individual one, which cannot be decided quickly, and to give a layout which would be entirely suitable or even desirable for general mills conditions is not an especially good policy. Dyeing Instructions:- The following dyeing instructions may be used for the dyeing of this kind of material. In a general way, the goods will be worked in the dye liquor for approximately three-quarters of an hour at the boiling point. The amounts of color are based on the supposition that 100 pounds of material is to be dyed, and for this amount of material, there will be required somewhere in the vicinity of 180 gallons of liquor. The amounts of dyestuffs and other materials are those necessary for the first batch of material:- (i) BLUE:- 3/4% Oxamlne Blue, 3 B.N.; 10-20% Glauber's salt crystals; (ii) PINK:- 1-25% Cotton Red 4 B.X.; 10-20% Glauber's salt crystals; (iii) RED:- 2-1/2% Thiazine Red R.; 10-20% Glauber's salt crystals; (iv) BROWN:- 2-1/2% Cotton Brown G.; 10-20% Glauber's salt crystals; (v) ORANGE:- 2-1/2% Pyramine Orange R.R.; 10-20% Glauber's salt crystals; (vi) SLATE:- 1-10 of 1% Oxamine Black, R.N.; 10-20% Glauber's salt crystals; (vii) YELLOW:- 1% Stilbene Yellow, 2 G.P. extra Conc.; 10-20% Glauber's salt crystals. / уточина. пряжи высокой крутки. Вуаль дё Лен ('Voile de Laine'). Под Вуалью, от Французского слова Voile, означающее Завеса или Покрывало, понимается:- (1) гладкая тонкая прозрачная, вырабатываемая из шерстяной, хлопчатобумажной или шёлковой пряж, шерстяная, хлопчатобумажная или шёлковая ткань, из которой изготовляют платья, шарфы. Вуаль бывает белёная, крашеная и набивная, лицевая сторона ткани часто украшается вышитыми рисунками. Применяется главным образом для шитья дамских платьев. (2) прозрачная тонкая сетка, прикреплённая к женской шляпке и иногда закрывающая лицо.

VOIR DIRE = ВУАР ДИР (или СОБЕСЕДОВАНИЕ С ПРИСЯЖНЫМИ) – Voir Dire:- in law, process of questioning by which members of a jury are selected from a large panel, or venire, of prospective jurors. The veniremen are questioned by the judge or by the attorneys for the respective parties. The voir dire attempts to detect bias or preconceived notions of guilt or innocence on the part of the veniremen. The parties, including the prosecution in a criminal case, may challenge potential jurors and dismiss an unlimited number for cause. They also have a limited number of peremptory challenges, which enable them to dismiss a juror without giving a reason. Voir Dire is a legal phrase for a variety of procedures connected with jury trials. It originally referred to an oath taken by jurors to tell the truth (Latin:- Verum Dicere), i.e. to say what is true, what is objectively accurate or subjectively honest, or both. It probably comes from the Anglo-Norman language. The word Voir (or Voire), in this combination, comes from Old French and derives from Latin Verum (That Which Is True). It is related to the modern French word Voire (Indeed), but not to the more common word Voir (To See), which derives from Latin Vidēre. William Blackstone referred to it as Veritatem Dicere, which was translated by John Winter Jones as 'To Speak The Truth'. However, the expression is now often interpreted by false etymology to mean 'To See (Them) Say'. The term is

used (as Le Voir-Dire) in modern Canadian legal French. / Вильэм Блэкстоун (William Blackstone) Дьжон Винтё Дьжонз (John Winter Jones).

VOITH SCHNEIDER PROPELLER = КРЫЛЬЧАТЫЙ ДВИЖИТЕЛЬ ФОЙТ ШНАЙДА – On a Voith-Schneider Propeller the blades project below the ship hull and rotate about a vertical axis, having an oscillatory motion about its own axis superimposed on this uniform motion. The blade's oscillating movement determines the magnitude of thrust through variation of the amplitude, the phase correlation determining the thrust direction between 0 and 360 degrees. It is mounted inside a protective nozzle on the bottom of the ship to protect it against underwater obstructions and from ships hulls. The Voith Schneider Propellers are located in the forebody, with free inflow and outflow in all directions. The thrust forces act ahead of the vessel axis of rotation. A type of propulsion unit used on a tug. / Фойт Шнайда (Voith Schneider; название Немецкой компании). Тип устройства для движения вперёд, используемый на буксирах. Под Крыльчатым Движителем понимается судовой движитель с расположенными на равных угловых расстояниях на диске (который вращается вокруг вертикальной оси) удлинёнными лопастями, перпендикулярными к диску. Поворот лопастей вокруг собственной оси, осуществляемый дистанционно с поста управления судном, меняет направление тяги крыльчатого движителя вплоть до противоположного, поэтому крыльчатые движители применяют на судах, которые должны обладать высокой манёвренностью (буксирные суда, тральщики, плавучие краны и другие).

VOL = VOLATILE ORGANIC LIQUID

VOL = VOLUME

VOLATILE = НЕСТАБИЛЬНОЕ (или ЛЕТУЧЕЕ, или ЛИХОРАДОЧНОЕ) – (1) Volatile:- readily vaporized at a relatively low temperature. Volatile:- description of any substance that evaporates readily.

(2) Volatile:- tending to vary often or widely, as in price:- the ups and downs of volatile stocks. See also Volatile Market. / Лихорадочное или Неустойчивое:- термин характеризует состояние рынка, описывающее величину и частоту колебаний цен на данную акцию, облигацию, товар или сырьё. Лихорадочное (Volatile):- подверженный быстрым и резким колебаниям. Этот термин используется для описания размеров и частоты колебаний цен на определённые акции, облигации или товарно-сырьевую продукцию. Акции могут быть лихорадочными, поскольку перспективы компании выглядят неопределённо или на руках акционеров находится небольшое число акций (смотрите также Thin Market), или вследствие иных причин. В том случае, если колебания связаны с причинами, исходящими из ситуации в компании, выпустившей данные ценные бумаги, а не обусловлены рыночными условиями, то доход измеряется с помощью коэффициента Альфа (Alpha). Акции с коэффициентом Альфа, равным 1.25, могут подняться в цене на 25% за год вследствие роста их внутренней стоимости, например, роста доходов в расчёте на акцию, независимо от состояния рынка в целом. Лихорадочность, связанная с рынком, также называется Систематическим Риском (Systematic Risk), она измеряется с помощью коэффициента Бета (Beta). Смотрите также (Duration).

VOLATILE CORROSION INHIBITOR METHOD = МЕТОД ИНГИБИТОРА ЛИХОРАДОЧНОЙ КОРРОЗИИ – Volatile Corrosion Inhibitor (VCI) Method is a method used to inhibit corrosion. Inhibitors are substances capable of inhibiting or suppressing chemical reactions. They may be considered the opposite to catalysts, which enable or accelerate certain reactions. Unlike the protective coating method, the VCI method is an active corrosion protection method, as chemical corrosion processes are actively influenced by inhibitors. In simple terms, the mode of action is as follows:- due to its evaporation properties, the VCI substance (applied onto paper, cardboard, film or foam supports or in a powder, spray or oil formulation) passes relatively continuously into the gas phase and is deposited as a film onto the item to be protected (metal surfaces). This change of state proceeds largely independently of ordinary temperatures or humidity levels. Its attraction to metal surfaces is stronger than that of water molecules, resulting in the formation of a continuous protective layer between the metal surface and the surrounding atmosphere which means that the water vapor in the atmosphere is kept away from the metal surface, so preventing any corrosion. VCI molecules are, however, also capable of passing through pre-existing films of water on metal surfaces, so displacing water from the surface. The presence of the VCI inhibits the electrochemical processes which result in corrosion, suppressing either the anodic or cathodic half-reactions. Under certain circumstances, the period of action may extend to two years. The mode of action dictates how VCI materials are used. At item to be protected is, for example, wrapped in VCI paper. The metallic surfaces of the item should be as clean as possible to ensure the effectiveness of the method. The VCI material should be no further than 30 cm away from the item to be protected. Approximately 40 g of active substances should be allowed per 1 m^3 of air volume. It is advisable to secure this volume in such a manner that the gas is not continuously removed from the package due to air movement. This can be achieved by ensuring that the container is as well sealed as possible, but airtight heat sealing, as in the desiccant method, is not required. The VCI method is primarily used for articles made from carbon steel, stainless steel, cast iron, galvanized steel, nickel, chromium, aluminium and copper. The protective action provided and compatibility issues must be checked with the manufacturer. N.B.:- The use of water-miscible, water-mixed and water-immiscible corrosion protection agents, corrosion protection greases and waxes, volatile corrosion inhibitors (VCI) and materials from which volatile corrosion inhibitors may be released (e.g., VCI paper, VCI films, VCI foam, VCI powder, VCI packaging, VCI oils) is governed by the German Technical Regulations for Hazardous Substances, TRGS 615 'Restrictions on the use of corrosion protection agents which may give rise to N-nitrosamines during use'. Comparison Of Advantages And Disadvantages Of The VCI Method:- Advantages:- (i) since the gas also penetrates holes and cavities, these areas also receive adequate protection; (ii) the period of action may extend to two years; (iii) the wrapping need not be provided with an airtight heat seal; and (iv) on completion of transport, the packaged item need not be cleaned, but is immediately available. Disadvantages:- (i) the VCI method is not suitable for all metals; it may cause considerable damage to nonmetallic articles (plastics, etc); and (ii) most VCI active substances may present a hazard to health, so it is advisable to have their harmlessness confirmed by the manufacturer and to obtain instructions for use.

VOLATILE MARKET = ЛИХОРАДОЧНЫЙ РЫНОК (или НЕУСТОЙЧИВЫЙ РЫНОК) – Volatile Markets are ones where the price moves vigorously and unpredictably. Some commodities are more volatile in character than others but volatility is mainly a varying characteristic that affects all markets at different times. If a market tends to be generally too volatile for your liking, then you are best advised to avoid that particular market because you will not feel comfortable having it as part of your trading universe. Otherwise, you need volatility to some degree in your markets because if prices do not move sufficiently, you will not be able to make money trading them. Volatility is closely related to risk. The more volatile the market, the more risky it will be to trade – but you must take risks if you want to make money. Risk is inextricably tied to prospective return as well – so we have a real tie up here! What it all amounts to is that you must have some volatility but not more than is justified by the prospective return 'on offer' to you as a trader. Even if the return is well balanced with the volatility (risk) you still must not have more risk than suits your own personal comfort – otherwise you will not stick to your system. You must also have a way of measuring volatility against the return your system can deliver – and this needs to be embodied in your trading method. Getting back to volatile markets, how is their volatility measured? The standard deviation indicator is the best known measure of volatility and this is commonly incorporated into other indicators and methods to produce ratios traders employ to asses market performance. A market may be making firm progress by moving up vigorously but even in this type of market, there will be downward moves as well as upward ones. You can expect 2 or 3 days in 7 to be 'reversal' days when the price moves

back in the opposite direction to the one the market is taking. In a vigorous market, these reversals are vigorous too and this pinpoints a major area of risk. Is the market changing direction or is it just reversing vigorously? Nobody knows the answer and no system can predict what will happen. As a trader, your dilemma will be – how to avoid being shaken out whilst at the same time avoid being caught by a big setback? Volatile markets are more likely than others to pose these questions – but if as a systems trader, you have tested and evaluated your system thoroughly, you will know that it will deal with these problems competently. Volatile Market is the foreign exchange market which sees numerous unpredictable price variations. Volatile markets represent a greater degree of risk to forex traders, despite the necessity of some movements in order to facilitate currency trades. Opposite of Stable Market. Volatile Market is a market with a great deal of price instability. Volatile markets are highly risky; for example, a security with a volatility of 50% is considered very high risk because it has the potential to increase or decrease by up to half its value. Volatile Market:- unpredictable and vigorous changes in price within the stock market. It is necessary for some movement within the market in order to sell commodities, however a volatile market represents the most risk to investors. / Изменчивый Рынок. Лихорадочный Рынок:- рынок с с огромной нестабильностью цен сделок. Лихорадочные рынки являются высоко рискованными; например, ценная бумага с лихорадочностью в 50% рассматривается как бумага с очень высоким риском потому что она имеет потенциал к повышению или снижению до половины её стоимости. Лихорадочный Рынок:- непредсказуемые и сильные изменения в цене на фондовом рынке. Необходим для некоторого движения на рынке с тем, чтобы продать сырые материалы, однако лихорадочный рынок представляет для инвесторов больший риск.

VOLATILE MATTER = ЛЕТУЧЕЕ ВЕЩЕСТВО – Volatile Matter:- those products, exclusive of moisture, given off by a material as gas or vapor. Volatile matter is determined by heating the coal to 950 degrees Centigrade under carefully controlled conditions and measuring the weight loss, excluding weight of moisture driven off at 105 degrees Centigrade. Volatile Matter:- those products given off by a material as gas or vapor, determined by definite prescribed methods. / Летучие Вещества:- (в горючих ископаемых) – газо- и парообразные продукты, выделяющиеся при разложении органического вещества при нагревании горючих ископаемых в стандартных условиях при t порядке 850 °С (ГОСТ 6382–65, для антрацитов 7303–54). Гигроскопическая влага и карбонатная углекислота в это понятие не входят. Повышенное содержание материалов, выделяющих при нагревании летучие продукты, вносит искажение в цифры выхода летучих веществ; твёрдый остаток после удаления летучих веществ называется Нелетучим Остатком. С повышением степени углефикации выход летучих веществ падает. Гумолиты отличаются пониженным выходом летучих веществ по сравнению с сапропелитами и липтобиолитами. Гелифицированные компоненты дают более низкий выход летучих веществ, чем липоидные компоненты, и более высокий, чем компоненты фюзенизированные. Выход летучих веществ в клареновых разностях гумусовых углей, начиная с низших газовых, используется как один из важнейших показателей степени их углефикации.

VOLATILE ORGANIC COMPOUND = ЛЕТУЧЕЕ ОРГАНИЧЕСКОЕ СОЕДИНЕНИЕ – Volatile Organic Compound (VOC) is any organic compound which participates in atmospheric photochemical reactions except for those designated by the EPA administrator as having negligible photochemical reactivity.

VOLATILE SOLIDS = ЛЕТУЧИЕ ТВЁРДЫЕ ТЕЛА – Volatile Solids:- a solid material that is readily decomposable at relatively low temperatures.

VOLATILE SYNTHETIC ORGANIC CHEMICALS = ЛЕТУЧИЕ СИНТЕТИЧЕСКИЕ ОРГАНИЧЕСКИЕ ХИМИКАТЫ – Volatile Synthetic Organic Chemicals are the chemicals that tend to volatilize or evaporate from water.

VOLATILITY = ЛЕТУЧЕСТЬ (или НЕУСТОЙЧИВОСТЬ, или ИСПАРЯЕМОСТЬ) – Volatility is the property of a liquid fuel that defines its evaporation characteristics. RVP is an abbreviation for 'Reid Vapor Pressure', a common measure of and generic term for gasoline volatility. The Environmental Protection Agency (EPA) regulates the vapor pressure of gasoline sold at retail stations during the summer ozone season (June 01 to September 15) to reduce evaporative emissions from gasoline that contribute to ground-level ozone and diminish the effects of ozone-related health problems. EPA established a two-phase reduction in summertime commercial gasoline volatility. These rules reduce gasoline emissions of volatile organic compounds (VOC) that are a major contributor to ground-level ozone (smog). Phase I was applicable to calendar years 1989 through 1991. Depending on the state and month, gasoline RVP was not to exceed 10.5 pounds per square inch (psi), 9.5 psi, or 9.0 psi. Phase II is applicable to 1992 and later calendar years. Depending on the state and month, gasoline RVP may not exceed 9.0 psi or 7.8 psi. EPA provides a 1.0 psi RVP allowance for gasoline containing ethanol at 9 to 10 volume percent. In order to relax the applicable federal RVP standard in an area where the more stringent federal RVP of 7.8 psi is required, an area must be designated as (or redesignated to) an attainment area. The area must also submit a maintenance plan demonstrating continued attainment of the ozone NAAQS with the less stringent RVP standard in place. See also Vapor Pressure-Reid. Volatility:- this property describes the degree and rate at which a liquid will vaporize under given conditions of temperature and pressure. When liquid stability changes, this property is often reduced in value. Refiners are currently switching to make summer-grade gasoline ahead of the May 01 compliance date for refiners and product terminals. Summer-grade gasoline has a lower volatility than winter-grade gasoline to limit evaporative emissions that normally increase with warm weather and cause unhealthy ground-level ozone. Volatility is a measure of how easily a liquid (or solid) will change into a vapor. For gasoline, it is measured by Reid Vapor Pressure (RVP). The higher the RVP, the more volatile the gasoline. While the Environmental Protection Agency (EPA) requires lower-volatility summer gasoline, aside from any government regulation, gasoline's RVP must be limited to ensure that the fuel does not vaporize in the fuel system. If it does, the engine can stop running. It costs refiners several cents per gallon more to make summer-grade gasoline, compared with winter-grade fuel, which is part of the reason that retail pump prices can rise in the summer. Additionally, in parts of the country that require cleaner, reformulated gasoline (RFG), such gasoline must meet even stricter limits on volatility. The EPA, for example, requires use of RFG in high-smog areas to reduce smog-forming particulates and pollutants. States or regions also have gasoline quality requirements; California, for example, has stricter requirements than the federal government. For logistical reasons, the transition to low-RVP gasoline happens over the course of several spring months as temperatures rise and to facilitate lowering the RVP of remaining inventories of winter-grade gasoline. The federally mandated dates for summer-grade gasoline and reformulated gasoline, where required, are May 01 to September 15 for refiners and terminals, and June 01 to September 15 for gasoline retailers. In California switchover dates are earlier, and summer-grade gasoline must be in use for a longer period. A typical summer-grade gasoline is composed of fluid catalytic cracker gasoline, 40%; straight-run gasoline (directly from crude oil distillation), 25%; alkylate, 15%; reformate, 18%; and butane, 2%. Winter-grade gasoline usually contains more butane, which has an octane rating slightly below premium gasoline (91–93 octane). While butane is an economic component of gasoline, the high volatility of butane limits the amount of butane that can be used in summer-grade gasoline. / Упругость Пара–По Риду (Vapor Pressure-Reid). Volatility is a property of having a low boiling point or temperature of sublimation at normal pressure. Likewise, having a high vapor pressure at ambient conditions. / Под Летучестью понимается свойство жидких и твёрдых веществ переходить в газообразное состояние; мерой летучести является концентрация насыщенного пара данного вещества при рассматриваемой температуре. Летучесть выражается в миллиграммах на кубический метр (мг/м^3) или в миллиграммах на литр (мг/л) и рассчитывается по уравнению состояния идеальных газов (смотрите Уравнение Клапейрона). С повышением температуры

летучесть данного вещества увеличивается вследствие возрастания при этом давления его насыщенного пара. В термодинамике термин Летучесть используется также вместо термина Фугитивность. Фугитивность – величина, используемая для расчёта свойств реальных газов с помощью термодинамических соотношений, выведенных для идеальных газов (смотрите также Газы); введена Американским физико-химиком Гилбётом Ньютчэном Люисом (Gilbert Newton Lewis; 1875–1946) в 1901. Фугитивность f данного газа (компонента газовой смеси) – такая функция давления p, температуры T (и концентрации каждого из компонентов смеси), подстановка которой вместо давления (парциального давления) в термодинамическом уравнения для идеального газа делает их справедливыми и для реального газа при рассматриваемых условиях. Хотя этот приём является формально-математическим, однако он продуктивен, так как применение более сложных уравнений состояния реальных газов, во-первых, связано со значительными вычислительными трудностями и, во-вторых, не может обеспечить необходимую точность, поскольку любое уравнение состояния реального газа справедливо лишь в определённом интервале значений p и T. Отношение f/p называется Коэффициентом Фугитивности; очевидно, для идеального газа он при любых условиях равен 1. Таким образом, отличие значения f/p от 1 характеризует степень отклонения газа от идеального состояния. Роль фугитивности газа по отношению к его парциальному давлению аналогична роли активности компонента раствора по отношению к его концентрации. Поскольку фугитивность вещества, образующего конденсированную фазу или входящего в её состав, равна его фугитивности в насыщенном паре этой фазы, то фугитивность можно рассматривать и как величину, количественно характеризующую при заданных p, T и составе фазы способность вещества к выходу из неё (отсюда и название от Латинского слова Fugitivus, означающее Убежавший или Улетевший). Испаряемость – условная величина, характеризующая потенциально возможное (не лимитируемое запасами воды) испарение в данной местности при существующих в ней атмосферных условиях. Испаряемость измеряется либо с поверхности воды Испарителя, либо с поверхности крупного естественного пресноводного бассейна, либо с избыточно увлажнённой почвы. Испаряемость выражается в миллиметрах (мм) слоя испарившейся воды. Так, например, средняя годовая испаряемость в Ленинграде – 320, в Москве – 417, в Одессе – 584, в Нукусе (Средняя Азия) – 1 718 мм. Испаряемость может очень сильно отличаться от фактического испарения с поверхности почвы и растений, особенно в безводной пустыне, где фактическое испарение близко к нулю вследствие полного отсутствия воды, в то время как испаряемость достигает 2 000 мм в год и более.

VOLATILITY = ЛИХОРАДОЧНОСТЬ (или ЧЕХАРДА, или ШАРАХАНЬЕ, или БОЛТАНКА, или ШИРОКАЯ АМПЛИТУДА ИЗМЕНЧИВОСТИ) – Volatility is an indicator of the price fluctuation of a security or index during a certain period. Based on volatility it is possible – regardless of market performance – to assess a security's potential gain or loss. Since the ratio expresses the expected future change of a security, it is also of special importance in determining option prices. Generally speaking, the higher the volatility of a reference value, i.e. the extent and frequency of fluctuations, the higher the option premium, regardless of whether it is a call or put option. Volatility is a statistical measure called the Coefficient of Variation. Volatility is a statistical measure of the dispersion of returns for a given security or market index. Volatility can either be measured by using the standard deviation or variance between returns from that same security or market index. Commonly, the higher the volatility, the riskier the security. Measure of the stability of a particular instrument. If, say, a share price or a market index moves often and vacillates wildly, then it is said to be volatile. Volatility is a measure of risk based on the standard deviation of the asset return. Volatility is a variable that appears in option pricing formulas, where it denotes the volatility of the underlying asset return from now to the expiration of the option. There are volatility indexes. Such as a scale of 1–9; a higher rating means higher risk. A measure of the extent and frequency of fluctuation in the price of exchange rates, precious metals, interest rates, securities, options, etc. In securities trading, Volatility is the measurement of the change in price over a given time period. It is often expressed as a percentage and computed as the annualized standard deviation of percentage change in daily price. The market's price range and movement within that range. The direction of the price move, whether up or down, is not relevant. Volatility is a measure of a market's price swings over a given period of time. In a high volatility environment, futures prices will tend to make bigger moves between the daily high and low, as well as between subsequent settlement prices. Volatility is considered to be 'mean reverting'. A period of high volatility should be followed by a period of low volatility in order for the market to seeks its own average and equilibrium. Volatility is a statistical measurement of the rate of price change of an asset underlying an option. See also Historical Volatility, and Implied Volatility. Volatility is a value attributed to an underlying futures contract which determines the premium that is set by the grantor. Includes an element of historical volatility, and the volatility which the grantor of an option believes will still be seen in that futures contract. Refers to options:- Volatility is the rate of change in the price of the underlying asset. Volatility is a measurement of the change in price over a given time period. It is usually expressed as a percentage and computed as the annualized standard deviation of percentage change in daily price. The more volatile a stock or market, the more money an investor can gain (or lose!) in a short time. Volatility is a measure of variability, usually of prices, and a major factor influencing the price of an asset. The standard deviation of a price series is commonly used to measure price volatility. Volatility is a measure of the amount by which an asset price is expected to fluctuate over a given period. Normally measured by the annual standard deviation of daily price changes (historic). Can be implied from futures pricing implied volatility. Volatility (in financial markets) is a measure of the risk or uncertainty faced by participants in financial markets. It can be measured either from the past variation of asset prices. See also ARCH/Stochastic Volatility Models; Historic Volatility; and Implied Volatility. Volatility is a measurement of the change in price over a given time period. Volatility:- the annualized standard deviation, as a percentage, of possible future riskless short-term interest rates. Indicates the degree to which a security's price or yield is expected to rise or fall sharply within a short-term period. Volatility is a measure of variability, usually of prices, and a major factor influencing the price of an option. The standard deviation of a price series is commonly used to measure price volatility. Volatility:- the market's price range and movement within that range. The direction of the price move, whether up or down, is not relevant. Historic volatility indicates how much prices have changed in the past and is derived by using daily settlement prices for futures. Implied volatility measures how much the market thinks prices will change in the future, and is obtained from daily settlement prices for options. Volatility is a measure of stock price fluctuation. Mathematically, volatility is the annualized standard deviation of a stock's daily price changes. See also Historic Volatility, Implied Volatility, and Individual Volatility. Volatility is:- (i) a measure of the variability of a market factor, most often the price of the underlying instrument; (ii) the annualized standard deviation of the natural log of the ratio of two successive prices; the actual volatility realized over a period of time (the historic or historical volatility) can be calculated from recorded data; or (iii) one of the variables that must be specified in the Black-Scholes model of option pricing:- a vanilla or non-exotic option will cost more when volatility is high than when it is low. However, volatility is the only one of these variables whose value must be estimated. The estimate used (known as the Implied Volatility) can be derived from the prices of options in the market and the known input variables. However, the Black-Scholes model also assumes that volatility is constant, which is not true. New techniques have been developed to cope with volatility's variability, including mean-reverting models and stochastic volatility models. Volatility is a measure the tendency of price to move up and down, based on its daily price history over the some time period ranging from 30 days to 12 months. Volatility is a measure of the variability of a market factor, most often the price of the underlying instrument. Volatility is defined mathematically as the annualised standard deviation of the natural log of the ratio of two successive prices. The actual volatility realised over a period of time (the historical volatility) can be calculated from recorded data. Volatility is one of the variables that must be specified in the Black-Scholes model of option pricing:- a vanilla option will cost more when volatility is high than when it is low. However, volatility is the only one of these

variables whose value must be estimated. The estimate used (known as the Implied Volatility) can be derived from the prices of options in the market and the known input variables. However, the Black-Scholes model also assumes that volatility is constant, which is not true. New techniques have been developed to cope with volatility's variability, including mean-reverting models (such as Garch Model (short for the generalized autoregressive conditional heteroscedasticity model)) and stochastic volatility models. See also Black-Scholes Model; and Garch Model. Volatility is a measure of the risk or uncertainty faced by participants in financial markets. It can be measured either from the past variation of asset prices. Volatility – the relative rate at which the price of a security moves up and down. Volatility is found by calculating the annualized standard deviation of daily change in price. If the price of a stock moves up and down rapidly over short time periods, it has high volatility. If the price almost never changes, it has low volatility. Volatility is the amount by which futures prices fluctuate or are expected to fluctuate in a given period of time. Volatility (options):- a value attributed to an underlying futures contract which determines the premium that is set by the grantor. Includes an element of historical volatility, and the volatility which the grantor of an option believes will still be seen in that futures contract. / Лихорадочность (опционы):- присваиваемое базовому фьючерсному контракту значение, определяющее премию, установленную лицом, предоставившим опцион. Включает элемент исторической лихорадочности и той лихорадочности, которая по мнению лица, предоставившего опцион, будет продолжать наблюдаться в стоимости такого фьючерсного контракта. Блэк-Скоулз (Black-Scholes). и частота флуктуации (колебания) цены . Мера шараханья или лихорадочности, обычно цен, и основной фактор, воздействующий на стоимость актива. Для определения шараханья или лихорадочности цены широко используются серии стандартных отклонений цены. При значительном шараханьи или лихорадочности рынка краткосрочные колебания цены имеют широкую амплитуду. В современном Русскоязычном биржевом жаргоне некоторые участники рынка подменяют термин Шараханье или Лихорадочность термином Волатильность, однако же ни кому из них не приходит в голову мысль высказаться о ситуации на рынке, когда цены стремительно и значительно взлетают и падают, что 'цены волатилит', все говорят:- 'цены шарахаются из стороны в сторону' или 'цены лихорадит'. Лихорадочность или Изменчивость или Неустойчивость:- показатель тенденции цен на акции к резкому движению вверх или вниз, получаемый на основе ежедневных данных о поведении цен в течение последних 12 месяцев. Акции с более высокой лихорадочностью склонны к тенденции проявлять большие колебания в цене по сравнению с теми, которые показывают меньшую лихорадочность. Лихорадочность в размере 20% означает, что за последние 12 месяцев торговой активности акции колебались в цене примерно на 20% вверх и вниз от средней цены за этот период. Лихорадочность или Шараханье – показатель неустойчивости рыночных цен активов, лежащих в основе опционного контракта. При использовании в формулах опционного ценообразования рассчитывается как стандартное отклонение доходности базисного актива за период до истечения срока опциона. Лихорадочность или так называемая Волатильность:- присваиваемое базовому фьючерсному контракту значение, определяющее премию, установленную лицом, предоставившим опцион. Включает элемент исторической лихорадочности и той лихорадочности, которая по мнению лица, предоставившего опцион, будет продолжать наблюдаться в стоимости такого фьючерсного контракта. Лихорадочность:- признак цен на ценные бумаги, товарно-сырьевую продукцию или характеристика рынка, склонного к резким падениям и подъёмам цен в течение короткого периода времени. Мерой относительной неустойчивости (цен) акций, связанной с рынком в целом, является коэффициент Бета (Beta). Смотрите также Нестабильное или (Volatile). Лихорадочность:- показатель, характеризующий неустойчивость, изменчивость. Применительно к ипотечным кредитам Лихорадочность, как правило, измеряет отклонения от планового погашения задолженности. Волатильность (Volatility) – изменчивость цены. На высоковолатильных рынках краткосрочные колебания цены имеют большую амплитуду. Волатильность – относительная скорость, с которой цена перемещается вверх и вниз. Вычисляется годовое среднеквадратичное отклонение ежедневного изменения цены. Нестабильность (Volatility):- поведение ценной бумаги, характеризующееся значительным и/или частым изменением её рыночной цены, особенно если такие изменения не связаны с рыночными или иными внешними факторами. Будучи наиболее рискованными, такие бумаги в то же время предоставляют активным торговцам наибольшие возможности для получения прибыли.

VOLATILITY ALLOWANCE = ДОПУСК НА ЛИХОРАДОЧНОСТЬ (или ХХ) – Volatility Allowance is the largest difference in container availability taking into account past peaks in net demand after having removed the trend in container demand during the repositioning trade-off period.

VOLATILITY INDEX = ИНДЕКС ПО ЛИХОРАДОЧНОСТИ (или ИНДЕКС ПО ШАРАХАНЬЮ) – (1) The CBOE® Volatility Index (VIX®, and VOX, and VXN) measures fear and optimism as manifested in options activity. When large numbers of traders become fearful, the VIX® reading rises, and when complacency about the market reigns, the VIX® reading falls. And since the vast majority of put/call buyers are wrong and lose money, it's usually a smart move to fade (go counter to) what the VIX® says the the crowd is doing. The VIX® is an INVERSE indicator, which means that high readings are oversold (excess of bearishness) and low readings are overbought (excess of bullishness). Because of this Decision Point displays the VIX® chart with an inverted scale to make its interpretation more intuitive – overbought readings show at the top of the chart and vice versa. In September 2003 the CBOE® changed the way the VIX is calculated. The new VIX® is derived from the prices of all near-term at-the-money SPX puts and calls and out-of-the-money puts and calls. Deep-in-the-money options are excluded. This methodology is also used to calculate the NASDAQ 100 (NDX) volatility index (symbol:- VXN). The old VIX® is still avaliable but is now has the symbol VOX. It still uses the old calculation method, which uses the Black-Scholes pricing model. The VOX is calculated by taking the weighted average of the implied volatility of 8 OEX calls and puts with an average time to expiration of 30 days. The CBOE® calculated severals years history of closing values for the VIX®. That data was not live and doesn't have an open, high, or low associated with it. Those days will display as dots on the daily chart. The same is true for the VXN, which is only a few years older than the new VIX®. Raw VIX® numbers are of limited value. The VIX® indicator is most useful when used in combination with some type of overlay, and preferably one that employs channels or bands. Some technicians use Bollinger Bands® for this purpose, others use a short term (3 months or so) linear regression channel or percent bands. When used in this fashion, it is the VIX® position within the channel that's important, rather than the raw number reading. See also Market Volatility Index. Volatility readings can be a good forecaster of near- to intermediate-term moves. But the common approach often is not the best approach. Bull markets rise over extended periods because hope builds slowly and cautiously. Bear markets are short because fear can work its way through the marketplace in a relative instant. Often, traders maintain their bearish positions too long because they aspire to a certain price target that doesn't get hit because the time frame of the move has run its course. As a result, these traders must cover and give back hard-earned profits. What most traders don't grasp is that bear markets don't end at specific price points; they terminate when fear reaches certain levels. The volatility index, or VIX®, is an important indicator of market fear. It is a useful forecaster of near- to intermediateterm moves in equity indexes. It's a tool that enables the trader to estimate how much momentum may remain for a current leg. There are two paradigms at work with respect to the VIX®:- the mathematical interpretation for the sophisticated options player and the psychological factor that really drives markets. Technically speaking, the VIX® is a measure of implied volatility for S&P 500 Index options. It estimates expected stock market volatility over the next 30 days. It is calculated by the Chicago Board Options Exchange and is derived from a public domain, yet complex, formula that is expressed on a percentage basis. Reading the VIX®:- in simple terms, the VIX® reading refers to the annualized value of the expected

move over the next 30 days. For example, a VIX® of 17% projects the market will move 17%/ (square root of 12) = 4.9% over the next month. Likewise, a VIX® of 40% projects the market to move 40%/ (square root of 12) = 11.5%. This is a linear interpretation. Keep in mind that markets tend to move in decidedly non-linear fashion, especially when you least expect it. In practice, however, the specific forecast of the VIX® is not important. Instead, the current reading with respect to both long- and short-term relative values is key. Simply, a low VIX® translates into less movement over the next 30 days, while a high VIX® means a larger percentage move. But keep in mind, the reading is direction neutral. That said, there is a psychological factor at play. For traders, analysts and the financial media, high volatility connotes a market drop, while low volatility implies a rising market. In addition, many believe a low VIX® reading means more of the same, while a high VIX® reading means the market is poised to shift. But this conventional wisdom isn't necessarily correct. For instance, in 2002 when the S&P 500 bottomed at 768, the VIX® high was approximately 42% that week, but fell to 36% the day the market turned. Technically speaking, traders could have anticipated an approximate 10–12% move over the next 30 days. Further, traders following mainstream assumptions may have assumed the market would be lower over the next month. However, the low to high over the next 30 calendar days was 768 to 894, a difference of 16.4%. The opposite move higher is not such a stretch; when markets truly do bottom, everyone thinks prices are going down forever. However, the right approach is to buy when there is blood in the streets, expecting prices to rise as a result of all buying pressure having been extinguished. A similar misconception also is rampant on the upside. Traders who enter in a late-stage bull market are not psychologically ready for the turn; the most important number to them is not the VIX®, but rather how much skin they have in the game. Consider the true cost of improperly analyzing the VIX®. With respect to the 2002 move, instead of a 12% drop, we saw a 16.4% rise; this is really a 28% mistake. Approaching the VIX® correctly is critical to market survival. History Repeats:- most traders get hurt when the trend changes because they ignore signs that the tide has turned. Methodologies such as market-timing windows and the Gann price/time square are key here. Using the VIX® also can provide perspective, but remember, when the VIX® is low, it does not mean the market will keep rising. Conversely, a high VIX® does not always translate to lower market prices. Looking at a long-term S&P 500 chart, certain themes emerge (see 'Highs & Lows', right). Over this period, traditional intermediate-term corrections and bear markets tend to terminate near 45%, while bull markets terminate in a range from about 9–15%. During the 2008 financial crisis, the VIX® spiked to 89.53%, which was a generational extreme. Since that time, many bears have expected each crisis to replicate 2008. But consider the pure statistical message of the VIX® over the last 20 years:- that high was hit once out of 20 times, a 5% probability, which isn't good. Is it smart to expect a market to crash? History says no, yet traders look for this result constantly. That's an important lesson from the VIX® that often gets overlooked. Remember, as we just noted, when the VIX® gets low, the market tends to top; when the VIX® is high, the market tends to bottom. And swing traders, beware – the 30-day anticipation calculation may not work if you are trading close to a high or low. A better approach to using the VIX® is to realize that it should fall in value as the market rises, while a falling market should coincide with a rising VIX®. A rising market means the fear level tends to drop, and a sinking market should be accompanied by an indicator that shows fear is rising. If that doesn't happen, there's a problem. If the market sinks, but the VIX® doesn't rise, it's an indication of complacency. In 'Sentiment:- putting trading into context' (October 2012), we learned how complacency is a characteristic of an early stage correction or bear market. If a rising market is accompanied by a VIX that doesn't drop, that means the market is rising on a consistent fear basis, which also means it could be rising on a wall of worry, a key characteristic of a bull market. Those looking for a trade with a duration of longer than a few days to a couple of weeks should consider holding the position longer if the VIX® doesn't drop (by much). The takeaway here is that fear, or lack thereof, is the fuel that drives both bull and bear markets. The VIX® chart from 2009 shows a slow move downward with several sharp spikes that indicated fear rose quickly on the pullbacks. Like all generalities, there are exceptions. The VIX® bottomed at 9.39% in December 2006, yet the market didn't start peaking until the July-to-October period the following year. Then again, it's rare to see the VIX® register such a low reading. Bernard Baruch (the Warren Buffet of the first half of the XX century) said he didn't mind missing the first and last 10% of a move so long as he could participate in the middle 80%. By the time the VIX® got so low, a market top was going to happen. It wasn't a matter of if, but when. Recent bottoms also are instructive. When the market bottomed in 2011 amid a debt-ceiling debate, the VIX® hit 48.20%, and then 37.38% when it was retested again in October. Thus, the suggestion that a VIX® over 45% indicated an intermediate- to long-term low gave the market a lot of fuel to move higher. On the other hand, when the market bottomed in June 2012, the VIX® reached a high of 27%. Do not anticipate the same kind of market move with a rally originating from a VIX® of 27%, or lower, as you would when the market bottoms at a VIX® of 36% or 48%. The October 2011 low in the S&P 500 with a high VIX® reading produced a 32% move to the April 2012 high. The June 2012 low with a much lower VIX® reading only produced roughly a 16% move by the September high. By the time the market found the next low in November 2012, the VIX® only was in a range from roughly 15.93% to 18.64%. This indicates that while long-term traders seem to enjoy low volatility, history suggests they would be better off taking a longer-term position with the VIX® near 30% or above. Inconsistencies:- it has been more than year since the VIX® maintained a lower reading. The trouble started during the Santa Claus rally of 2011. From December 05 through December 19, 2011, the VIX dropped while the S&P 500 peaked around 1267 then fell to 1202. All calculations aside, that's when fear left the market, which was OK because the VIX® was in the high 20s. Since the latter part of 2012, though, the market has not been able to make good progress. Last (2012) year was dominated by the lower VIX® reading. Indeed, there was one key sequence when it was repeatedly reported the VIX® was no longer relevant because pundits were expecting a market turn on the low readings. Consequently, the market peaked and corrected approximately a week later. We should have learned from the Internet bear and real estate bubble that sooner or later prices revert to the mean, and when sentiment seems to suggest a new normal, that's precisely the time risk is getting high and a turn is imminent. As we've seen, the VIX® follows a 20-plus year trend. Is it realistic to think the market is going to adopt a new normal? On a day-to-day basis, it's important to keep track of how much fear comes into the market based on the current sequence. With respect to the VIX®, a quick look will allow you to to gauge your fellow traders and determine the potential of a move. However, one of the most important lessons is one of the hardest to follow with respect to human nature. A trader positioned late in the move should use an extreme VIX® reading as a warning sign that an important turn could be imminent. Volatility Index is a widely used measure of market risk. Sometimes referred to as the 'Investor Fear Gauge'. The Market Volatility Index (VIX®) measures the volatility of the market. A recent news story described it as 'the options market's gauge of investor fear'. Traders use VIX® as a general inverse indicator of market volatility and sentiment. High numbers mean that there's excess bearishness, and low numbers indicate excess bullishness. The VIX® is updated intraday by the Chicago Board Options Exchange (CBOE®), using Standard & Poors 500 Index (SPX) bid/ask quotes. It was created in 1993. The CBOE® Volatility Index – more commonly referred to as 'VIX®' – is an up-to-the-minute market estimate of expected volatility that is calculated by using real-time S&P 500® Index (SPX) option bid/ask quotes. VIX® uses nearby and second nearby options with at least 8 days left to expiration and then weights them to yield a constant, 30-day measure of the expected volatility of the S&P 500® Index. Volatility Index (VIX®; also $VIX) is the ticker symbol for the Chicago Board Options Exchange Market Volatility Index, a popular measure of the implied volatility of S&P 500 index options. This index is often referred to as the fear index. It represents one measure of the market's expectation of stock market volatility over the next 30 day period. The VIX® Index was introduced by Prof. Robert Whaley of Vanderbilt University in 1993. The VIX® is calculated and disseminated in real-time by the Chicago Board Options Exchange. It is a weighted blend of prices for a range of options on the S&P 500 index. On March 26, 2004, the first-ever trading in futures on the VIX® Index began on CBOE Futures Exchange (CFE). As of February 24, 2006, it became possible to trade VIX® options contracts. A few Exchange Traded Fund seek to track its performance.

The formula uses a kernel-smoothed estimator that takes as inputs the current market prices for all out-of-the-money calls and puts for the front month and second month expirations. The goal is to estimate the implied volatility of the S&P 500 index over the next 30 days. / был представлен в 1993 Профессором Робэтом Вэйли (Prof. Robert Whaley) из Вэндэбилтского Университета (Vanderbilt University). (2) Volatility Index (VXN) is the implied volatility on the Nasdaq 100 (NPX) option. This volatility is meant to be a forward looking volatility. It is calculated from both calls and puts that are near the money. VOLATILITY/MODIFIED DURATION = ЛИХОРАДОЧНОСТЬ/МОДИФИЦИРОВАННАЯ ПРОДОЛЖИТЕЛЬНОСТЬ (или ЛИХОРАДОЧНОСТЬ/МОДИФИЦИРОВАННАЯ ДЮРАЦИЯ) – Volatility/Modified Duration:- the sensitivity of the market price of an investment. A highly volatile investment is one which has a very unstable price. For fixed interest bonds, volatility is specifically defined as the rate of change in the dirty price (P) of the bond for a change in the gross redemption yield (y).

VOLATILITY OF THE UNDERLYING ASSET = ЛИХОРАДОЧНОСТЬ СООТВЕТСТВУЮЩЕГО АКТИВА (или ШАРАХАНЬЕ СООТВЕТСТВУЮЩЕГО АКТИВА) – The Volatility Of The Underlying Asset is the variance of price around the mean. Generally, measured on an annual basis. The Volatility Of The Underlying Asset is known and constant. The Volatility Of The Underlying Asset, specified in the form of the standard deviation of the log return, is assumed to be known at all times and does not change over the life of the option. This assumption is the most critical, and we take it up again in a later section. In reality, the volatility is definitely not known and must be estimated or obtained from some other source. In addition, volatility is generally not constant. Obviously, the stock market is more volatile at some times than at others. Nonetheless, the assumption is critical for this model. Considerable research has been conducted with the assumption relaxed, but this topic is an advanced one and does not concern us here. / Отклонение цены от среднего значения. VOLATILITY QUOTE TRADING = ТОРГОВЛЯ ПРИ ЛИХОРАДОЧНОМ КОТИРОВАНИИ – Volatility Quote Trading is a method of quoting option contracts whereby bids and asks are quoted according to their implied volatilities rather than prices. Used mainly by sophisticated investors, volatility quotes benefit those investors who trade upon volatility rather than price. These investors are typically interested in the likelihood of a contract moving up or down in price rather than in its actual cost. Refers to the quoting of bids and offers on option contracts in terms of their implied volatility rather than as prices. Volatility Quote Trading is a way to quote an option contract according to its volatility rather than its price. Option investors use volatility quote trading when they are more interested in the likelihood of contract increasing or decreasing in price rather than the price itself.

VOLATILITY RATIO = СООТНОШЕНИЕ С ЛИХОРАДОЧНОСТЬЮ (или СООТНОШЕНИЕ С ШАРАХАНЬЕМ) – The Volatility Ratio identifies days with exceptionally wide trading ranges (the distance between High and Low) and is used to signal likely reversal days. The Volatility Ratio is typically signified with a primary line on a chart, apart from price bars. Although there is no hard-and-fast number used to determine when a breakout is probable, a volatility of 0.5 is most often used by technical traders. Volatility Ratio is a technical indicator used to identify price ranges and breakouts. The volatility ratio uses a true price range to determine a stock's true trading range and is able to identify situations where the price has moved out of this true range. True Range is defined as the largest of the following:- (i) the distance from today's high to today's low; (ii) the distance from yesterday's close to today's high; and (iii) the distance from yesterday's close to today's low. Volatility – the relative rate at which the price of a security moves up and down. Volatility is found by calculating the annualized standard deviation of daily change in price. If the price of a stock moves up and down rapidly over short time periods, it has high volatility. If the price almost never changes, it has low volatility. Volatility is a measure of the risk or uncertainty faced by participants in financial markets. It can be measured either from the past variation of asset prices. The range of a day's trading is simply:- High – Low. True range extends it to yesterday's closing price if that was outside today's range, i.e. True Range = Max (High, $Close_{prev}$) – Min (Low, $Close_{prev}$). / , то есть . Соотношение с лихорадочностью равно истинному диапазону текущего дня, делённому на истинный диапазон предшествующего n-дневного периода (например, n = 15 дней).

VOLATILITY RISK = РИСК ЛИХОРАДОЧНОСТИ – Volatility Risk is the risk in the value of options portfolios due to the unpredictable changes in the volatility of the underlying asset. Volatility Risk is the risk that a specific security price will increase or decrease by greater increments than the general market. / Риск Лихорадочности – риск в стоимости портфеля опционов вследствие непредсказуемых изменений в лихорадочности соответствующего актива. Риск Лихорадочности – риск того, что цена конкретной ценной бумаги будет возрастать или снижаться с большими изменениями, нежели общий рынок.

VOLATILITY SKEW = ЛИХОРАДОЧНОСТЬ НАИСКОСЬ – Volatility Skew:- the difference in implied volatility between out-of-the-money puts and calls. The origins of the volatility skew are not always clear, but factors may include reluctance to write calls rather than puts, sentiment about market direction, and supply and demand. See also Implied Volatility.

VOLATILITY SMILE = УЛЫБКА ЛИХОРАДОЧНОСТИ (или УЛЫБКА ШАРАХАНЬЯ) – Represent the notion that options usually have implied volatilities that are highest for deep in-the-money calls and puts, and lowest for those derivatives that are approximately at-the-money. As a result, the graph of implied volatility vs. strike price often appears as slightly U-shaped. This is commonly referred as the Volatility Smile. Volatility Smile is a graph of the implied volatility of an option versus its strike (for a given tenor) typically describes a smile-shaped curve – hence the term 'Volatility Smile'. This can be attributed to the belief that the underlying distribution is leptokurtic, since this tends to increase the value of out-of-the-money options. Volatility Smile:- if the implied volatility of an option is plotted against its strike on a graph, the chart is typically shaped like a smile (less frequently a frown). It may reflect the fact that out-of-the-money events are more common than geometric Brownian motion would predict. This leads to extra value for out-of-the-money options. See also Implied Volatility. / Отражает мнение, что опционы обычно имеют подразумеваемые уровни лихорадочности, которые бывают более высокими для прибыльных опционов на покупку и продажу и более низкими для этих производных инструментов, когда они практически бесприбыльны. сходной цене, зачастую выглядит в форме Английской буквы Ю. (U), похожей на улыбку на лице. Для таких случаев и используется термин Улыбка Лихорадочности.

VOLATILITY SPREAD = КУРСОВАЯ РАЗНИЦА ПО ЛИХОРАДОЧНОСТИ (или СПРЭД НА ЛИХОРАДОЧНОСТЬ) – Volatility Spread is a Delta-neutral option spread designed to speculate on changes in the volatility of the market rather than the direction of the market.

VOLATILITY TERM STRUCTURE = СТРУКТУРА ЛИХОРАДОЧНОСТИ ПО СРОКАМ – Volatility Term Structure:- the curve depicting the differing implied volatilities of options with differing maturities. The term structure is curved because the volatility implied by short-dated option prices changes faster than that implied by longer-term options, but other effects, such as mean reversion, may also play a part. See also Implied Volatility.

VOLATILITY TRADING = ТОРГОВЛЯ ПРИ ЛИХОРАДОЧНОСТИ (или ТОРГОВЛЯ ПРИ ШАРАХАНЬИ) – Volatility Trading is a trading, usually through the options markets, based on the belief that implied volatility will not match the volatility actually realized over a given period, or that the difference in implied volatility between different options will alter over a given period. Options are used because of their sensitivity to volatility. Volatility Trading:- strategies designed to speculate on changes in the volatility of the market rather than the direction of the market. Volatility Trading Strategies:- as previously explained, volatility is essentially the risk aspect of the market. It is the perception of risk that is 'securitized' in the time value component of an option premium. The volatility can be implied in the options price (which includes traders' expectations of future price movements) or be based upon the actual fluctuations in the price of the asset which underlies the option. Traders buy or sell volatility as their perception of risk in the future changes. The ideal way to trade volatility is to maximize the exposure to both kinds of volatility (actual and implied) and minimize the exposure to the other factors which influence option prices, such as small movements in the underlying market and if possible time decay. This is done by using the 'Greeks' to assess the exposure the trading strategy has to all the variables which drive option prices. To benefit from a change in actual volatility of the market, the trader will want to establish a gamma positive or negative position. To benefit from a change in implied volatility, the trader will focus on her Kappa (Vega) exposures. For the other derivatives such as Delta, Theta, and Rho, she will try to minimize her exposure to these 'Greeks' by driving their level to zero. By doing so, the trader can focus her viewpoint on volatility alone. When one is completely neutral to the underlying market and is just trading volatility, it is termed pure volatility trading. In addition to pure volatility trading one can establish trading strategies that are initially neutral to the underlying market but can become an equivalent long or short position as the underlying market price moves to a particular level. These trades are usually called Leaning Volatility Trades. Below we examine some of the pure volatility strategies. 'Pure' Buying Volatility Strategies:- suppose one purchased a call option which is an equivalent long position. If volatility increases one will profit. If the same person also bought a put option, which is an equivalent short position, in combination with the long call what would we have? The put option has an opposite exposure to the underlying market, but will also benefit if volatility increases. These two trades can be combined in such a way that they will be neutral to the underlying market but they will still have a long volatility bias. That is how you go 'long' volatility; by buying options. If one buys both a call and a put and adjusts carefully for the delta exposure of each, then the position can be neutralized to the underlying asset and will then be purely a volatility trade. Depending on which strike prices you choose, this combination trade is called either a Straddle or a Strangle. Types of the Strategies:- (i) Buying a Straddle; (ii) Buying a Strangle; and (iii) Long Straddles and Strangles in the Strategy Matrix. 'Pure' Selling Volatility Strategies:- strategies which benefit from quiet times and static markets are probably the most common use for options in volatility trading. Many option trading professionals make money from selling options. Since options are securitized risk, some people think of them in a similar light to a casino. Strictly speaking this is not correct. Risk in an underlying market existed prior to the intoduction of options. On the other hand, casinos create risk that did not previously exist in order to provide a vehicle for gambling. Nevertheless, gambling does provide an insight when considering the selling of options. In casinos the consistent winners over time are the gambling houses which sell the bets. Option sellers will win over time if they have the 'edge'. The 'edge' is the difference between theoretical option values and actual option prices. The option seller attempts to sell options at prices higher than their theoretical value and option buyers do the reverse. In volatility selling strategies, trades are established to maximize the edge from overvalued market prices fro options. The key element in the determination of the theoretical value of the option is an accurate estimation of future volatility. Suppose that a trader determines that the future volatility for options should be 20% while the current implied volatility in the market is 25%. To gain the edge, he will select those strategies which would profit from the implied volatility falling from 25% to 20%. In essence he will select those strategies which have a negative Vega (Kappa). Types of the Strategies:- (i) Selling the Straddle; (ii) Selling the Strangle; (iii) Buying a Butterfly Spread; and (iv) Short Straddles, Strangles, and Butterflies in the Strategy Matrix. / Стратегии, рассчитанные на изменения состояния лихорадочности рынка, а не на направление движения цен на рынке.

VOLCANIC GLASS = ВУЛКАНИЧЕСКОЕ СТЕКЛО – Volcanic Glass – any glassy rock formed from lava or magma that has a chemical composition close to that of granite (quartz plus alkali feldspar). Such molten material may reach very low temperatures without crystallizing, but its viscosity may become very high. Because high viscosity inhibits crystallization, a sudden cooling and loss of volatiles, as when lava extrudes from a volcanic vent, tends to chill the material to a glass rather than to crystallize it. Volcanic glass is unstable and tends to change spontaneously (devitrify) from the glassy to the crystalline state in periods of time that are relatively short by geologic standards; the material takes on a stony appearance due to the presence of minutely crystalline aggregates. Geologically ancient glasses are therefore very rare, and most glassy rocks are of Tertiary age or younger (less than 66.4 million years old). There is good reason to believe that glassy rocks were abundant in ancient geologic time, but nearly all of these have since devitrified. Devitrification commonly begins along cracks in the glass or around large crystals and may spread outward until eventually the entire mass has been converted to fine crystals of quartz, tridymite, and alkali feldspar. Characteristic of many natural glasses is a streaked or swirly structure that consists of bands or trains of crystals and crystalline bodies. This structure is believed to have been formed by the flowage of viscous lava. Some flow structures consist of alternating bands of different-colored material; in others, layers of bubble-free glass alternate with highly vesicular glass. VOLCANO = ВУЛКАН – Volcano – plural Volcanoes, or Volcanos, any vent in the crust of the Earth or other planet or satellite, from which issue molten rock, pyroclastic debris, and steam. Volcanism (vulcanism) is the name given to the processes and phenomena associated with the surficial discharge of such material from volcanoes, geysers, and fumaroles. Volcanoes figure prominently in the mythology of many peoples who have learned to live with eruptions, but science was late in recognizing the important role of volcanism in the evolution of the Earth. One major XVIII-century school of thought held that molten rock and volcanoes were simply accidents caused by burning coal seams. Geologists today agree that volcanism is a profound process resulting from the thermal evolution of planetary bodies. Heat does not easily escape from large bodies by conduction or radiation. Instead, partial melting and buoyant rise of

magma are major contributors to the process of heat flux from the Earth's interior. Volcanoes are the surface manifestation of this thermal process, which has its roots deep inside the Earth and which hurls its ashes high into the atmosphere. The term volcano can either mean the vent from which magma erupts to the surface, or it can refer to the landform created by the solidified lava and fragmental volcanic debris that accumulate near the vent. One could say, for example, that large lava flows are erupted from Kilauea Volcano in Hawaii, the word volcano here signifying a vent. By contrast, one could say that Kilauea is a gently sloping volcano of modest size as Hawaiian volcanoes go, the reference in this case being to a landform. Broadly defined, all igneous rocks are the result of volcanism. If igneous rocks solidify from magmas that have not reached the surface, they are called Intrusive Igneous Rocks, and this process in a more restricted sense is termed plutonism. Igneous rocks that cool and solidify at the Earth's surface are known as Extrusive Igneous Rocks, and these are unequivocally products of volcanism. Volcanoes (and their products) are not the realm of any single scientific discipline. Rather, they require study by many scientists from several specialties:- geophysicists and geochemists to probe the deep roots of volcanoes; geologists to decipher prehistoric volcanic activity; biologists to learn how life becomes established and evolves on barren volcanic islands; and meteorologists to determine the effects of volcanic dust and gases on the atmosphere, weather, and climate. This article discusses volcanism both by topics and by examples. Under the topic of types of volcanic activity, the 1980 eruption of Mt. St. Helens in southwestern Washington is used as an example of an explosive eruption that involves ejection of pyroclastic fragments. The 1984 eruption of Mauna Loa Volcano in Hawaii serves to illustrate a 'quiet' eruption involving the effusion of lava. The widely varying composition of volcanic gases from fumaroles is explained by studies at Kilauea Volcano, and Yellowstone National Park in the western United States provides classic examples of hot springs and geysers. Volcanic landforms evolve from the cumulative effects of both constructive and destructive eruptions. Mt. Fuji exemplifies a stratovolcano and Mauna Loa typifies a shield volcano. Iceland provides fine examples of volcanic plateaus, and since it sits astride the Mid-Atlantic Ridge, it is also a logical starting place for a discussion of submarine volcanic structures. Volcanoes are closely associated with tectonic activity. Most of them occur on either the overriding or the diverging margins of the enormous lithospheric plates that make up the Earth's surface. The volcanoes of Japan provide an excellent example of the former, while those of the Mid-Atlantic Ridge the latter. Intraplate volcanoes such as those of the Hawaiian chain provide important evidence as to the direction and rate of plate motion. Volcanoes affect humankind in many ways. Their destructiveness is awesome, but the risk involved can be reduced by assessing volcanic hazards and forecasting volcanic eruptions. Volcanism provides fertile soils, valuable mineral deposits, and geothermal energy. Over geologic time volcanoes recycle the Earth's hydrosphere and atmosphere, and explosive eruptions can affect climate. Types Of Volcanic Activity:- Volcanoes:- volcanoes can be classified by their eruptive habits and are generally arranged by progressive increases in the explosiveness of their eruptions. The type of volcanic eruption also plays an important role in the evolution of a volcanic landform, thus forming a significant link between eruptive habit and volcanic structure. Less explosive eruptions involve the effusive outpouring of basaltic magma that is relatively low in viscosity and in gas content. (The term Lava is applied to molten magma after it has erupted to the surface.) More explosive eruptions generally involve magma that is more viscous and has a higher gas content. Such magma is shattered into pyroclastic fragments by explosive boiling during an eruption. Types Of Eruptions:- in classification schemes based on character of eruption, volcanic activity and volcanic areas are commonly divided into six major types in order of increasing degree of explosiveness:- (1) Icelandic, (2) Hawaiian, (3) Strombolian, (4) Vulcanian, (5) Pelean, and (6) Plinian. The Icelandic type is characterized by effusions of molten basaltic lava that flow from long parallel fissures. Such outpourings often build lava plateaus. The Hawaiian type is similar to the Icelandic variety. In this case, however, fluid lava flows from summit and radial fissures to form shield volcanoes. The Strombolian type involves moderate bursts of expanding gases that eject clots of incandescent lava in cyclical or nearly continuous small eruptions. Because of such small intermittent outbursts, Stromboli Volcano (off the west coast of Italy) has been called the 'Lighthouse Of The Mediterranean'. The Vulcanian type, named for the island of Vulcano that neighbours Stromboli, generally involves moderate explosions of gas laden with volcanic ash (i.e. fine volcanic particles). This mixture forms dark, turbulent eruption clouds that rapidly ascend and expand in convoluted shapes. The Pelean type is associated with explosive outbursts that generate dense mixtures of hot volcanic fragments and gas. It is named for the destructive eruption of Mt. Pelée in Martinique in 1902. The fluidized slurries produced by Pelean-type eruptions are heavier than air but are of low viscosity and pour down valleys and slopes at velocities exceeding 100 kilometers per hour (60 miles per hour). Variously called Nuées Ardentes, glowing avalanches, ash flows, or pyroclastic flows, such hot fluidized flows of volcanic gases and fragments are extremely destructive. The Plinian type is an intensely violent kind of volcanic eruption exemplified by the outburst of Mt. Vesuvius in AD 79 that killed the famous Roman scholar Pliny the Elder, from whom the name is taken. In this type, gases boiling out of gas-rich magma generate enormous, nearly continuous jetting blasts that rip apart and core out the magma column. The uprushing gases and volcanic fragments appear like a gigantic rocket blast directed vertically upward. Plinian eruption clouds can rise into the stratosphere and are sometimes sustained for several hours. Figure 1 features schematic diagrams of these eruption types. There are, however, many gradations among – and exceptions to – such idealized types, and it is not unusual for an eruption sequence to involve more than one type of activity. For example, the eruptions of Mt. St. Helens from 1980 to 1986, in sequence, consisted of small Vulcanian-type explosions, large Pelean and Plinian explosions, and extrusions of viscous lava into a lava dome that caps the vent. The different types of volcanic activity can best be described by comparing specific eruptions. Some Notable Examples:- Mt. St. Helens, Washington, 1980–86:- Prior to 1980 Mt. St. Helens was a steep, conical volcanic peak rising to 2 950 meters (9 680 feet). Its summit was capped by snowfields and small glaciers. It had erupted during at least 20 intervals over the past 4 500 years, with the last active period between 1831 and 1857. Dwight Crandell and Donal Mullineaux of the US Geological Survey studied the volcanic deposits in the vicinity of Mt. St. Helens and noted in their 1978 report that the volcano would probably erupt violently and intermittently, just as it had in the recent geologic past, 'within the next 100 years, and perhaps even before the end of this century'. Two years later these prophetic words became reality. On March 20, 1980, an earthquake swarm began near Mt. St. Helens. By March 25 the swarm increased to its maximum energy release with 47 earthquakes of magnitude 3 or greater on the Richter scale within a 12-hour period. Seismographs located the source of the earthquake swarm at shallow depth beneath the north flank of the mountain. An eruption was expected, and it soon began. The first small explosions on March 27 excavated a crater about 70 meters wide on the ice-covered summit. Several such small Vulcanian-type eruptions occurred daily. They ejected dark, turbulent clouds of volcanic ash that blackened the downwind snowfields. No new magma appeared in the ash, however; only old volcanic debris was thrown out. These small explosive eruptions apparently resulted from groundwater in the volcanic cone being heated above its subsurface boiling point and flashing into steam. The crater was enlarged by the small explosive eruptions to an oval basin 500 by 300 meters wide and 200 meters deep. At the peak of seismic energy release on March 25, large east-west cracks formed across the summit of Mt. St. Helens. Soon after this, people familiar with the mountain noticed changes in its shape and in ice fracture patterns on the high north face of the volcano. Geodetic surveys and aerial photographs in April and early May 1980 confirmed that a growing bulge nearly two kilometers (1.2 miles) in diameter on the high north slope was moving upward and outward by as much as one to two meters per day. Most of the scientists studying the mountain at this time agreed that an intrusion of magma was being injected at a shallow depth beneath the north side of the volcano. Whether this intrusion would erupt at the surface – and if so, when – were unanswered questions. On the morning of May 18, Mt. St. Helens was shaken by an earthquake of about 5 Richter magnitude, and ice falls occurred within the crater. The entire north side of the summit then began to move as one huge mass. This giant landslide, composed of more than two cubic kilometers (0.48 cubic mile) of rock and ice, was immediately followed by an enormous explosion of

expanding steam and volcanic gases. Fluidized by the expanding gases, the avalanche reached velocities as high as 250 kilometers per hour. One lobe swept into Spirit Lake, but the main body of the debris avalanche roared 21 kilometers down the valley of the Toutle River, forming a hummocky deposit one to two kilometers wide and up to 150 meters deep. As the great avalanche suddenly released the pressure inside the volcanic cone, superheated groundwater flashed into steam, and gases dissolved in the magma boiled out with explosive violence. These expanding gases formed a lateral blast of hot, dense, debris-filled clouds that surged northward along the ground at high speed. The blast devastated 550 square kilometers (210 square miles) of mountain terrain to the northeast, north, and northwest of Mt. St. Helens. The ground-hugging black clouds of steam and hot rock fragments rolled over four major ridges and valleys as far as 28 kilometers from the volcano's summit. The destruction was awesome. For the first few kilometers everything was obliterated. Great conifer trees up to three meters in diameter were uprooted and blown away. Beyond this was a blowdown zone where virgin Douglas firs were snapped off like matchsticks. The US Forest Service estimated that 10 000 000 trees were felled by the blast. At the limits of the blast cloud, trees were still standing but their needles were scorched beyond recovery. About 55 to 60 people were killed by the avalanche and blast. As the ground-hugging blast clouds raced northward, a Plinian eruption began to jet upward from the exposed-magma column. This vertical eruption cloud mushroomed to more than 20 kilometers in altitude and was sustained most of the day by the escaping gases as they cored out the gas-rich magma. Northeast and east winds blew ash from the Plinian cloud in a wide swath over Washington, Idaho, and Montana. At Ritzville, Wash., 330 kilometers east-northeast of Mt. St. Helens, volcanic ash that appeared 'like gray talcum powder' was seven centimeters (nearly three inches) thick. The weight of the measured ashfall equaled 0.15 cubic kilometer of magma, and the fine ash and gases dispersed into the stratosphere were estimated to equal another 0.1 cubic kilometer of magma. During the afternoon of May 18, pyroclastic flows of fine ash and pumice blocks began rushing down the north slope of Mt. St. Helens through the deep breach in the north face of the mountain. These fluidized emulsions of hot rock fragments mixed with hot volcanic gases were denser than the ascending ash cloud, and they issued from the crater beneath the uprushing cloud. In effect, both Plinian- and Pelean-type eruptions occurred at the same time. Floods and mudflows consisting of slurries of volcanic ash and fine rock particles mixed with water poured down the rivers draining Mt. St. Helens. The largest mudflow occurred in the north fork of the Toutle River where it exceeded historic flood levels by nine meters. The May 18 eruption displaced 2.7 cubic kilometers of volcanic rock, including 0.5 cubic kilometer of new magma, and destroyed the summit of Mt. St. Helens. Before the eruption the peak was 2 950 meters high (Figure 2). This was replaced by a horseshoe-shaped crater two kilometers across and roughly 750 meters deep, whose rim has an elevation of 2 400–2 550 meters – 400 meters below the old summit elevation. Overall, Mt. St. Helens lost about 1 100 meters of elevation from the old peak to the new crater floor. Following the great eruption of May 18, Mt. St. Helens produced five smaller explosive eruptions during the summer and fall of 1980. After 1980 a dome of lava grew intermittently in the crater. This lava is so viscous that it does not flow away; instead it piles up into a steep mound or dome over the vent. By 1986 the dome measured about 250 meters high and 1 000 meters wide, and it contained some 75 000 000 cubic meters of dacitic lava (see below Determinants of size and shape; see also Figure 3). Explosive eruptions of fragmental volcanic rocks vary greatly in scale. Measured by the volume of new magma involved, the May 18 eruption of Mt. St. Helens was only a moderate eruption. The explosive eruption of Tambora Volcano in Indonesia in 1815 is estimated to have expelled from 50 to 100 cubic kilometers of magma, and the 1883 eruption of Krakatoa (spelled Krakatau in Bahasa Indonesia), another Indonesian volcano, about 18 cubic kilometers. Fortunately, as the eruptive magnitude increases, the frequency of eruptions greatly decreases. Civilizations have never been tested by a cataclysm on the scale of the eruption at Yellowstone about 2 000 000 years ago; that eruption involved nearly 3 000 cubic kilometers of explosively boiling magma. Mauna Loa, Hawaii, 1984:- the May 18, 1980, eruption of Mt. St. Helens is a classic example of explosive volcanism. The 1984 eruption of the great shield volcano Mauna Loa, by contrast, is illustrative of effusive volcanism. Every three to four years, on average, Mauna Loa erupts with fountains and streams of incandescent lava. The summit of the volcano is 4 170 meters above sea level and more than 9 000 meters above the seafloor that surrounds the Hawaiian Ridge. Its volume above the seafloor, estimated to be about 40 000 cubic kilometers, qualifies it as the world's largest volcano. Following a year of increased seismicity, Mauna Loa began erupting at 01:25 am on March 25, 1984. The outbreak began along a fissure that split the long axis of the summit caldera, a cliff-bounded basin with a three-by-five-kilometer diameter that had been formed by prehistoric subsidence. Lava fountains along the fissure formed a curtain of fire that illuminated the clouds and volcanic fume into a red glow backlighting the black profile of the volcano's huge but gently sloping summit. Lava from the summit fissure ponded in the caldera, and the first observers in the air reported that much of the caldera floor was covered by a lake of orange-red molten rock, which quickly cooled to a black crust with zigzag, still incandescent fractures. At dawn the summit fissure began to propagate down the northeast rift zone, and a new line of lava fountains formed at an elevation of 3 800 meters. Two hours later the fracture broke an additional six kilometers down the northeast rift, forming another curtain of fire about two kilometers long and 50 meters high at an elevation of 3 450 meters. As new vents opened at lower elevations, the higher vents stopped erupting. The vents at 3 450 meters continued to erupt throughout the early afternoon, sending a small lava flow down the high southeast flank of Mauna Loa. At about 04:00 pm the lava fountains dwindled, and a swarm of new earthquakes indicated that the fissure was breaking even farther down the rift. The new and final vents opened at 04:40 pm at an elevation of 2 900 meters, some seven kilometers down the ridge from the 3 450-meter vents. The output of lava from these vents was vigorous. Although the fountains were only about 20 meters high, the volume of lava amounted to approximately 500 000 cubic meters per hour (about 17 600 000 cubic feet per hour). In 24 hours the river of lava flowed 12 kilometers northeast toward the city of Hilo. The temperature of the erupting lava was 1 140 °C (2 084 °F) and its viscosity about 10^3 Poise (roughly the same as liquid honey at 20 °C). The fissure did not break any farther down the northeast rift zone of Mauna Loa, and the vents at 2 900 meters remained in steady eruption for the next 10 days. Even though the eruption rate remained high, the advance of the front of the lava flow slowed – six kilometers the second day, four kilometers the third day, and three kilometers the fourth day. This progressive slowing of the lava-flow front was caused by several factors:- slow widening of flows at higher elevations; thickening of flows at higher elevations by overplating (i.e. accumulation of new layers on top of layers only a few hours or days old); thickening and widening of flows at lower elevations where the slope of the land is more gradual; and branching of the flows upstream into new lobes that robbed the lower flows of their lava supply. A household analogue of a Hawaiian lava flow in miniature is the slow and erratic advance of molten wax as it adds new lobes to a pile of candle drippings. By April 5 the output from the vents at 2 900 meters began to wane, and by April 15 the eruption was over. The longest flows traveled 27 kilometers, stopping at an elevation of 900 meters – 10 kilometers from the outskirts of Hilo. The total volume of the eruption was 220,000,000 cubic meters, and new lava flows covered 48 square kilometers. No one was hurt, and the only significant damage was the cutting of power lines and the blocking of a few jeep roads. Why are some volcanic eruptions so explosive while others are so spectacular but relatively harmless? The answer involves at least three factors:- the amount of gas dissolved in the magma, the viscosity of the magma, and the rate of decompression of the magma as it rises toward the surface. Volcanoes related to converging plate margins (see below) generally have a high gas content and their magma is very viscous. This is an explosive combination because the gases cannot easily boil out; rather, they remain pent up until they reach the pressure at which they blow the viscous magma into fragments. The rate at which pressure is reduced also controls the explosiveness. If magma moves slowly toward the surface its dissolved gases are released slowly. At Mt. St. Helens the avalanche that initiated the eruption caused very rapid decompression of the shallow intrusion, resulting in violent and explosive boiling of the trapped gases. Other Manifestations Of Volcanic Activity:- Volcanic Gases:- the most common volcanic gases are carbon dioxide, water, sulfur dioxide, and hydrogen

sulfide. Small quantities of other volatile elements and compounds also are present; e.g., hydrogen, helium, nitrogen, hydrogen chloride, hydrogen fluoride, and mercury. The specific gaseous compounds released from magma depend on temperature, pressure, and overall composition of the volatile elements present. The amount of available oxygen is of critical importance. When oxygen is lacking, methane, hydrogen, and hydrogen sulfide are stable, but when hot volcanic gases mix with atmospheric gases, carbon dioxide, water, and sulfur dioxide are stable. Some volcanic gases are less soluble in magma than others and separate at higher pressures. Studies at Kilauea Volcano indicate that carbon dioxide begins to separate from its parent magma at depths of about 40 kilometers, whereas most of the sulfur gases and water are not released until the magma has nearly reached the surface. Fumaroles (volcanic gas vents) near Halemaumau Crater at Kilauea's summit are rich in carbon dioxide that leaks from the magma chamber located at three to four kilometers beneath the surface. Fumaroles on the rift zones of Kilauea, however, are richer in water and sulfur because much of the carbon dioxide leaks away at the summit before the magma is intruded laterally into the rift zones. Hydrothermal Features:- hot springs and geysers also are manifestations of volcanic activity. They result from the interaction of groundwater with magma or with solidified but still hot igneous rocks at shallow depths. Yellowstone National Park is one of the most famous areas of hot springs and geysers in the world. The total heat flux from these thermal features is estimated to be 300 MegaWatts. The last great eruption at Yellowstone occurred about 600 000 years ago when some 1 000 cubic kilometers of rhyolite magma were ejected in huge ash flows and resulted in the formation of a caldera approximately 45 by 75 kilometers in size. (A caldera is a large circular or oval depression caused by surface collapse into the subsurface region from which magma had been removed.) Yellowstone Lake now occupies part of this giant caldera. Since that last great outburst, about 1 200 cubic kilometers of rhyolite lava flows and domes have erupted in numerous smaller events. The cooling roots of such past eruptions, or possibly new intrusions of magma at shallow depth, are the apparent sources of heat for the Yellowstone hot springs and geysers. Geysers are actually hot springs that intermittently spout a column of hot water and steam into the air. This action is caused by the water in deep conduits beneath a geyser approaching or reaching the boiling point. At 100 meters below the surface, the boiling point of water increases to approximately 150 °C because of the increased pressure of the overlying hot water. As bubbles of steam or dissolved gas begin to form and hot water spills from the vent of a geyser, the pressure is lowered on the water column below. Water at depth then momentarily exceeds its boiling point and more water flashes into steam. This chain reaction continues until the geyser exhausts its supply of boiling water. After a geyser stops spouting, the conduits at depth refill with groundwater and reheating to near the boiling point begins again. In geysers such as Yellowstone's Old Faithful, the spouting and recharge period is quite regular. This famous geyser has gushed to heights of 35–50 meters about every 40–80 minutes for more than 100 years. Other geysers have much more erratic recharge times. Volcanic Landforms:- Determinants Of Size And Shape:- the common mental image of a volcano is that of a steep symmetrical cone sweeping upward in a concave curve to a sharp summit peak. Mt. Fuji in Japan is the archetypal volcanic landform, but only a few volcanoes attain this ideal shape. The shape and size of a volcano are controlled by several factors. These include (1) the volume of volcanic products, (2) the composition of volcanic products, (3) the sequence of eruption (e.g., many small eruptions with short repose times between eruptions, or a few large eruptions with long repose times), (4) the variety of volcanic eruption types, (5) the geometry of the vent, and (6) the environment into which the volcanic products are erupted. Volumes released in any one eruption can vary enormously from a few cubic meters of magma to as much as 3 000 cubic kilometers. Small volumes tend to build up mounds close to the vent, whereas very large eruptions create plateaus of lava or ash flows. Eruptions of large ash-flow plateaus almost always form a caldera several kilometers in diameter over the eruption site. The chemical composition of magma affects its physical properties, which in turn have a major influence on the landform built by a volcanic eruption. Four common volcanic rock types are shown in Table 1:- basalt, andesite, dacite, and rhyolite. As the silica content increases, these rock types generally become more viscous; and as the magmatic gas content increases, they become more explosive. Effusive eruptions form lava plateaus or gently sloping shield volcanoes; moderately explosive eruptions form stratovolcanoes; and giant explosive eruptions form ash-flow plateaus. Naturally, since many other factors are involved in determining volcanic landforms, there are exceptions to these rules. A series of small eruptions usually build up their products near their vents, whereas a large-volume eruption tends to disperse its products over a greater distance. Lava flows that erupt at high-volume rates usually travel greater distances from their vents. Other physical properties are, however, important in determining the character of lava flows. Hot basaltic lava forms pahoehoe flows (smooth to ropy surfaces), which, other conditions being equal, will flow farther than the cooler aa flows of the same composition (rough, broken surfaces). If a volcano has consistent eruption habits, its landform will reflect that character. The shape of the huge but gently sloping shield volcano Mauna Loa, for example, indicates a long record of eruption of fluid lava flows from the summit and two persistent rift zones. It is these rift zones that give Mauna Loa its elongate shape. The beautiful symmetrical shape of the stratovolcano Mt. Fuji indicates a long record of moderately explosive eruptions from its summit, the eruptions generally consisting of explosions of fragments followed by thick viscous lava flows. Such alternating layers of ash and lava make up the strata denoted by the name stratovolcano. They are not layers in a blanketlike sense, however, but are overlapping lobes or tongues of ash and lava. For this reason, many geologists refer to stratovolcanoes as composite volcanoes. In contrast to simple shield and stratovolcanoes, many volcanoes change their eruptive habits – both in eruption type and in the location of their vents – over time. This results in a mixture of volcanic landforms called a Complex Volcano. The geometry of the vent or vents also exerts profound control on volcanic landforms. In Iceland the volcanic vents often are long fissures parallel to the rift zone. Renewed eruptions generally occur from new parallel fractures offset by a few hundred to thousands of meters from the earlier fissures. This distribution of vents and voluminous eruptions of fluid basaltic lava usually build up a thick lava plateau rather than a single volcanic edifice. Hekla Volcano in Iceland is transitional between plateau-building fissure eruptions and the single-major-vent eruptions that produce a symmetrical stratovolcano. Hekla erupts from a fissure that is parallel to the Mid-Atlantic Ridge and about 20 kilometers in length. Eruptions recur from this fracture – many from its central part. The result is a volcano shaped like an overturned canoe. Viewed along the fissure, Hekla looks like a stratovolcano; perpendicular to the fissure, it appears as an elongate ridge. Multiple point-source vents that erupt only once or a few times at most form a volcanic field of dozens of small cinder cones instead of a single large volcanic edifice. Finally, but not of least importance, is the environment into which the volcanic products are erupted. Submarine volcanoes are surprisingly similar to their counterparts on land, but their slopes are generally steeper because water cools the lavas more rapidly. Deep submarine volcanism tends to be less explosive or nonexplosive, since the pressure of the water prevents explosive boiling. Subglacial volcanism is drastically different in form from subaerial volcanism. This is particularly apparent in Iceland where glaciers covered the entire island 15 000 years ago and large ice caps still cover extensive areas today. Fissure eruptions beneath the ice form steep ridges of broken lava fragments rather than lava-flow plateaus, while subglacial eruptions from point-source vents that erupt repeatedly form table mountains. Table mountain volcanoes have steep sides of pillow lavas that formed in deep lakes or water-filled caverns within the ice. Pillow lavas are sacklike structures that form from underwater flows of basaltic lava. These structures are capped by several tens of meters of broken lava fragments from explosive shallow-water eruptions. The broken lava fragments in turn are overlain by shield-building lava flows erupted above the glacial surface. Major Types Of Volcanic Landforms:- each of the more than 1 300 potentially active volcanoes or volcanic areas listed in the Smithsonian Institution's Volcanoes of the World (1981) has a distinct form, but most can be generalized into nine categories (Table 2). Some of these categories were already described, but they are treated below in order of their numerical importance. Stratovolcanoes:- these are steep volcanic cones built by both pyroclastic and lava-flow eruptions. They are composed of volcanic rock types that vary from basalt to rhyolite, but their

composition is generally andesite. Stratovolcanoes may erupt many thousands of times over life spans of millions of years. A typical eruption would begin with ash explosions and end with extrusion of thick viscous lava flows. The cone-shaped form begins gradually and becomes steeper (up to 35°) toward the summit, which generally contains a crater. Shield Volcanoes:- structures of this type are large, dome-shaped mountains built of lava flows (the name derives from their similarity in shape to a warrior's shield lying face up on the ground). They are usually composed of basalt. Small shield volcanoes may form rapidly from almost continuous eruptions, but the larger shields are formed by hundreds of thousands of effusive eruptions of fluid lavas from their summits and rift zones over a span of about 1 000 000 years. The slopes of shield volcanoes are gentle and seldom exceed 6°. The summits are nearly flat but generally indented by cliff-walled craters or calderas. Submarine Volcanoes:- these structures occur in various forms, but many are cone-shaped seamounts. Some ancient island volcanoes were eroded flat or covered with a coral cap at sea level before they sank. These flat-topped seamounts are called Guyots. Most of the known active submarine volcanoes occur at shallow depths beneath the sea. They are known because their explosive eruptions can be detected and located by hydrophones. Active submarine volcanoes at depths of a few thousand meters are probably common, particularly along the mid-ocean ridges, but the water pressure at these depths prevents explosive boiling and the eruptions are undetectable. One exception to this is the submarine volcano Loihi, a seamount whose summit caldera occurs one kilometer below sea level, 30 kilometers Southeast of the island of Hawaii. Although eruptions of this youngest volcano of the Hawaiian chain have not been directly observed, swarms of earthquakes at shallow depth beneath the summit of Loihi in 1971–72 and 1975 were recorded by seismographs. This is indirect evidence, but not proof, of submarine eruptions at Loihi Seamount. Calderas:- large circular or oval depressions more than one kilometer in diameter, most calderas have formed by inward collapse. Many have steep cliffs bounding the depression, and some are filled with lakes. The terms crater and caldera are often used synonymously, but calderas are larger than craters. A crater can occur inside a caldera, but not the other way around. Calderas are often associated with large eruptions (10 cubic kilometers or more) of dacitic or rhyolitic magma that form pyroclastic plateaus. Calderas also occur on shield volcanoes and are thought to form when large rift eruptions or intrusions remove tremendous quantities of magma from the shallow magma chambers beneath the summit. The collapse and refilling of calderas on active Hawaiian volcanoes probably recur many times during a volcano's lifetime. Whether a volcano is designated a caldera or shield or stratovolcano with a caldera depends on the principal landform feature. For example, Crater Lake in Oregon in the northwestern United States is designated a caldera in Table 2, but Kilauea Volcano in Hawaii is designated a shield volcano even though it has a large summit caldera. Complex Volcanoes:- such structures are mixed landforms. In most cases, they occur because of changes either in eruptive habit or in location of the principal vent area. A stratovolcano may form a large explosion crater that later becomes filled by a lava dome, or several new cones and craters may develop on a caldera's rim. One stratovolcano cone may overlap another and have multiple summits. The Three Sisters volcanic complex in Oregon is an example of a complex volcano with three summits. Cinder Cones:- these are relatively small volcanic landforms: steep, angle-of-repose (about 30°) cones of loose pyroclastic fragments, most of which are in the cinder-size range (Table 3). Generally, the crater from which the cinder-sized fragments were ejected is located in the center of the cone. In areas with strong prevailing winds, however, the crater may be upwind of the cone. The rock type involved in cinder cone volcanoes is generally basalt or basaltic andesite, and the eruption type is Vulcanian or high-lava-fountain Hawaiian. Some cinder cones such as Parícutin in Mexico form during a single eruption. Parícutin is approximately 410 meters high and one kilometer wide; it formed during nearly continuous eruptions from 1943 to 1952. Cinder cones also form at some vents on shield volcanoes, but they are not included in Table 2 because they are not separate, individual volcanoes. Certain cinder cones have multiple eruptions, but if activity continues for thousands to tens of thousands of years from the same vent, they probably develop into stratovolcanoes or complex volcanoes. Volcanic Fields:- such areas have many geologically young cinder cones or other features that have not been individually identified as separate volcanoes. If the conduits through which magma ascends to the surface are scattered over a broad area, many short-lived volcanoes are formed rather than a major volcano with repeated eruptions. The area in which Parícutin formed is a volcanic field with dozens of prehistoric – but geologically young – cinder cones and lava flows. The most likely place for the birth of a new volcano is in a known volcanic field. Fissure Vents:- these features constitute the surface trace of dikes (underground fractures filled with magma). Most dikes measure about one-half to two meters in width and several kilometers in length. The dikes that feed fissure vents reach the surface from depths of a few kilometers. Fissure vents are common in Iceland and along the radial rift zones of Hawaiian volcanoes. Curtain-of-fire eruptions from fissure vents produce low ramparts of basaltic spatter on both sides of the fissure. More isolated lava fountains along the fissure produce crater rows of small spatter and cinder cones. The fragments that form a spatter cone are hot and plastic enough to weld together, while the fragments that form a loose cinder cone have cooled enough during their rise and fall not to stick together. The largest effusive eruption of lava in recorded history occurred in 1783 in Iceland from the Laki fissure. This vent produced high lava fountains, a 25-kilometer-long crater row, and 565 square kilometers of basaltic lava flows with a volume of approximately 12 cubic kilometers. Lava Domes:- landforms of this sort consist of steep domal mounds of lava so viscous that the lava piles up over its vent without flowing away. The rock types that form lava domes are generally andesites, dacites, or rhyolites. Somehow these viscous lavas have lost much of their gas content in prior eruptions or by slow rise to the surface. Even so, it is not unusual for an actively growing lava dome to have an explosive eruption that disrupts all or part of the dome. Many lava domes grow by internal intrusion of lava that causes swelling and oversteepening of the dome. Rockslides build up an apron of talus blocks around the lower sides of the dome. Lava domes can form mounds several hundred meters high and from several hundred to more than 1 000 meters in diameter. Thick lava flows sometimes move short distances from the dome and distort its generally circular or oval shape. The dome currently forming in the explosion crater at Mt. St. Helens is a good example of a lava dome. Other Volcanic Structures And Features:- less common volcanic forms have also been described, and sometimes other names have been used for those cited above. Such inconsistency of nomenclature stems from the fact that no one volcanologist has examined all the world' volcanoes, and the descriptions that exist have been made by many people with diverse backgrounds. Other types and terms that may be encountered include volcanic cones, simply a descriptive term pertaining to shape with no implication of size, rock type, or genesis; explosion crater, a large circular, elongate, or horseshoe-shaped excavation with ejected debris on its rim or flanks; hydrothermal regions, fumarole fields, and solfatara fields, areas of hot springs and gas vents where magma or still-hot igneous rocks at shallow depth are leaking gases or interacting with the groundwater system; maar, a low-relief crater often filled with water and surrounded by a rim of ejected material that was probably formed by explosive interaction of magma and groundwater; tuff rings and tuff cones (Figure 4), landforms that resemble maars but that have higher rims and are not filled with water (a tuff is a compacted pyroclastic deposit that often includes some sediments); pumice cone, a structure similar to a cinder cone but made up of volcanic glass fragments so filled with gas-bubble holes that it resembles a sponge and is very lightweight; pyroclastic cone, a cone-shaped volcano composed almost entirely of pyroclastic material; scoria cone, a synonym for cinder cone (cinders or scoriae are vesicular pyroclastic fragments usually heavier than pumice); somma volcano, a caldera partially filled by a new central cone, named for Mt. Somma in Italy; and subglacial volcano, a volcanic form produced by eruptions beneath a glacier or beneath the surface of a lake within a glacier. Taking a more distant view of volcanic landforms from space, one can see that individual volcanoes form linear to arcuate belts across the Earth's surface. It is now clear that these volcanic chains are closely related to global tectonic activity. Volcanism And Tectonic Activity:- active volcanoes are not scattered over the Earth randomly; instead, most occur in belts, especially in the island arcs and mountain ranges bordering the Pacific Ocean (Figure 5). The concept of seafloor spreading and, more broadly, the theory of plate tectonics offer a logical explanation for the

location of most volcanoes. Volcanoes Related To Plate Boundaries:- topographic maps reveal the locations of large earthquakes and indicate the boundaries of the 12 major tectonic plates. For example, the Pacific Plate is bounded by the earthquake zones of New Zealand, New Guinea, the Mariana Islands, Japan, Kamchatka, the Aleutian Islands, western North America, the East Pacific Rise, and the Pacific-Antarctic Ridge. The Earth's plates, which move horizontally with respect to one another at a rate of a few centimeters per year, form three basic types of boundaries: convergent, divergent, and side-slipping. Japan and the Aleutian Islands are examples of convergent boundaries where the Pacific Plate is pushing beneath the adjacent continental plates – a process known as Subduction. The San Andreas Fault system in California exemplifies a side-slipping boundary where the Pacific Plate is moving northwest relative to the North American Plate – a process called Strike-Slip, or Transform, Faulting. The East Pacific Rise is representative of a divergent boundary where the Pacific Plate and the Nazca Plate (west of South America) are pulling apart – a process known as Rifting. Volcanoes occur along both subduction and rift zones but are generally absent along strike-slip plate margins. Of the 1 144 volcanoes listed in Table 2, 80 percent occur along subduction zones and 15 percent along rift zones. These percentages are somewhat misleading, however, because most of the Earth's rift zones are about two to three kilometers below sea level. At those inaccessible depths active submarine volcanoes have yet to be observed, though a few hydrothermal areas have been found along submarine rift zones with deep-diving submarines. Iceland, a rare above-water section of the Mid-Atlantic Ridge, has 70 volcanoes that have erupted during the past 10 000 years. If this is a typical number for a short section of the world rift system, it suggests that there may be several thousand potentially active volcanoes along the largely submarine world rift system that follows the crest of the mid-ocean ridges. Most subduction-related volcanoes are explosive and build stratovolcanoes, while rift volcanoes tend to be more effusive and build shield volcanoes, though there are exceptions to both these generalities. Subduction-related volcanoes erupt basalt, andesite, dacite, and rhyolite, with andesite the predominant rock type. Rift-related volcanoes, especially on the ocean floor, erupt mainly basalt. Figure 6 is a schematic cross section showing conceptual models of how subduction and rift volcanoes may form. As an oceanic plate (2) is subducted beneath a continental plate (3), seafloor sediments rich in water and carbon dioxide are carried beneath the overriding plate. These compounds may act as fluxes and reduce the melting temperature of magma. Frictional heating also may be important in the formation of subduction-zone magmas, but since the subducted plate is colder than the mantle rocks it is penetrating, this would counteract any frictional heating. Although the process is not clearly understood, magma apparently forms and rises by buoyancy from a depth of 100 to 200 kilometers. Subduction-zone volcanoes occur on the overriding plate and are offset inland from the actual plate boundary along the ocean trench. The rising subduction-zone magma is probably basaltic in composition and is formed by the partial melting of mantle rocks. As the rising magma moves slowly up through the continental crust of the overriding plate, however, two things may occur to increase significantly the silica content of the magma. Crystallization of olivine and pyroxene minerals from the basalt can leave the residual melt enriched in silica and depleted in magnesium, iron, and calcium. This process is called Fractional Crystallization. Also, basaltic magmas have enough excess heat to partially melt the continental host rocks through which they are ascending. Because continental rocks are generally higher in silica, potassium, and sodium than are oceanic rocks, this process of assimilation and mixing can also play an important role in producing the wide range of compositions that occur in rocks from subduction volcanoes. The additional gas content of many magma batches at subduction volcanoes (which, coupled with their often high-viscosity magma, makes them dangerously explosive) also may be explained by more than one process. Additional water and carbon dioxide may come from both subducted seafloor sediments and assimilated crustal rocks. Furthermore, any fractional crystallization tends to concentrate volatile elements in the residual melt. If volcanic gases form separate fluid phases within batches of ascending magma (carbon dioxide is most likely to do this), these fluid phases may ascend more rapidly than the overall magma body and be concentrated in the upper portion. Explosive boiling of these volcanic gases at atmospheric pressure is the apparent reason for the highly explosive nature of many subduction volcanoes. Rift volcanoes, as shown in Figure 6, form when magma rises into the gap between diverging plates (1 and 2). They thus occur at or near actual plate boundaries. Measurements in Iceland suggest that the separation of plates is a continuous process but that the fracturing is intermittent. An analogy would be a rubber band that is slowly stretched until it snaps. Earthquake swarms and volcanic eruptions occur when the stretching exceeds the strength of the near-surface rocks, which then fracture along steeply dipping cracks parallel to the rift. Basaltic magma rising along these fractures causes Icelandic fissure eruptions. Rift volcanoes in continental locations such as East Africa are more complex. Assimilation of continental crust apparently gives them some of the characteristics more generally associated with subduction volcanoes; e.g., having a wider range of rock types and explosive habits. The volcanoes on the western and northern margin of the Pacific Plate (New Zealand, New Guinea, Mariana Islands, Japan, Kamchatka, and the Aleutian Islands) are all subduction volcanoes. The rift volcanoes, except for a few near Baja California, are hidden along the submarine crest of the East Pacific Rise and the Pacific-Antarctic Ridge at depths of two to three kilometers below sea level. The Cascade volcanoes in the northwestern United States and the volcanoes in Mexico and Central America are subduction volcanoes related to the small Juan de Fuca and Cocos plates on the east side of the Pacific Plate. Similarly, the volcanoes of the Andes are related to the subduction of the Nazca Plate beneath the South American Plate. Intraplate volcanism:- the 5 percent of known world volcanoes that are not closely related to plate margins are generally regarded as hot-spot volcanoes. Hawaiian volcanoes are the best examples of this type, and though they occur near the centre of the Northern portion of the Pacific Plate, they show a dramatic relationship to the past movements of that plate. Kilauea and Mauna Loa volcanoes on the island of Hawaii at the southeast end of the Hawaiian volcanic chain are two of the most active volcanoes in the world. In addition, the five volcanoes that form the island of Hawaii are all less than 1 000 000 years old. Northwestward along the Hawaiian chain each island is progressively older. The extinct volcano that formed the island of Kauai is about 5 000 000 years old. Assuming that the hot spot that generates Hawaiian volcanoes is relatively fixed in place – and there is good evidence to support this assumption – then the movement of the Pacific Plate during the past several million years has been northwestward at a rate of about 10 centimeters per year. Topographic maps show a major submarine continuation of the Hawaiian Ridge to the northwest of the Hawaiian Islands, and then a dogleg bend into the Emperor Seamounts, which comprise an entirely submarine ridge continuing northward to the edge of the Pacific Plate. Ages of rocks obtained by dredging and drilling the Emperor Seamounts indicate that the Hawaiian-Emperor Ridge is a progressively older volcanic chain formed by volcanism at the Hawaiian hot spot. This major centre of volcanism in the Pacific has been active for at least 80 000 000 years, and the Pacific Plate has moved over it, first northward and later northwestward, at a rate of approximately eight to 10 centimeters per year. The bend between the Emperor Seamounts and the Hawaiian Ridge occurred about 40 000 000 years ago and indicates a significant shift in the direction of movement of the Pacific Plate. It is not known how a volcanic hot spot maintains its position for millions of years while a plate passes over it. One concept suggests that a hot spot is a deep-mantle plume (Figure 7), which is caused by very slow convection of highly viscous mantle material. As hot but solid mantle rock moves upward, partial melting may occur from the lowering of its pressure-dependent melting temperature. Detailed seismic sounding of the mantle over the next decade or two should help to resolve this problem of the mechanism of hot spots. Small and isolated intraplate volcanoes may simply be the result of deep fractures within the plates that allow pockets of partial melt in the low-velocity layer below to leak to the surface. The low-velocity layer begins about 50 to 150 kilometers below the surface and extends to a depth of roughly 300 kilometers; it is so named because earthquake waves travel more slowly in this hot, low-strength layer than in the overlying rigid plates (Figure 6). Some studies indicate that there may be a few percent partial melt within the low-velocity layer. Once a sufficient volume of magma forms in the subsurface, it tends to rise from its own buoyancy. Any fracture system at the plate margins or within the

plates will facilitate this process. Impact Of Volcanic Activity On Humankind And The Environment:- since the late 1700s volcanoes have caused more than 250 000 deaths. Most of these occurred during four disastrous eruptions. The largest eruption of the four occurred at Tambora Volcano on Sumbawa Island, Indonesia, on April 10–11, 1815. Fifty cubic kilometers of magma were expelled in Plinian ash clouds and pyroclastic flows. Ash greater than one centimeter thick fell on more than 500 000 square kilometers of Indonesia and the Java Sea. Before the eruption Tambora was a 4 300-meter-high stratovolcano; following the eruption 1 400 meters of the summit cone were missing and in its place was a collapsed caldera measuring six by seven kilometers wide and one kilometer deep. About 10 000 people were killed by the explosive eruption and the tsunamis caused by massive pyroclastic flows entering the sea. Agricultural losses from the thick ash deposits resulted in famine and disease, leading to an additional 82 000 deaths. The second largest eruption of the XIX century also occurred in Indonesia. Krakatoa (or Krakatau), a compound volcano on a small uninhabited island between Sumatra and Java, erupted explosively on August 26–27, 1883. The eruption was similar to the Tambora outburst but smaller, involving only about 18 cubic kilometers of magma erupted in Plinian ash clouds and pyroclastic flows. Krakatoa was a much smaller volcano than Tambora, and when the eruption had emptied its magma chamber, it collapsed to form a caldera that was partly below sea level. Twenty-three square kilometers of the island of Krakatoa disappeared, and where a volcanic peak 450 meters high once stood was water as deep as 275 meters. The largest explosion on the morning of August 27 produced an ash cloud that was reported to have reached 80 kilometers high, and the detonation was heard in Australia, 4 800 kilometers away. A tsunami, over 30 meters high, followed the explosion and apparent caldera collapse, killing about 36 000 people on the adjacent shores of Java and Sumatra. On May 08, 1902, there occurred a violent eruption of Mt. Pelée, a stratovolcano on the island of Martinique in the Caribbean Sea. Although less than one cubic kilometer of magma was erupted, much of it formed a high-velocity glowing avalanche of hot gases and pyroclastic fragments that swept down a steep valley to the port of St. Pierre. Within minutes the town and virtually all of its inhabitants (some 29 000 people) were incinerated. The second worst volcanic disaster of the XX century occurred on November 13, 1985, when a relatively small eruption of Nevado del Ruiz, a stratovolcano in Colombia, killed 25 000 people. This 5 400-meter-high volcano has a glacial ice cap, and when a brief explosive eruption dumped several million cubic meters of hot pyroclastic fragments on the ice cap surrounding the summit crater, a sudden surge of meltwater sent massive mudflows down canyons on both the east and west sides of the Andean volcano. Much of the town of Armero, built on a low plain beside the Lagunilla (also spelled Lagunillas) River 50 kilometers east of and nearly five kilometers below the summit of Nevado del Ruiz, was buried by the mudflows. Twenty-two thousand of its inhabitants were killed. About 70 percent of the people who died from volcanic eruptions in the past 200 years perished in those four outbursts. The remaining 30 percent were killed in many other less devastating eruptions. As world population increases, however, so does the risk of greater loss of life from volcanic eruptions. This was made all too clear by the tragedy at Armero. In 1845 a mudflow from Nevado del Ruiz killed approximately 1 000 people on farms near the site where the town of Armero was later built. In the 1985 mudflow, which was smaller in volume than the 1845 mudflow, more than 20 times as many people were killed. Property damage from volcanic eruptions is difficult to estimate because of differing value systems and changes in land use. One study estimates an average of USD100 000 000 per year in property damage worldwide from volcanic eruptions. As with casualties, a few eruptions cause staggering damage, while most are much less destructive. The Mt. St. Helens eruption in 1980 did more than USD1 000 000 000 worth of damage, mainly to the timber industry. Hazards From Various Types Of Volcanic Eruptions:- the list of hazards associated with volcanic eruptions is long and varied: explosions, toxic gas clouds, ash falls, pyroclastic flows, avalanches, tsunamis, mudflows, and lava flows, as well as secondary effects such as fluoride poisoning, starvation, and disease. The sudden depressurization of a shallow hydrothermal system or gas-charged magma body or the rapid mixing of magma with groundwater can cause rapid gas expansion and massive explosions. Large blocks ejected in these explosions are sometimes hurled as far as 20 kilometers from the explosive vent. A directed blast in which one side of a volcanic cone fails, as happened at Mt. St. Helens in 1980, can cause destruction of several hundred square kilometers on the failed flank of the volcano. This is especially true if the blast cloud is heavily laden with fragmental debris and becomes a dense fluidized flow. It then takes on characteristics similar to a pyroclastic flow. Even beyond the limit of explosive destruction, the hot, ash-laden gas clouds associated with an explosive eruption can scorch vegetation and kill people by suffocation. Gas clouds from a sudden increase in fumarole emissions may also contain poisonous or suffocating gases such as hydrogen sulfide, carbon monoxide, carbon dioxide, and sulfur dioxide. At a crater lake in Cameroon, West Africa, more than 1 700 people were killed by a sudden release of carbon dioxide in August 1986. Ash falls from continued explosive jetting of fine volcanic particles into high ash clouds generally do not cause any direct fatalities. Yet, where the ash accumulates more than a few centimeters, collapsing roofs from ash loads and failure of crops are major secondary hazards. Crop failure can occur over large areas downwind from major Plinian eruptions, and widespread famine and disease may result, especially in poorly developed countries. Lightning strikes are common close to Plinian ash clouds, adding one more element of terror to an explosive eruption. Pyroclastic flows are the most dangerous and destructive aspect of explosive volcanism. They occur in many sizes and types, but their common characteristic is that they form a fluidized emulsion of volcanic particles, eruption gases, and entrapped air, resulting in a flow of low enough viscosity to be very mobile and of high enough density to hug the ground surface. A pyroclastic flow can pour over the lip of an erupting vent, or it may form when an ash cloud becomes too dense to continue rising and falls back to the ground. In major caldera collapses associated with explosive volcanoes, huge pyroclastic flows may issue from the ring fractures as the caldera block subsides. Pyroclastic flows can move at speeds up to a few kilometers per minute and have temperatures ranging from 100 to 700 °C. They sweep away and incinerate nearly everything in their path. Smaller pyroclastic flows are confined to valleys and are called Nuées Ardentes. Large pyroclastic flows may spread out as a blanket deposit across many hundreds or even thousands of square kilometers around a major caldera collapse. During the past 2 000 000 years, the Yellowstone National Park area has undergone three major caldera collapses involving pyroclastic eruptions of 300 to 3 000 cubic kilometers of rhyolitic magma. Avalanches of rock and ice also are common on active volcanoes. They may occur with or without an eruption. Those without an eruption are often triggered by earthquakes, weakening of rock into clay by hydrothermal activity, or by heavy rainfall or snowfall. Those associated with eruptions are sometimes caused by oversteepening of a volcano's flank by intrusion of a shallow body of magma within or just beneath the volcanic cone, as happened at Mt. St. Helens. A caldera collapse that is in part or entirely submarine usually generates a tsunami; the larger and more rapid the collapse, the larger the tsunami. Tsunamis also can be caused by avalanches or large pyroclastic flows rapidly entering the sea on the flank of a volcano. Mudflows are common hazards associated with stratovolcanoes and can happen even without an eruption. They occur whenever floods of water mixed with ash, loose soil, or rocks that have been altered to clay by hydrothermal activity sweep down the valleys draining the sides of large stratovolcanoes. The huge mudflows generated by meltwater from the ice cap of Nevado del Ruiz Volcano in 1985 are classic examples of mudflows associated with eruptions. Heavy rainfall or earthquake-induced avalanches of ice or hydrothermal clay also can cause mudflows on steep volcanoes during periods of repose. A lava flow engulfs and buries the land it covers, but new soil and vegetation eventually develop again. In warm humid climates the recovery is rapid; a few decades will hide the rocky surface of flows. In desert or arctic climates recovery is slower; flows more than 1 000 years old may still retain their barren appearance. The greatest hazard at potentially active volcanoes is human complacency. The physical hazards can be reliably estimated by studying the past eruptive activity as recorded in history or in the prehistoric deposits around a volcano. Volcano observatories can monitor the local earthquake activity and the surface deformation of a potentially active volcano and make useful, if not yet precise, forecasts of eruptions. Increased earthquake activity beneath Mauna Loa in 1983 led to a

forecast of an increase in probability of an eruption for 1984 or 1985; an eruption occurred in March 1984. The major eruption of Mt. St. Helens on May 18, 1980, was much larger than anticipated, but the high level of local earthquakes and the bulge forming on the north flank of the mountain provided enough warning to encourage a partial evacuation of the surrounding area. Some lives were lost, but the toll would have been much higher if access to the area had not been restricted by the local authorities. A major problem in reducing volcanic risk is that most explosive volcanoes have such long repose periods that people living nearby consider them extinct rather than dormant. Effects Of Volcanic Eruptions On Soil And Climate:- not all volcanic phenomena are destructive. The oceans, atmosphere, and continents owe their origin and evolution in large measure to volcanic processes throughout geologic time. Volcanic ash slowly weathers to form rich loamy soils. On volcanic Java, terraced rice paddies support a dense population. Across the Java Sea is Kalimantan (part of Borneo) with a similar climate but no volcanoes. The jungles of Kalimantan provide only temporary slash-and-burn agriculture and support a much smaller population. Climate, too, is subject to the effects of volcanic activity. High ash clouds from Plinian eruptions, especially if they are rich in sulfur dioxide, can inject much fine dust and aerosol droplets of sulfuric acid into the stratosphere. Above rain clouds, these fine particles are not washed quickly back to Earth but spread slowly into haze layers that can blanket a hemisphere or even the entire Earth. World climate seems to have been affected by the eruptions of Krakatoa in 1883 and of Agung Volcano in Bali in 1963 in the form of a lowering of average world temperature by about 0.5 °C over the few years following these eruptions. Although world temperature data was poorly recorded in the early 1800s, the eruption of Tambora in April 1815 was followed in 1816 in North America and Europe by what was called ‘The Year Without A Summer’. Other large volcanic eruptions such as Katmai in Alaska in 1912, however, appear to have produced no cooling effect. Records of average world temperature over the past several decades often show changes of 0.1–0.3 °C from year to year unrelated to any known volcanic eruptions, so it is difficult to establish clearly whether or not volcanic eruptions have a major impact on climate. Direct sampling of the stratosphere has shown that the major haze-forming agent from volcanic eruptions is not fine dust but an aerosol of tiny sulfuric acid droplets. This indicates that the composition of high volcanic ash clouds may be as important as their volume in affecting climate. Atmospheric chemists are discovering that not only volcanic eruptions but also man-made aerosols of chlorofluoromethanes (commonly called Freon), exhaust from high-altitude jet aircraft, and a general increase in carbon dioxide from burning fossil fuels are perturbing the atmosphere. The Earth has many buffers that maintain its environment, but their interactions are not well understood. Questions as to how volcanic and human activity affect climate remain essentially unanswered, and they are important problems for future research and for survival. Geothermal Energy:- geothermal energy is plentiful, but geothermal power is not. Temperatures increase below the Earth’s surface at a rate of about 30 °C per kilometer in the first 10 kilometers. This internal heat of the Earth is an immense store of energy. In the upper 10 kilometers of rock beneath the conterminous United States, it amounts to $3.3 \cdot 10^{25}$ Joules, or about 6 000 times the energy contained in the world’s oil reserves. The problem in utilizing geothermal energy is extracting it. The natural escape of the Earth’s heat through its surface averages only 0.06 Watt per square meter. To make geothermal power practical, some special situation must exist to concentrate the Earth’s heat energy in a small area. Underground reservoirs of steam or hot water that can be funneled into a drill hole provide this special situation. Some geothermal steam wells can produce six MegaWatts of thermal power, an amount equal to the normal heat flux from 100 square kilometers of land surface. The key to this concentration is the mass transfer of heat from deeper levels to the near surface by volcanism. Magma at temperatures close to 1 200 °C moves upward to depths of only a few kilometers, where it transfers heat by conduction to groundwater. The groundwater then circulates by convection and forms large underground reservoirs of hot water and steam. Some of this thermal water may escape to the surface as hot springs or geysers. Holes drilled into a subsurface geothermal system allow rapid mass transfer of hot water or steam to the surface. At The Geysers geothermal field north of San Francisco, superheated steam is directly tapped from porous underground reservoirs. In most other geothermal fields, the hot water is at or below its subsurface boiling temperature – about 300 °C at a depth of one kilometer. Hot water that is near its subsurface boiling temperature partially flashes to steam at the reduced pressures in a drill hole. This mixture of steam and hot water is separated at the well head, and the steam is used to drive the turbine of an electric generator. Hot water from lower temperature geothermal reservoirs can be used for space heating. This form of geothermal power is utilized extensively in Iceland. Some geothermal systems act as natural distilleries in the subsurface, dissolving trace amounts of gold, silver, and other rare elements from their host rocks. These elements may then be deposited at places where changes in temperature, pressure, or composition favor precipitation. Many hydrothermal ore deposits have been formed by once active – and in a few cases still active – geothermal systems. Gold is one more legacy of volcanism. / Американские вулканологи Двайт Рэймэнд ‘Роки’ Крэндэл (Dwight Raymond ‘Rocky’ Crandell; 1923–2009) и Донэл Рэй Малыно (Donal Ray Mullineaux; 1925–). Под Вулканами, по имени бога огня Вулкана из древнеримской мифологии, понимаются геологические образования, возникающие над каналами и трещинами в земной коре, по которым извергаются на земную поверхность из глубинных магматических источников лавы, горячие газы и обломки горных пород. Обычно вулканы представляют отдельные горы, сложенные продуктами извержений. Вулканы разделяются на действующие, уснувшие и потухшие. К первым относятся:- вулканы, извергающиеся в настоящее время постоянно или периодически; вулканы, об извержениях которых существуют исторические данные; вулканы, об извержениях которых нет сведений, но которые выделяют горячие газы и воды (сольфатарная стадия). К уснувшим относят вулканы, об извержениях которых нет сведений, но они сохранили свою форму и под ними происходят локальные землетрясения. Потухшими называются сильно разрушенные и размытые вулканы без каких-либо проявлений вулканической активности. В зависимости от формы подводящих каналов вулканы разделяют на центральные и трещинные. Глубинные магматические очаги могут находиться в верхней мантии на глубине порядка 50–70 километров (км) (вулканы Ключевская Сопка на Камчатке и Килауэа на Гавайских островах) или в земной коре на глубине 5–6 км (вулканы Везувий, Италия) и глубже. Вулканические Явления:- Извержения бывают длительными (в течение нескольких лет, десятилетий и столетий) и кратковременными (измеряемые часами). К предвестникам извержения относятся вулканические землетрясения, акустические явления, изменения магнитных свойств и состава фумарольных газов и другие явления. Извержение обычно начинается усилением выбросов газов сначала вместе с тёмными, холодными обломками лав, а затем с раскалёнными. Эти выбросы в некоторых случаях сопровождаются излиянием лавы. Высота подъёма газов, паров воды, насыщенных пеплом и обломками лав, в зависимости от силы взрывов, колеблется от 1 до 5 км (во время извержения вулкана Безымянного на Камчатке в 1956 она достигла 45 км). Выброшенный материал переносится на расстояния от нескольких до десятков тысяч километров. Объём выброшенного обломочного материала порой достигает нескольких кубических километров ($км^3$). При некоторых извержениях концентрация вулканического пепла в атмосфере бывает настолько большой, что возникает темнота, подобная темноте в закрытом помещении. Это имело место в 1956 в посёлке Ключи, расположенном в 40 км от вулкана Безымянного. Извержение представляет собой чередование слабых и сильных взрывов и излияний лав. Взрывы максимальной силы называются Кульминационным Пароксизмом. После них происходит уменьшение силы взрывов и постепенное прекращение извержений. Объёмы излившейся лавы – до десятков $км^3$. Типы Извержений:- Извержения вулканов не всегда одинаковы. В зависимости от количественных соотношений извергаемых вулканических продуктов (газообразных, жидких и твёрдых) и вязкости лав выделены 4 главных типа извержений:- эффузивный, смешанный, экструзивный и эксплозивный, или, как их чаще называют, соответственно – Гавайский, стромболианский, купольный и вулканский. Гавайский тип извержения, создающий чаще всего щитовидные вулканы, отличается относительно спокойным излиянием жидкой (базальтовой) лавы, образующей в кратерах огненно-жидкие озёра и

лавовые потоки. Газы, содержащиеся в небольшом количестве, образуют фонтаны, выбрасывающие комки и капли жидкой лавы, которые вытягиваются в полёте в тонкие стеклянные нити (вулкан Килауэа). В стромболианском типе извержений, создающем обычно стратовулканы, наряду с достаточно обильными излияниями жидких лав базальтового и андезито-базальтового состава (образуют иногда очень длинные потоки), преобладающими являются небольшие взрывы, которые выбрасывают куски шлака и разнообразные витые и веретенообразные бомбы (вулканы Стромболи на Липарских островах, Михара, некоторые извержения Ключевской Сопки). Для купольного типа характерно выжимание и выталкивание вязкой (андезитовой, дацитовой или риолитовой) лавы сильным напором газов из канала вулкана и образование куполов (вулканы Пюи-де-Дом и Центральный Семячик на Камчатке), криптокуполов (вулкан Сёва-Синдзан), конусокуполов (вулкан Иванова) и обелисков (вулкан Шивелуч на Камчатке). В вулканском типе большую роль играют газообразные вещества, производящие взрывы и выбросы огромных чёрных туч, переполненных большим количеством обломков лав. Лавы вязкие андезитового, дацитового или риолитового состава образуют небольшие потоки (вулканы Вулькано, Авачинская Сопка и Карымская Сопка на Камчатке). Каждый из главных типов извержений разделяется на несколько подтипов. Из них особо выделяются пелейский и катмайский, промежуточные между купольным и вулканским типами. Характерной особенностью первого является образование куполов и направленные взрывы очень горячих газовых туч, переполненных самовзрывающимися в полёте и при скатывании по склону вулканов обломками и глыбами лав (вулкан Монтань-Пеле на острове Мартиника). Извержения катмайского подтипа отличаются выбрасыванием очень горячего, весьма подвижного песчаного потока (вулкан Катмай на Аляске). Куполообразующие извержения иногда сопровождаются раскалёнными или достаточно охлаждёнными лавинами, а также грязевыми потоками. Ультравулканский подтип выражается в весьма сильных взрывах, выбрасывающих огромные количества обломков лав и пород стенок канала. Извержения подводных вулканов, расположенных в очень глубоких местах, обычно незаметны, так как большое давление воды препятствует взрывным извержениям. В мелких местах извержения выражаются взрывами (выбросами) огромных количеств пара и газов, переполненных мелкими обломками лавы. Взрывные извержения продолжаются до тех пор, пока извергаемый материал не образует острова, поднимающегося над уровнем моря. После чего взрывы сменяются или чередуются с излияниями лавы. Продукты извержения вулканов бывают газообразными (смотрите Вулканические Газы), жидкими (смотрите Лава) и твёрдыми (смотрите Вулканические Горные Породы). В зависимости от характера извержений и состава магмы на поверхности образуются сооружения различной формы и высоты. Они представляют собой вулканические аппараты, состоящие из трубообразного или трещинного канала, жерла (самой верхней части канала), окружающих канал с разных сторон мощных накоплений лав и вулканообломочных продуктов и кратера (чашеобразной впадины, расположенной на вершине сооружения). Наиболее распространёнными формами сооружений являются конусообразные (при преобладании выбросов обломочного материала), куполообразные (при выжимании вязкой лавы) и пологие щитовидные (при преобладании излияний жидкой лавы). Извержения происходят не только через вершинный главный кратер, но и через побочные (паразитические) кратеры, расположенные на склонах и на некотором удалении от них. При однократных извержениях газов, пробивающих канал до земной поверхности, нередко образуются воронкообразные впадины, окаймленные кольцевым валом из глыб различных пород; такие воронки, нередко заполненные водой, называются Маарами. Сильные извержения иногда сопровождаются обрушениями части вулканического сооружения, а часто и прилегающей местности; образующиеся впадины диаметром от нескольких км до первых десятков км называются Кальдерами. Географическое Размещение Действующих Вулканов:- Современные вулканы расположены вдоль молодых горных хребтов или вдоль крупных разломов (грабенов) на протяжении сотен и тысяч км в тектонически подвижных областях. Почти две трети вулканов сосредоточены на островах и берегах Тихого Океана (Тихоокеанский Вулканический Пояс). Из других районов по количеству действующих вулканов выделяется район Атлантического Океана. Причины Деятельности Вулканов:- Географическое размещение вулканов указывает на тесную связь между поясами вулканической деятельности и дислоцированными подвижными зонами земной коры. Разломы, образующиеся в этих зонах, являются каналами, по которым происходит движение магмы к земной поверхности. Движение магмы по трещинам и трубообразным каналам к земной поверхности, по-видимому, происходит под влиянием тектонических процессов. На глубине, когда давление растворённых в магме газов становится больше давления вышележащих толщ, газы начинают стремительно продвигаться и увлекать магму к земной поверхности. Возможно, что газовое давление создаётся во время процесса кристаллизации магмы, когда жидкая часть её обогащается остаточными газами и паром. Магма как бы вскипает и вследствие интенсивного выделения газообразных веществ в очаге создаётся высокое давление, которое также может явиться одной из причин извержения.

VOLCANOLOGY = ВУЛКАНОЛОГИЯ – Volcanology, also spelled Vulcanology, is a scientific discipline concerned with all aspects of volcanic phenomena. Volcanology deals with the formation, distribution, and classification of volcanoes, as well as with their structure and the kinds of materials ejected during an eruption (e.g., lava, dust, ash, and gas). It also involves research on the relationships between volcanic eruptions and other large-scale geological processes, such as mountain building and earthquakes. One of the chief objectives of this research is determining the nature and causes of volcanic eruptions for the purpose of predicting their occurrence. Another practical concern of volcanology is securing data that may aid in locating commercially valuable deposits of ores, particularly those of certain metallic sulfides. Interest in volcanic phenomena extends back to ancient times. The eruption of Vesuvius in AD 79 was recorded in considerable detail by Pliny the Younger. Studies of volcanoes, however, were not conducted systematically until the early XIX century. Since that time volcanology has become an important branch of physical geology. Specialists in the field, using the principles and methods of geophysics and geochemistry and the tools of seismology, have obtained much knowledge of processes occurring deep within the Earth's interior. / Под Вулканологией, от имени бога огня из древнеримской мифологии – Вулкан и Греческого слова Lógos, означающее Слово или Учение, понимается один из разделов динамической геологии. Изучает процессы и причины образования вулканов, их развитие, строение и состав продуктов извержений (лавы, газы и другие), закономерности размещения вулканов на земной поверхности, изменения характера их деятельности во времени. Практической целью вулканологии является разработка методов предсказания извержений и использования вулканического тепла горячих вод и пара для нужд народного хозяйства. Вулканология для решения теоретических и практических задач использует данные геологии, геотектоники, геофизики, геохимии, физико-химии и петрологии. В комплексе этих знаний вулканология участвует в решении общих теоретических вопросов геологических наук:- об источниках вулканической энергии, условиях эволюции магмы, размещении магматических глубинных и промежуточных очагов, роли вулканизма в формировании земной коры и прочих. Первые сведения о вулканологии относятся к середине 1-го тысячелетия до Нашей Эры (Гераклит – VI век и Аристотель – IV век, Греция; Страбон – I век и Плиний Младший – I век, Рим). Страбон описал извержение вулкана Каймени (Санторин), происшедшее в 196 до Нашей Эры, а Плиний Младший – катастрофическое извержение Везувия в 79, очевидцем которого он был. В 1842 было организовано специальное научное учреждение – вулканологическая обсерватория, построенная на склоне вулкана Везувий. Её создание явилось началом всестороннего изучения вулканической деятельности. В 1911 была создана вулканологическая обсерватория на вулкане Килауэа на Гавайских островах. Затем появилась обсерватория в Индонезии и целый ряд обсерваторий и станций в Японии. В бывшем Союзе Советских Социалистических Республик (СССР) вулканология развивалась учёными геологами Францем Юльевичем Левинсон-Лессингом (Franz Yulievich

Levinson-Lessing; 1861–1939), Александром Николаевичем Заварицким (1884–1952), Владимиром Ивановичем Влодавцем (1893–1993). Вулканологические учреждения были созданы в 1935 в первую очередь на Камчатке. Существовавшая с 1945 в Москве Лаборатория Вулканологии в конце 1962 преобразована в Институт Вулканологии (Петропавловск-Камчатский). Кроме упомянутых учреждений, вулканологические исследования производятся Лабораторией Вулканологии Сахалинского Комплексного Научно-Исследовательского Института, а также геологическими институтами Армении, Грузии и другими. Исследования Советских вулканологов занимают видное место в работе Международной Ассоциации Вулканологов. Наблюдения и исследования в области вулканологии печатаются в специальных изданиях Академии Наук (АН) СССР:- Бюллетень Вулканологической Станции. АН СССР (с 1937) и Труды Института Вулканологии (с 1940). Из специальных международных изданий печатался с 1914 по 1938 журнал Zeitschrift für Vulkanologie с приложениями к нему; с 1924 издаётся Bulletin Volcanologique – орган Международной Ассоциации Вулканологии; с 1932 – Bulletin of the Volcanological Society of Japan.

VOLCKER RULE = ПРАВИЛО ВОЛКЁРА – Volcker Rule is a proposal to restrict banks from making speculative proprietary investments and/or trading. Proposed by economist and former US Federal Reserve Chairman Paul Volcker. Volcker was appointed by President Obama as the chair of the President's Economic Recovery Advisory Board on February 06, 2009 and the Volcker Rule was publicly endored by President Obama on January 21, 2010 and was partially implemented in the Dodd-Frank Act. Volcker Rule prohibits banking entities from:- (1) engaging in proprietary trading; (2) investing in or sponsoring a hedge fund or private equity fund; or (3) entering into certain transactions with a hedge fund or private equity fund advised, managed or sponsored by the banking entity. The idea of Volcker Rule was conceptualized in order to restrict large US banks from making risky speculative bets with funds from their own accounts through proprietary trading. The Volcker Rule, which is Section 619 of the Dodd-Frank Wall Street Reform and Consumer Protection Act, was scheduled for implementation in July 21, 2010, but was repeatedly delayed. On December 10, 2013, the Volcker Rule was approved by representatives of the five agencies who now implement it. These include the Securities and Exchange Commission (SEC), the Federal Reserve, the Commodities Futures Trading Commission (CFTC), the Federal Deposit and Insurance Corporation (FDIC) and the Office of the Comptroller of the Currency, a division of the Treasury Department. On December 10, 2014, the Rule was implemented and began to take effect from April 01, 2014. We briefly explain the Volcker Rule, the challenges it brings to banks and how they can be addressed:- What Is The Volcker Rule? The Volcker Rule is named after Paul A. Volcker, Chairman of the Federal Reserve during the 1980s and an elder statesman of the financial world. He acted as an advisor for President Obama in 2008 and was instrumental in the passing and creation of the Rule. It aims to prevent large banks from engaging in speculative trading activity with the idea that important banks support the economy by lending to consumers and businesses. The Rule seeks to prevent banking entities from taking unwarranted risks, especially with regard to federally insured deposits. To this end, it curtails banking entities from engaging in two specific practices:- (1) Proprietary Trading:- The first category of activities the Rule prohibits is proprietary trading. This generally means that a banking entity cannot serve as the principal of its own trading accounts through which it purchases or sells financial instruments. (2) Hedge And Private Equity Fund Activities:- The second category prohibits banking entities from serving as principals in transactions in which they directly or indirectly obtain or keep ownership interests in certain types of 'covered funds'. These include private equity, venture capital, and hedge funds as defined by the Investment Company Act of 1940, as well as certain commodity pools under the Commodity Exchange Act and certain foreign funds that resemble US covered funds. Volcker Rule also prohibits banks from sponsoring covered funds. This means that banks cannot serve as general partners, managing members or trustees of covered funds. Banks also may not serve as operators of commodity pools with respect to covered funds, nor may they select or control the majority of a covered fund's directors, trustees or management. Finally, banks cannot share names or variations of names with covered funds for commercial purposes. At their core, the second set of restrictions related to covered funds prohibits banks from indirectly accomplishing activities from which they are directly prohibited by the first category's private trading restrictions. Timelines:- July 2010:- Volcker Rule provisions scheduled to be implemented as part of Dodd-Frank Act. April 2014:- The Final Rule becomes effective April 01, 2014, with banks asked to comply until July 21, 2015. June 2014:- Starting on June 30, 2014, entities with USD50 billion or more in consolidated trading assets and liabilities brought under the purview of Volcker Rule must report quantitative measurements. April 2016:- Banking entities with between USD25 and 50 billion in consolidated trading assets and liabilities subject to the Rule's requirements on April 30, 2016. Banking entities with between USD10 and USD25 billion in assets subject to Volcker Rule on December 31, 2016. On December 18, 2014, the Federal Reserve extended the Volcker Rule's conformance period for 'legacy covered funds' (a defined term) until July 21, 2016, and indicated it would likely extend the period further to July 21, 2017. The extension to 2016 is the second of three possible one-year extensions the Federal Reserve may issue under the Dodd-Frank Act. The Dodd-Frank Wall Street Reform and Consumer Protection Act commonly referred to as Dodd-Frank was signed into federal law, as a response to the late 2000s recession, by President Barack Obama on July 21, 2010. It brought the most significant changes to financial regulation in the United States and has impacted the entire financial sector of the United States. Volcker Rule is Section 619 of Dodd-Frank Act. The rule is often referred to as a ban on proprietary trading by commercial banks. The rule is designed to cap high-risk trading activities to ensure a transparent financial system. / Пол Эй. VOLD = VOLUME DIFFERENCE

VOLENTI NON FIT INJURIA = ВОЛЭНТИ НОН ФИТ ИНЪЮРИА (или ИЗЪЯВЛЯЮЩЕМУ СОГЛАСИЕ, ОБИДА НЕ В ОБИДУ) – Volenti Non Fit Injuria:- Latin for lawyers translates it as 'That to which a man consents cannot be considered an injury'. Sometimes truncated to Volenti. Also, voluntary assumption of risk, or damage by consent, is not a cause of action. Volenti non fit injuria is a defence in tort that means where a person engages in an event accepting and aware of the risks inherent in that event, then they cannot later complain of, or seek compensation for an injury suffered during the event. This is used often to defend against tort actions as a result of a sports injury. The volenti maxim has had a colurful past. In one olde case (Wilson v Glossop), a husband sued his wife for damages as a result of her alleged adultery. The claim was barred as the evidence revealed that he had connived in the adultery. In another case, in an era when spring-guns were not illegal, a man was hurt by the gun after having been warned by the landowner of it. The maxim prevented his claim for damages (Ilott v Wilkes). Similarly, a person who crosses a barrier into a leopard cage to retrieve a smouldering cigarette, and gets mauled by the leopard, was prevented from suing based on the volenti maxim (Sylvester v Chapman). Judicially, the expression is still alive and kicking. Volenti Non Fit Injuria:- that to which a man consents cannot be considered an injury. Volenti Non Fit Injuria is a legal principle that one who knowingly and voluntarily consents to and takes on a risk (for example, by participating in a potentially dangerous sport, such as motor racing or skiing) cannot ask for compensation for the damage or injury resulting from it. In some jurisdictions (such as United Kingdom), however, neither the knowledge nor the willingness of the inherent risk of injury is considered assent, only a written waiver of the right to claim compensation for negligence suffices. Latin for, To A Willing Person It Is Not A Wrong or To A Willing Person, Injury Is Not Done or To One Who Is Willing, No Harm Is Done. / Вилсэн против Глосэпа (Wilson v Glossop). Илэт против Вилкса (Ilott v Wilkes). Сылвэстё против Чэпмэнах (Sylvester v Chapman). Volenti Non Fit Injuria (Изъявляющему Согласие, Обида Не В Обиду) – положение Римского права, выражающее тот принцип, что согласие потерпевшего устраняет ответственность лица, причинившего ущерб. Принцип этот находит полное применение

в области гражданского права, но здесь он должен быть понимаем в следующем смысле:- лицо может отказаться от права на возмещение ущерба, причинённого ему данным действием другого лица, но не от права на возмещение какого бы то ни было ущерба; другими словами, лицо может отказаться от определённого конкретного права, например, от права на данный иск, но оно не может отказаться от своей гражданской правоспособности, например, от права вообще искать в суде. По особым соображениям, закон иногда совершенно исключает в области некоторых частноправовых отношений возможность изъявления предварительного согласия на причинение данного ущерба. Так, в силу 5 Статьи Общего Устава Российских Железных Дорог 1885, всякие предварительные, на случай могущего последовать вреда или убытка, сделки или соглашения железных дорог с пассажирами и отправителями или получателями грузов, клонящиеся к изменению ответственности, возлагаемой на железные дороги постановлениями этого устава, или к совершенному освобождению дорог от сей ответственности, признаются недействительными. Такое же правило установлено и для пароходных предприятий, но лишь по отношению к ответственности их за вред или убыток, вследствие смерти или повреждения в здоровье, причинённых при эксплуатации пароходных сообщений (Статья 683, Том X, Часть 1 Свода Законов).

VOLICITIN = ВОЛИЦИН (или ВОЛИЦИТИН) – Volicitin is a chemical compound produced by Beet Armyworm Caterpillars (Spodoptera Exigua). Volicitin, in the 'spit' from Beet Armyworms, causes Corn plants to produce volatile compounds that act as signaling compounds for parasitoid wasps. Draw the three hydrolysis products that form from volicitin that match the common names given below:- (a) glutamic acid (α-aminoglutaric acid); (b) ammonia; (c) 17-hydroxylinolenic acid. / Волицин (Volicitin):- химическое вещество, продуцируемое Жучком Совкой Малой (Spodoptera Exigua), источник линолевой жирной кислоты.

VOLSTORAGE = ХРАНИЛИЩА ДЛЯ ЛЕТУЧИХ ЖИДКОСТЕЙ – Volstorage:- volatile organic liquid (VOL) storage facilities. VOL storage service is a crucial part of production and consumption of VOLs in that it is nearly a fixed component of plant design. / для хранения летучих органических жидкостей.

VOLT = ВОЛЬТ – Volt (V) is the SI unit of electric potential. Separating electric charges creates potential energy, which can be measured in energy units such as Joules. Electric potential is defined as the amount of potential energy present per unit of charge. Electric potential is measured in Volts, with one Volt representing a potential of one Joule per Coulomb of charge. The name of the unit honors the Italian scientist Count Alessandro Volta (1745–1827), the inventor of the first battery. Volt is the electrical potential difference or pressure across a one Ohm resistance carrying a current of one Ampere. Named after Italian physicist Count Alessandro Volta (1745–1827). Volt is the unit of electrical potential, potential difference and electromotive force in the metre–kilogram–second system (SI); it is equal to the difference in potential between two points in a conductor carrying one Ampere current when the power dissipated between the points is one Watt. An equivalent is the potential difference across a resistance of one Ohm when one Ampere is flowing through it. The Volt is named in honour of the XVIII–XIX-century Italian physicist Alessandro Volta. These units are defined in accordance with Ohm's Law, that resistance equals the ratio of potential to current, and the respective units of Ohm, Volt, and Ampere are used universally for expressing electrical quantities. See also Electric Potential; Electromotive Force. Volt (V) is a unit of electromotive force. It is the amount of force required to drive a steady current of one Ampere through a resistance of one Ohm. Electrical systems of most homes and office (in the USA) have 120 Volts. The Volt (V) is the International System of Units (SI) measure of electric potential or electromotive force. A potential of one Volt appears across a resistance of one Ohm when a current of one Ampere flows through that resistance. Reduced to SI base units, 1 V = 1 kg times m^2 times s^{-3} times A^{-1} (kilogram meter squared per second cubed per Ampere). / Кулон. Под Вольтом понимается единица СИ электрического напряжения, разности электрических потенциалов, электродвижущей силы (эдс). Названа в честь Итальянского физика и физиолога Графа Алессандро Вольта (Count Alessandro Volta; 1745–1827) одного из основателей учения об электричестве. Обозначение:- В (V). 1 В = 10^8/с единиц СГСЭ = 1/300 единиц СГСЭ = 10^8 единиц СГСМ, с – значение скорости света в вакууме. Вольт, единица электрического напряжения, разности электрических потенциалов, электродвижущей силы (эдс); входит в Международную Систему Единиц. Название по имени Итальянского учёного Алессандро Вольта, обозначается В или V. Вольт был впервые принят на 1-м Международном Конгрессе Электриков (1881) как практическая единица эдс, равная 10^8 единицам Системы Единиц СГС. С 1893 до 1948 применялся международный Вольт ($В_{межд}$), равный напряжению или эдс, которые в проводнике, имеющем сопротивление в 1 $Ом_{межд}$, производят ток силой в 1 $Ампер_{межд}$. Точная величина международного Вольта устанавливалась эталоном – группой нормальных элементов Вестона. С 1948 в связи с переходом на абсолютные практические электрические единицы (смотрите Система Единиц МКСА) Вольт ($В_{абс}$) стал производной единицей, что сохранено и в Международной Системе Единиц (СИ):- 1 Вольт – электрическое напряжение, вызывающее в электрической цепи постоянный ток силой 1 Ампер (А) при мощности 1 Ватт (Вт). Единица СГСЭ и СГС разности потенциалов равна 300 $В_{абс}$ (точнее 10^{-8}·с Вольт, где с – числовое значение скорости света в вакууме, выраженное в сантиметрах в секунду (см/сек)). 1 $В_{межд}$ = 1.000 35 $В_{абс}$.

VOLTAGE = НАПРЯЖЕНИЕ (или ВОЛЬТАЖ) – Voltage is the difference in electrical potential between any two conductors or between a conductor and ground. It is a measure of the electric energy per electron that electrons can acquire and/or give up as they move between the two conductors.

VOLTAGE DROP = ПАДЕНИЕ НАПРЯЖЕНИЯ – Voltage Drop is a Voltage reduction due to impedances between the power source and the load. These impedances are due to wiring and transformers and are normally minimized to the extent possible.

VOLTAGE–GATED ION CHANNEL = ПОТЕНЦИАЛОЗАВИСИМЫЙ ИОННЫЙ КАНАЛ (или ХХ) – Voltage-Gated Ion Channel:- a transmembrane (i.e. extending from one side of a cell membrane to the other side) ion channel. Passage (e.g., of ions, atoms) through a Voltage-gated ion channel is controlled (i.e. this channel is opened, or closed) by membrane potential (i.e. electrical charge difference between one side of the cell membrane and the other). / Потенциалозависимый Ионный Канал (Voltage-Gated Ion Channel):- ионный канал, обеспечивающий потенциал клеточной мембраны.

VOLTAGE IN AN ALTERNATING CURRENT CIRCUIT = НАПРЯЖЕНИЕ В ЦЕПИ ПЕРЕМЕННОГО ТОКА – VAC is a common symbol for the Voltage In An Alternating Current (AC) Circuit (see also VAR for comments on alternating current). The SI does not allow symbols to be modified with additional information; instead of '12 VAC', write 'AC 12 V'.

VOLTAGE IN A DIRECT CURRENT CIRCUIT = НАПРЯЖЕНИЕ В ЦЕПИ ПОСТОЯННОГО ТОКА – VDC is a common symbol for the Voltage In A Direct Current (DC) Circuit. In DC circuits, both voltage and current are constant. The SI does not allow symbols to be modified with additional information; instead of '12 VDC', write 'DC 12 V'.

VOLTAGE OF A CIRCUIT = НАПРЯЖЕНИЕ ЦЕПИ – Voltage Of A Circuit (electric utility):- the electric pressure of a circuit, measured in Volts. Usually a nominal rating, based on the maximum normal effective difference of potential between any two conductors of the circuit.

VOLTAGE REDUCTION = СНИЖЕНИЕ НАПРЯЖЕНИЯ – Voltage Reduction:- any intentional reduction of system Voltage by 3 percent or greater for reasons of maintaining the continuity of service of the bulk electric power supply system.

VOLTAGE REGULATOR = РЕГУЛЯТОР НАПРЯЖЕНИЯ – Voltage Regulator is any electrical or electronic device that maintains the Voltage of a power source within acceptable limits. The Voltage regulator is needed to keep Voltages within the prescribed range that can be tolerated by the electrical equipment using that Voltage. Such a device is widely used in motor vehicles of all types to match the output Voltage of the generator to the electrical load and to the charging requirements of the battery. Voltage regulators also are used in electronic equipment in which excessive variations in Voltage would be detrimental. In motor vehicles, Voltage regulators rapidly switch from one to another of three circuit states by means of a spring-loaded, double-pole switch. At low speeds, some current from the generator is used to boost the generator's magnetic field, thereby increasing voltage output. At higher speeds, resistance is inserted into the generator-field circuit so that its Voltage and current are moderated. At still higher speeds, the circuit is switched off, lowering the magnetic field. The regulator switching rate is usually 50 to 200 times per second. Electronic Voltage regulators utilize solid-state semiconductor devices to smooth out variations in the flow of current. In most cases, they operate as variable resistances; that is, resistance decreases when the electrical load is heavy and increases when the load is lighter. Voltage regulators perform the same function in large-scale power-distribution systems as they do in motor vehicles and other machines; they minimize variations in Voltage in order to protect the equipment using the electricity. In power-distribution systems the regulators are either in the substations or on the feeder lines themselves. Two types of regulators are used:- (i) Step Regulators, in which switches regulate the current supply; and (ii) Induction Regulators, in which an induction motor supplies a secondary, continually adjusted voltage to even out current variations in the feeder line.

VOLT AMPERE = ВОЛЬТ–АМПЕР – Volt Ampere (V·A) is a unit of electrical load used in power engineering. In an alternating current circuit, if the potential (measured in Volts) and the current (measured in Amperes) vary in phase with each other, then the power delivered (measured in Watts) is the product of the potential and the current. In actual circuits, the potential and current are usually out of phase (see VAr (Volt-Ampere-reactive)), causing the device receiving the power to draw more current than its Wattage requirements would suggest. The product of the potential and the actual current is the load, in Volt Amperes. VA is an abbreviation for Volt Ampere. Unit of apparent power. Volt Ampere is the unit of apparent power equal to the mathematical product of a circuit Voltage and Amperes. Here, apparent power is in contrast to real power. On ac systems the voltage and current will not be in phase if reactive power is being transmitted. Usually abbreviated VA. / Под Вольт-Ампер понимается единица СИ полной мощности электрической цепи переменного тока, то есть мощности электрической цепи при действующих значениях силы тока 1 Ампер (А) и напряжения 1 Вольт (В). Рассматривают также активную мощность, выражаемую в Ваттах (Вт), и реактивную мощность, выражаемую в ВАрах (VAr). Обозначение:- В·А (V·A). Вольт-Ампер, единица полной мощности переменного тока, обозначается В·А или VA. Полная мощность переменного тока определяется как произведение действующих значений тока в цепи (в Амперах или А (A)) и напряжения на её зажимах (в Вольтах или В (V)). Действующие значения тока и напряжения измеряют Амперметрами и Вольтметрами переменного тока. Понятие о полной мощности введено в отличие от активной мощности электрической цепи, выражаемой в Ваттах (Вт (W)) и равной UI cos j, где (j – угол сдвига фаз между напряжением U и током I, и от реактивной мощности, равной UI sin j) и выражаемой в единицах ВАр (VAr).

VOLTMETER = ВОЛЬТМЕТР – Voltmeter is an instrument that measures Voltages of either direct or alternating electric current on a scale usually graduated in Volts, milliVolts (0.001 Volt), or kiloVolts (1 000 Volts). The typical commercial or laboratory standard Voltmeter in use today is likely to employ an electromechanical mechanism in which current flowing through turns of wire is translated into a reading of Voltage. Other types of Voltmeters include the electrostatic Voltmeter, which uses electrostatic forces and, thus, is the only Voltmeter to measure Voltage directly rather than by the effect of current. The potentiometer operates by comparing the Voltage to be measured with known Voltage; it is used to measure very low Voltages. The electronic Voltmeter, which has largely replaced the vacuum-tube Voltmeter, uses amplification or rectification (or both) to measure either alternating- or direct-current Voltages. The current needed to actuate the meter movement is not taken from the circuit being measured; hence, this type of instrument does not introduce errors of circuit loading. The instruments just described provide readings in analogue form, by moving a pointer that indicates Voltage on a scale. Digital Voltmeters give readings as numerical displays. They also provide outputs that can be transmitted over distance, can activate printers or typewriters, and can feed into computers. Digital Voltmeters generally have a higher order of accuracy than analogue instruments. An instrument that also measures Ohms and Amperes (in milliAmperes) is known as a Volt-Ohm-Milliammeter, or sometimes as a Multimeter. / Вольтметр, электрический прибор для измерения эдс или напряжений в электрических цепях. Вольтметр включается параллельно нагрузке или источнику электрической энергии. Первым в мире Вольтметром был 'указатель электрической силы' Русского физика Георга Вильхэльма Рихмана (Georg Wilhelm Richmann; 1711–1753) в 1745. Принцип действия 'указателя' используется и в современном электростатическом Вольтметре (смотрите Электростатический Прибор). Наиболее просты в изготовлении, дёшевы и надёжны в эксплуатации Вольтметры электромагнитные (смотрите Электромагнитный Прибор). Они применяются главным образом как стационарные на распределительных щитах электростанций и промышленных предприятий и более редко в качестве лабораторных приборов. Недостатки таких Вольтметров – относительно большое собственное потребление энергии (3–7 Ватт (Вт)) и большая индуктивность обмотки, приводящая к существенной зависимости показаний Вольтметра от частоты. Наиболее чувствительны и точны Вольтметры магнитоэлектрические (смотрите Магнитоэлектрический Прибор), пригодные, однако, для измерений только в цепях постоянного тока. В комплекте с термоэлектрическими, полупроводниковыми или электронно-ламповыми преобразователями переменного тока в постоянный они применяются для измерения напряжения в цепях переменного тока. Такие Вольтметры, называются термоэлектрическими, выпрямительными и электронными, применяются главным образом в лабораторной практике. Выпрямительные Вольтметры используют для измерений в диапазоне звуковых частот, а термоэлектрические и электронные – на высоких частотах. Недостаток этих приборов – существенное влияние на правильность их показаний формы кривой измеряемого напряжения. Электронные Вольтметры имеют сложные схемы с применением недостаточно стабильных элементов (электронных ламп, малогабаритных электрических сопротивлений и конденсаторов), что приводит к снижению их надёжности и точности. Однако они незаменимы при измерениях в маломощных радиотехнических цепях, так как имеют большое входное сопротивление и работают в широком диапазоне частот (от 50 Герц (Гц) до 100 МегаГерц (МГц)) с погрешностями, не превышающими 3% от верхнего предела измерения. Изготовляются также электронные Вольтметры для измерения амплитуды импульсов напряжения длительностью от десятых долей микросекунды (мксек) при скважности до 2 500. В начале XX века широко применялись Вольтметры тепловой и индукционной систем; в настоящее время промышленное производство их прекращено из-за присущих им недостатков – большое собственное потребление энергии и зависимость показаний от температуры окружающей среды.

VOLUME = ОБЪЁМ – (1) Volume is a size or measure of anything in three dimensions. / Под Объёмом понимается занимаемое чем-либо пространство.

(2) A term 'Volume' often confused with Turnover, although in some instances they may be used to mean the same thing. Strictly, volume is the number of units traded, whereas turnover refers to the value of the units traded. / Термин Объём часто путают с Оборотом (Turnover), хотя в некоторых инстанциях он действительно может быть использован в качестве такого значения.

Более точно, под объёмом понимается количество проданных или купленных единиц, в то время как оборот относится к стоимости этих проданных или купленных единиц. Объём:- показатель активности торговли, обычно за определённый период. На Лондонской Фондовой Бирже (London Stock Exchange), например, количество проданных или купленных за день акций называют Объёмом, а суммарную стоимость этих акций называют Оборотом (Turnover).

(3) Volume is the number of trades in a security over a period of time. On a chart, volume is usually represented as a histogram (vertical bars) below the price chart. The New York Stock Exchange (NYSE®) and NASDAQ® measure volume differently. For every buyer, there is a seller:- 100 shares bought = 100 shares sold. The NYSE® would count this as one trade and as 100 shares of volume. However, the NASDAQ® would count each side of the trade and as 200 shares volume. On the commodities market, a term Volume refers to the quantity of soft commodities traded, and turnover refers to the tonnage of metals traded over a particular period of time, normally over a day of trading. Volume is the total number of transactions of a particular contract traded during a specified period of time on the market (rather than the volume they represent). The number of shares, bonds, or contracts traded during a given time period. Volume is the number of shares or contracts traded in a security or an entire market during a given period. Volume is usually considered on a daily basis and a daily average is computed for longer periods. Volume is the number of contracts that change hands during a specified period of time. Volume is the number of contracts (either the long or the short side of the market) traded during a specified period of time, often the total transactions for one trading day. A buy and corresponding sell make a total volume of one contract traded. It may be quoted as the number of contracts traded or in the total of physical units, such as bales, bushels, pounds or dozens. Volume highlights unusual trading activity and provide powerful confirmation of price signals. Volumes (trading):- trading volume on an exchange is simply the total number of shares which trade in a given trading session. It is a measure of activity. For any given stock, it is the number of shares which trade. Low volumes mean poor liquidity for investors. This is particularly important for junior stocks, i.e. 'Small Caps'. On futures exchanges, Volume is the number of contracts traded in a session. Volume:- this is the daily number of shares of a security that change hands between a buyer and a seller. Also known as Volume Traded. Also see Up Volume and Down Volume. Volume is the number of purchases or sales of a commodity futures contract made during a specified period of time, often the total transactions for one trading day. Volume is the number of futures contracts (either the long or the short side of the market) traded during a specified period of time. It is a measure of intensity in the market. Other things equal, any sell or buy signal is more strongly confirmed when it occurs on high volume. Volume is the number of units traded in an asset during a period of time. Volume:- this is the daily number of shares of a security that change hands between a buyer and a seller. Volume is the number of futures contracts traded per month, which can vary seasonally. Volume is the number of contracts traded for each delivery month during a specified trading period. The number of stocks traded during a given trading period. The Volume figure is useful for tracking if there has been an unusually large amount of activity in a particular instrument. Some instruments (like spot Forex) do not have volume figures available for them. In cases such as this, traders will sometimes use ticks as a proxy. Volume is the total number of contracts traded during a given day. / (НЙФБ® или Эн.Уай.Эс.И.® (NYSE®)). НЭЗДЭК® (NASDAQ®) . Объём:- количество контрактов (будь-то на покупку или продажу на данном рынке), заключённых в течение спецификационного периода времени, часто полное количество сделок за один торговый день. Покупка и соответствующая продажа составляют общий объём одного проданного контракта. Он может выражаться как количество проданных или купленных контрактов или в подытоженном количестве физических единиц, таких как кипы или бушели, фунты или дюжены. На товарно-сырьевых рынках под Объёмом понимается суточное количество проданных или купленных контрактов (фьючерсных или опционных). Объём – количество контрактов, по которым заключались сделки в течение определённого периода времени – дня, недели и так далее. Объём (Volume):- общее число акций, облигаций или товарно-сырьевых фьючерсных контрактов, участвующих в сделках за определённый период времени. Показатели объёма ежедневно сообщаются на биржах, они относятся к конкретным выпускам ценных бумаг, а также к общему числу торговых операций на бирже. Технические аналитики придают большое значение объёму торгов ценными бумагами или фьючерсными контрактами. Резкое увеличение объёма означает будущее резкое увеличение или снижение цены, поскольку отражает увеличение интереса инвесторов к данным ценным бумагам, товарно-сырьевой продукции или рынку. Смотрите также Технический Анализ (Technical Analysis), и Turnover. Объём – это уровень активности торгов по валюте, фьючерсам или опционам. Увеличение объёма в направлении текущей ценовой тенденции служит подтверждением этой тенденции.

(4) Volume:- in national accounts figures that refer to the value of a transaction in the numeraire of the base year. Volume figures are quality adjusted. / Объём (Volume):- число транзакций в течение данного периода времени.

VOLUME ALERT = ТРЕВОГА ПО ОБЪЁМУ – Volume Alert:- create alerts based on price movement, time and date, trading volume or the state of your margin cushion. Alert actions include sending a notification such as a pop-up message on your trading screen, an email or a text message, or initiating an order, specifically a buy or sell order. For example, if a volume of any commodity futures is greater than or equal to 1 000 contracts then send e-mail message and display pop-up message and play sound (siren); this alert will be active until cancelled; the conditions can be satisfied outside regular trading hours; this alert will be cancelled by system once it is triggered. Now specify the action(s) that the alert will trigger. You can select from email, SMS, pop-up message and audio alerts, and elect to have an order triggered. Alerts Duration:- by default, the alert will remain active until you cancel it. You can elect to have the alert remain active through a specific date and time by selecting Alert active until ... and setting a date in the format YYYYMMDD hh:mm:ss. If you want the condition(s) to be able to trigger outside regular trading hours, check the 'Allow condition to be satisfied ...' box. / Тревога По Объёму:- резкое изменение объёма, происходящее, когда объём акций или объём рыночного индекса превышает его скользящее среднее значение за данный период времени согласно определённым заранее критериям.

VOLUME BAR CHART = ШТРИХОВОЙ ГРАФИК ОБЪЁМА – Volume Bar Chart:- at the bottom of most graphs of stocks there will be a bar graph which visually depicts the number of shares traded for that period of time.

VOLUME–BASED ALLOCATION = ВЫДЕЛЕНИЕ, ОСНОВАННОЕ НА ОБЪЁМЕ – A Volume-Based Allocation is an allocation of factory overhead costs based on a unit of activity, rather than a cost. Examples of such allocation bases are:- (i) amount of square footage used; (ii) number of labor hours used; (iii) number of machine hours used; and (iv) number of units produced. An improved level of allocation accuracy can be achieved when several overhead cost pools are created, with the costs in each one being assigned using the most relevant basis of allocation.

VOLUME CHARGE = СБОР ЗА ОБЪЁМ – Volume Charge is a charge for carriage of goods based on their volume (aircargo).

VOLUME CHART = ОБЪЁМНЫЙ ГРАФИК (или ГРАФИК ОБЪЁМА) – A Volume Chart is a chart, it can be a bar or candle chart, where each bar is made up of price changes that occurred when a constant (fixed) number of contracts were traded. A Volume Chart is also often referred to as a Constant Volume Chart. On a Volume Chart, each time the specified number of contracts are traded, a new bar or candle is created from which the Open, High, Low, and Close prices are collected for that bar. Here is a discussion of various chart types and each of their merits:- Chart Types.

VOLUME COUNTING = ПОДСЧЁТ ОБЪЁМА – Volume Counting:- the US Securities and Exchange Commission (SEC) dictates how volume is counted. Thus, volume is counted in the same manner on all markets based on the above reporting structure. Any time money changes hands (or any time capital is risked), it must be counted as a trade. Examples:- (1) One registered market participant on Nasdaq buys 100 shares into inventory from another registered market participant or from one of its clients. In either case, it is counted as 100 shares. (2) One member firm on the NYSE® or Amex® buys 100 shares from another member firm. The Specialist matches the order between the two firms and it is counted as 100 shares. (3) The Specialist sells 100 shares from his inventory to a member firm on the NYSE®. It is counted as 100 shares. (4) A Market Maker receives an order to buy 100 shares from it's client. It does not have 100 shares in its inventory. It must go buy 100 shares from someone else. It then sells these 100 shares to the client. Thus, there are two trades in this example for a total of 200 shares. / НЭЗДЭК® (NASDAQ®). НЙФБ® или Эн.Уай.Эс.И.® (NYSE®) или АМЭКС® (AMEX®).

VOLUME DELETED = ОБЪЁМ УДАЛЁН – Volume Deleted:- a note appearing on the consolidated tape when the tape is running behind under heavy trading, meaning that only the stock symbol and price will be shown for trades under 5 000 shares. / Объём Удалён или Без Указания Объёма:- предупреждение, часто появляющееся на консолидированной информационной ленте (consolidated tape), обычно, когда лента отстаёт более чем на 2 или более минуты из-за большого объёма сделок в результате интенсивных торгов. Это предупреждение означает, что по сделкам с пакетами менее чем в 5 000 акций будут указываться только символ акции (stock symbol) и цена сделки.

VOLUME DIFFERENCE = РАЗНИЦА В ОБЪЁМЕ – The Volume Difference (VOLD; also $VOLD) is the difference between the up volume and down volume on the New York Stock Exchange (NYSE), i.e. NYSE $UVOL minus $DVOL; the net up volume. If you consider that VOLD is the net value between UVOL (up volume) and DVOL (down volume) then you need to understand these two to understand VOLD. UVOL or DVOL are a total of the volume on all stocks that are up or down in price. Up or down is based on the previous session's closing price. The size of the stock's price change is irrelevant. If the stock is up only USD0.01, then its volume is grouped into the UVOL total. If that stock's price then drops by USD0.02 it will be down USD0.01 and the day's volume for that stock will now be grouped with the DVOL total. Note that when a stock moves from being an up stock to a down stock its volume will be removed from the UVOL total and added to the DVOL total. Say the stocks volume is 1 million shares when it moves from up to down. The DVOL will increase by 1 million and the UVOL will decrease by 1 million which means that VOLD will decrease by 2 million. Compare this to VOLDQ which is the net up volume on the NASDAQ ($UVOLQ – $DVOLQ).

VOLUME DISCOUNT = СКИДКА ЗА ОБЪЁМ – Volume Discount:- a reduction in price based on the purchase of a large quantity. / Скидка За Объём:- любое сокращение цены в результате покупки чего-то в большом количестве. Скидка За Объём:- институциональные организации, которые осущетсвляют крупные инвестиции, часто предоставляют комиссионную скидку, когда заказ велик, а именно на 500 000 Долларов США и более.

VOLUME GAIN = ПРИРОСТ ОБЪЁМА – Volume Gain is to obtain advantages due to increase in volume, such as value increase, points in gross margin or profit.

VOLUME INCENTIVE PROGRAMME = ОБЪЁМНАЯ ПОБУДИТЕЛЬНАЯ ПРОГРАММА – Volume Incentive Programme (VIP) refunds offered by conference after predetermined levels have been attained; discount on ocean freight dependent on volume; rebate designed for importers, offering a legalized rebate based on a specific revenue during a specified time span.

VOLUME INDEX = ИНДЕКС ПО ОБЪЁМУ (или УКАЗАТЕЛЬ ПО ОБЪЁМУ) – A Volume Index is most commonly presented as a weighted average of the proportionate changes in the quantities of a specified set of goods or services between two periods of time; volume indices may also compare the relative levels of activity in different countries, e.g., those calculated using purchasing power parities (PPPs). Context:- a major aim of economic analysis is to develop an understanding of changes taking place in an economy over time. This includes the measurement of short-term growth or decline. To achieve this for key economic value aggregates, such as the value of industrial production or the value of retail turnover, it is necessary to distinguish between changes arising solely from price changes and those arising from other influences such as quantity and quality, which are referred to as changes in 'volume'. Volume movements are determined by holding the price constant. By keeping fixed the prices on each item included in the volume index, period to period changes in the constant price estimates for aggregates of items reflect changes in the quantities and/or the quality of the different products. For example, if there is a fall in the total quantity of goods produced or goods consumed, volume data will decrease. Volume data will also decrease where the production or consumption pattern is changing towards cheaper goods (even if total quantity is not decreasing). It should be noted that although a change in volume terms reflects changes in quantity and or quality, it cannot in itself tell which of the factors is responsible. Further investigation is required before it can be ascertained how much of the change is due to quantity and how much to quality influences. The expression Constant Prices is often used interchangeably with Volume. However, there is a slight distinction between the terms even though both have had the effects of price changes removed from the underlying value series. More specifically, the term Constant Prices describes aggregate data for several periods compiled using a fixed-base Laspeyres formula so that all the items are expressed in their respective prices of the base period and for which the components and totals are additive. However, for an annually chained volume series the resulting data is non-additive and it is no longer strictly correct to describe then as being at constant prices although for convenience they may be described as such. / Формула Ласпьерэса (Laspeyres Formula; по имени Немецкого экономиста Профессора Эрнста Люи Этьена Ляспэра (или Ласпьерэса; Ernst Louis Étienne Laspeyres); 1834–1913).

VOLUME INDEX OF CAPITAL SERVICES = ИНДЕКС ПО ОБЪЁМУ КАПИТАЛЬНЫХ УСЛУГ (или ОБЪЁМНЫЙ ИНДЕКС ПО КАПИТАЛЬНЫМ УСЛУГАМ) – A Volume Index Of Capital Services measures the flow of services into the production process from the different types of assets included in the capital stock.

VOLUME OF AIR = ОБЪЁМ ВОЗДУХА – Volume Of Air is the number of cu ft of air per min expressed at fan outlet conditions.

VOLUME OF BUILDINGS = ОБЪЁМ ЗДАНИЙ – The Volume Of Buildings is the total volume included between the outer surface of the outer walls measured from the level of the lowest storey to the roof of the building. See also Building – UN, Floor Area.

VOLUME OF FREIGHT = ОБЪЁМ ГРУЗА (или ОБЪЁМ ФРАХТА) – Volume Of Freight:- the volume weight or the size of the package. The calcuation is always based on the following equation regardless of whether you are paying for the weight or the space:- Length (cm) x Width (cm) x Height (cm) / 6 000 (equals the volume weight in kg). Type Of Transport Volume Calculation:- (i) Air freight:- 1 m^3 = 167 kg; (ii) Truck:- 1 m^3 = 333 kg; and (iii) Sea freight:- 1 m^3 = 1 000 kg. / Объём Груза:- ставка, применимая с учётом определённого объёма (веса) груза. Сравните с Вес/Мера (Weight/Measure).

VOLUME OF FREIGHT TRAFFIC = ОБЪЁМ ГРУЗОПОТОКА (или ОБЪЁМ ГРУЗОВЫХ ПЕРЕВОЗОК, или ОБЪЁМ ГРУЗОПЕРЕВОЗОК) – Volume Of Freight Traffic is the official statistic indicator in logistics, usually used to measure of a city or a

country's level of logistics capabilities. A term Volume of Freight Traffic refers to the number of actual delivery of goods in a certain period by all means of transport. / Объём Грузопотока или Объём Грузовых Перевозок:- .

VOLUME OF TRADE = ОБЪЁМ ТОРГОВЛИ – Volume Of Trade is the number of contracts traded during a specified period of time. It may be quoted as the number of contracts traded or in the total of physical units, such as bales or bushels, pounds or dozens. See also Volume. / Объём Торговли:- в биржевых операциях, количество контрактов, проданных или купленных в течение спецификационного периода времени. Он может выражаться как количество проданных или купленных контрактов или в подытоженном количестве физических единиц, таких как кипы или бушели, фунты или дюжены. В торговле фьючерсными контрактами стоит однако учитывать, что количество проданных или купленных контрактов определяется по одной стороне сделки, то есть либо по покупателям, либо по продавцам. Что в этом случае имеется в виду? Например, продавец продал, а покупатель купил один контракт. Объём торговли в этом случае будет равен одному контракту, хотя маржу (залог) за открытую позицию внесёт и продавец и покупатель данного фьючерсного контракта, и у каждого из них в открытой и удерживаемой позиции будет числиться по одному фьючерсному контракту. Смотрите также Объём (Volume).

VOLUME OF TRADING (OR SALES) = ОБЪЁМ ТОРГОВЛИ (ИЛИ ПРОДАЖ) – Volume Of Trading (Or Sales) or Volume Of Trade is the total quantity of shares or contracts traded for a specified security. It can be measured on any type of security traded during a trading day. Volume of trade or trade volume is measured on stocks, bonds, options contracts, futures contracts and all types of commodities. Volume of trade measures the total number of shares or contracts transacted for a specified security during a specified time period. It includes the total number of shares transacted between a buyer and seller during a transaction. When securities are more actively traded, their trade volume is high, and when securities are less actively traded, their trade volume is low. Each market exchange tracks its trading volume and provides volume data. The volume of trade numbers is reported as often as once an hour throughout the current trading day. These hourly reported trade volumes are estimates. A trade volume reported at the end of the day is also an estimate. Final, actual figures are reported the following day. In the meantime, investors can use tick volume, or the number of changes in a contract's price, as a surrogate for trade volume, since prices tend to change more frequently with a higher volume of trade. Volume tells investors about the market's activity and liquidity. Higher trade volumes for a specified security mean higher liquidity, better order execution and a more active market for connecting a buyer and seller. When investors feel hesitant about the direction of the stock market, futures trading volume tends to increase, which often causes options and futures on specified securities to trade more actively. Volume overall tends to be higher near the market's opening and closing times, and on Mondays and Fridays. It tends to be lower at lunchtime and before a holiday. Traders use various trading factors in technical analysis. Trade volume is one of the simplest technical factors analyzed by traders when considering market trades. The trade volume during a large price increase or decrease is often important for traders as high volumes with price changes can indicate specific trading catalysts. High volumes associated with directional changes in price can also help to reinforce support for the value of a security. Volume levels can also help traders decide on specified times for a transaction. Traders follow the average daily trading volume of a security over short-term and longer-term periods when making decisions on trade timing. See also Volume. Volume Of Trading is the total number of futures transactions made in one trading session. Because purchases equal sales, only one side of the trade is counted. Volume Of Trading is the number of contracts traded during a specified period of time. It may be quoted as the number of contracts traded or in the total of physical units, such as bales, bushels, pounds or dozens. / Объём Торговли (Или Продаж):- показатель представляет собой результат простого суммирования последовательных сделок с фьючерсами. Эта сумма продаж (или покупок) фьючерсных контрактов, а не сумма того и другого вместе.

VOLUME OSCILLATOR = ОСЦИЛЛЯТОР ОБЪЁМА – The Volume Oscillator consists of two moving averages of volume, one fast and one slow. The fast volume moving average is then subtracted from the slow moving average. The Volume Oscillator is often interpreted using the same principles as volume analysis:- (i) an increase or decrease in price accompanied by an increase in volume may be considered a sign of strength in the prevailing trend. Therefore, when the fast volume moving average (default 14-period) is above the slow volume moving average (default 28-period), the Volume Oscillator is above the zero line and may be confirming price direction, whether it be up or down. (ii) An increase or decrease in price accompanied by a decrease in volume may be considered a sign of weakness in the prevailing trend. Therefore, when the fast volume moving average is below the slow volume moving average, the Volume Oscillator is below the zero line and may be warning that the price direction is lacking strength and conviction. The Volume Oscillator can be used as a confirmation indicator. See also Percentage Volume Oscillator. / Осциллятор Объёма показывает разность между двумя скользящими средними объёма торгов по данной ценной бумаге. Эта разность может быть выражена либо в пунктах, либо в процентах. Разность между двумя скользящими средними объёма можно использовать для определения направления общей тенденции объёма. Если осциллятор объёма поднимается выше нулевого уровня, значит, короткое скользящее среднее объёма поднялось выше длинного и, следовательно, краткосрочная тенденция объёма сильнее (то есть объём растёт) чем долгосрочная. Существует много способов интерпретации изменений в тенденциях объёма. По общепринятому мнению, рост цен при растущем объёме и падение цен при падающем объёме – бычий признак. И наоборот:- если объём увеличивается, когда цены падают, и уменьшается, когда цены растут, то это – признак внутренней слабости рынка. Данная точка зрения имеет простое логическое обоснование. Рост цен при росте объёма означает, что большее число участников рынка занимает длинные позиции (на рынке больше покупателей), а это должно поддерживать подъём. И наоборот:- падение цен при повышенном объёме (больше продавцов) означает сокращение числа длинных позиций.

VOLUME PROFILE = ОБЪЁМНЫЙ ПРОФИЛЬ (или ПРОФИЛЬ ОБЪЁМА) – A Volume Profile is similar to a Market Profile inasmuch as they both show a profile (a bell curve) against the Y-axis of the chart to represent the most traded area(s) of the time period that they have been constructed against. The major difference, a significant one, is that a Volume Profile is constructed using the volume traded at each price while Market Profile is constructed based on time brackets traded that the market traded at each price called Time Price Opportunities (TPOs). Against each price on the vertical axis you will typically see a bar that represents the number of contracts that were traded at that price. This type of chart can also be normalized to show a percentage of the day's total volume traded at that price. Volume Profile is agnostic about time that the market remained at each price. The philosophy behind Market Profile is that the more Time Periods at Price = N in which an issue trades, the more significant is that price. Volume Profile does not care when an issue trades at Price = N, it cares only how much of an issue trades at a particular price. In theory, an issue could trade one contract at Price = N in each of 48 1/2 hour time periods during a trading day. The same issue could trade 50 000 contracts at Price = X in only a single 1/2 hour time period. In Market Profile, Price = N would appear as a 'peak' and Price = X would appear as a 'valley'. In Volume Profile, X would be the 'peak' and N would be the 'valley'.

VOLUME RATE = СТАВКА ЗА ОБЪЁМ – Volume Rate is a rate applicable in connection with a specified volume (weight) of freight. To request volume rate quote service, you should complete a special form of a carrier or freight forwarder. / Ставка За Объём – ставка, применяемая в отношении определённого объёма (веса) груза.

VOLUME RATIO = СООТНОШЕНИЕ С ОБЪЁМОМ – The Volume Ratio is the number of messages submitted for each executed contract in a given product. This ratio is calculated by some exchanges (typically futures and options exchanges such as the Chicago Mercantile Exchange (CME) in order to prevent abuse and market manipulation. Typically, a clearing firm will be fined if they allow their members to excessively place and withdraw orders on the exchange and cause a flood of unexecuted orders to potentially slow down the speed at which the exchange operates.

VOLUME REBATE = УСТУПКА ЗА ОБЪЁМ – Volume Rebates, usually one percent to five percent, are based on a percentage of the invoice price paid to the distributor. The volume rebate increases on an incremental increase in sales. The objective is to encourage the distributor to move additional cases over a given period. At the end of this period – for example, one year – an adjustment is made on the final payment to reflect the actual cases purchased. This is a retail performance incentive. Volume rebates, once offered to a retailer, are often difficult to withdraw. Before offering them, you should determine if your competitors are doing so, because rebates aren't offered for all product categories. Volume Rebate is a rebate earned from the factory for purchasing predetermined amounts of product, typically computed on an annual basis.

VOLUME RENDERING = ОБЪЁМНАЯ ВИЗУАЛИЗАЦИЯ (или ОБЪЁМНОЕ ПРЕДСТАВЛЕНИЕ) – A term Volume Rendering refers to technologies utilized (e.g., in a confocal microscope, ultrasound imaging machines, data mining, etc) to convert numerous 'slices' (2-D) of a given 3-D volume (e.g., the inside of a living cell, a living organ within a body, etc) into a compiled-together 3-D (three-dimensional) image. / Объёмная Визуализация (Volume Rendering):- метод формирования изображения, при котором представляется не только общий вид, но и внутреннее строение трёхмерного объекта.

VOLUME RESISTIVITY = (УДЕЛЬНОЕ) ОБЪЁМНОЕ СОПРОТИВЛЕНИЕ – Volume Resistivity is the ration of the potential gradient parallel to the direction of current flow in a compound to the current density after a specified time of voltage application. Volume Resistivity:- electrical resistance between opposite faces of a 1-centimeter cube of insulating material, commonly expressed in Ohm-centimeters. Also known as Specific Insulation Resistance.

VOLUMES AT CONSTANT EXCHANGE RATES OF PERIOD T0 = ОБЪЁМЫ ПРИ ПОСТОЯННЫХ КУРСАХ ОБМЕНА ПЕРИОДА T0 – Volumes At Constant Exchange Rates Of Period t0 are series at constant domestic prices (reference year t0) converted to a common currency by way of constant exchange rates of period t0. Context:- when expressed as a volume index, this corresponds to a weighted average of the volume index of each country in the area with weights based on exchange rates of period t0.

VOLUMES AT CONSTANT EXCHANGE RATES OF PERIOD T–1 = ОБЪЁМЫ ПРИ ПОСТОЯННЫХ КУРСАХ ОБМЕНА ПЕРИОДА T–1 – Volumes At Constant Exchange Rates Of Period t-1 are series at constant domestic prices (reference year t-1) converted to a common currency by way of constant exchange rates of period t-1. Context:- when expressed as a volume index, this corresponds to a weighted average of the volume index of each country in the area with weights based on exchange rates of period t-1. Thus, exchange rate based weights are periodically updated.

VOLUMES AT CONSTANT INTERNATIONAL PRICES OF PERIOD T0 (AT PPPS OF PERIOD T0) = ОБЪЁМЫ ПРИ ПОСТОЯННЫХ МЕЖДУНАРОДНЫХ ЦЕНАХ ПЕРИОДА T0 (ПРИ ППС ПЕРИОДА T0) – Volumes At Constant International Prices Of Period t0 (At PPPs Of Period t0) are series at constant domestic prices (reference year t0) converted to a common currency by way of constant purchasing power parities (PPPs) of period t0. Context:- when expressed as a volume index, this corresponds to a weighted average of the volume index of each country in the area with weights based on PPPs of period t0. / Паритет покупательской способности.

VOLUMES AT CONSTANT INTERNATIONAL PRICES OF PERIOD T–1 (AT PPPS OF PERIOD T–1) = ОБЪЁМЫ ПРИ ПОСТОЯННЫХ МЕЖДУНАРОДНЫХ ЦЕНАХ ПЕРИОДА T–1 (ПРИ ППС ПЕРИОДА T–1) – Volumes At Constant International Prices Of Period t-1 (At PPPs Of Period t-1) are series at constant domestic prices (reference year t-1) converted to a common currency by way of constant purchasing power parities (PPPs) of period t-1. Context:- when expressed as a volume index, this corresponds to a weighted average of the volume index of each country in the area with weights based on PPPs of period t-1. Thus, PPP-based weights are periodically updated. / Паритет покупательской способности.

VOLUME SIMILARITY INDEX = ИНДЕКС ПО СХОДСТВУ ОБЪЁМА – Volume Similarity Index:- xxxxx. See also Quantity Similarity Index.

VOLUME TENDER = КОНКУРС СТОИМОСТИ – In a Volume Tender (or Fixed-Rate Tender) procedure, the interest rate is set for the central bank money on offer. Commercial banks submit bids specifying the amount of money they want to acquire. The allocation rate is calculated on the basis of the total intended allocation volume in relation to the total sum bid. In addition to the volume tender, there is what is called the Variable Rate Tender. The problem associated with the volume tender is that the commercial banks tend to submit higher volume bids than they actually require due to the low interest rate. As a result, they do better at the subsequent pro-rata allocation. Because of the continual and massive overbidding, the European Central Bank (ECB) changed over to the variable rate tender procedure for executing open market transations in 2000.

VOLUME–TO–PAYLOAD RATIO = СООТНОШЕНИЕ ВМЕСТИМОСТИ (или ОБЪЁМА) С ЧИСТОЙ ГРУЗОПОДЪЁМНОСТЬЮ (или УДЕЛЬНАЯ ГРУЗОВМЕСТИМОСТЬ) – The Volume-To-Payload Ratio of the containers can be determined from their volume and payload information, which can be obtained beforehand from prospectuses or documents provided by the container owners. The volume-to-payload ratios for the containers shown are calculated as follows:- (i) 20' container = 33.5 m^3 / 21.75 t = 1.54 m^3/t; (ii) 40' container = 67.7 m^3 / 26.74 t = 2.53 m^3/t. This means that for every metric ton of payload on the 20' container, 1.54 m^3 of packing space is available, and on the 40' container there is 2.53 m^3 available per metric ton of cargo mass. The volume-to-payload ratio of a transport container therefore answers the question:- How many cubic meters of stowage volume are available per metric ton of payload? The dimensions and masses of the items to be loaded can be used to determine the stowage factor of the load. Assuming that a consignment of 200 metric tons is to be loaded:- The volume of the items is calculated to be 440 m^3. The net stowage factor of the cargo is calculated by dividing the cargo volume by the cargo mass. Net stowage factor of the cargo = 440 m^3 / 200 t = 2.2 m^3/t. This means that, if the load is packed with no wasted space, a volume of 2.2 m^3 would be required for every metric ton of cargo. Since most loads are not 100% suitable for modular packing, certain losses will result from stowage or packing. Experienced practitioners can estimate these losses well or know from their own records what values are to be taken for calculation purposes. This information can also be obtained from relevant specialist literature. For our example, let us assume stowage loss of 10%. The gross stowage factor will then not be 2.2 m^3/t but in fact 2.42 m^3/t. Experts also say:- Cargo is stowed by a factor of 2.42. A comparison with the volume-to-payload ratios of the containers immediately reveals that economical transport can only be expected with the 40' containers. If a consignment of 300 m^3 volume and 230 t mass were waiting for loading and it were known that 15% stowage loss is to be expected, the net stowage factor of the cargo would be 300 m^3/ 230 t = 1.30 m^3/t and the gross stowage factor 1.5 m^3/t. In this case, experts would say:- Cargo is stowed by one and a half times; or:- Cargo is stowed by a factor of 1.5. By comparing the numeric values, it can immediately be seen that only 20' containers can be considered for economical transportation. The Volume-To-Payload Ratio of a

means of transport specifies the volume available per unit weight payload. In the metric system, it is usual to specify the ration in cubic meters per metric ton (m^3/t). In english-speaking countries, it is usual to use cubic feet per ton (cu.ft/t). / Соотношение вместимости/объёма с чистой грузоподъёмностью, используемое при обозначении средства перевозки, специфицирует вместимость/объём, доступный в отношении единицы веса полезной нагрузки. В метрической системе оно обычно специфицируется как отношение кубических метров к метрической тонне ($м^3$/т). В Англоязычных странах оно обычно специфицируется как отношение кубических футов к тонне (куб. ф/т). Грузовместимость тесно связана с чистой грузоподъёмностью. От соотношения этих величин зависит количество того или иного груза, которое может быть погружено на судно. Это соотношение называют удельной грузовместимостью судна. Она определяется как отношение вместимости к грузоподъёмности.

VOLUMETRIC = ВОЛЮМЕТРИЧЕСКОЕ (или ОБЪЁМНОЕ) – Volumetric:- a notional or calculated weight for bulky goods sent by air. Generally stated as 6 000 cm^3 = 1 kg, meaning that the total volume in cubic centimeters is divided by 6 000 to give an equivalent weight in kgs. The airline or forwarder will charge whichever is the greater of the actual weight and volumetric weight. Also shown sometimes as 167 kg = 1 cbm. Volumetric Weight:- also known as Dimensional Weight is used to used by freight industries and courier services around the world to invoice for the actual space that a parcel, package or pallet takes up in a vehicle or storage area. A vehicle can quickly become full of bulky, lightweight articles long before it reaches it's capacity in weight which makes for inefficient use of space.

VOLUMETRIC ANALYSIS = ВОЛЮМЕТРИЧЕСКИЙ АНАЛИЗ (или ОБЪЁМНЫЙ АНАЛИЗ) – Volumetric Analysis is any method of quantitative chemical analysis in which the amount of a substance is determined by measuring the volume that it occupies or, in broader usage, the volume of a second substance that combines with the first in known proportions, more correctly called Titrimetric Analysis (see also Titration). The first method is exemplified in a procedure devised by a French chemist, Jean-Baptiste-André Dumas, for determining the proportion of nitrogen combined with other elements in organic compounds. A weighed sample of the compound is burned in a furnace under conditions that ensure the conversion of all the nitrogen to elemental nitrogen gas, N_2. The nitrogen is carried from the furnace in a stream of carbon dioxide that is passed into a strong alkali solution, which absorbs the carbon dioxide and allows the nitrogen to accumulate in a graduated tube. The mass of the nitrogen can be calculated from the volume it occupies under known conditions of temperature and pressure, and therefore the proportion of nitrogen in the sample can be determined. A volumetric method is also applied in the analysis of nitrates, which can be converted into nitric oxide, NO, a gas. Production or consumption of carbon dioxide during biological processes often is measured volumetrically. The composition of fuel gases and combustion products can be determined by measuring the changes in volume that occur when the sample is treated successively with reagents that specifically absorb such components as carbon dioxide, carbon monoxide, oxygen, and others. / Французский химик Жо-Батист-Андрэ Дюма (Jean-Baptiste-André Dumas). Объёмный Анализ, совокупность методов химического количественного анализа, основанных на измерении объёмов для установления концентрации (содержания) определяемого вещества. К объёмным методам анализа относят распространённые в лабораторной практике различные варианты титриметрического анализа, основанного на измерении объёма израсходованного раствора реагента известной концентрации, необходимого для достижения точки эквивалентности. Иногда титриметрические методы не совсем точно отождествляют с объёмными методами. К объёмному анализу относят также многие методы газового анализа, когда при выполнении определения измеряют объём какого-либо поглотившегося или выделившегося газа. Имеются методы объёмного анализа, основанные на измерении объёма осадков, например, количество серы в чугуне можно определять по объёму осадка сульфата бария в градуированной центрифужной пробирке. Количество вещества определяют по объёму полученного осадка в ультрамикрохимическом анализе, когда взвешивание затруднено или невозможно.

VOLUMETRIC PRODUCTION PAYMENT = ОБЪЁМНЫЙ ПЛАТЁЖ ЗА ПРОДУКЦИЮ – Volumetric Production Payment (VPP) is an extension of credit where resource producers agree to deliver a certain amount of production over a set period of time (e.g., forward sale of production), ranging from 5–15 years. Banks pay a fixed price, as a lump-sum cash payment in advance. The seller is responsible for delivering gas up to the agreed upon amount and the operating cost to produce gas. The collateral to this transaction is the physical delivery of future production.

VOLUMETRIC RISK = ВОЛЮМЕТРИЧЕСКИЙ РИСК (или ОБЪЁМНЫЙ РИСК) – Volumetric Risk is the effect of fluctuations in demand for a product or service on revenue.

VOLUMETRIC UNIT = ВОЛЮМЕТРИЧЕСКАЯ ЕДИНИЦА (или ОБЪЁМНАЯ ЕДИНИЦА) – Volumetric Unit (vu) is a unit of volume equal to 200 cubic feet (5.663 cubic meters), used in the US forest products industry for wood chips and other by-products of lumber production.

VOLUMETRIC WATER CONTENT = ВОЛЮМЕТРИЧЕСКОЕ СОДЕРЖАНИЕ ВОДЫ (или ОБЪЁМНОЕ СОДЕРЖАНИЕ ВОДЫ) – Volumetric Water Content:- the water content of the soil on a per volume basis (cm^3 of water per cm^3 of soil); it is equal to the gravimetric water content multiplied by the soil bulk density.

VOLUMETRIC WEIGHT = ВОЛЮМЕТРИЧЕСКИЙ ВЕС (или ОБЪЁМНЫЙ ВЕС) – Volumetric Weight is a measure of the size of a package used for billing purposes in the airline industry. The volumetric weight of a package, in kilograms, is equal to lwh/6 000, where l, w, and h are the maximum length, width, and height measurements of the package, in centimeters. Shippers are billed for the larger of the volumetric weight and the actual weight of the package. Since the calculation assumes a density of only 1/6 gram per cubic centimeter (1/6 the density of water), the volumetric weight is used only for rather light packages that take up a lot of space on the aircraft.

VOLUMETRIC WIRES CHARGE = ОБЪЁМНЫЙ СБОР ЗА ПРОВОДА – Volumetric Wires Charge is a type of charge for using the transmission and/or distribution system that is based on the volume of electricity that is transmitted. See also Quantity Wires Charge.

VOLUME UNIT = ЕДИНИЦА ОБЪЁМА (или ОБЪЁМНАЯ ЕДИНИЦА) – Volume Unit (vu) is a unit used in telecommunications to describe the volume of a radio or television signal carrying complex information such as speech or music. These waves vary wildly in amplitude in order to represent the message they carry, so it is difficult to describe mathematically how large their 'average' amplitude is. To solve this problem, the American Standards Association decided in 1951 to establish as a reference a signal which generates 1 milliWatt of power in a circuit having an impedance of 600 Ohms. The volume of an incoming signal, in volume units, is equal to the number of deciBels (dB) by which it exceeds this reference level. Thus the volume unit is (in a complicated way) a variation of the deciBel.

VOLUME VARIANCE = ВАРИАНСА ОБЪЁМА (или РАСХОЖДЕНИЕ ОБЪЁМА) – A Volume Variance is the difference between the actual quantity sold or consumed and the budgeted amount expected to be sold or consumed, multiplied by the standard price per unit. This variance is used as a general measure of whether a business is generating the amount of unit volume for which it had planned. If the variance relates to the sale of goods, the variance is called the Sales Volume Variance, and the formula is:- (Actual

Quantity Sold – Budgeted Quantity Sold) x Budgeted Price. If the volume variance relates to direct materials, the variance is called the Material Yield Variance, and the formula is:- (Actual Unit Quantity Consumed – Budgeted Unit Quantity Consumed) x Budgeted Cost Per Unit. If the volume variance relates to direct labor, the variance is called the Labor Efficiency Variance, and the formula is:- (Actual Labor Hours – Budgeted Labor Hours) x Budgeted Cost Per Hour. If the volume variance relates to overhead, the variance is called the Overhead Efficiency Variance, and the formula is:- (Actual Units Consumed – Budgeted Units Consumed) x Budgeted Overhead Cost Per Unit. Every volume variance involves the calculation of the difference in unit volumes, multiplied by a standard price or cost. As you can see from the various variance names, the term Volume does not always enter into variance descriptions, so you need to examine their underlying formulas to determine which ones are actually volume variances. The standard costs for products that are used in a volume variance are usually compiled within the bill of materials, which itemizes the standard unit quantities and costs required to construct one unit of a product. This usually assumes standard production run quantities. The standard costs for direct labor that are used in a volume variance are usually compiled within a labor routing, which itemizes the time required for certain classifications of labor to complete the tasks needed to construct a product. A volume variance is more likely to arise when a company sets theoretical standards, where the theoretically optimal number of units are expected to be used in production. A volume variance is less likely to arise when a company sets attainable standards, where usage quantities are expected to include a reasonable amount of scrap or inefficiency. If the standards upon which the volume variance is calculated are in error or wildly optimistic, employees will have a tendency to ignore negative volume variance results. Consequently, it is best to use standards that are reasonably attainable. Also known as Quantity Variance.

VOLUME WEIGHT = ОБЪЁМНЫЙ ВЕС – Volume Weight:- used when calculating air freight when the size of the carton is greater than the average weight, calculated by multiplying the length times the width times the height and dividing by 166.

VOLUME WEIGHTED AVERAGE PRICE = УСРЕДНЁННАЯ ОБЪЁМНЫМ ВЕСОМ ЦЕНА (или СРЕДНЯЯ ВЕЛИЧИНА ЦЕНЫ XX) – Volume Weighted Average Price (VWAP):- if a future (or other security, commodity or stock) trades to a high price of 1 010 and a low price of 1 000 during the day and also trades at all other prices in between during the day then the average price that the future traded at would be 1 005. This is a simple average. It adds up all the prices that were traded at during the day and divides by the number of price points that were observed. Now imagine that there were two trades during the day. The first was for 20 000 contracts at a price of 1 010. The second was for 1 contract at a price of 1 000. Would the average of 1 005 fairly reflect the price at which the future traded at on that day? Probably not because 99.9% of the trades took place at 1 010. The Volume Weighted Average Price (VWAP) takes this into account and will calculate the VWAP price to be 1 010 instead of the average price of 1 005.

VOLUNTARISM = ВОЛЮНТАРИЗМ – Voluntarism is any metaphysical or psychological system that assigns to the will (Latin:- Voluntas) a more predominant role than that attributed to the intellect. Christian philosophers have sometimes described as voluntarist:- the non-Aristotelian thought of St. Augustine because of its emphasis on the will to love God; the post-Thomistic thought of John Duns Scotus, a late medieval scholastic, who insisted on the absolute freedom of the will and its supremacy over all other faculties; and the position of the French writer Blaise Pascal, who in religion substituted ‘reasons of the heart’ for rational propositions. Immanuel Kant’s categorical imperative as an unconditional moral law for the will’s choice of action represented an ethical voluntarism. A metaphysical voluntarism was propounded in the XIX century by the German philosopher Arthur Schopenhauer, who took will to be the single, irrational, unconscious force behind all of reality and all ideas of reality. An existentialist voluntarism was present in Friedrich Nietzsche’s doctrine of the overriding ‘will to power’ whereby man would eventually re-create himself as ‘Superman’. And a Pragmatic voluntarism is evident in William James’s reference of knowledge and truth to purpose and to practical ends. / Дьжон Данз Скотэс (John Duns Scotus). Французский писатель Блез Паскаль (Blaise Pascal). Иммануэль Кант (Immanuel Kant). Немецкий философ Атуа Шопэнхауа (Arthur Schopenhauer). в доктрине Фридрихя Ницшэ (Friedrich Nietzsche). Вильэм Дьжеймз (William James). Под Волюнтаризмом, от Латинского слова Voluntas, означающее Воля, понимается идеалистическое направление в философии, рассматривающее волю в качестве высшего принципа бытия. Выдвигая в духовном бытии на первый план волю, волюнтаризм противостоит интеллектуализму (или рационализму) – идеалистическим философским системам, которые считают основой сущего интеллект, разум. Элементы волюнтаризма имелись уже в философии христианского теолога и философа Святого Орэлиуса Огустинуса Хипонэнсис (или Блаженного Аврелия Августина Хипоненского (Aurelius Augustinus Hipponensis Sanctus) или просто Святого Огастина из Хипо (St Augustine of Hippo); 354–430), видевшего в воле основу всех других духовных процессов, и Британского философа теолога Дьжона Данза (John Duns; 1266–1308), известного как Дунс Скот (Duns Scotus), с его подчёркиванием примата воли перед интеллектом (voluntas est superior intellectu = воля выше мышления). Предпосылкой новейшего волюнтаризма явилось учение Немецкого философа и учёного Иммануэля Канта (Immanuel Kant; 1724–1804) о примате практического разума; хотя существование свободной воли нельзя, по Канту, теоретически ни доказать, ни опровергнуть, практический разум требует постулировать свободу воли, ибо иначе нравственный закон потерял бы всякий смысл. Исходя из этого, Немецкий философ и общественный деятель Йохан Готлиб Фихьтэ (Johann Gottlieb Fichte; 1762–1814) видел в воле основу личности, а в волевой деятельности Я – абсолютный творческий принцип бытия, источник духовного самопорождения мира. При этом воля у Фихьтэ (как и у Канта, а также последующих представителей Немецкой классической философии – Фридрихя Вильхэльма Йозэфа фон Шелиня (Friedrich Wilhelm Joseph von Schelling; 1775–1854) и Георга Вильхэльма Фридрихя Хейгеля (Georg Wilhelm Friedrich Hegel; 1770–1831)) является разумной по своей природе, источником осуществления нравственного начала. В противоположность этому Немецкий философ-идеалист Атуа Шопэнхауа (или Артур Шопенгауэр (Arthur Schopenhauer); 1788–1860), в философии которого волюнтаризм впервые оформляется как самостоятельное направление, даёт иррационалистическую трактовку воли (смотрите Иррационализм) как слепого, неразумного, бесцельно действующего первоначала мира. Кантовскую ‘вещь в себе’ Шопэнхауа истолковывает как волю, проявляющуюся на различных ступенях объективации; сознанию и интеллекту Шопэнхауа отводит роль одного из вторичных проявлений воли. У Шопэнхауа, как и у другого Немецкого философа-идеалиста Каля Робэта Эдуада фон Хатмана (Karl Robert Eduard von Hartmann; 1842–1906), волюнтаризм тесно связан с пессимизмом, представлением о бессмысленности мирового процесса, имеющего своим источником бессознательную и слепую волю. Волюнтаристические идеи Шопэнхауа явились одним из источников философии Немецкого философа Фридрихя Вильхэльма Ницшэ (Friedrich Wilhelm Nietzsche; 1844–1900). Смотрите также Воля. Термин Волюнтаризм употребляется также для характеристики социально-политической практики, не считающейся с объективными законами исторического процесса и руководствующейся субъективными желаниями и произвольными решениями осуществляющих её лиц. Смотрите также Субъективизм. Термин Волюнтаризм ввёл в обращение Немецкий социолог и философ Фэрдинанд Тонис (Ferdinand Tönnies; 1855–1936) в 1883.

VOLUNTARY ACCUMULATION PLAN = ПЛАН ДОБРОВОЛЬНОГО НАКОПЛЕНИЯ (или ДОБРОВОЛЬНЫЙ ПЛАН ПО НАКОПЛЕНИЮ) – Voluntary Accumulation Plan is an investment method in which a retail investor periodically invests (at its discretion) relatively small amounts of funds into a mutual fund, building a large position over an extended period. By investing savings into a mutual fund gradually over time with a voluntary accumulation plan, an investor can build a large investment at his or her own

pace. Contributions are voluntary, although common practice is to invest a fixed amount at specified intervals. By spreading the contributions over a period of time, investors reap the benefits of Dollar-cost averaging, as the fixed contributions will buy more shares of a mutual fund when its price is low than when it is high. Voluntary Accumulation Plan is an arrangement allowing shareholders of a mutual fund to purchase shares over a period of time on a regular basis, and in so doing take advantage of dollar cost averaging. Voluntary Accumulation Plans are an example of an investing strategy that allows incremental contributions to a mutual fund. Over time, the use of a voluntary accumulation plan allows the mutual fund shareholder to build a substantial position with the fund. This can be an excellent solution for anyone who wishes to build an investment portfolio, but is not in a position to invest a large sum of money at one time. Along with the advantage of being able to build up an investment over an extended period of time, the voluntary accumulation plan has the benefit of being an investment option with mutual funds that are considered to be relatively low risk. While it is true that low risk investments do not yield a high rate of return, the investor can still anticipate a profit that is higher than the average rate of interest on a standard savings account. For an investor who does not have a great deal of disposable income, this aspect of the voluntary accumulation plan can be very attractive. A second benefit is that the plan will allow mutual fund shareholders to take advantage of Dollar-cost averaging over the period of accumulation. Essentially, this means that shares can be purchase when the price per unit is relatively low. The result is more shares for the investor at a lower initial cost. When the current price per unit is higher, the investor continues to make incremental contributions to the plan, allowing the balance to build up until another temporary dip in price makes it feasible to purchase more shares. Setting up a voluntary accumulation plan is not difficult to accomplish. A financial advisor can evaluate the current economic status of the investor and determine a reasonable amount to contribute to this type of plan on a recurring basis. In many cases, the advisor can also make recommendations of mutual fund plans that permit the voluntary accumulation method. There are variations of the voluntary accumulation plan that are structured for individual investors, as well as employees who wish to participate in a plan of this nature through a corporate plan. Voluntary Accumulation Plan is a plan to acquire additional shares in a mutual fund on a more or less regular basis, at the discretion of the shareholder. Voluntary Accumulation Plan is a method such as Dollar cost averaging by which an investor regularly makes contributions to acquire mutual fund shares. Many investors will set up voluntary accumulation plans to contribute a set amount money in fixed intervals to invest into mutual fund portfolios. Dollar cost averaging is the most popular type of voluntary accumulation plan. Over time investors should end up with an average price that is lower than their average cost per share. Voluntary Accumulation Plan is an arrangement allowing shareholders of a mutual fund to purchase shares over a period of time on a regular basis, and in so doing take advantage of Dollar cost averaging. Voluntary Accumulation Plan is an investment strategy in which shareholders of a mutual fund to buy more and more shares in the fund on a regular basis. It especially refers to situations in which a shareholder puts in a fixed amount of money on a regular basis, regardless of how many shares that amount buys. Generally speaking, this lowers the average price one pays per share. Thus, if one buys using a voluntary accumulation plan and later sells all shares at once, this could result in a higher profit. It is also called a Contractual Plan. / План Добровольного Накопления:- программа добровольного накопления ценных бумаг. План, на который подписывается акционер взаимного фонда (mutual fund), для регулярного накопления акций этого фонда в течение определённого периода времени. Денежные суммы, которые помещаются в фонд, и периодичность платежей определяются по усмотрению акционера. План, при котором фиксированные суммы вносятся в соответствии с упорядоченным графиком, называются Планами Усреднения Долларовой Стоимости или Постоянными Долларовыми Планами (Constant Dollar Plans). План Добровольного Накопления:- программа, на которую подписываются владельцы акций взаимного фонда, желающие накапливать акции в этом фонде на регулярной основе в течение определённого периода времени. Сумма денег, помещаемых в фонд, и интервалы времени, через которые они будут инвестированы, находятся на усмотрении владельца акций.

VOLUNTARY ALIENATION = ДОБРОВОЛЬНОЕ ОТЧУЖДЕНИЕ – Voluntary Alienation is a transfer of real property through one's intentional actions. Contrast with Involuntary Alienation, such as a foreclosure. Voluntary Alienation is the process of property title transfer through a deed. / Добровольное Отчуждение:- . Синоним термина Передача Титула (Transfer Of Title).

VOLUNTARY ARRANGEMENT = ДОБРОВОЛЬНАЯ ДОГОВОРЁННОСТЬ – Voluntary Arrangement is a procedure enabling an insolvent company to come to an arrangement with its creditors and resolve its financial problems, often in compliance with a court order. Voluntary Arrangement is an agreement between an insolvent or financially-strapped debtor entity and its creditors, aimed at avoiding the liquidation of its assets. Under a voluntary arrangement, the entity continues its normal existence and pays off its debts over an agreed upon period, without or without any court-issued administration order. / Добровольная Договорённость:- в Соединённом Королевстве, процедура, предусмотренная Актом О Неплатёжеспособности от 1986, которая состоит в том, что компания может самостоятельно прийти к договорённости с кредиторами о погашении долгов и управлять делами так, что она окажется в состоянии преодолеть финансовые затруднения. Такая договорённость может быть предложена директорами, администратором, действующим в соответствии с распоряжением об администрировании (administration order), или ликвидатором (liquidator). Для наблюдения за ходом выполнения договорённости должен назначаться квалифицированный специалист по случаям неплатёжеспособности. Это может быть администратор или ликвидатор, который обязан организовать встречу членов компании и кредиторов для обсуждения договорённости. Предлагаемая договорённость может быть изменена или одобрена в ходе встречи, однако, будучи однажды одобренной, она связывает всех, кто получил уведомление о собрании. Суд имеет право выносить соответствующие распоряжения, направленные на придание договорённости юридической силы. В случае любого отклонения от договорённости сама договорённость может быть опротестована в суде. Цель добровольной договорённости состоит в том, чтобы помочь компании разрешить финансовые проблемы, не прибегая к ликвидации. Смотрите также Ликвидация (Liquidation).

VOLUNTARY ASSOCIATION = ДОБРОВОЛЬНАЯ АССОЦИАЦИЯ – Voluntary Association is a group of individuals joined together on the basis of mutual interest or common objectives, especially a business group that is not organized or constituted as a legal entity. For example, legitimate government can be formed only by the voluntary association of all who contribute to its support. Voluntary Association is an unincorporated group associated for some specific purpose – used chiefly of commercial or financial associations. A Voluntary Association is a group or organization that people may join or leave freely, that is free of external control, and whose purpose, goals, and methods are up to the members to determine. Sociologically, voluntary associations are often seen as crucial to the functioning of democracy, especially by providing a way for individuals to become involved in public life beyond the privacy of home and family. Voluntary Association is the name given to a group of people who get together voluntarily to form an organisation to carry out public good. Voluntary Association is an unincorporated society or body of individuals, formed for social, political, moral, religious, benevolent, protective, or mutual purposes, or to promote some public, scientific or educational object, or to facilitate business, and not for purposes of trade or direct pecuniary profit. By its incorporation a voluntary association is merged in the corporate body, its members become the constituent members of the corporation, and its property becomes the property of the corporation. / Добровольная Ассоциация.

VOLUNTARY BANKRUPTCY = ДОБРОВОЛЬНОЕ БАНКРОТСТВО – Voluntary Bankruptcy is a type of bankruptcy where an insolvent debtor brings the petition to a court to declare bankruptcy because he or she (in the case of an individual) or it (in the case of a business entity) is unable to pay off debts. The bankruptcy is intended to create an orderly and equitable settlement of the debtor's obligations. Voluntary bankruptcy is a bankruptcy proceeding initiated by a debtor who knows that they will not be able to satisfy the debt requirements of creditors. Voluntary bankruptcy is typically commenced when and if a debtor finds no other solution to the financial situation. Voluntary bankruptcy differs from involuntary bankruptcy which occurs when one or more creditors petitions a court to judge the debtor as insolvent (unable to pay). Voluntary Bankruptcy is the process where the debtor petitions the court for bankruptcy protection. See also Bankruptcy, and Involuntary Bankruptcy. Voluntary Bankruptcy is the US term for legal proceedings whereby a debtor entity, on its own initiative, files a petition seeking relief from creditors. See also Voluntary Winding Up. Voluntary Bankruptcy is the legal proceeding that follows a petition of bankruptcy. / Добровольное Банкротство – юридическая процедура, которая следует после подачи петиции о банкротстве (bankruptcy) в соответствующий Окружной Суд США в соответствии с Актом О Банкротстве (Bankruptcy Act). Петиции о добровольном банкротстве могут быть поданы любыми несостоятельными коммерческими предприятиями или частными лицами, за исключением ассоциаций по строительству и планированию зданий, а также муниципальных, железнодорожных, страховых или банковских корпораций. VOLUNTARY CONTRIBUTION = ДОБРОВОЛЬНАЯ КОНТРИБУЦИЯ – Voluntary Contribution is an extra contribution paid in addition to the mandatory contribution a member can pay to the pension fund in order to increase the future pension benefits. See also Contribution (to a pension plan), and Mandatory Contribution. Voluntary Contribution:- additional funds sent in by an individual in a dividend reinvestment plan account, used to purchase additional shares. Also known as an Optional Cash Payment.

VOLUNTARY CONVEYANCE OR DEED = ДОБРОВОЛЬНАЯ ПЕРЕДАЧА ПРАВА ИЛИ ВОЛЕИЗЪЯВЛЕНИЕ – Voluntary Conveyance Or Deed:- a conveyance or transfer of property made without valuable or adequate consideration is a voluntary conveyance. For example, a deed in favor of a relative is a voluntary conveyance. Such conveyances, once made cannot be cancelled. Voluntary conveyances are sometimes made with actual intent to hinder, delay, or defraud a creditor. Voluntary Conveyance is a conveyance without valuable consideration; such as a deed or settlement in favor of a wife or children. Voluntary Conveyance is a transfer of title from a delinquent homeowner to a lender to satisfy the balance on a loan in default. The delinquent borrower transfers title on a voluntary basis, in order to avoid foreclosure. Voluntary conveyance also refers to a transfer of property made without adequate consideration, such as a deed transferring title to a family member or relative. In this case, a voluntary conveyance has obvious potential for fraud, and in fact, is one of the vehicles used by unscrupulous parties to defraud creditors. Some municipalities in the US use the voluntary conveyance method as an alternative to the standard tax foreclosure process to accelerate the development of abandoned or tax-delinquent properties. Voluntary conveyance can aid municipalities by saving them the expense of tax foreclosure and reducing urban blight, while benefiting property owners whose municipal liens may be discharged. However, the application of voluntary conveyance is limited by the requirement for clear title. / Акт Добровольной Передачи:- инструмент передачи титула собственности от его владельца держателю права удержания. Обычно подобная передача служит для того, чтобы избежать юридической процедуры судебного разбирательства. Применение акта добровольной передачи свидетельствует о недостаточном обеспечении для удовлетворения задолженности и происходит без передачи каких-либо ценностей в порядке компенсации.

VOLUNTARY DISSOLUTION = ПРЕКРАЩЕНИЕ ДЕЯТЕЛЬНОСТИ В ДОБРОВОЛЬНОМ ПОРЯДКЕ (или РОСПУСК В ДОБРОВОЛЬНОМ ПОРЯДКЕ) – Voluntary Dissolution is an action by shareholders, incorporators or initial directors to dissolve a corporation. A voluntary dissolution can remove companies from the UK Companies House Register if certain conditions are met. Beware! You cannot use dissolution unless all of the conditions are met (see detailed guide below). Providing you meet the conditions, company dissolution is a very useful and cost effective tool. It means there is no need to incur liquidation costs, no investigation into your directors' activity and very little publicity.... See also Administrative Dissolution, Dissolution, Involuntary Dissolution, and Judicial Dissolution. A Voluntary Dissolution is a provision in the UK Companies Act to allow the removal of the company from the Companies Register, typically when the company is dormant. If the company serves no useful purpose, its dissolution removes the need for the filing of annual returns and accounts. However, bear in mind that the company can only be dissolved (removed from the Companies House Register), if the following conditions apply:- (i) the company has not traded for three months; this must be a genuine cessation of trade!; (ii) the company has no assets, property or cash at the bank; (iii) the creditors are circulated, requesting their permission for the company to be dissolved under this process; (iv) creditors are given three months to consider the request to dissolve the company and can reject such a request; (v) the company has not changed its name in this period; and (vi) the company has not disposed of any property or assets (this may include land and buildings, plant and equipment, debtors and other assets). Please note that paying off debts does not necessarily constitute trading, but for detailed advice on this and all other aspects of dissolution, please call on +44-800-9700539 (in the United Kingdom) for further advice. Dissolution cannot be used if:- (i) a formal insolvency procedure is in place, or proceedings have been commenced. These procedures include a creditors voluntary liquidation (CVL), company voluntary arrangement (CVA), administration, receivership or compulsory liquidation under the Insolvencies Act 1986, or scheme of arrangement under the Companies Act 1985. (ii) Any petition has been issued against a company (for administration or compulsory liquidation) then dissolution cannot be used. Advantages of dissolution:- (i) it is a quick and clean removal of a dormant company from the Companies House Register; (ii) it avoids the costs of liquidation, fees and expenses; and (iii) it avoids formal investigation into the conduct of the directors as required in liquidation or receivership. Disadvantages of dissolution:- (i) creditors may reject the application; their permission is required to proceed with a dissolution; (ii) any shareholder, creditor or liquidator can apply to revive the company for up to 20 years after dissolution; (iii) they may revive the company of the following applies:- (a) notice required to creditors was not given correctly or adequately, (b) it comes to light that the company was trading during the three months period prior to making application to dissolve, and (c) it comes to light that some fraud, misfeasance or other unjust action was committed by the company or the directors before or during the dissolution process; (iv) whilst a commonsense approach to collecting assets and distributing them to creditors in proper order usually suffices, there is no prescribed method. This could of course be open to abuse and if performed incorrectly can lead to a revival of the company as above. If you have any doubt as to the application of this methodology please do not hesitate to contact us by e-mail or on our freephone number +44-800-9700539 (in the United Kingdom); (v) dissolution cannot terminate leases, HP agreements or contingent liabilities. receivership, administration, CVL or CVA need to be used whenever such circumstances exist. This is clearly a very difficult technical area and the directors should take proper advice from a turnaround practitioner or insolvency practitioner who is well-versed in the rules in this regard; and (vi) from a creditors' perspective dissolution avoids a formal investigation into the director's conduct. Of course if any transactions such as a preference, transactions defrauding creditors or basic fraud have been committed dissolution does not afford an investigation into past conduct. If the creditors are of the opinion that such transactions may have occurred they can of course refuse permission and the company will either be liquidated voluntarily or compulsorily. / Смотрите также Прекращение Деятельности (Dissolution), Прекращение Деятельности В Административном Порядке (Administrative Dissolution), Прекращение Деятельности В Принудительном Порядке (Involuntary Dissolution), и Прекращение Деятельности В Судебном Порядке (Judicial Dissolution).

VOLUNTARY EXCESS = ДОБРОВОЛЬНЫЙ ЭКСЦЕСС – Voluntary Excess is an excess which the insured agrees to bear in consideration of a reduction in premium. / Под Эксцессом, от Латинского слова Excessus, означающее Выход или Отступление, понимается:- (1) крайнее проявление чего-либо; излишество (невоздержанность); и (2) нарушение нормального хода чего-либо, например, общественного порядка.

VOLUNTARY EXPORT QUOTA = ДОБРОВОЛЬНАЯ КВОТА НА ВЫВОЗ (или ДОБРОВОЛЬНАЯ ЭКСПОРТНАЯ КВОТА) – Voluntary Export Quota is a government-imposed limit on the quantity of some category of goods that can be exported to a specified country during a specified period of time. / Добровольная Экспортная Квота:- количественное ограничение, которое страна устанавливает для себя в отношении вывоза (или экспорта) определённого товара в другую страну. Обычно является результатом жалобы страны-импортёра на то, что её отечественная промышленность терпит урон из-за продолжающегося вывоза (или экспорта) данного товара из страны – торгового партнёра.

VOLUNTARY EXPORT RESTRAINTS = ДОБРОВОЛЬНЫЕ ВЫВОЗНЫЕ ОГРАНИЧЕНИЯ (или ДОБРОВОЛЬНЫЕ ЭКСПОРТНЫЕ ОГРАНИЧЕНИЯ, или ДОБРОВОЛЬНЫЕ ОГРАНИЧЕНИЯ ВЫВОЗА, или ДОБРОВОЛЬНЫЕ ОГРАНИЧЕНИЯ ЭКСПОРТА) – Voluntary Export Restraint (VER) is a trade restriction on the quantity of a good that an exporting country is allowed to export to another country. This limit is self-imposed by the exporting country. Typically, VERs are a result of requests made by the importing country to provide a measure of protection for its domestic businesses that produce substitute goods. VERs are often created because the exporting countries would prefer to impose their own restrictions than risk sustaining worse terms from tariffs and/or quotas. The most notable example of VERs is when Japan imposed a VER on its auto exports into the US as a result of American pressure in the 1980s. The VER subsequently gave the US auto industry some protection against a flood of foreign competition. However, there are ways in which a company can avoid a VER. For example, the exporting country's company can always build a manufacturing plant in the country to which exports would be directed. By doing so, the company will no longer need to export goods, and should not be bound by its country's VER. Voluntary Export Restraints (VER) are arrangements between exporting and importing countries in which the exporting country agrees to limit the quantity of specific exports below a certain level in order to avoid imposition of mandatory restrictions by the importing country. The arrangement may be concluded either at the industry or government level. / Добровольные Ограничения Экспорта (ДОЭ):- .

VOLUNTARY FOREIGN CREDIT RESTRAINT PROGRAM = ПРОГРАММА ДОБРОВОЛЬНОГО ОГРАНИЧЕНИЯ ИНОСТРАННЫХ КРЕДИТОВ – The Voluntary Foreign Credit Restraint (VFCR) Program (VFCRP) is one of several elements in the government's over-all program to strengthen the US balance of payments position. It provided guidelines to banks and other financial institutions for the reduction of their Dollar outflows had been introduced in 1965. In 1965 and 1966 we did manage, with the help of the voluntary foreign credit restraint program, to reduce our payments deficit to about USD1.3 billion each year, but in 1967 we came up with another whopping deficit – USD3.6 billion on the so-called Liquidity Basis. It was USD800 million greater than the liquidity deficit for 1964, and you may recall that it was the size of the deficit in that year that led to the imposition of the program and other balance-of-payments measures in early 1965. / Программа Добровольного Ограничения Иностранных Кредитов.

VOLUNTARY GUARDIAN = ДОБРОВОЛЬНЫЙ ЗАЩИТНИК (или ДОБРОВОЛЬНЫЙ ПОПЕЧИТЕЛЬ, или ДОБРОВОЛЬНЫЙ ОПЕКУН) – In the United States, Voluntary Guardian is an individual who is recognized by the Department of the Treasury as authorized to act for an incapacitated person as provided in the regulations governing US Savings Bonds (31 CFR 315.64 (31 CFR is short for the Code of Federal Regulations:- Title 31) also in Section 315.64 in Department of the Treasury Circular No. 530; 31 CFR 353.64 also in Section 353.64 in Department of the Treasury Circular, Public Debt Series No. 3-80; and, 31 CFR 360.64 also in Section 360.64 in Department of the Treasury Circular, Public Debt Series No. 2-98).

VOLUNTARY IASP = ДОБРОВОЛЬНАЯ ПРАКТИКА МЕЖДУНАРОДНОГО АКТУАРНОГО СТАНДАРТА – Voluntary IASP is a class 2 International Actuarial Standard of Practice (IASP). This is an actuarial standard of practice that is not mandatory. However, it would apply with mandatory effect whenever an actuary asserted compliance with a standard. An IAA (International Actuarial Association) Member Association may impose it on its individual members. It may be that a third party, such as a client, a regulator, or a security exchange commission, could require its application. In those circumstances an opinion or report that did not comply with the relevant voluntary standard would be of little value to the client, hence effectively making it mandatory on actuaries engaged in the relevant practice area.

VOLUNTARY IMPORT EXPANSIONS = ДОБРОВОЛЬНЫЕ ПРИВОЗНЫЕ РАСШИРЕНИЯ (или ДОБРОВОЛЬНЫЕ ИМПОРТНЫЕ РАСШИРЕНИЯ, или ДОБРОВОЛЬНЫЕ РАСШИРЕНИЯ ПРИВОЗА) – Voluntary Import Expansions:- a change in a country's policies to allow more imports. Examples include lowering tariffs or dropping import quotas. Voluntary import expansion may occur as part of a trade agreement with another country, in which both partners move to expand imports, or it may be a result of international pressure. A Voluntary Import Expansion (VIE) is an agreement to increase the quantity of imports of a product over a specified period of time. In the late 1980s, VIEs were suggested by the US as a way of expanding US exports into Japanese markets. Under the assumption that Japan maintained barriers to trade that restricted the entry of US exports, Japan was asked to increase its volume of imports on specified products including semiconductors, automobiles, auto parts, medical equipment and flat glass. The intention was that VIEs would force a pattern of trade that more closely replicated the free trade level. Since the early 1990s, VIEs have rarely been mentioned in public policy discussions. / Добровольные Расширения Привоза (ДРВ):- страна реагирует на угрозу другой страны применить торговые санкции согласием покупать большое количество определённых товаров у этой страны.

VOLUNTARY INTERMODAL SEALIFT AGREEMENT = СОГЛАШЕНИЕ О ДОБРОВОЛЬНОЙ ИНТЕРМОДАЛЬНОЙ МОРСКОЙ ПЕРЕВОЗКЕ – Voluntary Intermodal Sealift Agreement (VISA) provides the US defense community with 'assured access' to commercial intermodal capacity to move sustainment cargoes during time of war or national emergency. In return, during peacetime, the carriers receive preference in the carriage of DOD cargoes (short for the US Department of Defense cargoes).

VOLUNTARY LIQUIDATION = ДОБРОВОЛЬНАЯ ЛИКВИДАЦИЯ – Voluntary Liquidation or Voluntary Winding-Up is a corporate liquidation that has been approved by the shareholders of the company. Voluntary liquidations stand in contrast to involuntary liquidations, which are a result of Chapter 7 bankruptcy. The shareholder vote allows the company to liquidate its assets to free up funds to pay debts. Voluntary liquidations in the UK are divided into two categories. One is the Creditors' Voluntary Liquidation, which occurs under a state of corporate insolvency. The other is the Members' Voluntary Liquidation, which only requires a corporate declaration of bankruptcy. Under the second category, the firm is solvent, but needs to liquidate their assets to meet their upcoming obligations. Voluntary liquidation can also happen if a vital member of the organization leaves the company and the shareholders decide not to continue operations. See also Creditors' Voluntary Liquidation; and Members' Voluntary Liquidation. Voluntary Liquidation is a liquidation that is supported by a company's shareholders, as opposed to an Involuntary Liquidation forced by Chapter 7 bankruptcy. A voluntary liquidation can occur in two situations. One is a members' voluntary liquidation when the directors of a solvent company decide to liquidate the company (with shareholder approval), and declare that they will be able to fulfill all creditor obligations in 12 months. The other situation is a creditors' voluntary liquidation, when the directors approach an insolvency professional for

assistance in liquidation since they will not be able to fulfill creditors' obligations. Voluntary Liquidation:- liquidation proceedings that are supported by a company's shareholders. / Добровольная Ликвидация или Добровольное Закрытие (Voluntary Winding-Up):- . VOLUNTARY OCCUPATIONAL PENSION PLANS = ДОБРОВОЛЬНЫЕ ПРОФЕССИОНАЛЬНЫЕ ПЕНСИОННЫЕ ПЛАНЫ – Voluntary Occupational Pension Plans:- the establishment of these plans is voluntary for employers (including those in which there is automatic enrolment as part of an employment contract or where the law requires employees to join plans set up on a voluntary basis by their employers). In some countries, employers can on a voluntary basis establish occupational plans that provide benefits that replace at least partly those of the social security system. These plans are classified as voluntary, even though employers must continue sponsoring these plans in order to be exempted (at least partly) from social security contributions. See also Mandatory Occupational Plan, and Occupational pension plan.

VOLUNTARY PERSONAL PLANS = ДОБРОВОЛЬНЫЕ ПЕРСОНАЛЬНЫЕ ПЛАНЫ – Voluntary Personal Plans:- participation in these plans is voluntary for individuals. By law individuals are not obliged to participate in a pension plan. They are not required to make pension contributions to a pension plan. Voluntary personal plans include those plans that individuals must join if they choose to replace part of their social security benefits with those from personal pension plans. See also Mandatory Personal Plan.

VOLUNTARY PLAN = ДОБРОВОЛЬНЫЙ ПЛАН – Voluntary Plan is a pension plan supported partially by the employee by pension contributions deducted from each paycheck. Voluntary Plans offer many benefits to both employees and employers (and they can be a gold mine for brokers!). / Добровольный План:- сокращённое название для Плана Контрибуций По Добровольным Отчислениям У Работника (Voluntary Deductible Employee Contribution Plan) – вид пенсионной программы, при которой работники соглашаются производить пенсионные отчисления (в зависимости от программы могут производиться до или после удержания налогов) путём вычета соответствующих сумм из всех видов оплаты труда. Добровольный План – тип программы накоплений для инвестиций на регулярной основе, но без какого-либо очерченного периода времени или установленной предельной суммы инвестиций. Комиссия за продажу применяется индивидуально к каждой сделанной покупке.

VOLUNTARY PROGRAM = ДОБРОВОЛЬНАЯ ПРОГРАММА – Voluntary Program is a program that allows producers to choose whether to participate without loss of market access. The cornerstone of current federal programs is that they are voluntary.

VOLUNTARY QUOTA RESTRUCTURING SCHEME = ДОБРОВОЛЬНАЯ СХЕМА РЕСТРУКТУРИРОВАНИЯ КВОТЫ – Voluntary Quota Restructuring Scheme was established as part of the reform of the European Union's Common Market Organisation (CMO) for sugar in February 2006 to apply for four years from 01 July 2006. Under the scheme, sugar producers receive a degressive payment for permanently surrendering sugar production quota, in part or in entirety, over the period 2006–07 to 2009–10.

VOLUNTARY REPORTING REQUIREMENTS = ТРЕБОВАНИЯ О ДОБРОВОЛЬНОЙ ОТЧЁТНОСТИ (или ХХ) – Voluntary Reporting Requirements are situations where there is no legal obligation for reporters to provide the requested information.

VOLUNTARY RESERVES = ДОБРОВОЛЬНЫЕ РЕЗЕРВЫ – Voluntary Reserves are the reserves over and above the provisions required by law. These may be stipulated in the articles of association or formed in response to resolutions by the supervisory body, e.g., General Meetings of Shareholders.

VOLUNTARY RESTRAINT AGREEMENTS = ДОБРОВОЛЬНЫЕ СОГЛАШЕНИЯ ОБ ОГРАНИЧЕНИИ – Voluntary Restraint Agreements (VRAs):- informal bilateral or multilateral arrangements through which the exporting nations voluntarily restrain certain exports, usually through export quotas, to avoid economic dislocation in an importing country and to avert the possible imposition of mandatory import restrictions by the importing country. Voluntary Restraint Agreements:- an agreement between countries to limit imports or exports to a fixed number that is not set down in any laws or regulations. Voluntary Restraint Agreement is an agreement between two or more countries in which each limits exports to the other. While this reduces trade between the counties involved, it can help domestic industries and, in any event, can reduce tensions because fewer workers in the involved countries may be worried about outsourcing. Voluntary Restraint Arrangement (VRA) is the bilateral arrangement whereby an exporting country (government or industry) agrees to reduce or restrict exports without the importing country having to make use of quotas, tariffs or other import controls. / Добровольные Соглашения Об Ограничении (ДСО (VRAs)):- двусторонние соглашения, по которым страна-экспортёр соглашается сократить или ограничить вывоз (или экспорт), с тем чтобы страна-импортёр не должна была прибегать к квотам, пошлинам или другим методам привозного (или импортного) контроля. Такие соглашения заключают во избежание действий страны-импортёра против привоза (или импорта), способного причинить вред или как-то угрожать позициям отечественных фирм соответствующей отрасли. Ещё один пример действий, законность которых в рамках Генерального Соглашения о Тарифах и Торговле (ГСТТ) не определена достаточно чётко. Сравните с Соглашениями об Упорядоченной Торговле (Orderly Marketing Agreements). Смотрите также Европейский Внутренний Рынок (European Domestic Market).

VOLUNTARY RETAILER = ДОБРОВОЛЬНЫЙ РОЗНИЧНЫЙ ТОРГОВЕЦ – Voluntary Retailer is another name for Symbol Retailer. Any member of a voluntary group of independent retailers, often using a common name or symbol, formed to obtain better prices from wholesalers or manufacturers in competition with supermarket chains. / Добровольный Розничный Торговец:- . Смотрите также Символический Розничный Торговец (Symbol Retailer).

VOLUNTARY SCRAPIE FLOCK CERTIFICATION PROGRAM = ПРОГРАММА ДОБРОВОЛЬНОЙ СЕРТИФИКАЦИИ СКРЭЙПИ У СТАДА – Voluntary Scrapie Flock Certification Program:- a voluntary, cooperative effort among producers, allied industry representatives, accredited veterinarians, state animal health officials, and the Animal and Plant Health Inspection Service (APHIS). The program provides participating producers with the opportunity to protect their sheep from scrapie and to enhance the marketability of their animals through certifying their origin in scrapie-free flocks. In addition, APHIS regulations restrict the interstate movement of sheep from scrapie-infected and source flocks. / Скрэйпи или Овечья Трясучка – болезнь.

VOLUNTARY SHIP = ДОБРОВОЛЬНОЕ СУДНО – Voluntary Ship is any ship which is not required by treaty or statute to be equipped with radiotelecommunication equipment.

VOLUNTARY TERMINATION = ДОБРОВОЛЬНОЕ ЗАВЕРШЕНИЕ – Voluntary Termination is a termination of employment initiated by the employee or by mutual agreement with the employer in which a letter of resignation is submitted. In most cases of voluntary termination, employees will provide notice of their intent to resign to allow for a more orderly transition of responsibilities. Voluntary

Termination is a situation in which a person quits his/her job. One may undergo voluntary termination for any number of reasons, including finding a better job, dissatisfaction with one's current position, or retirement. Voluntary Termination is:- (1) an employee's decision to leave a job of his or her own accord; (2) the voluntary cancellation of personal financial contracts such as car leases or cell phone contracts; and (3) the voluntary cancellation of institutional level contracts such as credit default swaps and interest rate swaps. An employee may choose to leave a job for one or more reasons – changes in personal circumstances, dissatisfaction with working conditions, a hostile supervisor and so on. Another common reason for voluntary termination is a new and better job, typically one that offers higher remuneration or improved career prospects. This is more likely to be cited as a reason for leaving a job during periods of strong economic and job growth than during recessionary times. Voluntary cancellation of financial contracts may or may not incur penalties. In case a penalty will be incurred, the party who wishes to terminate the contract may be able to rationalize the termination decision if the net benefit from terminating the contract is substantially larger than the penalty. / Добровольное Завершение – ликвидация срочного контракта по взаимному согласию сторон.

VOLUNTARY TRUST = ДОБРОВОЛЬНЫЙ ТРАСТ – Voluntary Trust is a type of living trust that is created during the lifetime of the trustor, and is also known as an Inter Vivos Trust. In a voluntary trust, the trustor retains legal title of the gift transferred to the beneficiary, even though the beneficiary has actual title and possession. A voluntary trust is also defined as an obligation arising out of a personal confidence reposed in, and voluntarily accepted by, one individual for the benefit of another. This is in contrast to an involuntary trust, which is created by law. No consideration is made in a voluntary trust. In a voluntary trust, the recipient of the trust gives nothing in exchange for the trust but receives it as a pure gift. This distinguishes voluntary trusts from trusts for value, which are trusts made in favor of purchasers and mortgagees. Voluntary Trust is a trust in which property is transferred to a beneficiary by a grantor who keeps legal title to the property. Despite this arrangement, the beneficiary has actual title and use of the property. See also Revocable Trust. Voluntary Trust is a type of living trust that is not founded on consideration. The person setting up the trust retains legal title of the gift transferred to the beneficiary, even though the beneficiary has actual title and possession. Voluntary trust can also refer to an obligation arising out of a personal confidence reposed in a person, which is voluntarily accepted by, one for the benefit of another. Voluntary Trust:- this is the name given to trust where the trustee agrees to be the trustee for another person. / Траст, учреждённый добровольно и не связанный со смертью лица.

VOLUNTARY UNDERWRITER = ДОБРОВОЛЬНЫЙ РАСПИСЧИК (или ДОБРОВОЛЬНЫЙ АНДЕРРАЙТЕР) – Voluntary Underwriter is an individual or corporation that purchases a security from an issuer or affiliated person and offers it for public sale under an effective registration statement. / Добровольный Андеррайтер – лицо, партнёрство или корпорация, которые покупают ценные бумаги у эмитента или связанного с ним лица и затем предлагают ценные бумаги для публичной продажи при наличии действующего документа о регистрации ценных бумаг.

VOLUNTEER COTTON = ХЛОПЧАТНИК САМОСЕВ – Volunteer Cotton:- are plants that have germinated, emerged and established unintentionally. See also Volunteer Plant.

VOLUNTEER INCOME TAX ASSISTANCE = ПОДДЕРЖКА ПО НАЛОГУ НА ДОХОД ДОБРОВОЛЬЦЕВ – The Volunteer Income Tax Assistance (VITA) program offers free tax help to people who generally make USD54 000 or less, persons with disabilities and limited English speaking taxpayers who need assistance in preparing their own tax returns. IRS-certified volunteers provide free basic income tax return preparation with electronic filing to qualified individuals. In addition to VITA, the Tax Counseling for the Elderly (TCE) program offers free tax help for all taxpayers, particularly those who are 60 years of age and older, specializing in questions about pensions and retirement-related issues unique to seniors. The IRS-certified volunteers who provide tax counseling are often retired individuals associated with non-profit organizations that receive grants from the IRS. Before going to a VITA or TCE site, see Publication 3676-B for services provided and check out the What to Bring page to ensure you have all the required documents and information our volunteers will need to help you. Note:- available services can vary at each site due to the availability of volunteers certified with the tax law expertise required for your return. Some VITA sites offer CAA (short for Certified Acceptance Agent) service to taxpayers along with their VITA program. Volunteer Income Tax Assistance (VITA) is the US Internal Revenue Service (IRS) program designed to help low and moderate-income taxpayers complete their annual tax returns at no cost. Volunteer Income Tax Assistance or VITA is the US Internal Revenue Service (IRS) program that provides free tax preparation services to low-income taxpayers. VITA is a resource available to qualified low-income taxpayers through which volunteers provide tax assistance and advice. VITA sets up its services at a variety of public locations such as libraries, schools and shopping malls, and in certain other high-need areas. In addition to the tax preparation services offered, many locations offer free electronic filing services to qualifying taxpayers. With access to professional tax services, any individual can benefit from the guidance of someone versed in the complex rules for certain tax credits. Specifically the VITA program helps people who make USD54 000 or less, persons with disabilities and taxpayers who speak limited English. The IRS makes VITA available to any individual from these populations who needs assistance in preparing their tax returns. It has been instrumental in helping households receive thousands of dollars in additional refunds. Benefits of Having a Specialist Help You Prepare Your Taxes:- Many people use online tax software to file their income taxes. These programs offer convenience and often are easy to use, but when it comes to more complex tax returns, a tax professional may be able to get you more money back. Not only do tax professionals know how to get you the most money on your return, but you are less likely to face an audit when you use a tax professional. While online tax programs work well for simple tax returns, they may not be your best bet for complex returns with multiple W2s, deductions or tax breaks. If your tax return has multiple W2s or if you have several deductions, exemptions or tax breaks, you may want to have a tax professional prepare your return. Other Tax Assistant Programs:- In addition to VITA, the IRS provides certified Tax Counseling for the Elderly or TCE. TCE offers free tax help for all taxpayers, but particularly to individuals 60 years of age and older. The TCE, as opposed to the VITA program, specializes in pensions and retirement-related issues unique to seniors. The IRS funds the TCE. The IRS provides a variety of resources on its website and has teamed with a number of tax preparation services and software companies to provide free tax service for many individuals. In order to receive free service you must meet certain qualifications, such as earning less than USD57 000 per year and being between the ages of 23 and 55.

VOLUNTEER PLANT = САМОСЕВНОЕ РАСТЕНИЕ (или РАСТЕНИЕ САМОСЕВ) – Volunteer Plant:- (1) A fruit, vegetable, or crop that springs up as a result of an unintentionally included seed or a previous year's planting. Also Rogue (plants). (2) Use of volunteer pilot slaughtering plants by the Food Safety and Inspection Service to test whether new government slaughter inspection procedures, applied in conjunction with plant Hazard Analysis and Critical Control Point System controls, can improve food safety and increase consumer protection. Volunteer Plant is a plant that is growing from an unintentionally included seed, a seed that is shed or dropped by a previous crop. Also called a Rogue. / Под Самосевом понимается:- (1) естественное обсеменение почвы осыпавшимися семенами растений; и (2) молодые древесные растения, выросшие из семян; в лесоводстве используются для возобновления леса. Под Самосевом древесных пород понимаются молодые растения, выросшие из семян материнского насаждения (смотрите Подрост). В лесоводстве самосев используют при естественном возобновлении леса. Самосев может вырасти на сплошных вырубках из семян деревьев старого леса, примыкающего к вырубке, из семян специально оставляемых деревьев (семенных). Появляется группами на наиболее благоприятных для прорастания семян местах, где обеспечены лучшие

условия для его роста и сохранности (защита от солнцепёка, заморозков и конкуренции трав). В некоторых случаях развитие самосева задерживается различными вредителями (личинки Пластинчатоусых, Долгоносиков, Медведок) и болезнями (шютте и другими).

VOMITOXIN = ВОМИТОКСИН – Vomitoxin is a toxin produced by mold that grows on poor-quality grain (Wheat, Corn, or Grain by-product). Also known as Deoxynivalenol (DON). See also Fusarium, and Mycotoxin. Vomitoxin or Deoxynivalenol is a mycotoxin produced by Fusarium Graminearum. / Вомитоксин:- токсичное вещество, продуцируемое плесневым Грибом (Fusarium Graminearum). Вомитоксин или Дезоксиниваленол (Deoxynivalenol) означает микотоксин (mycotoxin), произведённый Грибом Фусариум Граминэарум (Fusarium Graminearum).

VOMMA = BOMMA – The Vomma is the rate at which the Vega of an option will react to volatility in the underlying market. It is the second order derivative of the option value with respect to volatility. It demonstrates the convexity of Vega. A positive value for Vomma indicates that a percentage point increase in volatility will result in an increased option value. This is known as Positive Vega Convexity. For options that are sensitive to changes in the underlying market, Vomma is considered especially important. Vomma is one of the Greeks of option pricing. All the Greeks:- Delta, Gamma, Vega, Theta, and Vomma. With positive Vomma, a position will become long Vega as implied volatility increases and short Vega as it decreases, which can be scalped in a way analogous to long Gamma. And an initially Vega-neutral, long-Vomma position can be constructed from ratios of options at different strikes. Vomma is positive for options away from the money, and initially increases with distance from the money (but drops off as Vega drops off).

VOTE = ГОЛОС – Vote:- in politics and government, a formal expression of opinion or will that indicates approval or disapproval of a proposal, motion, or candidate for office. See also Election.

VOTING CERTIFICATE = ГОЛОСУЮЩИЙ СЕРТИФИКАТ (или СВИДЕТЕЛЬСТВО ДЛЯ ГОЛОСОВАНИЯ) – Voting Certificate:- certificates issued by a voting trust to stockholders in exchange for their common stock, which represent all the rights of common stock except voting rights.

VOTING INSTRUCTION CARD = КАРТА С ИНСТРУКЦИЕЙ ПО ГОЛОСОВАНИЮ – Voting Instruction Cards:- a notice in card form containing the voting issues to be discussed at a shareholder's meeting. The cards are prepared by the depositary in conjunction with the Company and sent to Depositary Receipt holders upon receipt of notice from the Company that it is conducting a meeting where issues to be voted on will be discussed. The notice is sent only if the Company's are voting shares and if the US Exchange, the Deposit Agreement or the Company requires that votes be solicited. Voting Instruction Card is the voting card sent to participants in an employee plan giving the trustee of the plan the authority to vote the shares as indicated on a proxy card.

VOTING POWER = ПОЛНОМОЧИЕ ГОЛОСОВАНИЯ – Voting Power is concerned with a collective body (assembly) whose members decide by yes/no vote whether to adopt a proposed resolution. The decision rule (also known as Voting Game) under which the assembly operates specifies whether any particular proposed resolution can at all be put to a vote and, if put to a vote, what kind of support it must have among the assembly's members in order to pass. An assembly can use various decision rules for voting on various kinds of proposed resolution. We first distinguish between a priori (or de jure) and a posteriori (or de facto) voting power. The a priori voting power of a voter within the assembly (who can be a single individual or a bloc of individuals acting as a single person), is the extent that this voter can control the outcome of the voting merely through the resources made available to this voter by the decision rule. In contrast, assessment of a voter's a posteriori voting power ought to take into account additional relevant resources that may be available to this voter, such as rhetorical persuasiveness, bargaining ability, prior bias regarding the issues voted upon, and affinity or disaffinity between him/her and other voters. In order to measure a voter's past de facto voting power during a certain period of time, one would need data on how all voters have voted and the final outcome of all divisions that occurred during that period. Such data are often available. However, current and future de facto voting power requires mathematical modelling of voter's preferences, affinities etc – a task that poses difficult and controversial theoretical and empirical problems. Most of the research to date on voting power has concentrated on a priori voting power. This type of voting power can be divided into two sub-types dubbed by Felsenthal

and Machover (op. cit.) I-power and P-power. A priori I-power is the degree to which a given voter is able to influence the outcome of the vote, i.e. whether the proposed resolution will pass or fail. A voter's I-power, as first defined by Lionel Penrose in 1946, is measured by the probability that s/he will be decisive given the decision rule, and assuming that all voters vote independently of one another, and that every voter supports or opposes a proposed resolution with equal chance. The relative I-power of a given voter, known as the voter's Banzhaf index is equal to the absolute I-power of that voter divided by the sum of absolute I-powers of all voters. Several alternative I-power indices have been proposed in the literature, but they all suffer from various theoretical deficiencies. The second sub-type of a priori voting power, that of P-power, views the ultimate outcome of the voting process as the distribution of a fixed purse – the prize of power – among the victors, eg the distribution of cabinet portfolios among the members of a governmental winning coalition. From this viewpoint, a voter's (relative) voting power, the extent of his or her control of the ultimate outcome, is usually defined as that voter's expected or estimated share in the fixed purse. Since so far no completely satisfactory solution has been found to the n-person bargaining problem, there exists no undisputed measure for P-power. The measure commonly used in the literature to assess a voter's P-power is the Shapley-Shubik Index. Voting Power means the total number of votes entitled to be cast on the issue at the time the determination of voting power is made, excluding a vote which is contingent upon the happening of a condition or event which has not occurred at the time. Where a class is entitled to vote as a class for directors, the determination of voting power of the class shall be based on the percentage of the number of directors the class is entitled to elect out of the total number of authorized directors. / Фэлзэнсол (Felsenthal) и Мэковё (Machover). Лайэнэл Пэнроуз (Lionel Penrose). Банцаф (Banzhaf). Индекс от Шяпли-Шубика (Shapley-Shubik Index). Право Голоса.

VOTING RIGHT = ПРАВО НА ГОЛОСОВАНИЕ (или ПРАВО ГОЛОСА) – Voting Right is a right of a shareholder to vote at a company's annual general meeting (AGM). This right depends on which type of shares are held; generally, ordinary shares carry voting rights whereas debentures do not. The articles of association and the company's prospectus detail which shares carry voting rights and which do not. Voting Right is the common stockholders' right to vote their stock in the affairs of a company. Preferred stock usually has the right to vote when preferred dividends are in default for a specified period. The right to vote may be delegated by the stockholder to another person. See also Cumulative Voting, Nonvoting Stock, and Proxy. Each holder of an ordinary share is entitled to voting rights exercised at the stock company's General Meeting. Voting rights are exercised according to the nominal amount of shares. Normally, each ordinary share grants the shareholder one vote. Voting rights can also be exercised by an authorized person:- proxy voting right. Voting Right is the right to vote on matters that are put to a vote of security holders. For example, the right to vote for directors. / Право Голоса:- предоставляемое держателям большинства обыкновенных акций право голосовать – лично или через своего представителя, по доверенности (proxy) – на собраниях акционеров корпорации и при выборе её директората. Смотрите также (Nonvoting Stock).

VOTING RIGHT SHARE = АКЦИЯ С ПРАВОМ НА ГОЛОСОВАНИЕ (или АКЦИЯ С ПРАВОМ ГОЛОСА) – Voting Right Share is a share which carries a greater voting right in relation to the other shares of the same company despite having the same par value. Alternatively, it may carry identical voting rights despite having a lower par value. Such shares confer preferential rights upon the shareholder in regard to voting rights (qualified voting rights).

VOTING RIGHT STOCK = АКЦИЯ С ПРАВОМ НА ГОЛОСОВАНИЕ (или АКЦИЯ С ПРАВОМ ГОЛОСА) – Voting Right (Stock) is Stock in a publicly-traded company that gives the holder the right to vote at the company's annual meeting. Votes are usually allocated on the basis of one vote per share. The right to vote gives the holder of voting stock a great deal of control over the company; in exchange, voting stock usually has few or no other rights associated with it. For example, most preferred stock is nonvoting, but preferred stock has a guaranteed dividend while most voting stock does not. Voting Right Stock:- the shares in a corporation that entitle the shareholder to vote. Voting Right Stock is a stock for which the holder has the right to vote in the election of directors, in the appointment of auditors, or in other matters brought up at the annual meeting. Most common stock is voting stock. / Акция С Правом Голоса:- право акционера голосовать своей акцией по вопросам дел в компании. Большинство обыкновенных акций имеют право одного голоса на акцию. Привилегированные акции обычно предоставляют право голоса в тех случаях, когда просрочены платежи по дивидендам по привилегированным акиям. Право голоса обычно делегируется по доверенности владельцем акции другому лицу.

VOTING SHARES = ГОЛОСУЮЩИЕ АКЦИИ – Voting Shares are shares that give the stockholder the right to vote on matters of corporate policy making as well as who will compose the members of the board of directors. Different classes of shares, such as preferred stock, sometimes don't allow for voting rights. Voting Shares are the ordinary shares that allow the shareholders to cast a vote for each share held at a company's annual general meeting. Voting Shares are shares of stock that allow the owner to vote on company matters. Stocks, also known as Equities, represent ownership interests in corporations. If you own one, 100, or 100 million shares of stock in a company, you're an owner of the company. Corporations sell stock, or ownership in the company, in return for cash to run their businesses. There are a number of different kinds of stocks, and their classifications largely depend on the rights they confer on the holder. Investors evaluate these categories based on their investment objectives, and they look for stocks that meet those objectives. The two most popular categories of stock are common stock and preferred stock. The most prominent characteristics of common stock are that they entitle the shareholder to vote on corporate matters (typically, the shareholder gets one vote for every share he or she owns, though that is not always the case) such as whether the company should acquire another company, who the board members should be, and other big decisions. Common stock also often comes with pre-emptive rights, which means the shareholder has a 'right of first refusal', or first dibs on buying any new stock the company tries to issue. Perhaps the most important attribute of common stock is that their holders are the last in line when it comes to getting their money back. If the company goes bankrupt and has to sell off all its assets, the cash from the asset sale first goes to pay off lenders, employees, and lawyers. The shareholders get whatever is left (which is usually nothing, or just a few pennies for every Dollar they originally invested). This pecking order is why preferred stock, the other popular category of stock, exists. Although preferred shares aren't usually voting shares, they usually receive a steady dividend and their claim to the company's assets 'outrank' the common stockholders' claims (i.e. in the event of bankruptcy, the company must pay off lenders, preferred shareholders, employees, and lawyers before the common shareholders get anything). Voting shares carry a lot of power, and they represent the inherent communal nature of the ownership of corporations. Plenty of companies also issue nonvoting shares so that the voting shares can be retained by the founding family, for example, or the original investors, and these actions only emphasize the power inherent in voting shares. Without shareholders voting in approval, corporations often can't do things such as re-elect directors or merge with another company, for example. Accordingly, investors must consider the voting rights attached to any investment and decide whether those rights are important. / Голосующие Акции:- акции компании, которые дают своим владельцам право голосовать на общих ежегодных собраниях акционеров и на всех чрезвычайных собраниях членов компании. Акции, обладающие правом голоса, являются, как правило, обыкновенными акциями (ordinary shares) в отличие от акций типа А (A shares) или долговых обязательств (debentures). Какие из акций обладают правом голоса, определено уставом компании. Голосующая Акция:- акции корпорации, которые дают право акционеру участвовать в голосовании, а также представительствовать (proxy). Когда акционер депонирует эти акции у

доверенного лица или опекуна (custodian), который действует в качестве доверенного лица (trust) при голосовании, то он сохраняет права на доходы и дивиденды, но передаёт права на участие в голосовании. Смотрите также (Common Stock; (Proportional Representation); и (Voting Trust Certificate).

VOTING STOCK = ГОЛОСУЮЩАЯ АКЦИЯ – Voting Stock:- the shares in a corporation that entitle the shareholder to vote. Voting Stocks are equity/shares that give voting rights to the holder. These can either be 'listed voting stocks' (that is, equity/shares that are listed on an official stock exchange), or 'unlisted voting stock' (that is, equity/shares that are not listed on a official stock exchange. See also Non-Voting Stocks. / Голосующая Акция – акция, дающая акционеру право голосовать на собрании акционеров лично или через доверенное лицо.

VOTING TRUST = ГОЛОСУЮЩИЙ ТРАСТ (или XX) – Voting Trust is a legal trust created to combine the voting power of shareholders. With the establishment of the voting trust, the shareholders' legal title (their stock) and voting rights are transferred to a designated trustee for a set duration. There are many reasons stockholders may wish to form these trusts. For example, they may create one in the hopes of maintaining control within a corporation through a unified vote. Or they may want to use it as a form of protection from corporate creditors. The laws of different states usually have limitations on the duration of a trust, as it is a legally binding agreement. Voting Trust is a voting agreement under which shareholders transfer their voting shares to a trustee in exchange for voting-trust certificates. The trustee votes the trust shares as a block in accordance with the terms of the agreement. Voting Trust is a type of agreement by which two or more individuals who own corporate stock that carries voting rights transfer their shares to another party for voting purposes, so as to control corporate affairs. A voting trust is created by an agreement between a group of stockholders and the trustee to whom they transfer their voting rights or by a group of identical agreements between individual shareholders and a common trustee. Such agreements ordinarily provide that control of stock is given to the trustee for a term of years, for a time period contingent upon a certain event, or until the termination of the agreement. Voting trust agreements may provide that the stockholders can direct how the stock is to be voted. Voting Trust is a trust formed when individual shareholders transfer both the legal title and voting rights in their shares to a trustee. The trustee then controls a unified voting block – with a stronger voice on matters of corporate governance than the individual shareholders could have on their own. Voting trusts are created to last for a specified period of time, and represent one way to defend against hostile takeovers. / Голосующий Траст – договор, согласно которому владельцы акций предоставляют право голоса небольшой группе лиц, которые именуются доверенными лицами, получающими право голосования в голосующем трасте.

VOTING TRUST CERTIFICATE = СЕРТИФИКАТ ГОЛОСУЮЩЕГО ТРАСТА (или СВИДЕТЕЛЬСТВО XX) – Voting Trust Certficate is a certificate issued by the limited-life trust of a corporation established to limit the control of a corporation to a few individuals. A voting trust certificate is issued to a stockholder in exchange for their common stock, and represents all of the normal rights of a shareholder except the right to vote. The life of a voting trust certificate is usually limited to five years, at which point the common stock, with voting rights, is returned to the shareholder. A voting trust certificate allows a few individuals, known as Voting Trustees, to gain control and make decisions regarding the corporation without interference. The purpose is typically to allow reorganization when a corporation is in financial turmoil. Voting Trust Certificate is a trust in which control of a corporation is given to a few individuals, usually to support reorganization of a corporation without interference. Voting-Trust Certificate refers to a certificate issued by a voting trustee to the beneficial holders of shares that is held by the voting trust. The most important feature of a voting-trust certificate is that it is readily transferable. When transferred, it carries with it all incidents of ownership, except the power to vote. The holders of voting-trust certificates, generally are spoken of as equitable owners whose rights, are protected in equity in accordance with the principles applicable to trusts. / Сертификат Участия В Голосующем Трасте:- подлежащий передаче сертификат на долевое участие в предприятии, управляемом путём голосующего траста (voting trust) по доверенности с ограниченным сроком действия. Доверенность предназначена для сосредоточения управления корпорацией в руках нескольких частных лиц. Эти лица называются Голосующими Доверенными Лицами (Voting Trustees). Сертификаты, которые обычно выдаются акционерам в обмен на их обыкновенные акции, предоставляют все права, закреплённые за обыкновенными акциями, за исключением права участвовать в голосовании. Обыкновенные акции затем регистрируются в учётных документах корпорации на имя доверенных лиц. Обычно целью подобной передачи прав является облегчение реорганизации (reorganization) корпорации, испытывающей финансовые затруднения, путём предотвращения вмешательства в управление корпорацией. Срок действия сертификатов о передаче права на голосование ограничивается пятью годами действия траста (trust), но может быть продлён по взаимному соглашению акционеров и доверенных лиц. Сертификат Голосующего Траста – свидетельство, выдавамое при образовании Голосующего Траста; расписки за обыкновенные акции, помещённые у доверенного лица по голосующему трасту. Она сохраняет за акционеромвсе предоставленные права, за исключением права голоса.

VOUCHER = ВАУЧЕР (или РАСПИСКА) – (1) A Voucher is an internal document describing and authorizing the payment of a liability to a supplier. It is most commonly used in a manual payment system. A voucher typically contains the following information:- (i) the identification number of the vendor; (ii) the amount to be paid; (iii) the date on which payment should be made; (iv) the accounts to be charged to record the liability; (v) any applicable early payment discount terms; and (vi) an approval signature or stamp. Voucher information may be assembled into a packet, where the basic voucher document is attached to the supplier invoice, evidence of receipt, and purchase order. This packet is useful for keeping related documents in one place, and makes it easier to both justify and audit payables transactions. A voucher is created following the receipt of an invoice from a supplier. It is stamped 'paid' when a check or electronic payment is made to a supplier, and is then archived, along with any supporting documents. Vouchers are useful for maintaining a higher level of control over the payables process. If vouchers are used for all payables, their totals can be aggregated to determine the total amount of accounts payable outstanding. This function is not needed in a computerized system, where the aged payables report is used instead. A voucher is not created when a liability has only been accrued (which is in the absence of a supplier invoice). Also, vouchers are not used in the payroll process. Voucher is:- (a) a piece of substantiating evidence; a proof; or, (b) a written record of expenditure, disbursement, or completed transaction; or, (c) a written authorization or certificate, especially one exchangeable for cash or representing a credit against future expenditures. A Voucher is a bond which is worth a certain monetary value and which may be spent only for specific reasons or on specific goods. Examples include (but are not limited to) housing, travel, and food vouchers. The term Voucher is also a synonym for Receipt and is often used to refer to receipts used as evidence of, for example, the declaration that a service has been performed or that an expenditure has been made. The term is also commonly used for education vouchers, which are somewhat different. Voucher:- entitles you to cash, and/or to goods and services. Often provided to you free by your employer, in which case they are taxable. Voucher:- (1) a piece of substantiating evidence. For example, a written record of expenditure, disbursement, or completed transaction. (2) In the State's (Florida) Project Aspire, a Voucher is what was formerly known by the State as an Invoice. / Ваучер (в бухгалтерском учёте):- письменное разрешение на осуществление расходов и основание для учётных записей в системе ваучеров. Ваучер – расписка за деньги или любой другой документ, который проводится в бухгалтерских счетах. Ваучер:- (1) приватизационный чек, документ, дающий право на участие в

приватизации посредством его обмена на акции приватизируемого предприятия; или (2) письменное свидетельство, поручение, гарантия.

(2) In governmental accounting, documents used by government entities to substantiate their expenses. In accounting, a Voucher is a document, such as a receipt, that supports or proves entries in books of prime entry. A Voucher is an accounting document representing an internal intent to make a payment to an external entity, such as a vendor or service provider. A voucher is produced usually after receiving a vendor invoice, after the invoice is successfully matched to a purchase order. A voucher will contain detailed information regarding the payee, the monetary amount of the payment, a description of the transaction, and more. In accounts payable systems, a process called a 'Payment Run' is executed to generate payments corresponding to the unpaid vouchers. These payments can then be released or held at the discretion of an accounts payable supervisor or the company controller. The term can also be used with reference to accounts receivable, where it is also a document representing intent to make an adjustment to an account, and for the general ledger where there is need to adjust accounts within that ledger; in that case it is referred to as a Journal Voucher. Any documentary evidence supporting the entries recorded in the books of accounts, establishing the arithmetic accuracy of the transaction, may also be referred to as a Voucher – for example, a bill, invoice, receipt, salary and wages sheet, memorandum of association, counterfoil of paying-in slip, counterfoil of cheque book, trust deed. Voucher is a receipt, entry or other document which establish the accounts.

(3) In tourism, Vouchers are used in the tourism sector primarily as proof of a named customer's right to take a service at a specific time and place. Service providers collect them to return to the tour operator or travel agent that has sent that customer, to prove they have given the service. So, the life of a voucher is as below:- (i) customer receives vouchers from tour operator or travel agent for the services bought; (ii) customer ation site and forwards the voucher to related provider and asks for the service to be give; (iii) provider sends collected vouchers to the agent or operator that sends customers from time to time, and asks for payment for those services; and (iv) uncollected vouchers do not deserve payment. This approach is most suitable for free individual tourist activities where pre-allocation for services are not necessary, feasible or applicable. It was customary before the information era when communication was limited and expensive, but now has been given quite a different role by B2C (short for the business-to-consumer) applications. When a reservation is made through the internet, customers are often provided a voucher through email or a web site that can be printed. Providers customarily require this voucher be presented prior to providing the service. / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо).

(4) Mobile phones:- a Voucher is a recharge number sold to a customer to recharge their SIM card with money and to extend the card's availability period. Vouchers are typically sold at retail outlets, such as phone stores run by the mobile operator or by distributors, grocery stores, and gas stations. Vouchers are the prevalent form of recharge for prepaid mobile phones in many countries such as Italy and Spain where well over 90% of consumers use vouchers, and the UK where over 60% buy vouchers at retail. In other countries such as the United States, Ireland, and many Nordic countries, there is a growing trend of customers using Card Not Present recharge options such as online payments, or by using their mobile handsets to call the operator and recharge with a representative (CSR) or through their IVR (Interactive Voice Response) system. A growing number of prepaid mobile operators such as Meteor in Ireland and T-Mobile USA are offering the option to send an SMS (text to pay), or use handset applications such as WAP or BREW technology in the northern times.

(5) Internet:- a Voucher can also be used online in the form of an e-voucher. These types of vouchers can be entered when shopping online and the relevant vouchers value added to your order. It can take the form of any code. Many companies have opted to use voucher codes for the last few years but with a massive incline in use towards the end of 2008/early 2009. There are many internet websites devoted to promoting these deals and vouchers online, as well as Facebook groups offering items such as student discounts and 2-for-1 restaurant voucher deals. There are a small number of sites that use a disreputable method of click to reveal method for dropping cookies on the consumer's computer, which has led to the introduction of guidelines for voucher use in Internet Marketing. Most video game special editions come with a voucher for exclusive content in-game. For example, the Gran Turismo 5 Collector's Edition comes with a voucher for 5 exclusive DLC 'Chrome Line' cars for the full game. Also, pre-ordering games at certain shops may get you vouchers to content only available if you pre-order at that store.

VOUCHER CHECK = ВАУЧЕРНЫЙ ЧЕК – Voucher Check:- a two-part combination of a check and voucher. Also known as a Remittance Advice, the voucher details the reason for the payment by the issuer of the check. The recipient of the voucher check detaches the voucher and retains it for record-keeping before cashing the check. Voucher checks that are used in computerized accounting systems have three parts that together fit on standard A4-sized sheets of paper for ease of use in printers. In addition to a check and voucher, a three-part voucher check has a check stub that is retained by the issuer. Perforations make the different sections easy to separate. Voucher Check is a check carrying a notation of the invoices or items covered either on its face or on a detachable stub. Voucher Check is a check with a perforated or other attachment indicating the reason for and the amount of the check. The voucher allows one to keep records of one's checks after they are deposited. This is important for balancing one's checkbook. Voucher Check is a check to which is attached a form (voucher) describing the purpose of the check, and/or explaining various items on which the check is based. The voucher is detached before the check is cashed. Voucher Check is a specific type of check which includes a segment (known as the Voucher) which details the reason or purpose for the check. The voucher would include explanations of the payment, such as 'Payment for advertisement running April 01–April 30' or 'USD300 for agreed upon fee, USD50 for late payment'. The person or organization who receives the check detaches the voucher before cashing or depositing the check, and will often keep the voucher for their records. / Чек-расписка.

VOUCHERLESS CHEQUE COLLECTION = ИНКАССИРОВАНИЕ БЕЗВАУЧЕРНЫХ ЧЕКОВ (или БЕЗВАУЧЕРНОЕ ИНКАССИРОВАНИЕ ЧЕКОВ) – Voucherless Cheque Collection (VCC):- in the VCC procedure, the cheques in question are no longer presented for payment in voucher form to the bank specified on the cheque. The cheques concerned here are bearer cheques or order cheques issued in EUR up to a value of €5 999.99 and drawn on a domestic bank. The cheque data are captured on electronic media (DME; short for the data medium exchange) by the bank transferring the cheques using the VCC procedure.

VOUCHERLESS DATA MEDIUM EXCHANGE = БЕЗВАУЧЕРНЫЙ ПРОМЕЖУТОЧНЫЙ ОБМЕН ДАННЫМИ – Voucherless Data Medium Exchange (DME):- for the settlement of cashless payments using the voucherless DME procedure, DME files instead of vouchers (bank transfers, debit transfers, cheques), are exchanged between banks or between banks and their customers on magnetic tapes, diskettes, cassettes or by remote data transfer (RDT). The payment data are not made available to the payee or the payer in voucher form but are notified to him directly on his account statement.

VOUCHER SPECIMENS = ВАУЧЕРНЫЕ ЭКЗЕМПЛЯРЫ (или ВАУЧЕРНЫЕ ОСОБИ) – Voucher Specimens are a series of individuals from a specific population deposited in a professionally curated collection. A Voucher Specimen is any specimen, usually but not always a cadaver, that serves as a basis of study and is retained as a reference. Specimen means the whole animal or a part thereof. A voucher should be in an accessible collection; however, even if it is not, it remains a voucher. Type specimen is a particular

voucher specimen which serves as a basis for taxonomic description of that subspecies. Collection of voucher specimens is a legitimate and important part of scientific research. However, it is a practice of concern to some sections of the community. Voucher Specimen is any specimen that serves as a basis of study and is retained as a reference. It should be in a publicly accessible scientific reference collection. A type specimen is a particular voucher specimen which serves as a basis for the taxonomic description of a species. Specimens that permanently document data in an archival report are called Voucher Specimens. Such specimens and corresponding data assembled during field studies of mammals, particularly the small and medium-size species that are difficult to identify and often poorly known, are critical for accurate identification of the animals studied and for verification of the data gathered and reported as resulting from the investigation. In addition, voucher specimens are critical for a wide array of future studies. Voucher specimens with extensive associated materials, such as tissue samples, chromosomes, and parasites, are particularly valuable. Such complete vouchers allow many different research projects to be linked in a network through the primary voucher. Primary specimen identification is important not only for research documentation, but also for assessment of change caused by natural or human perturbation. Voucher specimens will, therefore, play an increasingly important role in research on biological diversity. We highly recommend that vouchers with high-quality ancillary data be preserved. Vouchers physically and permanently document data by (1) providing for confirmation of the identities of mammals accumulated and used in a study and (2) assuring that the study can be repeated, reviewed, and reassessed accurately. Vouchers are the only reliable means of corroborating provenance of data accumulated during a study and documented in any reports of that study. The accurate identification of mammals is essential for providing credibility to the studies of these animals and to the publications that result from such investigations. It is convenient to view mammalian voucher specimens in three groups:- (i) type specimens, upon which names of taxonomic units are based; (ii) taxonomic support specimens, which document identifications in taxon-based studies other than nomenciarural studies; and (iii) biological documentation specimens, which document identifications of individuals obtained for genetic studies or environmental impact projects. Through time, a voucher specimen collected in a biodiversity study may serve all three functions. Photographs may suffice to document observations of especially large mammals or of protected species. Handling of these valuable materials should follow procedures similar to those described for actual specimens. Standardized requirements exist for the data that should be affixed to each voucher specimen. In addition, a considerable array of ancillary materials and data may be obtained and recorded for each voucher specimen. Recording and handling of data associated with voucher specimens of mammals must be taken as seriously as the handling of the specimen itself, because voucher specimens without accurate data are either suspect or worthless. / Контрольные Образцы (Voucher Specimens):- коллекция растений, беспозвоночных и небольших позвоночных животных, помогающая определять собранные виды.

VOUCHER SYSTEM = ВАУЧЕРНАЯ СИСТЕМА (или СИСТЕМА ВАУЧЕРОВ) – A Voucher System is a method for authorizing the disbursement of cash. A voucher is filled out that identifies what is to be paid for, the amount to be paid, and the account number to be charged. Once this voucher is approved, the disbursement system is authorized to issue payment. Thus, a voucher system is a control used to ensure that cash is only spent on authorized purchases. / Система Ваучеров (в бухгалтерском учёте):- система учёта и контроля, обеспечивающая документальное подтверждение и письменное разрешение той или иной хозяйственной операции. Обычно используется по операциям с мелкими наличными расходами (petty cash).

VOUCHING = ПОРУЧИТЕЛЬСТВО (или РУЧАТЕЛЬСТВО, или ЗАВЕРЕНИЕ) – Vouching is the act of reviewing documentary evidence to see if it properly supports entries made in the accounting records. For example, an auditor is engaged in vouching when examining a shipping document to see if it supports the amount of a sale recorded in the sales journal. Vouching can work in two directions. For example, an auditor can trace actual inventory items back to the accounting records to see if the items are properly documented, or start with the inventory records and trace back to the warehouse shelves to see if the inventory exists. When engaged in vouching, an auditor is looking for any errors in the amount recorded in the accounting records, as well as ensuring that the transactions are recorded in the correct accounts. The auditor is also verifying that transactions have been properly authorized. When vouching uncovers an error, the auditor may need to increase the sample size being audited in order to gain assurance that a system operates properly. An alternative is to engage in different auditing procedures.

VOW = ОБЕТ (или КЛЯТВА) – Vow is a sacred voluntary promise to dedicate oneself or members of one's family or community to a special obligation that goes beyond usual social or religious requirements. In the ancient Middle East, individuals often made vows to a deity to perform certain acts or to live in a certain way in return for a divine favor. Hannah, the mother of the Old Testament judge Samuel, for example, vowed that if Yahweh, the God of Israel, would grant her a son she would devote him to the service of the Lord. She did bear a son, and she kept her vow. Persons dedicated to the service of Yahweh might be released from their vows, however, by paying a certain amount of money. Ancient Roman religion encouraged vows to a deity in the name of the state, thereby putting the vow-giver in debt to the gods until the vows were fulfilled. During wars, vows were made to Mars, the god of war, to sacrifice a large number of animals in exchange for support in battle. Among the Vikings, vows to the gods, often considered a type of prayer, were viewed as sacrosanct, and those who broke vows were cast out of their community. Vows are very common in Hinduism, Buddhism, and Jainism, not only among ordained religious persons but also among lay devotees. Hindu followers of the bhakti (devotion) movements often vow to render special service to their gods; individual Hindus also often vow special fastings or offerings to priests and gods on special days. Buddhist monks, who follow the rules of the sangha (community of believers), vow to practice 10 precepts, which include nonviolence, chastity, and honesty. Buddhist laymen and laywomen also take on some of the vows of monks and nuns at some time or times during their lives. Mahāyāna (Greater Vehicle) Buddhists sometimes adopt the vow of the bodhisattva (one destined to be enlightened), which is very strict and involves certain stipulated preliminary actions or abilities, as well as the personal power to generate the thought of enlightenment. Jaina monks follow the five vows, or vratas of Mahāvīra, the VI-century BC reformer of their religion – renunciation of killing, lying, taking what is not given, sexual pleasures, and all attachments. Among the followers of Judaism, Christianity, and Islām, vows are taken by laypersons as well as by members of religious orders. In Judaism, vows (Hebrew nedarim) may be positive or negative. A positive neder is a voluntary pledge to consecrate something to God or to do something in God's honor that is not required by law. A negative neder (Hebrew issar) is a voluntary pledge to abstain from or deprive oneself of a legitimate pleasure. In general, however, the taking of a vow in Judaism was not encouraged by the Talmudic rabbis, unless it was to be used as a last resort. Roman Catholic religious orders in general take three vows – poverty, chastity, and obedience – and in some cases an added vow of stability, i.e. to remain in a monastery. In Protestantism, vows are made during certain rites (e.g., confirmation, ordination, and marriage ceremonies). Muslim saints revered for their curative or spiritual powers are sometimes appealed to by the faithful, who offer vows of various sorts in return for specific help. / Ханна (Hannah), Самуил (или Шамуэль (Samuel)), Явэ (Yahweh).

VOYAGE = РЕЙС (или ВОЯЖ) – Voyage is a journey by sea from one port another or, in case of a round trip, to the same port. Synonym:- Trip. The trip designation (trade route and origin/destination) identifier, usually numerically sequential. / Под Рейсом, от Немецкого слова Reise, означающее Путешествие, понимается маршрут автобуса, автомашины, корабля, самолёта и тому подобного в один конец. Под Вояжем, от Французского слова Voyage, скрывается устаревший или иронический термин для обозначения поездки или путешествия.

VOYAGE CHARTER = ЧАРТЕР НА РЕЙС (или РЕЙСОВЫЙ ЧАРТЕР) – Voyage Charter is a contract under which the shipowner agrees to carry an agreed quantity of cargo from a specified port or ports to another port or ports for a remuneration called Freight, which is calculated according to the quantity of cargo loaded, or sometimes at a lumpsum freight. A contract whereby the shipowner places the vessel at the disposal of the charterer for one or more voyages, the shipowner being responsible for the operation of the vessel. Voyage Charter:- the shipowner hires out his vessel, subject to various conditions, for the carriage of cargo for a single voyage. / Рейсовый Чартер – чартер судна или грузового пространства на судне на фиксированное число рейсов в отличие от чартера на фиксированный период (как чартер на срок (time charter)). Владелец судна обычно гарантирует, что судно прибудет в указанный порт к указанной дате, будет способно к плаванию и должным образом снаряжено. Фрахтователь же обязуется загрузить и разгрузить судно в течение согласованного числа дней стоянки (lay days). Рейсовый Чартер:- судовой чартер на перевозку груза одним рейсом между обусловленными портами или регионами. Плата, обычно из расчёта за тонну веса или объём (вместимость) судна, включает эксплуатационные (рейсовые) расходы.

VOYAGE COSTS = РЕЙСОВЫЕ РАСХОДЫ – Voyage Costs are the costs directly related to a specific voyage, e.g., bunker, port and canal charges. Voyage Costs:- bunkers and port charges. / Рейсовые Расходы:- топливо, портовые и канальные сборы.

VOYAGE NUMBER = НОМЕР РЕЙСА – Voyage Number is the reference number assigned by the carrier or his agent to the voyage of the vessel.

VOYAGE POLICY = РЕЙСОВЫЙ ПОЛИС – Voyage Policy is a financial protection plan that provides coverage for goods in transit by sea. In order for a voyage policy to be valid, the vessel transporting the cargo must be in good condition and capable of making the journey, and the vessel's crew must be competent. This requirement exists because a voyage policy, like any insurance policy, is intended to protect against unforeseen risks, not against preventable risks. Voyage policies are important in the export business. A voyage policy may also be called Marine Cargo Insurance. In addition to the seaworthiness exclusion described above, a voyage policy will also exclude losses caused by willful misconduct, ordinary leakage, ordinary wear and tear, improper or inadequate packaging, labor strikes and acts of war. Also, the policyholder may need to purchase additional insurance to cover the cargo during the entire transport process. Voyage policy may not cover a loss that occurs while the goods are being loaded onto the ship, for example. Voyage Policy is the marine insurance policy that (unlike a time policy) provides cover for one trip, and usually protects only the cargo and not the ship (vessel). / Рейсовый Полис:- морской страховой полис, выданный только под конкретный рейс.

VRENELI = ФРЭНЭЛИ – The Swiss 20 Francs Vreneli gold coin is one of the world's classic gold coins and quite popular among investors. Switzerland, neutral since its creation by the Congress of Vienna in 1815, has long been synonymous with stability and fiscal strength due to its practice of backing its currency with large quantities of gold. The obverse of this Swiss 20 Franc, considered by some as the loveliest of all Swiss coin designs, features a bust of a Vreneli, the charming 'Swiss Miss' of Swiss lore. With braided hair, she wears a garland of flowers and appears against the background of the Swiss Alps. Above her head appears the word 'HELVETIA', which is why this coin is also referred to as a Helvetia. The reverse of the coin features a Swiss shield over a background of an oak branch tied with ribbons. The denomination (20 FR) and the date also appear on this side. All Vreneli Swiss 20 Francs were minted in the country's lone mint facility located in Bern and are composed of 90% gold. In 1879, 29 known pieces were struck with bright Valaisan gold from Gondo. These coins are distinguished with a small cross punched in the center of the Swiss cross on the reverse. Helvetia is now known as a Western Region in Switzerland, but it once referred to the entire area and its people. Julius Caesar conquered the Helvetii for the Roman Empire in 58 BC. The name stayed with the people and the region up through the beginning of the XIX century. In fact, the country was named the Helvetian Republic in 1798 during Napoleon's rule over the region. Once Napoleon was defeated, the Congress of Vienna recognized Switzerland's sovereign nature. From this point on, Switzerland has remained neutral during foreign wars. Vreneli is the Swiss gold coin with a face value of 20 Francs issued as legal tender in the period 1897–1935. It had a fineness of 900 and a fine gold content of 0.186 7 Troy ounces. The Swiss Goldvreneli derives its name from Verena, a personification of the Confederation of Switzerland. It is one of the world's most popular gold coins and became the successor of the Swiss Helvetia, which was manufactured between 1883 and 1896. The Bern-based Swiss Mint started producing the Goldvreneli with a nominal value of 20 Francs in early 1897 yet the first few coins were thought to have been released to the public in 1896. The total production of the Swiss gold coin reached about 58,634 million pieces and is one of the most desired and popular gold coins among global collectors. A smaller version of the Goldvreneli was minted between 1911 and 1922, which had a face value of 10 Swiss Francs. A total amount of about 2.65 million 10 Franc gold coins were manufactured. In 1925 the Swiss Mint issued a new edition of the Swiss Goldvreneli with a nominal value of 100 Francs. However, only 5 000 pieces of this edition were issued, of which the Swiss National Bank melted down 1 200 pieces at a later date. As a result, only 3 800 of the 100-Franc coins exist today; unsurprisingly they are highly popular among global collectors. The Swiss Goldvreneli's production was in line with the statutes of the Latin Currency Union, a system adopted to create a monetary community between France, Belgium, Italy, Greece, and Switzerland from 1865 to 1914. In 1897 a special edition of the Swiss Goldvreneli was issued, which only comprised 29 pieces. These coins were minted from lighter Gondo gold, which was mined in Switzerland's federal state Wallis. Besides copper, Gondo gold is also alloyed with silver providing the coin with its lighter color. The 10, 20, and 100 Franc coin versions were all mined in a millesimal fineness of 90 per cent (.900) and are

alloyed with a share (10 per cent) of copper. The Swiss Goldvreneli's three different coin versions all show an image of Vreneli, the delightful 'Swiss Miss'. Around Vreneli's neck is a garland of flowers. The woman's dress is embroidered with Edelweiss. In the background a picture of the Swiss Alps is depicted. Above her head the Swiss word HELVETIA is inscribed in capital letters. A competition in 1895 aimed to creatively rework the obverse side of the predecessor coin Helvetia, the Neuenburg artist Fritz Ulysse Landry was finally entrusted with the task by the Swiss Federal Council. The 20 Franc coin's reverse side contains the Swiss shield encircled by oak branches. These Oak branches are decorated with ribbons. The year of issue, the coin's respective denomination as well as FR (for Swiss Francs) is inscribed around the Swiss shield. Right of the year of issue B is displayed being a placeholder for Switzerland's capital Bern. The coin edges were endued by 22 stars until the year 1935. With the beginning of the year 1947 the gold coins show the Latin inscription AD LEGEM ANNI / MCMXXXI. Both the 10 Franc as well as the 100 Franc coin show the Swiss cross in the upper half of their reverse side framed by a corona. In the center of the coin, the nominal value 10 or 100 Francs respectively is inscribed on the left side and FR (for Swiss Franc) is displayed on the right. The year of issue is shown underneath these indications. At the bottom the traditional Swiss plants alpine rose and gentian are displayed. Right of the year of issue, B is displayed – indicative of Switzerland's capital Bern. In contrast to the 10 Franc version of the Vreneli, the 100 Franc version shows the Latin inscription DOMINUS PROVIDEBIT (translation:- the lord will provide). Vreneli is the Swiss 20-Franc gold coin featuring the head of a woman. A Swiss 10-Franc gold coin is known as a 1/2 Vrenely. The 20-Franc pieces have a fine gold content of 5.806 grams and a gross weight of 6.45 grams. As in the case of other gold coins, the trading price is determined by supply and demand. The Swiss 20 Franc gold coin – Vreneli or Helvetia:- there are two different types of Swiss 20 Franc coins. The first type with a laureate head of Liberty, wearing a coronet bearing the word 'LIBERTAS', with the inscription 'CONFEDERATIO HELVETICA'. The reverse shows a 5 pointed star above the red cross of Switzerland on a simple shield within a wreath. The inscription at either side of the shield 20 FR, with the date below. The letter B, the mintmark for Bern, appears below the wreath. This type was issued form 1886 to 1896 inclusive. The second type known as Vreneli or sometimes Helvetia and commonly known as Swiss 20 Francs is undoubtedly one of the world's most dignified and classically designed Swiss gold coins. The obverse of the Swiss Helvetia depicts 'Vreneli', the charming 'Swiss Miss' of folk lore, wearing flowers and facing left, framed against the majestic Alps. The reverse has an image of the traditional Swiss arms, featuring the famous Swiss cross over oak leaves tied with ribbons and shows the face value of 20 FR and the date. The name 'Helvetia' dates back to Roman times when it was the term for the original inhabitants of what is now Switzerland. In fact, the country for a time was named the Helvetian Republic during Napoleon's rule over the region. Switzerland's central location, privacy laws, and political stability have helped make it one of the world's most important financial centers. Swiss currency has never been devalued. Swiss gold coins, like these Helvetias, are cherished worldwide for their fine gold content and excellent minting. Because of their wide and constant availability, Helvetias trade remarkably close to their intrinsic gold value. You should never pay a high premium (price over gold value) for Helvetias in today's market. / Фритц Улис Ландри (Fritz Ulysse Landry). Френэли (Vreneli) или Хэльвеция (Helvetia). Фрэнэли – народно-обиходное название Швейцарских золотых монет в 10, 20 и 100 Франков, на лицевой стороне которых под названием страны Хэльвеция (Helvetia) изображена голова девушки Фрэнэли (Vreneli – уменьшительная форма от имени Вероника (Veronica)). Монеты в 10 Франков чеканились в 1897–1916, в 1922, 1925–1927, 1930, 1935, 1947 и 1949, в 100 Франков – в 1925. Чеканились также новоделы.

VRN2 GENE = ГЕН ВИ.АР.ЭН.2 (или ГЕН VRN2) – VRN2 Gene:- a term Vernalization refers to the process via which plants 'sense' the cold of winter, and activate the plant's innate defense response to cold stress, i.e. thereby waiting for spring to begin their flowering. For example, in the Wheat plant (Triticum Aestivum), a gene known as VRN2 represses flowering. However, exposure of that plant to prolonged cold will down-regulate that gene (thereby enabling flowering to begin when spring's warm weather arrives). / Вернализация (Vernalization) или Яровизация (Jarovization), от Латинского слова Vernus, означающее Весенний, – индукция под действием ряда факторов (в основном низкой температуры) ускоренного перехода растений от вегетативного развития к генеративному (цветению и плодоношению). Процесс вернализации имеет генетическую основу. Например, у Arabidopsis Thaliana ген FLC супрессирует формирование цветков в холодный период времени, а ген VRN2 выключает эту супрессию. Явление вернализации было открыто в 1918 Немецким Профессором ботаники Йоханом Густафом Гасна (Johann Gustav Gassner; 1881–1918). В 1929 Советский учёный Трофим Денисович Лысенко (1898–1976) предложил для обозначения наблюдаемого явления термин 'Яровизация'. Термин 'Вернализация' был предложен в 1933 Ар.Оу. Вайтом (R.O. Whyte) и Пи.Эс. Хадсэном (P.S. Hudson). В отличие от Риса и многих других зерновых культур, Пшеница легко приспосабливается к самым разным климатическим условиям. Она устойчива к низким температурам и не требует много влаги. Люди выращивают Пшеницу уже более 10 тысяч лет. Своими широкими адаптивными возможностями это растение обязано двум генам – VRN1 и VRN2, контролирующим его рост и размножение и определяющим сроки цветения. Так, например, ген VRN2 подавляет образование цветков у озимой Пшеницы, тем самым защищая растения от повреждения морозами.

VULCANIZATION = ВУЛКАНИЗАЦИЯ – Vulcanization is a chemical process by which the physical properties of natural or synthetic rubber are improved; finished rubber has higher tensile strength and resistance to swelling and abrasion, and is elastic over a greater range of temperatures. In its simplest form, vulcanization is brought about by heating rubber with sulfur. The process was discovered in 1839 by the US inventor Charles Goodyear, who also noted the important function of certain additional substances in the process. Such a material, called an Accelerator, causes vulcanization to proceed more rapidly or at lower temperatures. The reactions between rubber and sulfur are not fully understood, but in the product, the sulfur is not simply dissolved or dispersed in the rubber; it is chemically combined, mostly in the form of cross-links, or bridges, between the long-chain molecules. In modern practice, temperatures of about 140–180 °C are employed, and in addition to sulfur and accelerators, carbon black or zinc oxide is usually added, not merely as an extender, but to improve further the qualities of the rubber. Anti-oxidants are also commonly included to retard deterioration caused by oxygen and ozone. Certain synthetic rubbers are not vulcanized by sulfur but give satisfactory products upon similar treatment with metal oxides or organic peroxides. In rubber processing, Vulcanization or Curing. It is accomplished either by heat treatment or by treatment in cold sulfuryl chloride solution. / в 1839 Американским изобретателем Чарлзом Гудиэ (Charles Goodyear). Под Вулканизацией понимается превращение каучука в резину, осуществляемое с участием так называемых Вулканизирующих Агентов (например, серы, органических пероксидов, некоторых синтетических смол) или под действием ионизирующей радиации. В результате вулканизации повышаются прочность, твёрдость, эластичность, тепло- и морозостойкость каучука, снижается его растворимость в органических растворителях. Под Вулканизацией понимается технологический процесс резинового производства, при котором пластичный ‘сырой’ каучук превращается в резину. При вулканизации повышаются прочностные характеристики каучука, его твёрдость, эластичность, тепло- и морозостойкость, снижаются степень набухания и растворимость в органических растворителях. Сущность вулканизаци – соединение линейных макромолекул каучука в единую ‘сшитую’ систему, так называемую Вулканизационную Сетку. В результате вулканизации между макромолекулами образуются поперечные связи, число и структура которых зависят от метода вулканизации. При вулканизации некоторые свойства вулканизуемой смеси изменяются со временем не монотонно, а проходят через максимум или минимум. Степень вулканизации, при которой достигается наилучшее сочетание различных физико-механических свойств резин, называется Оптимумом Вулканизации. Вулканизации подвергается обычно смесь каучука с различными веществами, обеспечивающими необходимые эксплуатационные свойства резин (наполнители, например, сажа, мел, каолин, а также мягчители, противостарители и другие). В большинстве случаев каучуки общего назначения (натуральный, бутадиеновый, бутадиен-стирольный) вулканизуют, нагревая их с элементарной серой при 140–160 °C (Серная Вулканизация). Образующиеся межмолекулярные поперечные связи осуществляются через один или несколько атомов серы. Если к каучуку присоединяется 0.5–5% серы, получается мягкий вулканизат (автомобильные камеры и покрышки, мячи, трубки и так далее); присоединение 30–50% серы приводит к образованию жёсткого неэластичного материала – Эбонита. Серная вулканизация может быть ускорена добавлением небольших количеств органических соединений, так называемых Ускорителей Вулканизации – каптакса, тиурама и другие. Действие этих веществ в полной мере проявляется только в присутствии активаторов – окислов металлов (чаще всего окиси цинка). В промышленности серную вулканизацию производят нагреванием вулканизуемого изделия в формах под повышенным давлением или же в виде неформовых изделий (в ‘свободном’ виде) в котлах, автоклавах, индивидуальных вулканизаторах, аппаратах для непрерывной вулканизации и других. В этих аппаратах нагревание осуществляют паром, воздухом, перегретой водой, электричеством, токами высокой частоты. Формы обычно помещают между обогреваемыми плитами гидравлического пресса. Вулканизация с помощью серы была открыта Чарлзом Гудиэ (Charles Goodyear; 1800–1860) в США в 1839) и Томэсом Хэнькоком (Thomas Hancock; 1786–1865) в Великобритании в 1843. Для вулканизации каучуков специального назначения применяют органические перекиси (например, перекись бензоила), синтетические смолы (например, феноло-формальдегидные), нитро- и диазосоединения и другие; условия процесса те же, что и для серной вулканизации. Вулканизация возможна также под действием ионизирующей радиации – g-излучения радиоактивного кобальта, потока быстрых электронов (Радиационная Вулканизация). Методы бессерной и радиационной вулканизации позволяют получать резины, обладающие высокой термической и химической стойкостью.

VULGARIS = ВУЛЬГАРИС (или ВУЛЬГАРНОЕ, или ОБЫКНОВЕННОЕ, или ОБЫЧНОЕ, или ПРИВЫЧНОЕ, или ОБЩЕПРИНЯТОЕ, или ОБЫДЕННОЕ, или ОБИХОДНОЕ, или ОБЩЕДОСТУПНОЕ, или ПУБЛИЧНОЕ, или ПРОСТОЕ, или ПРОСТОНАРОДНОЕ) – Vulgaris:- common. Vulgaris, a Latin adjective meaning Common, or something that is derived from the masses of common people, may refer to:- (i) Vulgaris Aerae, the Latin translation for the Common Era; (ii) Era Vulgaris, pseudo-Latin

for Common Era (in Latin this means Common Mistress); or (iii) Sermo Vulgaris, the vulgar Latin. / Вульгарис (Vulgaris) или Обыкновенный (о виде в роду). Под Вульгарным, от Латинского слова Vulgaris, означающее Обыкновенный или Простой, понимается чрезмерно упрощённое изложение какого-либо учения, понятия, искажающее его сущность; грубо упрощённое; опошленное.

VULNERABILITY = УЯЗВИМОСТЬ (или БЕЗЗАЩИТНОСТЬ, или РАНИМОСТЬ) – Vulnerability is a measure of the extent to which a community, structure, service or geographical area is likely to be damaged or disrupted, on account of its nature or location, by the impact of a particular disaster hazard. / Уязвимость (Vulnerability) – любая часть программного кода, позволяющая использовать его для нарушения работы системы.

VULNERABILITY ANALYSIS = АНАЛИЗ УЯЗВИМОСТИ – Vulnerability Analysis is the process of estimating the vulnerability to potential disaster hazards of specified elements at risk. Vulnerability Analysis is the assessment of elements in the community that are susceptible to damage should a release of hazardous materials occur.

VULNERABLE SPECIES = УЯЗВИМЫЕ ВИДЫ – Vulnerable Species are taxa of various types, including:- (a) Taxa believed likely to move into the 'endangered' category in the near future if the relevant causal factors continue to operate. These factors may include overexploitation, extensive destruction of habitat and other environmental disturbances. (b) Taxa with populations that have been seriously depleted and whose ultimate security has not yet been assured. And (c) taxa with populations that are still abundant but are under threat from severe adverse factors throughout their range.

VULNERABLE ZONE = УЯЗВИМАЯ ЗОНА – Vulnerable Zone is an area over which the airborne concentration of a chemical involved in an accidental release could reach the level of concern.

VULPINUS = ЛИСИЙ (или ЛИСЯТА) – Vulpinus:- fox-like.

VULTURE FUND = ФОНД СТЕРВЯТНИК (или ФОНД НАЖИВЫ) – Vulture Fund is a pool of investor money that makes investments in securities from distressed issuers (usually bonds). How It Works:- let's say Company XYZ has lost 75% of its customers due to a food-poisoning scandal. The stock has lost 90% of its value, and the market does not believe the company can recover. Company XYZ still owns, however, a patent on a packaging technique that could be licensed and applied in other industries. Vulture Fund ABC knows this and buys high-yield bonds in Company XYZ, betting that the value of that patent might resurrect the company or at least ensure the return of capital plus interest if the patent is sold during bankruptcy. Vulture funds often also purchase debt from lenders. So, for instance, if Bank DEF had lended USD15 million to Company XYZ and Bank DEF wants to get this debt off the books, it might sell that debt to a vulture fund, similar to how credit card companies might sell customer debts to collection agencies. The vulture fund then negotiates with Company XYZ to secure a payout greater than the vulture fund's initial investment. Vulture funds also invest in sovereign debt, which is the debt of countries' governments. When countries are struggling, vulture funds might purchase this debt and then become heavily involved and influential in the government's restructuring. Why It Matters:- vulture funds often get a bad rap for circling dying companies in the hopes of picking off the last meat on a carcass for a quick profit. However, the analogy should sometimes be more like giving conditional prepayment rate (CPR). Vulture funds are often the last chance companies have to come back to life, and the funds' offers to provide cash may be the last attempt these companies can make to rescuscitate themselves. Vulture Fund is a fund that buys distressed debt of commercial companies or sovereign nations at a cheap price and then often sues them for the entire value of the debt. The resemblance to vultures is because these funds profit from the debt of failing companies or poor nations. Vulture Fund is a mutual fund that invests predominately or exclusively in high risk stock and high-yield debt. That is, a vulture fund invests in companies that are in or near bankruptcy. The idea behind a vulture fund is to buy securities at low prices and to earn an extraordinarily high return, even if it forces a company to do things against its best interest. For example, some vulture funds may force a company to repay debt when the company would be better served by declaring bankruptcy and not paying. As a result, the term is somewhat derogatory. See also Vulture Capitalist. Vulture Fund is a pool of investment money used to purchase distressed financial assets or real estate at bargain prices. Vulture funds are relatively risky but offer large potential profits. The performance of a vulture fund is dependent upon the skill of the fund's managers in identifying and purchasing undervalued assets that can be turned into profitable investments. Vulture Fund is a fund that buys securities in distressed investments, such as high-yield bonds in or near default, or equities that are in or near bankruptcy. Even highly leveraged firms may be targeted if there is a chance that the owners will not be able to make all required debt payments. As the name implies, these funds are like circling vultures patiently waiting to pick over the remains of a rapidly weakening company. The goal is high returns at bargain prices. Some people have looked down upon hedge funds that operate like vulture funds, which have preyed on the cheap debt of struggling companies and forced these companies to pay it back, plus interest. Vulture Fund:- like the scavenging bird of prey that lends its name to the fund, a vulture fund seeks out depressed or endangered investments. Many vulture funds focus on real estate, but others invest in bonds that have been downgraded or are in default and other high-risk securities. The strategy behind vulture investing is that such troubled securities have the potential to provide a large return eventually, in spite of their current vulnerable position. Most vulture funds are limited partnerships, but some are retail mutual funds that are open to individual investors. / Буквально Фонд-Стервятник – тип товарищества с ограниченной ответственностью (limited partnership), инвестирующего средства в обесценившуюся собственность, обычно в недвижимость, с целью получения значительной прибыли после того, как цены вновь вырастут. Фонды-Стервятники (Vulture Funds) – денежные средства, объединённые инвесторами в поисках пустующих конторских зданий, жилищных комплексов и полос пространства земли, которые могут быть приобретены по низким ценам. Синоним термина Фонды Для Поглощения Недооценённой Собственности (Funds To Acquire Underperforming Properties).

VXN^{SM} = ВИ.ЭКС.ЭН.^{ЗО} – CBOE Nasdaq Volatility Index – VXN^{SM} is a measure of market expectations of 30-day volatility for the Nasdaq-100 index, as implied by the price of near-term options on this index. The VXN^{SM} index is a widely watched gauge of market sentiment and volatility for the Nasdaq-100, which includes the top 100 US and international nonfinancial securities by market capitalization listed on the Nasdaq®. The VXN^{SM} is quoted in percentage terms, just like its better-known counterpart the VIX, which measures implied volatility for the S&P 500. The Chicago Board Options Exchange (CBOE®) launched the VXN^{SM} January 23, 2001.

The VXN℠ was introduced in 2001 as the technology / dot-com bubble was deflating. CBOE® developed the VXN℠ because of the massive divergence between volatility on the Nasdaq® market and the broad US equity market from early 1999 onward. The Nasdaq® index soared 137% in a 15-month period from January 1999 to its peak level of 5 132 in March 2000, before plunging 52% to just below 2 500 by December 2000. The S&P 500, by comparison, only gained 26% from January 1999 to its March 2000 peak, and declined 15% by end-2000. The higher the VXN℠ level, the greater the expectation for Nasdaq-100 volatility. Like the VIX, the VXN℠ functions best as a 'fear gauge' or indicator of market nervousness about the technology sector. Since its introduction, the highest level reached by the VXN℠ was 86.52 in October 2008, at the height of the global financial crisis, while the lowest level was 11.34 in March 2013. The average level for the VXN℠ over this period was 28.26; by way of comparison, the average level for the VIX over this time frame was 21.71. These two volatility measures correlate closely, and they generally – but not always – trade in lockstep with each other. The methodology used by the CBOE® to calculate the VXN℠ – whose value it disseminates continuously during trading hours – is identical to that used for the VIX. VXN℠ components are near-term (with at least one week to expiration) put and call options, and next-term options in the first and second Nasdaq-100 contract months. The selected options are out-of-the-money Nasdaq-100 puts and calls centered on an at-the-money strike price. VXN℠:- the implied volatility on the Nasdaq 100 (NPX) option. This volatility is meant to be a forward looking volatility. It is calculated from both calls and puts that are near the money. The CBOE NASDAQ-100 Volatility Index℠ (VXN℠) is a key measure of market expectations of near-term volatility conveyed by NASDAQ-100 Index (NDX) option prices. It measures the market's expectation of 30-day volatility implicit in the prices of near-term NASDAQ-100 options. VXN℠ is quoted in percentage points, just like the standard deviation of a rate of return, e.g., 19.36. CBOE® disseminates the VXN℠ index value continuously during trading hours. The VXN℠ Index is a leading barometer of investor sentiment and market volatility relating to the NASDAQ-100 Index. CBOE Nasdaq Volatility Index data is compiled for the convenience of site visitors and is furnished without responsibility for accuracy and is accepted by the site visitor on the condition that transmission or omissions shall not be made the basis for any claim, demand or cause for action. VXN℠:- the volatility of an index option in which the underlying index is the NASDAQ 100, also called an NPX Option. It is calculated by taking into account near-the-money NPX calls and puts. VXN℠ is the implied volatility on the Nasdaq-100 (NPX) option. This volatility is meant to be a forward looking volatility. It is calculated from both calls and puts that are near the money. / СИБО® (CBOE®). НЭЗДЭК® (NASDAQ®).

W–2 FORM = ФОРМА ДАБЛ.Ю.–2 – W-2 Form:- Wage and Tax Statement, is the form US employers are required by the Internal Revenue Service (IRS) to issue for each employee before February 28th of the following year. The W2 form lists the employee's total wages/compensation and taxes withheld within the calendar year of the year preceding. / Форма Дабл.Ю.-2 – это документ, в котором содержится полная информация о Вашей зарплате и уплаченных налогах. В соответствии с законами США Ваш работодатель обязан заполнить и выслать форму W-2 в Январе. Форма W-2 является основным документом при возврате налогов. Что такое чек последней зарплаты? Работодатель платит Вам зарплату чеками. Чаще всего эти чеки состоят из двух частей:- чека и корешка. На корешке чека представлена информация о Вашей зарплате и уплаченных налогах. Эта информация и используется для возврата налогов. Если нужных документов нет:- (i) Если у Вас нет формы W-2 или/и чека последней зарплаты, Вам придётся ждать до 15 Февраля. До этой даты Вы должны получить форму W-2 от каждого работодателя. (ii) Если до 15 Февраля Вы не получите форму W-2 или получите не от всех работодателей, сообщите нам (посредники) об этом. Наши коллеги в США свяжутся с Вашими работодателями и позаботятся о получении формы W-2. (iii) Если у вас нет визы, DS или Social Security card, то в любом случае обращайтесь к нам. Мы постараемся вам помочь. Способы возврата налогов:- Federal и State Income Tax (налоги Local ir City Tax не возвращаются). Предлагается несколько способов возвращения налогов:- (i) традиционный и (ii) быстрый. (1) Традиционный:- Необходимые документы:- (i) формы W-2 или чеки последних зарплат от всех работодателей, (ii) копия визы, и (iii) копия карточки Social Security. Срок возврата:- 60–90 дней со дня подписания документов. (2) Быстрый:- Для этого способа клиент должен иметь формы W-2 от всех работодателей. Возврат с чеками последней зарплаты невозможен. Необходимые документы:- (i) формы W-2 от всех работодателей, (ii) копия визы, и (iii) копия карточки Social Security. Срок возврата:- 30–45 дней со дня подписания документов. Social Security и Medicare Tax:- эти налоги возвращаются только при работе по программе Work and Travel/ При работе по программам H-2, Internship или при устройстве на работу другими способами эти налоги не возвращаются. Примечание:- для возврата налогов Social Security и Medicare необходима форма W-2. Даже если возврат федеральных и налогов штатов проводился с использованием последних чеков работодателей, для возврата налога Social Security нужна форма W-2. Срок возврата:- 4–7 месяцев. Срок в большой степени зависит от сотрудничества Вашего бывшего работодателя. Способы выплаты денег:- деньги могут быть выплачены двумя способами:- (i) деньги переводятся непосредственно на Ваш счёт, и (ii) деньги выплачиваются персональным чеком.

W–3 FORM = ФОРМА ДАБЛ.Ю.–3 – W-3 Form:- Transmittal of Wage and Tax Statements, is a form employers must use when filing paper W-2s with the Social Security Administration. Form W-3 summarizes the total wages, Social Security wages, federal income tax withheld, and FICA tax withheld from employees during the year and lists the number of W-2s being transmitted.

W–4 FORM = ФОРМА ДАБЛ.Ю.–4 – W-4 Form:- Employee's Withholding Allowance Certification, is completed by each employee so that the employer can withhold the correct federal income tax from the employee's pay. Because tax situations may change, employees may want to refigure their withholding each year.

W–8 FORM = ФОРМА ДАБЛ.Ю.–8 – W-8 Form is the certificate of Foreign Status form required by the US Internal Revenue Service (IRS) to tell the payer, transfer agent, broker or other middleman that an employee is a nonresident alien or foreign entity that is not subject to US tax reporting or backup withholding rules. W-8 Form is a form used by non-US citizens to certify that they are not citizens and are therefore not liable for taxation on income from dividends, interest, sales, etc.

W–9 FORM = ФОРМА ДАБЛ.Ю.–9 – (1) W-9 Form is the request for Taxpayer Identification Number and Certification form required by the US Internal Revenue Service (IRS) to furnish the payer, transfer agent, broker or other middleman with an employee's social security or taxpayer identification number, in order that the employee not be subject to backup withholding because of under-reporting of interest and dividends on his or her tax return. W-9 Form is the US Internal Revenue Service (IRS) form used to certify Tax Identification Numbers for investors in securities under the 1984 Tax Equity And Fiscal Responsibility Act (TEFRA Act).

(2) W-9 Form is a form used to certify a shareholder's social security or tax identification number as true and correct, in order to avoid federal tax withholding.

WACHOVIA ADJUSTABLE MORTGAGE = ПЕРЕОЦЕНИВАЕМАЯ ЗАКЛАДНАЯ ВАКОВИА – Wachovia Adjustable Mortgage:- xxxxx. As of May 06, 2011, Wachovia Mortgage Corporation was acquired by Wells Fargo Bank, National Association. Wachovia Mortgage Corporation provides mortgage and home equity products for home purchase or refinance. The company offers mortgage, community lending, construction mortgages, and home equity loans. It caters to the low-to-moderate, middle market, and wealth income segments through multiple origination channels. Wachovia Mortgage Corporation was formerly known as First Union Mortgage Corporation. The company is based in Charlotte, North Carolina. Wachovia was the name of a major financial services company that was acquired by Wells Fargo in 2008. The Wachovia name was retired after the integration of the two companies was completed in 2011, and former Wachovia web sites now link directly to Wells Fargo instead. Prior to being acquired by Wells Fargo, Wachovia was the fourth-largest bank in the United States, based on total assets, and offered a broad range of financial services, including wealth management and investment services. Financial difficulties encountered during the economic crisis of 2008 resulted in Wachovia's sale to Wells Fargo to prevent the company from failing. Wachovia Mortgages:- Wachovia's mortgage business has been completely transferred to Wells Fargo and no new mortgages are being originated under the Wachovia name. Borrowers who obtained mortgages through Wachovia are now being handled by Wells Fargo. Wells Fargo is one of the nation's largest banks and mortgage lenders, with mortgage rates that are very competitive on the market. Wells Fargo offers a full line of mortgage products, with fixed rate, adjustable rate (ARM), interest-only and jumbo mortgages available, as well as FHA- and VA mortgage (Federal Housing Administration mortgage and Veterans Administration mortgage) products. Wells Fargo has first time home buyer programs and programs for people with imperfect credit. Refinancing:- with the Wachovia brand retired, mortgages are no longer being refinanced under the Wachovia name. Homeowners who wish to refinance mortgages obtained through Wachovia may do so with Wells Fargo, or with any other mortgage lender, provided that they meet equity, credit and income requirements and other qualifications. Wachovia mortgage borrowers with little or no home equity, or who are underwater on their mortgage (owe more than their property is worth) may be able to refinance under the Home Affordable Refinance Program (HARP), provided that the loan is backed by Fannie Mae or Freddie Mac. Wachovia borrowers seeking a HARP refinance may seek to do so through the Wells Fargo mortgage department, but may also do so with any lender or broker who is accepting HARP applications from other lenders' customers. Home Equity Loans:- borrowers with a mortgage originated through Wachovia may apply for a home equity loan or home equity line of credit (HELOC) through Wells Fargo or any other lender offering home equity products. / Ваковиа (Wachovia). Процентная ставка корректируется каждый квартал в соответствии с процентной ставкой по Казначейским Векселям. Размер ежемесячного платежа остаётся неизменным в течение пяти лет, но новая ставка определяет, какая часть будет идти в счёт уплаты процентов и какая – в счёт уплаты основного долга. Каждые пять лет сумма ежемесячного платежа корректируется в большую или меньшую стороны в пределах 25%, и таким образом ссуда будет выплачена в срок. После 25 лет сумма ежемесячного платежа может быть скорректирована на величину, превышающую 25%, если существует опасение невыплаты ссуды в срок. Если по истечении 30 лет ссуда полностью не оплачена, заёмщик может осуществить рефинансирование. WAD = ВАД – Wad:- also called Bog Manganese, black and earthy substance that consists mainly of hydrated manganese oxides; it is an important ore of manganese. It varies considerably in chemical composition and contains different impurities, often in large amounts. Wad is very soft, readily soils the fingers, and may be considered to be a mixture chiefly of pyrolusite and psilomelane. It results from the decomposition of other manganese minerals and is often deposited in marshes or by springs; it bears the same relationship to manganese oxides that limonite and gummite do to iron and uranium oxides. / Вад – минерал группы псиломелана, собирательное название землистых и сажистых агрегатов водной MnO_2 с переменным содержанием примесей K, Ba, Cu, Zn, Fe, Pb, W, Li, Co, Ni. Разновидность вада – асболан (до 17% CoO наряду с Ni и Cu). Твёрдость 1–4; плотность 2.8–4.4 г/см^3. Гипергенный. Руда марганца, кобальта и никеля. Вад, высокодисперсное минеральное вещество, состоящее из $MnO_2 \cdot n\ H_2O$ и других водных окислов марганца. Описывался под различными названиями:- марганцевая чернь, марганцевая пенка и другие. В зависимости от содержания примесей выделяется ряд разновидностей:- CuO – лампадит; ZnO – туннерит; CoO^+NiO – асболаны, и так далее. Образует порошковатые пачкающие массы, корочки, дендритовидные налёты, конкреции. Цвет чёрный, чёрно-коричневый. Плотность 2 800–4 400 кг/м^3, твёрдость по минералогической шкале 1–4. Вад широко

распространён в природе как продукт выветривания различных марганецсодержащих минералов. Входит в состав осадочных марганцевых руд; образуется в донных морских и озёрных отложениях. Используется вместе с другими марганцевыми минералами как руда.

WADB = WEST AFRICAN DEVELOPMENT BANK

WADER = БОЛОТНИКИ (или БОЛОТНЫЕ САПОГИ) – Wader:- (plural) high waterproof boots or a one-piece waterproof garment usually consisting of pants with attached boots that are used for wading, as when fishing.

WADMAL = ВОДМЭЛ – Wadmal is a coarse rough woolen fabric formerly used in the British Isles and Scandinavia for protective coverings and warm clothing. / Водмэл – грубое сукно или грубая шерстяная ткань, используемая ранее в Британских Островах и Скандинавии для защитных покрытий и тёплой одежды.

WADTF = WESTERN ATMOSPHERIC DEPOSITION TASK FORCE

WAEC = WEST AFRICAN ECONOMIC COMMUNITY

WAFER = ПЛАСТИНКА – Wafer is a thin slice, typically 10–30 mils thick, sawed from a cylindrical ingot (boule) of extremely pure, crystalline silicon, typically six to eight inches in diameter. Arrays of ICs (short for the Integrated Circuits) or discrete devices are fabricated in the wafers during the manufacturing process. Wafer is a thin sheet of semiconductor (photovoltaic material) made by cutting it from a single crystal or ingot. / тонкий лист полупроводника (фотовольтаический материал), сделанный посредством его среза с одного кристалла или слитка.

WAFER = СУСАЛЬНОЕ ЗОЛОТО (или ВАФЛЯ) – Wafer:- gold bars which are stamped rather than cast, and therefore often thinner and flatter than cast bars are often called Wafers or Biscuits. Small, thin gold bars popular in the Middle East, South East Asia and Japan. Wafer is a generic term used to describe small gold bars, (usually less than 50 grams). So-called because they are thin and resemble a wafer biscuit.

WAFER BOARD = СТРУЖЕЧНАЯ ПЛИТА (или ДРЕВЕСНОСТРУЖЕЧНАЯ ПЛИТА) – Waferboard belongs to the subset of reconstituted wood panel products called Flakeboards, which is a type of particleboard. It is a structural material made from rectangular wood flakes of controlled length and thickness bonded together with waterproof phenolic resin under extreme heat and pressure. The layers of flakes are not oriented, which makes it easier to manufacture. Waferboard is used as a material to build cheap furniture. This type of furniture is usually laminated. A mat-formed structural panel board made of wood wafers, randomly arranged and bonded together with a waterproof and boilproof binder. Waferboard, also known as Oriented Strand Board or OSB, waferboard is a wood panel composed of flakes that are compressed to create a sturdy and workable building material. This type of chipboard is classified as one example of particleboard and can sometimes be used in building projects in the place of conventional plywood panels. While normally known as Particleboard in the United States, panels of this type are often referred to as Sterling Board in the United Kingdom. The creation of waferboard involves compressing individual flakes into a flat panel. In order to achieve the shape and consistency desired, the wood flakes are joined with the use of resins that effectively bind the flakes or wafers to one another. The panel is subjected to a high degree of heat and pressure, which helps to seal the bond and also compress the surface of the board until it is flat. As a result, the panels are relatively strong and can be used for a number of building projects. One of the more common applications of waferboard is in the creation of inexpensive but functional pieces of furniture. Items such as television stands, computer desks, and various types of shelving can be created using this type of board. The pieces are often covered with some sort of laminate designed to mimic the appearance of wood grain. Furniture of this kind is often sold in easy to assemble kits, and is often sold at discount retail stores. Just as with plywood and medium-density fiberboard (MDF), waferboard can be manufactured to any degree of thickness desired. Thinner boards may be ideal for use in creating temporary walls within an edifice, such as the preparation of a stage set in a theater. The thicker boards can be used to create functional shelving that can be mounted directly on a wall and support an equitable amount of weight. Most products made with this type of board are graded, allowing consumers to know how much stress the board can stand up to and remain functional. While waferboard is a versatile product, it is not always the best option for various building projects. Furniture created with the use of this type of board is less likely to last for extended periods of time than solid woods. Water can damage the integrity of waferboard, and in some cases even cause the flakes to begin separating. Fortunately, people who purchase inexpensive furniture made with this product usually are looking for an item that will be useful in the short term, while they set aside resources to purchase something that is more likely to last for many years. Wafer Board is a man made sheet of wood that is comprized of large pieces of wood joined together to make a 4’ 8’ sheet of wood. Wafer board is also known as Oriented Strand Board or OSB Board. OSB is made up of large pieces of wood that are glued together with a glue that is water proof. Wafer board is mainly used for residential construction. Also known as Oriented Strandboard. / Фенольное (Phenolic). окантованное (rectangular). водоотталкивающим и устойчивым к кипячению связующим. Известна также как Плита С Ориентированными Пучками (Oriented Strandboard). Под Древесностружечной Плитой (ДСП) понимается древесный материал, получаемый горячим прессованием древесных частиц (смеси древесных стружек) с небольшим количеством синтетического связующего вещества, обычно карбамидо- или феноло-формальдегидной смолы. По способу прессования различают древесностружечные плиты плоского прессования и экструзионные, то есть полученные выдавливанием. Древесностружечные плиты выпускают необлицованными и облицованными шпоном, бумагой, пропитанной смолой, синтетической плёнкой. По физико-механическим свойствам древесностружечные плиты близки к древесине, но менее водостойки. Размеры древесностружечных плит плоского прессования (мм):- длина 2 440–5 500, ширина 1 220–2 440, толщина 10–25. Такие плиты применяются в мебельной промышленности и строительстве. Стружечная Плита относится к одной из разновидностей древесных материалов, получается из спрессованных деревянных стружек путём их обработки давлением и пропиткой связующими материалами, склеиванием и так далее. Древесностружечная Плита (ДСП) – листовой материал, изготовленный путём горячего прессования древесных частиц, смешанных со связующим веществом. В качестве связующего применяют карбомидо-формальдегидные, фенол-формальдегидные и другие смолы. Древесностружечные плиты доводятся до номинальных размеров путём шлифовки. Сырьём для древесностружечных плит служат:- стружка (получаемая в строгальном производстве), отходы лесопильного производства (рейки, обапол и обрезки после оторцовки досок и так далее) и специально рубленная щепа. Древесностружечные плиты применяются в мебельном производстве, в строительстве, радиопромышленности и другом.

WAFER SEAL = СУРГУЧНАЯ ПЕЧАТЬ – Wafer Seal:- if you’ve ever received newsletters or brochures in the mail, chances are they were held together by wafer seals. They are are self-adhesive paper disks used to prepare self-mailing materials for delivery or to seal envelopes securely without glue. Some wafer seals are perforated to prevent damage while opening, while others may be serrated for decoration or embossed for personalization. Many stamp collectors also have an interest in certain vintage or historic seals. The use of wafer seals for envelopes and self-mailing documents was most likely derived from the earlier practice of using wax seals. Official wafer seals could also be commissioned in order to verify the authenticity of a decree or military order. Any hint of tampering or unauthorized reading could be detected by examining the seals. It is these elaborate versions that most interest stamp collectors today.

As other forms of document protection, such as the self-sealing envelope, became more common, the use of official wafer seals declined. The practice is now mostly used during ceremonies or as official seals on formal invitations. Today, most wafer seals are sold on rolls through office supply stores and party shops. The more generic versions may also be called Mailing Tabs. Their main functions are to seal self-mailing newsletters and other bulky brochures and to provide a decorative seal for envelopes. Changes in the postal system have resulted in an increased need for mailing tabs. Folded newsletters and other self-mailers can no longer be sealed with metal staples. The approved solution is to use one or two wafer seals along the bottom or top edge of the folded material for security. The seals must be placed in specific areas, usually near the edges, so they do not block any official mailing bar codes or address information. Wafer seals come in a variety of styles and colors, from utilitarian butterfly tabs to elaborately embossed invitation seals. Some are clear in color, while others can be shiny or metallic. There are also versions suitable for specific holidays or other occasions. / Сургучная Печать:- современная форма печать, используемая для скрепления документов. Обычно представляет собой небольшой красный диск, наносимый на документ для прикладывания печати. В настоящее время вместо воска для печатей может использоваться любой материал, с которым согласны все заинтересованные стороны.

WAFFLE = ВАФЛЯ – Waffle:- crisp raised cake baked in a waffle iron, a hinged metal griddle with a honeycombed or fancifully engraved surface that allows a thin layer of batter to cook evenly and crisply. Baking powder is the typical leavening in American waffles, and yeast waffles are eaten in Belgium and France. In the United States and Canada waffles are a popular breakfast food, topped with butter and maple syrup or fruit preserves. Waffles also can serve as a base for savoury mixtures such as seafood or poultry in sauce. In Belgium waffles are a popular snack food. They are mentioned in French poems from as early as the XII century, when they were sold as street food at fairs and religious festivals.

WAFFLE CLOTH = ВАФЕЛЬНОЕ ПОЛОТНО – Waffle, or sometimes Honeycomb Fabric is fabric, usually cotton or microfiber, woven in a way which makes it very absorbent. The waffle weave also allows air to flow through the towel so that it dries quickly. Waffle fabrics are made in a range of weights. Waffle fabric is used for cleaning surfaces in industry. The surface of the fabric is textured rather like an edible waffle, hence the name. This texture gives more surface area for absorption and cleaning than a normal flat surface. It is woven on a loom, and is therefore more durable than many chemically produced fibres. It is not a mechanical or chemical process that can be washed off after thorough or heavy use. Waffle fabrics are used for towels and bathrobes. Terry cloth is more often used for towelling. Waffle Cloth is a fabric with a characteristic honeycomb weave. When made in cotton it is called Waffle Pique. It is used for coatings, draperies, dresses, and toweling. Waffle weave fabric is a woven fabric with a recessed square pattern. The raised edges around the recessed squares give the pattern the look of the breakfast food called Waffles. It is available in different gauges from very fine to medium to coarse. Fine gauge waffle weave material contains tiny squares and the fabric is usually lightweight. This type of weave often makes fast-drying dishcloths or dishtowels and also works well for a summer weight bathrobe. Medium gauge fabric is commonly used in all types of towels. Coarse or large gauge waffle weave material makes very luxurious plush towels or bathrobes. Many home sewers like to make towels and robes from the large gauge waffle weave fabric because of the quality and the fact that it's usually very expensive to buy these items ready made. Of course, bath towels and robes you've sewn yourself from quality fabric make excellent gifts. You can add trims and embellishments to towels. Robes are basically 'one size fits most' so they are easy to size properly. Most crafters find waffle weaves easy to work with. The fabric can quite often be found with materials like terry cloth in many sewing sections. White is commonly available, but pastels and dark colors such as navy blue are also fairly easy to find. Some stuffed animal makers like to use the large gauge waffle weave fabric to add interest to animal shapes. Another use for larger gauge waffle weave fabrics is to make sofa covers since the fabric is considered durable enough for daily use. However, it is most often used where absorbency is needed, which is why all of the gauges work so well for towels and robes as well as exercise wear. Waffle weaves are highly absorbent while also being soft and comfortable. Waffle weave fabric is often 100% cotton, but may also be polyester-cotton blends or micro-fiber. Micro-fiber waffle weave cloth is ultra-soft and ultra-absorbent and often considered ideal for cleaning and polishing cars. These materials make great shower curtain and display towels for any bathroom as they add an interesting texture to any decor, even a neutral one. Waffle Cloth, also known as Waffle Weave Fabric or Honeycomb Fabric, is a woven fabric that has a recessed pattern created by cords running either vertically, horizontally or both, creating a square design (hence the waffle name). Waffle cloth is generally made of cotton, but can also be made of wool, polyester-cotton blends or microfiber. Waffle cloth comes in several different gauges from fine to medium to coarse. The color most commonly associated with waffle cloth is white, though it does come in a variety of colors and prints. It is woven in a way that makes it very absorbent, but also allows air to flow through it so it dries quickly. This makes waffle cloth ideal for anything where absorbency is needed. So what to make with waffle cloth? (i) Light Gauge:- Hand towels, dish towels or cleaning cloths; (ii) Medium Gauge:- Bath towels, aprons, pajamas or other clothing; and (iii) Coarse Gauge:- Plush bath towels, robes or slippers. / Вафельная Ткань – популярная разновидность продукции хлопчатобумажного производства. Этот материал давно завоевал любовь покупателей благодаря своей мягкой фактуре, достаточной плотности (120–240 г/кв.м) и отличной впитываемости. Такая ткань идеальный вариант для мам, которые приучают малышей самостоятельно пользоваться полотенцем. Ткань полотенечная вафельная незаменима на современной кухне. Полотенца и салфетки из этой ткани широко применяются в быту, современные хозяйки с удовольствием используют их для полировки мебели, чистки зеркал и стёкол, протирания кухонных принадлежностей. При этом вафельные салфетки легко отстирываются и не требуют особой обработки. Вафельное Полотно широко применяется в промышленности, отлично впитывает воду, масло, горючесмазочные материалы, краски. Ширина вафельной ткани, как правило, – 40 и 80 см. Минимальная партия – 200 погонных метров.

WAFFLESTOMPER = ВАФЛСТАМПЁР (или ТУРИСТСКИЙ БОТИНОК) – Wafflestomper is a hiking boot with a lug sole. Waffle Stomper is someone who takes a dump in the shower and tries to crush it down the drain with their feet. For example, 'I went to jump in the shower after Steve had finished only to find that fuckin' waffle stomper had left shrapnel all over the floor'. Wafflestomper is a hiking boot with a lug sole. / Стив (Steve).

WAFFLE WEAVE = ВАФЕЛЬНОЕ ПЕРЕПЛЕТЕНИЕ – Waffle Weave:- its characteristic recessed squares make this cotton fabric look just like the popular breakfast food it's named after. Although it can't be eaten, it can keep you warm which is why it's a staple in winter clothing like long johns. Waffle Weave is identical to honeycomb and thermal weaves. A weave resulting in fabrics with diamonds or rather geometric shapes resembling a waffle. See also Thermal. / Вафельное Переплетение – разновидность редьефных переплетений, создаёт на ткани узор из прямоугольных ячеек, грани которых рельефно выступают, а середина имеет углубление. Длинные основные и уточные перекрытия образуют выступающие грани прямоугольника, а места с короткими перекрытиями соответствуют углублениям ячеек. Вафельное переплетение применяется главным образом при выработке полотенечных тканей. Свободно лежащие перекрытия основных и уточных нитей повышают способность ткани к впитыванию влаги, что улучшает свойства полотенец. На тканях Вафельного Переплетения создаётся узор из прямоугольных ячеек, грани которых выступают, а середина углублена. Места с короткими перекрытиями соответствуют углублённой части ячейки, длинными перекрытиями образуются выступающие рельефные грани прямоугольника. Чаще всего вафельное переплетение применяют для выработки полотенечных тканей, так как свободно лежащие перекрытия нитей основы и утка

повышают способность ткани к впитыванию влаги. Вафельное Переплетение состоит из мелких клеток с полотняным переплетением, которые обрамляют участки с переплетением, состоящим из длинных настилов. Эти участки состоят из уточных и основных перекрытий на двух сторонах ткани. Из рисунков видно, что узор вафельного переплетения не даёт сколько-нибудь правильного изображения той структуры, которую приобретает ткань. Обрамление узора переплетения даёт одну клетку с полотняным переплетением и уточные и основные удлинённые перекрытия, которые окружают его. Эффект возвышений и углублений возникает вследствие того, что длинные основные и уточные перекрытия пытаются стянуть ткань, в то время как участки полотняного переплетении пытаются расширить поверхность ткани. Квадратная разбивка возникает вследствие наличия вертикальных основных перекрытий и горизонтальных уточных перекрытий.

WAG = WILD GUESS

WAGE = ОКЛАД (или ЗАРПЛАТА, или ЗАРАБОТНАЯ ПЛАТА) – (1) Wage is a monetary remuneration computed on hourly, daily, weekly, or piece work basis. A fixed weekly or monthly wage is usually called a Salary. See also Wages. Plural of Wage, most often used in plural to refer to one's total income for a time period. Wage is a form of pay given to employees in exchange for the work they have done. Traditionally, the term Wages applied to the weekly pay of manual, or nonprofessional workers. In modern usage, the term is often used interchangeably with salary. Payment made to a worker, normally fixed as a rate per hour, day or week, and usually paid weekly. Wage is a payment received by an employee in exchange for labor. It may be in goods or services but is customarily in money. The term in a broad sense refers to what is received in any way for labor, but wages usually refer to payments to workers who are paid by the hour, in contrast to a salary, which implies a more fixed and permanent form of income, e.g., payment by the month rather than by the hour. In economic theory, wages reckoned in money are called Nominal Wages, as distinguished from real wages, i.e. the amount of goods and services that the money will buy. Real wages depend on the price level, as well as on the nominal or money wages. Payment for labor or services to a worker, especially remuneration on an hourly, daily, or weekly basis or by the piece. Wage is the payment for the service of a unit of labor, per unit time. In trade theory, it is the only payment to labor, usually unskilled labor. In empirical work, wage data may exclude other compensation, which must be added to get the total cost of employment. A Wage is the amount of money paid for some specified quantity of labor. When expressed with respect to time (usually per hour), it is typically called the Wage Rate, and is specified in pre-tax amounts. It is often the main monetary item upon which the worker and the employer focus when negotiating an employment contract. Wage vs Salary:- the difference between wage and salary defines more than how much you end up making per year. We use the terms to often describe differences in types of work, as well as what is actually counted in the final total. Wages are generally paid per hour. This means that you have to be present and working in order to get paid. Most of the time, wage jobs are not as inclusive when it comes to things like paid vacations, or paid sick days. Wage earners often have to give up pay for leaving early, coming in late, missing a day, or taking a vacation. Salary refers to how much you get paid every year. Salary earners rarely have to punch a time clock, or keep an accurate account of their hours, because they get paid for performance rather than by the hour. Salaried workers are much more likely to have paid sick days and paid vacations, and are not docked pay for being late or leaving early from time to time. Salary can also be counted in terms other than money. Some companies consider reimbursement for things like medical insurance as part of your salary. You can even find some companies blending education and retirement contributions as part of your salary package. Historically, we often refer to manual labor jobs as wage jobs, and professional jobs as salaried positions. Wage earners are more likely to be found in positions with high turnover, while salaries are often assigned for positions with low turnover. We express wages as an hourly payment. We express salary as packages. You might find that you receive a base salary, stock options, retirement, benefits, and bonuses as a salary package. Wages are more likely to be added up into additional payments. If you work 50 hours in one week, you may receive your first 40 hours at the regular pay rate, and the additional 10 hours at 1 1/2 times your normal pay rate. Salary earners are not often given the opportunity to get paid extra for additional hours. Summary:- (i) wage earners are paid by the hour; (ii) salary earners are paid by the year; (iii) salary earners usually receive paid time when they are not working; (iv) wage earners often have to give up pay for time off; (v) salaries are often calculated as packages; (vi) wage earners get paid more for working more than 40 hours per week; (vii) salary workers are rarely offered overtime pay; and (viii) salaries can contain all kinds of benefits and perks. See also Salary. Wage is actual remuneration paid to an employee for services rendered. Minimum wages, in the USA, are established by the federal Fair Labor Standards Act. / , например, . , то есть . Смотрите также Жалованье (Salary). В Соединённом Королевстве под Wage (скорее Приработок) понимается:- когда есть сверхурочные, ночные смены и так далее, и оплата осуществляется отдельно. Оклад – размер заработной платы. Устаревшее наименование какого-нибудь денежного сбора или налога. Заработная Плата или Зарплата является превращённой формой стоимости и цены рабочей силы, и выступает в качестве оплаты труда. Различают номинальную и реальную заработную плату. Под номинальной заработной платой понимается заработная плата в денежном выражении. Она характеризует уровень заработной платы вне связи с ценами на товары и услуги. Под реальной заработной платой понимается заработная плата, выраженная в материальных благах и услугах. Она показывает, какое количество предметов потребления и услуг трудящийся может фактически приобрести на свою заработную плату. Реальная заработная плата определяется размером номинальной заработной платы, уровнем цен на предметы потребления и услуги, а также величиной взимаемых налогов. Заработная Плата (Оплата Труда Работника) – вознаграждение за труд в зависимости от квалификации работника, сложности, количества, качества и условий выполняемой работы, а также компенсационные выплаты (доплаты и надбавки компенсационного характера, в том числе за работу в условиях, отклоняющихся от нормальных, работу в особых климатических условиях и на территориях, подвергшихся радиоактивному загрязнению, и иные выплаты компенсационного характера) и стимулирующие выплаты (доплаты и надбавки стимулирующего характера, премии и иные поощрительные выплаты). Тарифная Ставка – фиксированный размер оплаты труда работника за выполнение нормы труда определённой сложности (квалификации) за единицу времени без учёта компенсационных, стимулирующих и социальных выплат. Оклад (Должностной Оклад) – фиксированный размер оплаты труда работника за исполнение трудовых (должностных) обязанностей определённой сложности за календарный месяц без учёта компенсационных, стимулирующих и социальных выплат. Базовый Оклад (Базовый Должностной Оклад), базовая ставка заработной платы – минимальные оклад (должностной оклад), ставка заработной платы работника государственного или муниципального учреждения, осуществляющего профессиональную деятельность по профессии рабочего или должности служащего, входящим в соответствующую профессиональную квалификационную группу, без учёта компенсационных, стимулирующих и социальных выплат. Чем отличается Оклад от Зарплаты? Оклад и Зарплата – понятия, относящиеся к одной экономической категории – оплата труда работника. Есть ли между ними различия или они тождественны друг другу? Необходимо разобраться в этом вопросе более подробно. Что такое оклад и зарплата? Оклад представляет ту сумму денежных средств, которую изначально предлагает работодатель для расчёта итоговой суммы. Этот показатель отражается в трудовом договоре сотрудника и указывается в приказе при поступлении на работу. Оклад является базисной характеристикой для последующего расчёта иных показателей. Зарплата – это та сумма денежных средств, которую получает работник после расчёта необходимых надбавок и удержания налога на доходы физических лиц. Для её расчёта используется величина оклада, к которой прибавляются проценты, обусловленные договором, надбавки и компенсации, например, за вредность производства, и удерживается налог на доходы физических лиц

(НДФЛ). Сравнение оклада и зарплаты:- В чём же разница между окладом и зарплатой? Самое существенное различие между ними заключается в том, что один показатель рассчитывается исходя из другого. Иными словами, имеется установленный базовый оклад на определённую должность согласно штатному расписанию, к которому прибавляются все проценты и бонусы за качественно выполненную работу и из которого вычитаются налог на доходы физических лиц, удержания за порчу имущества или возмещения за причинённый материальный ущерб. Оклад со всеми 'плюсами' и 'минусами' будет являться заработной платой сотрудника, то есть той суммой денежных средств, которую получит работник по истечении календарного месяца либо при его увольнении. Оклад, согласно действующему законодательству, должен быть указан в трудовом договоре, в то время как заработная плата является расчётным показателем, который не прописывается ни в каких документах кроме ведомости на выплату зарплаты. Отличие Оклада от Зарплаты заключается в следующем:- (i) Размер оклада указывается в документах при устройстве человека на работу, заработная плата рассчитывается после того, как он месяц проработал на предприятии или при его увольнении с должности. (ii) Оклад – фиксированная цифра в штатном расписании сотрудников, которая используется для расчёта заработной платы, а показатель зарплаты никоим образом не влияет на размер оклада. (iii) Оклад – базисная неизменная единица, а зарплата складывается из величины оклада и тех процентов, бонусов и вычетов, которые предусмотрены законодательством и условиями трудового договора сотрудника.

(2) Wage is the portion of the national product that represents the aggregate paid for all contributing labor and services as distinguished from the portion retained by management or reinvested in capital goods. In economics, Wages and Salaries are compensation paid on a regular basis by an employer to an employee for his or her labor, by the hour, week, month or some other period, or by units of output. In business usage, the term Salary is used to denote the earnings of executive, professional and clerical personnel, who are paid on a weekly or monthly basis, while Wage is reserved for the earnings of production workers, who are paid by the hour or day or by unit of production. Also known as Salary. / выработка (output).

WAGE ACCRUAL = НАЧИСЛЕНИЕ ОКЛАДА – Wage Accrual:- it is quite common to have some amount of unpaid wages at the end of an accounting period, so you should accrue this expense (if it is material). The accrual entry shown below is a simple one, because you typically clump all payroll taxes into a single expense account and offsetting liability account. After recording this entry, you reverse it at the beginning of the following accounting period, and then record the actual payroll expense whenever it occurs. Companies with predominantly salaried staffs frequently avoid making the accrued wages entry, on the grounds that the wages due to a small number of hourly personnel at the end of a reporting period have a minimal impact on reported financial results. The information for the wage accrual entry is most easily derived from a spreadsheet that itemizes all employees to whom the calculation applies, the amount of unpaid time, and the standard pay rate for each person. It is not necessary to also calculate the cost of overtime hours earned during an accrual period if the amount of such hours is relatively small.

WAGE AND LABOR COSTS = РАСХОДЫ НА ОКЛАДЫ (или ЗАРАБОТНЫЕ ПЛАТЫ) И ТРУД – Wage And Labor Costs may be described through use of three distinct and complementary indicators:- (i) average real wages; (ii) nominal and real wage rates and/or earnings; and (iii) average compensation costs. The first two may be viewed from the workers' standpoint and represent a measure of the levels and trends of their purchasing power and an approximation to their standard of living. The third measure provides an estimate of employers' expenditure on the employment of labor. Whilst these measures can be compiled for the total economy, they are more frequently available for the manufacturing sector. However, it should be noted that the development of wages and labor costs may vary across sectors.

WAGE AND SALARY = ОКЛАД (или ЗАРАБОТНАЯ ПЛАТА) И ЖАЛОВАНЬЕ – Wage And Salary:- income derived from human labor. Technically, all payments for the use of labor, mental or physical, are covered, but in ordinary usage the terms exclude income of the self-employed and are restricted to compensation of employees. Occasionally fringe benefits are included, but generally they are not. The terms are not fully synonymous with Labor Costs, which may include such items as cafeterias or meeting rooms maintained for the convenience of employees (such items are part of capital). Wages And Salaries, in economic terms, however, do include remuneration in the form of extra benefits, such as paid vacations, holidays, and sick leave, as well as supplements in the form of pensions and health insurance paid for by the employer. A worker in covered industries also receives the protection of government-provided unemployment compensation, old-age pensions, and industrial accident compensation. Government services provided for workers are of even greater significance in European countries than in the United States and must be taken into account when comparisons of earnings are made. Classical Theories:- theories of wage determination and the share of labor in the gross national product have varied from time to time and have changed as the economic environment has changed. The body of thought referred to today as wage theories could not have emerged until the old feudal system had disappeared and the modern economy with its modern institutions had come into existence. Adam Smith, in The Wealth of Nations (1776), failed to propose a definitive theory of wages, but he anticipated several theories that were developed by others later. Smith thought that wages were determined in the marketplace through the law of supply and demand. Workers and employers would naturally follow their own self-interest; labor would be attracted to the jobs where labor was needed most, and the result would be the greatest overall benefit to the workers and to society. But Smith gave no precise analysis of the supply of and demand for labor; he discussed many elements that were involved but did not weave them into a consistent theoretical pattern. Subsistence Theory:- subsistence theories emphasize the supply aspects and neglect the demand aspects of the labor market. They hold that change in the supply of workers is the basic force that drives real wages to the minimum required for subsistence. Elements of a subsistence theory appear in The Wealth of Nations, where Smith wrote that the wages paid to workers had to be enough to allow them to live and to reproduce themselves. Smith was more optimistic, however, than the British classical economists, such as David Ricardo and Thomas Malthus, who followed him, for he implied that – at least in an advancing nation – the wage level would have to be above subsistence to permit the population to grow enough to supply the additional workers needed. Ricardo maintained a more rigid view. He wrote that the 'natural price' of labor was the price necessary to enable the laborers to subsist and to perpetuate the race without increase or diminution. Ricardo's statement was consistent with the Malthusian theory of population, which held that population adjusts to the means of supporting it. The market price of labor could not vary from the natural price for long:- if wages rose above subsistence, the number of workers would increase and bring the wage rates down; if wages fell below subsistence, the number of workers would decrease and bring the wage rates up. At the time that these economists wrote, most workers were actually living near the subsistence level, and population appeared to be trying to outrun the means of subsistence. The subsistence theory seemed to fit the facts; and, although Ricardo said that the natural price of labor was not fixed and might be changed if custom and habit moderated population increases in relation to food supply and other items necessary to maintain labor, later writers tended to subscribe to the basic idea and not to admit exceptions. Their inflexible and inevitable conclusion earned the theory the name 'iron law of wages'. Wages-Fund Theory:- Smith said that the demand for labor could not increase except in proportion to the increase of the funds destined for the payment of wages. Ricardo maintained that an increase in capital would result in an increase in demand for labor. Statements such as these foreshadowed the wages-fund theory, which held that a predetermined fund of wealth existed for the payment of wages. The size of the fund could be changed over periods of time, but at any given moment the amount was fixed, and the average wage could be determined simply by dividing the fund by the number of workers.

Smith thought of the fund as surplus income of wealthy men – beyond the needs of their families and trade – which they would use to employ others. Ricardo thought of it in terms of capital – food, clothing, tools, raw materials, machinery, etc, necessary to give effect to labor. Regardless of the makeup of the fund, the obvious conclusion was that when the fund was large in relation to the number of workers, wages would be high. When it was relatively small, wages would be low. If population increased too rapidly in relation to food and other necessities (as outlined by Malthus), wages would be driven to the subsistence level. Therefore, it would be to the advantage of labor to help promote the accumulation of capital to enlarge the fund rather than to discourage it by forming labor organizations and making exorbitant demands. Also, it followed that legislation designed to raise wages would not be successful, for, with only a fixed fund to draw upon, increases gained by some workers could be maintained only at the expense of others. This theory was generally accepted for 50 years by economists, including such well-known figures as Nassau William Senior and John Stuart Mill, William Thomas Thornton, Francis Davy Longe, and Francis A. Walker were largely responsible for discrediting the theory during the decade following 1865. They pointed out that the demand for labor was not determined by a fund but was derived from the consumer demand for products. The proponents of the wages-fund doctrine had been unable to prove that there was a determinate wage fund, or any fund maintaining a predetermined relationship with capital or with the portion of the proceeds of labor's product paid out in wages. Actually the amount paid out depended upon a number of factors, including the bargaining power of labor. Yet, in spite of these telling criticisms, the wages-fund theory continued to exercise an important influence until the end of the XIX century. Marxian Surplus-Value Theory:- Karl Marx accepted Ricardo's labor theory of value, but he subscribed to a subsistence theory of wages for a different reason than that given by the classical economists. In Marx's mind, it was not the pressure of population that drove wages to the subsistence level but rather the existence of a large army of unemployed, which he blamed on the capitalists. He stated that the exchange value of any product was determined by the amount of labor time socially necessary to create it. He held that under the capitalistic system, labor was merely a commodity and could get only its subsistence. The capitalist, however, could force the worker to spend more time on his job than was necessary to earn his subsistence, and the excess product, or surplus value, thus created, was taken by the capitalist. From the point of view of classical theory, Marx's argument appeared persuasive, although the term 'Labor Time Socially Necessary' hid some serious objections. The fatal blow came when the labor theory of value and Marx's subsistence theory of wages were found to be invalid. Without them, the surplus-value theory collapsed. Residual-Claimant Theory:- the residual-claimant theory holds that, after all other factors of production have received their share of the product, the amount left goes to the remaining factor. Adam Smith implied such a theory for wages, since he said that rent would be deducted first and profits next. Francis A. Walker in 1875 worked out a residual theory of wages in which the shares of the landlord, capitalist, and entrepreneur were determined independently and subtracted, thus leaving the remainder for labor in the form of wages. It should be noted, however, that any of the factors of production may be selected as the residual claimant, assuming that independent determinations may be made for the shares of the other factors. It is doubtful, therefore, that such a theory has much value as an explanation of wage phenomena. Bargaining Theory:- the bargaining theory of wages holds that wages, hours, and working conditions are determined by the relative bargaining strength of the parties to the agreement. Smith hinted at such a theory when he noted that employers had greater bargaining strength than employees, because it was easier for employers to combine in opposition to employees' demands and also because employers were financially able to withstand the loss of income for a longer period than the employees. This idea was developed to a considerable extent by John Davidson, who argued, in 1898, that the determination of wages is an extremely complicated process involving numerous influences that interact to establish the relative bargaining strength of the parties. There is no one factor or single combination of factors that determines wages, and there is no one rate that necessarily prevails. Because there are many possibilities, there is a range of rates within which any number of rates may exist simultaneously. The upper limit of the range is set by the rate beyond which the employer refuses to hire certain workers. This rate is influenced by such considerations as the productivity of the workers, the competitive situation, the size of the investment, and the employer's estimate of future business conditions. The lower limit of the range is set by the rate below which the workers will not offer their services to the employer. This rate is influenced by such considerations as minimum wage legislation, the workers' standard of living, their appraisal of the employment situation, and their knowledge of rates paid to others. Neither the upper nor the lower limit is fixed, and either may move upward or downward. The rate or rates within the range are determined by relative bargaining power. The bargaining theory is very attractive to labor organizations, for, contrary to the subsistence and wages-fund theories, it provides a very cogent reason for the existence of unions. The bargaining strength of a union is much greater than that of the members acting as individuals. Also there are situations (bilateral monopoly, for instance) under which theoretical analysis arrives at a range of wage rates rather than a determinate rate. The actual rate must depend upon relative bargaining power. It should be observed, however, that historically labor was able to improve its situation before its bargaining power became more effective through organization. Factors other than the relative bargaining strength of the parties must have been at work. The bargaining theory often gives an excellent explanation of a short-run situation, such as the existence of certain wage differentials, but over the long run it fails to provide an adequate understanding of the changes that have taken place in the average level of wages. Marginal-Productivity Theory And Its Critics:- toward the end of the XIX century, marginal-productivity analysis was applied not only to labor but to other factors of production as well. It was not a new idea as an explanation of wage phenomena, for Smith had observed that a relationship existed between wage rates and the productivity of labor, and Johann Heinrich von Thünen, a German economist, had worked out a marginal-productivity type of analysis for wages in 1826. The Austrian economists made important contributions to the marginal idea after 1870; and, building on these grounds, a number of economists in the 1890s, including Philip Henry Wicksteed in England and John Bates Clark in the United States, elaborated the idea into the marginal-productivity theory of distribution. It is likely that the disturbing conclusions drawn by Marx from classical economic theory inspired this development. In the early 1930s refinements to the marginal-productivity analysis, particularly in the area of monopolistic competition, were made by Joan Robinson in England and Edward H. Chamberlin in the United States. As applied to wages, the marginal-productivity theory holds that employers will tend to hire workers of a particular type until the addition made by the last (marginal) worker to the total value of the product is equal to the addition to total cost caused by the hiring of one more worker. The wage rate is established in the market through the demand for, and supply of, the type of labor, and the operation of competition assures the workers that they will receive a wage equal to the marginal product. Under the law of diminishing marginal productivity, the contribution of each additional worker is less than that of his predecessor, but workers of a particular type are assumed to be alike, making them interchangeable, and any one could be considered the marginal worker. All receive the same wage, and, therefore, by hiring to the margin, the employer maximizes his profits. As long as each additional worker contributes more to total value than he costs in wages, it pays the employer to continue hiring. Beyond the margin, additional workers would cost more than their contribution and would subtract from attainable profits. The theory also provides an explanation of wage differentials. Wage differentials are caused by differences in marginal product. The wages of skilled workers are higher than those of unskilled workers because there are fewer skilled workers, and their marginal product, therefore, is higher. The marginal-productivity theory of wages became the prevailing wage theory, and, although it has been attacked by many and discarded by some, no acceptable alternative has been devised. The chief basis for criticism of the theory is that it rests on unrealistic assumptions, such as the existence of homogenous groups of workers whose knowledge of the labor market is so complete that they will always move to the best job opportunities. Workers are, in fact, not homogenous; usually they have little knowledge of the labor market; and because of home ties, seniority, and other considerations, they do not often move quickly from one

job to another. The assumption that employers are able to measure productivity accurately and compete freely in the labor market also is farfetched. Even the assumption that all employers attempt to maximize profits may be doubted. The profit motive does not affect charitable institutions or government agencies. For the theory to operate properly, labor and capital must be fully employed so that increased production can be secured only at increased cost; capital and labor must be easily substitutable for each other; and the situation must be completely competitive. Obviously these assumptions do not fit the real world, and some critics feel that the results of the theory are so misleading that the theory should be abandoned. The proponents argue, however, that productivity gives a rough approximation of wages, and that although productivity may not provide the immediate explanation in a particular case, it certainly indicates long-run trends. The theory, therefore, has important uses, and if the difficulties are kept in mind, it can be a valuable tool. In a modern economy, monopolistic or near monopolistic conditions exist in some important areas, particularly where there are only a few large producers (such as in the automobile industry) on one side of the bargaining table and powerful labor organizations on the other. Under such circumstances, the marginal productivity analysis cannot determine wages precisely; it can show only the positions that the union (as a monopolist of labor supply) and the employer (as a monopsonist, or single purchaser of labor services) will strive to reach, depending upon their current policies. Purchasing-Power Theory:- the purchasing-power theory of wages involves the relation between wages and employment and the business cycle and is not, therefore, a theory of wage determination. It stresses the importance of spending through consumption and investment as an influence upon the activity of the economy. The theory gained prominence during the Great Depression of the 1930s, when it became apparent that lowering wages might not increase employment as previously had been assumed. John Maynard Keynes, the British economist, maintained in his General Theory of Employment, Interest and Money (1936), that (1) depressional unemployment could not be explained merely by frictions in the labor market that interrupted the smooth movement of the economy toward full employment equilibrium and (2) the assumption that 'all other things remained equal' presented a special case that had no real applicability to the existing situation. Keynes related changes in employment to changes in consumption and investment, and he pointed out that stable equilibrium could exist with less than full employment. Because wages make up such a large percentage of the national income, changes in wages usually have an important effect upon consumption. It is possible that lowering wages will reduce consumption and that, with the decline in demand for goods and services, the demand for labor may also fall, thus decreasing employment rather than improving it. Whether this will be the result, however, depends upon several considerations, particularly the reaction upon prices. If wages fall more rapidly than prices, labor's real wages will be drastically reduced, and consumption will fall, accompanied by increased unemployment, unless total spending is maintained by increased investment. Entrepreneurs may look upon the lower wage costs in relation to prices as an encouraging sign toward greater profits, in which case they may increase their investments and employ more people at the lower rates, thus maintaining or even increasing total spending and employment. If employers look upon the falling wages and prices as an indication of further declines, however, they may contract their investments or do no more than maintain them. In this case, total spending and employment will decline. If wages fall less rapidly than prices, labor's real wages will increase, and consumption may rise. If investment is at least maintained, total spending in terms of constant dollars will increase, thus improving employment. If entrepreneurs look upon the shrinking profit margin as a danger signal, however, they may reduce their investments; and, if the result is a reduction in total spending, employment will fall. If wages and prices fall the same amount, there should be no change in consumption and investment; and, in that case, employment will remain unchanged. The purchasing-power theory involves psychological considerations as well as those that may be measured more objectively. Whether it can be used effectively to control the business cycle depends upon political as well as economic factors, because government expenditures are a part of total spending, taxes may affect private spending, etc. The applicability of the theory is to the whole economy rather than to the individual firm. WAGE AND TAX STATEMENT = ОТЧЁТ О ЗАРАБОТНОЙ ПЛАТЕ И НАЛОГАХ – Wage And Tax Statement:- most commonly referred to as a W-2. This form shows the amount of an individual's earnings and deductions.

WAGE ASSIGNMENT = ПЕРЕУСТУПКА ЗАРАБОТНОЙ ПЛАТЫ (или УСТУПКА ЗАРАБОТНОЙ ПЛАТЫ) – Wage Assignment is the procedure of taking money directly from an employee's compensation under the authority of a court order, in order to pay a debt obligation. Wage assignments are typically a last resort of a lender to receive repayment from a borrower who has previously failed to pay their debt obligation. Typical reasons for a wage assignment may be items such child support payments, court fines and taxes that have gone unpaid for a prolonged period of time. Once mandated by a court and served to an employer, wage assignments are processed as part of an employer's payroll procedure – the employee's regular paycheck is decreased by the amount of the assignment and noted on their pay stub. Employees may sometimes be able to voluntarily undergo wage assignment to pay for things like union dues or contribute to a retirement fund. Wage Assignment is a transfer of the right to receive wages, ordinarily effected by means of a contract. As such, wage assignments are not within the scope of the federal wage garnishment law. For purposes of this order, however, wages have been defined based on the federal wage garnishment law. Wages are defined as earnings or compensation paid for personal services whether called wages, salary, commission, bonus, or otherwise, and can include periodic payments under a pension or retirement program. (Title III, Section 302, PL 90-321) When required, withholdings shall be determined using the calculation sheet from SCAO-Approved form MC 14 (Garnishee Disclosure). Note:- SCAO is abbreviation for The State Court Administrative Office. Wage Assignment is the voluntary transfer in advance of a debtor's pay, generally in connection with a particular debt or judgment. A debtor may negotiate with a creditor a wage assignment plan in which a portion of the debtor's paycheck is transferred to the creditor by the employer. This voluntary agreement is in contrast to garnishment, in which a creditor obtains an order from the court to collect part of a debtor's wages from the employer. Both wage assignments and garnishment are governed by statutes in most states. A wage assignment is similar to an Assignment for Benefit of Creditors, in which the debtor assigns Personal Property to a trustee. Typically, the trustee sells the property and applies the proceeds to the debt. Any amount in excess of the debt is returned to the debtor. Since the 1980s wage assignments have become an important method of making Child Support payments in the United States. In 1984 the federal government required all states to implement child support guidelines for Welfare recipients. As time passed, those guidelines were implemented across the board in all cases involving child support. While a wage assignment has typically been viewed as a Voluntary Act by the assignee, courts now issue wage assignment orders directing employers to withhold child support payments and send the funds to a designated recipient such as a custodial parent, the court, or a state agency. Although the paying parent may be a responsible individual who would never miss a payment, and the recipient parent may honestly report all payments received, the wage assignment eliminates potential conflict by using a neutral third party to implement the paying and

reporting of payments. Employers generally do not impute bad character to an employee paying child support through a wage assignment, and the courts routinely issue orders without finding fault. Wage assignment orders are appropriate for salaried employees but do not work effectively for self-employed individuals or people in cash businesses. A wage assignment may also be used when an employee obtains a loan from his employer and wants to repay the loan by having the employer withhold money from future paychecks. An employer who lends an employee a sum of money cannot take it out of the employee's next paycheck without a proper, written, notarized assignment from the employee. State statutes require that legal formalities be followed, or the withholding of money can be considered an unlawful assignment of wages. Wage Assignment:- a loan agreement provision allowing the lender to deduct payments from an employee's wages in case of default. Wage Assignment:- when you owe money to a creditor, such as a mortgage lender or a credit card company, one of the standard methods of collection is a wage assignment. However, you don't want to get this confused with a wage garnishment, which is entirely different. A wage assignment is voluntary, and can be revoked at any time. When you take out a loan or begin a line of credit, you may be asked to fill out a wage assignment form, which is separate from the loan contract you signed. This form gives the creditor permission to remove a specific portion of your paycheck through your employer each pay period when you become delinquent. You don't have to fill out the form your sign your name, and if you don't, they can't use that method of collection. When you sign a wage assignment form, the creditor has the right to a portion of your wages if you ever become delinquent by at least forty days. Some of these forms give you sixty or ninety days to make good on what you owe, but the law requires that they wait no less than forty. If you do, they will provide the form to your employer and he will be obligated to take that money from your paycheck. A wage assignment is different from a wage garnishment, as mentioned above, because you have a choice in the former. If you don't sign the form, the creditor will have to pursue other methods of collection. With a wage garnishment, a court order compels your employer to withhold part of your earnings, and you have no say in how and when it goes into effect. If a wage assignment is activated and you don't think that you can survive on your remaining paycheck, you can stop the order by notifying your creditor in writing. Simply mail a letter by certified mail (return receipt requested) that tells them to stop the wage assignment on your account immediately. Sign and date it, and make sure to provide any relevant identifying information, such as your account number and date of birth. You should also provide a similar letter to the human resources department of your employer. Provide a copy of the letter you mailed to your creditor, and let them know that you have revoked the wage assignment from here on. This should keep them from deducting from your paycheck on subsequent pay periods, and should be effective immediately. The laws concerning wage assignments differ depending on where you live. If this is something you are currently dealing with, contact an attorney or your creditor to learn more about your options. Xxxxx. A Wage Assignment is a deduction from an employee's pay, which may be used to pay off debts, or to pay child or spousal support. Some loans stipulate to a wage assignment should they fail to make prompt payments to pay off the loan. In this case, if the loan is not repaid, money is deducted from an employee's paycheck, either a specific sum or a percentage of earnings to collect debts owed. There are two wage assignment types. One is voluntary, when an employee specifically asks his or her employer to deduct a portion of his/her wages to be paid to a designated third party. This is often easier for people than remembering to write important checks for loans or child support, or for things like payments of back taxes. The voluntary wage assignment tends not to reflect poorly on the employee, since it shows the employee is making a true effort to repay a loan or to honor financial obligations to others. The second type of wage assignment is involuntary. It can also be called Wage Garnishment. This second type may occur when a person refuses to pay debts or agreed upon payments to a third party. Wage assignments of this second type may need to be honored by employers and may be requested by court order. Again, amounts can vary depending upon the financial obligations of the employee. Some wage assignments that are involuntary take a percentage of a paycheck, almost all of the paycheck, or a set amount. If an employee's earnings increase or decrease, third parties may receive more or less money when the assignment is based on percentage. If you do have to make a set payment, such as child support, creating a voluntary wage assignment is not a bad way to go. An involuntary assignment or garnishing of the paycheck suggests you may not be trustworthy or be able to live up to your obligations. It implies, even when this is not the case, that you have specifically resisted paying your debts, or worse, paying child support or spousal support. This can reflect on the employee's character and might determine your future in a company. Some individuals, if they have lots of debt, may have more than one wage assignment on a paycheck. Governments usually set a priority of which debts must be first addressed. If there is adequate money to cover all debt, the employee may still be able to make voluntary wage assignments, though some employers do charge for this extra service. When the assignment is involuntary, generally companies must comply with any mandated assignments, in the order in which the government determines. Where there is one income supporting a person, the wage assignment usually can't remove all the money you make. Most assignments have to allow an employee to collect a subsistence income, unless that employee voluntarily assigns his/her wages in a different manner. Xxxxx. Wage Assignments are like a payment plan:- (i) Voluntary option. (ii) Total amount owed is USD300 or more and is set by the judge or magistrate. (iii) The documentation that is needed for a payment plan is also needed for a wage assignment. (iv) Defendants who receive Supplemental Security Income (SSI), disability, or unemployment are not eligible for a wage assignment. Their only option is a payment plan. (v) Need the last four digits of the defendant's social security number which is located on the financial statement. (vi) Need employer information. (vii) Indicate amount per check to be withheld per pay period based on employer's payroll cycle. (viii) Payment amount is based on defendant's financial statement – income versus expenses, without exceeding their budget. (ix) A note can be made to the Register of Actions (ROA) or file of the defendant that a wage assignment has been issued. List the employer's name and the amount per check to be withheld. Per a decision by our local judges, this court prints three copies:- (i) the Original is signed by the sentencing judge to be put in defendant's file; (ii) Copy 1 is stamped with the judge's signature and mailed to the defendant/employee; and (iii) Copy 2 is stamped with the judge's signature and mailed to the employer. Once the original has been signed by the judge, a copy is made and used to track payments. Form is printed on the back of the wage assignment copy that is used for tracking purposes. Fill in employer information, phone number, and a contact person. As payments are made, list amount paid and the date payment was received. The file is extended out 3 weeks from the date the wage assignment became effective. A note is made on paper calendar 3 weeks out to review for initial first payment from the employer. If payment is not received within 3 weeks, the employer is contacted. As payments are made, the due date is extended out for the next payment due date based on the employer's payroll cycle. A calendar (like the calendar used for payment plans), is generated to monitor and review payment history. A paper calendar or a spreadsheet will work in the same manner for tracking and monitoring payments. Employer receives a copy of the wage assignment with a total amount due to the court. Employer is obligated to withhold funds from employee/defendant's paycheck until total amount due is paid in full or otherwise notifies the court that employee was terminated or quit. A note can be made to the ROA or file of the defendant that the wage assignment has been terminated. / Переуступка Заработной Платы – условие кредитного соглашения, принятое в некоторых штатах, которое позволяет кредитору вычитать причитающиеся ему платежи непосредственно из заработной платы работника в случае неплатёжеспособности (default) последнего.

WAGE DIFFERENTIAL = ДИФФЕРЕНЦИАЛ ОКЛАДОВ (или РАЗЛИЧИЕ В ОКЛАДАХ) – Wage Differential refers to differences in wage rates due to the location of company, hours of work, working conditions, type of product manufactured, or other factors. It may be the difference in wages between workers with different skills working in the same industry or workers with similar skills working in different industries or regions. For example, wage differentials may also be used to compare wages between genders, union and non-union jobs, or wages of employees with and without college degrees. Wage Differential:- differences in wages arising between

individuals, occupations, industries, firms and regions. Wage Differential:- the difference in wages between workers with different skills in the same industry or between those with comparable skills in different industries or localities. / Дифференциал Окладов или Дифференциальные Ставки Окладов:- различие в окладах работников одинаковой квалификации, на работающих в разных отраслях, или работников различной квалификации, занятых в одной отрасли. Может существовать также разница в окладах между городскими и сельскохозяйственными рабочими или рабочими, работающими в разных регионах (в Великобритании наиболее высокие оклады выплачиваются на Юго-Востоке, где самая высокая стоимость жизни). Акт о Равной Оплате 1970 запретил различия в заработной плате мужчин и женщин, выполняющих одинаковую работу и имеющих одинаковую квалификацию.

WAGE DRIFT = СДВИГ В ОКЛАДАХ (или ОТКЛОНЕНИЕ ОКЛАДОВ) – Wage Drift is defined as the differential amount by which the wages paid to a worker exceeds the previously negotiated amount of wage, collectively agreed upon. The main reason for this occurring is the worker having worked for extended durations (excess overtime wages) or the ambient economic condition resulting in a shortage of worker availability. In the latter case, an employed worker will receive wages higher than the national wage rate. In the field of human resources, wage drift poses a real problem for HR managers to precisely predict and fix wages, the reason being the factors causing wage drift mostly lies beyond the control of the recognised procedure of scheduling wages. The mechanism of wage drift has two possible ways of occurrence. Firstly, when the earnings increase beyond the agreed upon terms, a worker's earnings between two successive raises may increase without any change in the degree of utilisation of his labor. Or, secondly, the earnings may remain constant but his labor may be underutilised. When earnings increase faster than labor inputs, unit labour cost to the company will increase irrespective of the cause being a wage drift or not. Wage Drift is the tendency for the average level of wages paid to rise faster than official wage rates. This is due to increases in overtime, or upgrading of job descriptions. Wage Drift:- the difference in a worker's basic locally-negotiated wage when it exceeds the level stated by nationally negotiated wage agreements. The increase is due to benefits such as overtime, bonus payments, stock options, etc. It's the result of ad hoc arrangements distorting expected outcomes from nationally agreed wage settlements.settlements. Wage Drift is a situation in which the average level of pay increases faster than official rates of pay. Wage Drift is the amount by which the wage or salary of a worker or group of workers exceeds a previously negotiated agreement. Wage drift may occur, for example, if an employee is asked to work unexpected overtime or if persons in a region are offered wages higher than the national rate during a labor shortage. Wage Drift is the tendency for the average level of wages actually paid to rise above wage rates through increases in overtime and other factors. Wage Drift:- the propensity for employees' actual earnings to rise faster than increases in their Wage Rate. This tends to occur when there is full employment or when there are labor shortages in particular labor markets, and often results from informal bargaining between workers, their representatives (Shop Stewards) and managers supplementing formal Collective Bargaining. It was considered to be a widespread problem in the UK in the 1960s and contributed to the decision to create a Royal Commission to investigate the state of UK Industrial Relations. / Сдвиг Окладов или Отклонение Окладов – отклонение фактических окладов от расчётных ставок окладов; различие между реально выплачиваемым окладом и расчётной ставкой оклада, возникающее в результате оплаты сверхурочной работы и выплаты бонусов. В периоды замораживания окладов (wage freeze) работодатели могут обходить замораживание путём выплаты бонусов и оплаты сверхурочной работы, сводя на нет антиинфляционный эффект замораживания.

WAGE FREEZE = ЗАМОРАЖИВАНИЕ ОКЛАДОВ – Wage Freeze is an occasion when a company or government sets the amount paid to workers and will not allow any increases. Wage Freeze:- government's attempt to slow a push for wages by keeping wages stable with a law. Wage Freeze is attempt by a government to restrain wage-push inflation by holding wages at their existing level by force of law. / Замораживание Окладов:- попытка правительства обуздать инфляцию путём фиксирования окладов на существующем уровне на определённый период. По различным причинам, включая отклонение окладов (wage drift), эта мера в настоящее время не считается эффективной.

WAGE GARNISHMENT = УДЕРЖАНИЕ ИЗ ЗАРАБОТНОЙ ПЛАТЫ – Wage Garnishment is a legal procedure in which a person's earnings are required by court order to be withheld by an employer for the payment of a debt such as child support. Title III of the Consumer Credit Protection Act (CCPA) prohibits an employer from discharging an employee whose earnings have been subject to garnishment for any one debt, regardless of the number of levies made or proceedings brought to collect it. Title III protects employees from being discharged by their employers because their wages have been garnished for any one debt and limits the amount of employees' earnings that may be garnished in any one week. An employee is only protected from discharge if the employee's earnings have been subject to garnishment for the first time. Title III applies to all individuals who receive personal earnings and to their employers. Personal earnings include wages, salaries, commissions, bonuses, and income from a pension or retirement program, but does not ordinarily include tips. For ordinary garnishments (i.e. those not for support, bankruptcy, or any state or federal tax), the weekly amount may not exceed the lesser of two figures:- 25 percent of the employee's disposable earnings, or the amount by which an employee's disposable earnings are greater than 30 times the federal minimum wage. Specific restrictions apply to court orders for child support or alimony. The garnishment law allows up to 50 percent of a worker's disposable earnings to be garnished for these purposes if the worker is supporting another spouse or child, or up to 60 percent if the worker is not. An additional 5 percent may be garnished for support payments more than 12 weeks in arrears. The wage garnishment law specifies that the garnishment restrictions do not apply to certain bankruptcy court orders, or to debts due for federal or state taxes. If a state wage garnishment law differs from the federal law, the law resulting in the smaller garnishment must be observed. See also Garnishment.

WAGE INDEXATION = ИНДЕКСАЦИЯ ОКЛАДА – Wage Indexation (for pension benefits):- the method with which pension benefits are adjusted taking into account changes in wages.

WAGE–PRICE CONTROL = КОНТРОЛЬ НАД ОКЛАДАМИ (или ЗАРАБОТНЫМИ ПЛАТАМИ) И ЦЕНАМИ – Wage-Price Control:- setting of government guidelines for limiting increases in wages and prices. It is a principal tool in incomes policy.

WAGE–PRICE SPIRAL = СПИРАЛЬ ЦЕНЫ ЗАРАБОТНОЙ ПЛАТЫ – A Wage-Price Spiral is an economic term that describes how prices increase when wages increase. How It Works (Example):- The general idea behind a wage-price spiral is a simple one of supply and demand. People can do only two things with money:- save it or spend it. If they have more money on hand, they likely will spend at least some of that money. Accordingly, putting more money in people's hands creates more demand for goods and services. Thus, something like a wage increase across the board (think, for example, of a rise in the minimum wage) creates more demand for goods and services and drives up the prices of those goods and services. In turn, goods and services eventually begin to look expensive to people, so they lobby for higher wages. The higher wages put more money in their hands, which in turn drives the prices of goods and services even higher. Why It Matters:- the wage-price spiral is a central part of many economic controversies and is a big part of Keynesian economic theory. Often, arguments against raising wages or for limiting the wage power of unions incorporate these ideas. Note too that the increased demand for goods and services can trickle across borders, driving up prices in countries that do not have increasing wages. Also called Cost-Push Inflation. Wage Price Spiral:- feedback loop in which wage hikes due to inflation cause companies to raise prices, and those rising prices lead to demand for further wage increases, perpetuating the cycle. The Wage-Price

Spiral is a macroeconomic theory used to explain the cause-and-effect relationship between rising wages and rising prices, or inflation. The wage-price spiral suggests that rising wages increases disposable income, thus raising the demand for goods and causing prices to rise. Rising prices cause demand for higher wages, which leads to higher production costs and further upward pressure on prices, creating a conceptual spiral. Wage-price spiral is an economic term that describes how prices increase when wages increase. It's a phenomenon that occasionally occurs when the general prices for goods and services increase, causing workers to demand a wage hike. The wage increase effectively increases general business expenses that are passed on to the consumer in the form of higher prices. It's essentially a loop or cycle that perpetuates itself by consistent prices increases. The wage-price spiral deals with the causes and consequences of inflation, and it is therefore most popular in Keynesian economic theory. It is also known as the Cost-Push origin of inflation. Another cause of inflation is known as Demand-Pull Inflation, which monetary theorists believe originates with the money supply. How a Wage-Price Spiral Begins:- a wage-price spiral is a simple matter of the effect of supply and demand on aggregate prices. People who make income above their cost of living usually decide on an allocation mix between savings and consumer spending. As wages increase, so too does a consumer's propensity to both save and consume. If the minimum wage of an economy increased, for example, it would cause consumers within the economy to purchase more product, increasing demand. The lift in aggregate demand and the increased wage burden causes businesses to increase the prices of products and services. Even though wages are higher, the increase in prices causes workers to naturally demand even higher wages. If the higher wages are granted, it will start a spiral where prices subsequently increase, repeating the cycle until wage levels can no longer be supported. Stopping a Wage-Price Spiral:- governments and economies like to have stable inflation – or price increases. A wage-price spiral often makes inflation increase higher than is ideal. Governments have the option of stopping this inflationary environment through the actions of the Federal Reserve or central bank. A country's central bank can use monetary policy, by way of the interest rate, reserve requirements or open market operations, to curb the wage-price spiral. However, the United States has done this in the past and actually caused a recession. The 1970s was a time of oil price increases by OPEC that resulted in increased domestic inflation. The Fed responded by raising interest rates to control inflation, stopping the spiral in the short-term but acting as the catalyst for a recession in the early 1980s. / Спираль роста заработной платы и цен.

WAGE PUSH INFLATION = ИНФЛЯЦИЯ, ПОДТАЛКИВАЕМАЯ ЗАРАБОТНОЙ ПЛАТОЙ – Wage Push Inflation is economic concept which attributes higher prices to higher labor costs passed on to the consumers by the producers. See also Cost-Push Inflation, Demand-Pull Inflation, and Inflation. WAGE RATE = СТАВКА ОКЛАДА (или ТАРИФНАЯ СТАВКА, или СТАВКА ЗАРАБОТНОЙ ПЛАТЫ) – Wage Rates measure the basic remuneration per time unit or unit of output. Although the Resolutions of the 12th International Conference of Labour Statisticians (ICLS, 1973) does not contain a specific definition of 'Wages' as such, it recommends the compilation of wage rate statistics which should include basic wages, cost-of living allowances and other guaranteed and regularly paid allowances, but exclude overtime payments, bonuses and gratuities, family allowances and other social security payments made by employers. Ex gratia payments in kind, supplementary to normal wage rates, are also excluded. Wage rate data should relate to an appropriate time period – hour, day, week or month. Wage rates may be viewed from the perspective of a 'price' of labor services. In a number of OECD Member countries wage rates are determined by law or regulation through collective bargaining agreements, etc. The statistics compiled on these award rates (which are generally minimum or standard rates) are clearly distinguished from statistics referring to wage rates actually paid to individual workers. The term 'Average Collectively Agreed Pay' is used in many countries, particularly in relation to the collection bargaining processes used for setting rates of pay. However, as would be expected, there is no internationally agreed definition of the concept and national definitions, particularly with respect to the wage components included, are determined on the basis of the current industrial relations institutional framework within each country. Furthermore, in some OECD Member countries the evolution to more decentralized enterprise based bargaining has meant the loss of economy-wide or industry-wide indicators of the outcomes of collective bargaining. Wage Rate is a rate of pay based on per unit of production or per period of worktime on the job. Wage Rate is the the amount of base wage paid to a worker per unit of time (as per hour or day) or per unit of output if on piecework. See also Wage (1). / Тарифная Ставка – фиксированный размер оплаты труда работника за выполнение нормы труда определённой сложности (квалификации) за единицу времени без учёта компенсационных, стимулирующих и социальных выплат. Оклад (Должностной Оклад) – фиксированный размер оплаты труда работника за исполнение трудовых (должностных) обязанностей определённой сложности за календарный месяц без учёта компенсационных, стимулирующих и социальных выплат. Базовый Оклад (Базовый Должностной Оклад), базовая ставка заработной платы – минимальные оклад (должностной оклад), ставка заработной платы работника государственного или муниципального учреждения, осуществляющего профессиональную деятельность по профессии рабочего или должности служащего, входящим в соответствующую профессиональную квалификационную группу, без учёта компенсационных, стимулирующих и социальных выплат.

WAGE RESTRAINT = ОГРАНИЧЕНИЕ РОСТА ОКЛАДОВ – Wage Restraint is an agreement between an employee and an employer not to demand wage or salary increases. Wage restraint may occur when a company is facing losses or lower profits and needs to live within its means. The employee may receive concessions (such as better health insurance) in exchange for wage restraint. See also Wage Freeze. Wage Restraint is an agreement not to demand or pay large wage increases. Wage Restraint:- the act of reducing the rate of increase in the amount that workers earn, or something that is done to achieve this reduction. Economists predict wage restraint will keep inflation low for some time. Wage Restraint is the act of keeping increases in wages under control. / Ограничение Роста Окладов представляет собой менее жёсткую меру контроля над ценами и достигается путём заключения с профсоюзом соглашения о том, что профсоюз ограничится только умеренными и обоснованными требованиями повышения окладов. WAGERING CONTRACT = РОЗЫГРЫШНЫЙ КОНТРАКТ (или КОНТРАКТ–ПАРИ) – Wagering Contract is a contract by which a promisor agrees that upon the occurrence of an uncertain event or condition he or she will render a performance for which there is no agreed consideration exchanged, and under which the promisee or the beneficiary of the contract is not made whole for any loss caused by such occurrence (as in options, insurance contracts, trading in futures, or betting contracts). Wagering Contract is a contract which is of the nature of wager. Contracts of this nature include various common forms of valid commercial contracts, as contracts of insurance, contracts dealing in futures, options, etc. Other wagering contracts and bets are now generally made illegal by statute against betting and gambling, and wagering has in many cases been made a criminal offence. A Wagering Contract is one by which two persons, professing to hold opposite views touching the issue of a future uncertain event, mutually agree that, dependent on the determination of the event, one shall win from the other, and that other shall pay or hand over to him, a sum of money or other stake; neither of the parties having any other interest in that contract than the sum or stake he will so win or lose, there being no other consideration for making of such contract by either of the parties. If either of the parties may win, it is not a wagering contract. Wagering contract in different countries and comparison with English law:- the great majority of common law jurisdictions have adopted

gaming laws based on the gaming law on the UK gaming act 1845. Legislation in all Australian jurisdictions (for example) is based on section 18 of the gaming act, which provides that the contracts by way of wagering and gaming are null and void. The gaming and wagering laws of Malaysia, Honk Kong and New Zealand are also modeled after the UK gaming act. Until the enactment of the gaming act of 1845, wagering agreements were not prohibited by law of England. But section 18 of the act declared that contracts and agreements by way of wager shall be null and void and that no suit shall be brought or maintained by any court of law and equity for recovering any sum of money or valuable thing alleged to be won upon any wager. However, certain dealings in investments by way of business are accepted from invalidity under section 18 even though they might amount to wagering contracts, e.g., contracts for differences or bets on stock market indices. Section 30 of the contract act 1872 is influenced by the English gaming act 1845. Heavily influenced by the English decisions, the judges have adopted the essential features of that of the gaming act, however there is a major difference between the English and the Bangladeshi laws relating to wagers, under the English gaming act, agreements collateral to the wagering agreement are also rendered to be void, 38 whereas in Bangladesh collateral agreements are not necessarily void. A number of Indian companies at loses in foreign exchanges dealings, construct an argument that derivative transactions are in the nature of wagering arguments, and are hence not enforceable in Indian courts under section 21, and hence don't give rise to any liability or financial obligations in respect of repayment of loan to the bank. As a result of this, many prudent Indian banks such as the State Bank of India refrained from entering into any sort of derivative transactions with their clients for a very long time. See also Gaming Contract. Gaming Contract is a contract in which participants agree to play a game of chance. For example, if two friends make a bet on who will win the World Series, they have entered a gaming contract and the loser is obliged to pay the winner the agreed-upon amount. However, a gaming contract may not be enforceable in a jurisdiction where gambling is illegal. / Контракт-Пари или Розыгрышный Контракт (Wagering Contract):- . WAGERING POLICY = РОЗЫГРЫШНЫЙ ПОЛИС – Wagering Policy is a policy of insurance in which the insurer has no insurable interest. A contract of insurance in which the owner of the policy has no beneficial interest in the subject matter of the insurance is a speculative or wagering contract and in which such person has an interest only in the loss or destruction of the property, Westfall v American States Insurance Co., 334 N.E.2d. 523, 43 Ohio App.2d. 176; and where it is a policy of life insurance, the person to be benefited by the policy is interested in the death, rather than the life of the insured. Geisler v Mutual Benefit Health Accident Association, 163 Kan. 518, 183 P.2d. 853. Wagering Policy is a policy in respect of which the assured has no insurable interest. Wagering Policy is a policy effected on a ship, etc, in which the insurer has no insurable interest. See also Interest. / Гайсля (Geisler) против .

WAGES = ОКЛАДЫ (или ЗАРПЛАТЫ, или ЗАРАБОТНЫЕ ПЛАТЫ) – Wages:- cost of using labor as opposed to cost of using capital or land. As a price of labor, it is subject to the forces of demand and supply in the labor market, which in turn is affected by productivity levels and ability of the employers to substitute labor with other factors of production such as machinery. See also Wage. / Обычно под Зарплатами или Заработными Платами понимаются заработные платы производственных рабочих; денежное вознаграждение за труд работников на почасовой ставке или работающих сдельно.

WAGES AND SALARIES = ОКЛАДЫ (или ЗАРАБОТНЫЕ ПЛАТЫ) И ЖАЛОВАНЬЯ – Wages And Salaries are defined by Eurostat as 'the total remuneration, in cash or in kind, payable to all persons counted on the payroll (including homeworkers), in return for work done during the accounting period' regardless of whether it is paid on the basis of working time, output or piecework and whether it is paid regularly or not. Wages and salaries include the values of any social contributions, income taxes, etc payable by the employee even if they are actually withheld by the employer and paid directly to social insurance schemes, tax authorities, etc on behalf of the employee. Wages and salaries do not include social contributions payable by the employer. Wages and salaries include:- all gratuities, bonuses, ex gratia payments, 'thirteenth month payments', severance payments, lodging, transport, cost-of-living, and family allowances, tips, commission, attendance fees, etc received by employees, as well as taxes, social security contributions and other amounts payable by employees and withheld at source by the employer. Wages and salaries which the employer continues to pay in the event of illness, occupational accident, maternity leave or short-time working may be recorded here or under social security costs, dependent upon the unit's accounting practices. Payments for agency workers are not included in wages and salaries. See also Wage And Salary. Wages And Salaries consist of the sum of wages and salaries in cash and wages and salaries in kind. Wages and salaries include the values of any social contributions, income taxes, etc payable by the employee even if they are actually withheld by the employer for administrative convenience or other reasons and paid directly to social insurance schemes, tax authorities, etc on behalf of the employee. Wages and salaries may be paid in various ways, including goods or services provided to employees for remuneration in kind instead of, or in addition to, remuneration in cash. What is the difference between Salary and Wages? The essential difference between a salary and wages is that a salaried person is paid a fixed amount per pay period and a wage earner is paid by the hour. Someone who is paid a salary is paid a fixed amount in each pay period, with the total of these fixed payments over a full year summing to the amount of the salary. This person is considered to be an 'exempt' employee. There is no linkage between the amount paid and the number of hours worked. For example, if a person has a USD52 000 salary and he is paid once a week, then the gross amount of each of the 52 paychecks he receives during the year is USD1 000 (USD52 000 / 52 weeks). The person receiving a salary is not paid a smaller amount for working fewer hours, nor is he paid more for working overtime. Someone who is paid wages receives a pay rate per hour, multiplied by the number of hours worked. This person is considered to be a 'non-exempt' employee. For example, a person who is paid a wage of USD20 per hour will receive gross pay of USD800 (USD20/hr x 40 hours) if he works a standard 40 hour week, but will only receive gross pay of USD400 (USD20/hr x 20 hours) if he works 20 hours in a week. A person who receives wages is also entitled to overtime pay of 1.5x his normal rate of pay if he works more than 40 hours per week. There is also a difference between salary and wages in regard to the speed of payment. If a person is paid a salary, he is paid through and including the pay date, because it is very simple for the payroll staff to calculate his salary, which is a fixed rate of pay. However, if a person is paid wages, he is usually paid through a date that is several days prior to the pay date; this is because his hours may vary, and the payroll staff needs several days to calculate his pay. If a person is paid wages and there is a gap between the last day worked for which he is paid and his pay date, that gap is paid in his next paycheck. This gap does not exist for a salaried worker, since he is paid through the pay date. Thus, pay is much more likely to be accrued in a company's financial statements for a person being paid wages than for someone being paid a salary. The expression of a person's pay rate varies depending on whether that person receives a salary or wages. Thus, a person may receive a salary of USD52 000, or wages of USD25.00 per hour. Assuming a standard work year of 2 080 hours per year, the person receiving wages of USD25.00 per hour is actually earning the same gross pay as the person receiving a salary of USD52 000 (2 080 hours x USD25/hour), though the person earning a wage has the opportunity to earn overtime, and so can be considered in a better compensation situation than the person being paid a salary.

WAGES AND SALARIES IN CASH = ОКЛАДЫ (или ЗАРАБОТНЫЕ ПЛАТЫ) И ЖАЛОВАНЬЯ В НАЛИЧНОСТИ – Wages And Salaries In Cash consist of wages or salaries payable at regular weekly, monthly or other intervals, including payments by results and piecework payments; plus allowances such as those for working overtime; plus amounts paid to employees away from work for short periods, e.g., on holiday; plus ad hoc bonuses and similar payments; plus commissions, gratuities and tips received by employees.

WAGES AND SALARIES IN KIND = ОКЛАДЫ (или ЗАРАБОТНЫЕ ПЛАТЫ) И ЖАЛОВАНЬЯ В НАТУРЕ – Wages And Salaries In Kind consist of remuneration in the form of goods and/or services that are not necessary for work and can be used by employees in their own time, and at their own discretion, for the satisfaction of their own needs or wants or those of other members of their households.

WAGES COUNCIL = СОВЕТ ПО ОКЛАДАМ – Wages Council is an organization made up of employers and employees' representatives which fixes basic employment conditions in industries where places of work are too small or too scattered for trade unions to be established. Wages Council (formerly, in Britain) is a statutory body empowered to fix minimum wages in an industry; abolished in 1994. Wages Council (in the UK) is one of a number of statutory bodies, now abolished, consisting of workers' and employers' representatives responsible for determining wages in particular industries. / Совет по Окладам – Британский орган, учреждённый Актом о Совете по Окладам 1954 (Wages Councils Act 1954) и Актом об Окладах 1986 (Wages Act 1986), который устанавливал минимальные ставки окладов в определённой отрасли. Каждый такой совет состоял из представителей работодателей и работников отрасли, а также независимых представителей. Советы обычно учреждались в отраслях, в которых возможности работников в заключении коллективных трудовых соглашений относительно невелики. Акт об Окладах 1986 запретил создание новых советов по окладам.

WAGES EXPENSE = РАСХОД ПО ОКЛАДАМ – Wages Expense:- the compensation earned by hourly-paid employees during the interval of time indicated in the heading of the income statement. Under the accrual basis of accounting, the date that wages are paid does not determine when the wages are reported as an expense. Wages Expense:- this account is used when a company pays an employee for his or her work during that accounting period. Wages Expense is the houry compensation cost incurred by a business for its hourly workers. This can be one of the largest expenses incurred by a business, especially in the services and production industries where there are many hourly employees. The amount recognized as wages expense in an organization's income statement varies, depending on whether it uses the accrual basis or cash basis of accounting. Under the accrual basis, the amount of wages expense recognized is the amount earned by workers during the reporting period. Under the cash basis, the amount of wages expense recognized is the amount paid to workers during the reporting period. Wages expense may be reported separately for numerous departments of a business, but is most commonly used in the production area, where there is the greatest concentration of employees who are paid on an hourly basis. Those wages paid in the production area may be aggregated in the income statement into the cost of goods sold line item. Wages expense can vary considerably by period, depending on the amount of overtime paid. If there is overtime, the associated additional expense is usually included in the wages expense – overtime is not charged to a different expense account. Wages expense can also vary by period, due to differing numbers of work days in each month. Some months may have as few as 18 work days, while others have 23 work days, depending on the presence of holidays and the total number of days in the month.

WAGES PAYABLE = ВЫПЛАЧИВАЕМЫЕ (или К ОПЛАТЕ) ОКЛАДЫ (или ЗАДОЛЖЕННОСТЬ ПО ЗАРАБОТНЫМ ПЛАТАМ) – Wages Payable is a current liability account that records the amount of wages that are owed to employees for work that was performed by the employees in prior periods. In other words, wages payable is the amount of wages that employee hasn't paid the employees for their work. Example:- the wages payable account is usually used at the end of a period like a year-end. Many times the end of the year doesn't fall exactly at the end of a payroll period. For example, assume employees are paid every Friday and December 31 lands on a Tuesday. This means that at the beginning of the next year, January 01, the employer owes the employees two days worth of pay for the Monday and Tuesday worked in December. Since the employer pays the employees on Friday, these employees will have to wait until January 03 to get their full December wages. At the end of December, the employer owes the employees two days worth of pay, so it has to record that liability in its accounting system and present it on its financial statements. On December 31, the employer simply debits the wage expense and credits the wages payable account for the Monday and Tuesday wages. Later in January when the wages are paid, the employer would debit the wages payable account because the wages are no longer owed to the employees and credit the cash account for the amount of cash paid to the employees. Wages Payable:- this account is used to record employee compensation that has not yet been received by the employee. Wages Payable is the liability incurred by an organization for wages earned by but not yet paid to employees. The balance in this account is typically eliminated early in the following reporting period, when wages are paid to employees. A new wages payable liability is created later in the following period, if there is a gap between the date when employees are paid and the end of the period. For example, a company pays its hourly employees once a month, on the last business day of the month. In order to have sufficient time to process payroll, the payroll staff only pays wages based on hours recorded through the 26th day of the month, leaving as many as five days at month-end that will not be paid until the following monthly payroll. In March, this unpaid amount is USD25 000. The company controller records this amount as a debit to wages expense and a credit to the wages payable liability account. The entry is set up as a reversing entry, so the accounting software automatically reverses it at the beginning of the following month. The net effect of the entry is to recognize the unpaid wages as an expense in the same period in which employees earned the wages. When a business pays its employees salaries as of the end of a reporting period, there is no wages payable liability, since salary payments match the amount earned by employees through the payment date. Wages payable is considered a current liability, since it is usually payable within the next 12 months. In the rare cases where the payment is due in later than 12 months, it is classified in the balance sheet as a long-term liability. If the amount of the wages payable liability is minor, a company that only produces financial statements for internal purposes might consider not recording the liability at all during interim reporting periods. However, it may still be necessary to recognize the liability for the year-end financial statements, in order to issue more accurate audited financial statements. Wages Payable:- current liability account that reports the amounts owed to employees for hours worked but not yet paid as of the date of the balance sheet.

WAGE THEORY = ТЕОРИЯ ЗАРАБОТНОЙ ПЛАТЫ – Wage Theory:- portion of economic theory that attempts to explain the determination of the payment of labor. The subsistence theory of wages, advanced by David Ricardo and other classical economists, was based on the population theory of Thomas Malthus. It held that the market price of labor would always tend toward the minimum required for subsistence. If the supply of labor increased, wages would fall, eventually causing a decrease in the labor supply. If the wage rose above the subsistence level, population would increase until the larger labor force would again force wages down. The wage-fund theory held that wages depended on the relative amounts of capital available for the payment of workers and the size of the labor force. Wages increase only with an increase in capital or a decrease in the number of workers. Although the size of the wage fund could change over time, at any given moment it was fixed. Thus, legislation to raise wages would be unsuccessful, since there was only a fixed fund to draw on. Karl Marx, an advocate of the labor theory of value, believed that wages were held at the subsistence level by the existence of a large number of unemployed. The residual-claimant theory of wages, originated by the American economist Francis A. Walker, held that wages were the remainder of total industrial revenue after rent, interest, and profit (which were independently determined) were deducted. In the bargaining theory of wages, there is no single economic principle or force governing wages. Instead, wages and other working conditions are determined by workers, employers, and unions, who determine these conditions by negotiation. The marginal productivity theory of wages, formulated in the late XIX century, holds that employers will hire workers of a particular type until the addition to total output made by the last, or marginal, worker to be hired equals the cost of hiring

one more worker. The wage rate will equal the value of the marginal product of the last-hired worker. Supporters of this theory maintain that the test of an economic theory should be its predictive power. They hold that the marginal-productivity theory is a guide to long-run trends in wage determination and applies more generally than the bargaining theory of wages. / Дэйвид Рикадо (David Ricardo) Томэс Малфис (Thomas Malthus). WAGON = ВАГОН – (1) Wagon is a railway vehicle normally intended for the transport of goods. Railcars and railcar trailers fitted only for the conveyance of goods are included. See also Rail Car. / Вагон – транспортное средство для перевозки пассажиров и грузов, приспособленное для движения на колёсах по рельсам. Вагон железнодорожный, от Французского слова Wagon, от Английского слова Waggon, означающее Повозка. Прототип вагона – небольшой ёмкости повозка, представлявшая собой ящик, передвигавшийся по деревянным рельсам на горных предприятиях вначале вручную, а затем конной тягой. Впервые появился в Англии, затем в Германии. В 1786 Ирландский политик, писатель и изобретатель Ричад Лавэл Эдьжвос (Richard Lovell Edgeworth; 1744–1817) предложил составлять поезда из таких повозок. Создание вагона связано с открытием конно-чугунных дорог, первая из которых построена в Графстве Суррей близ Лондона. На этой дороге конной тягой перемещались пассажирские и грузовые повозки. На Алтае Российский горный инженер и изобретатель Пётр Козьмич Фролов (1775–1839) в 1810 построил первую в России Змеиногорскую конночугунную дорогу с трёхвагонными составами. Железнодорожный состав из 12 грузовых вагонов и 21 пассажирского с паровой тягой испытан при открытии дороги между Стоктоном и Дарлингтоном (Англия) в 1825. Достижения в вагоностроении были продемонстрированы при открытии Манчестер-Ливерпулской железной дороги в Англии (1830), на котором присутствовали специалисты-путейцы многих стран, в том числе и России. В России первые грузовые и пассажирские вагоны различных типов построены на Александровском заводе в 1846. Это были крытые 4-осные вагоны и платформы с центральной сцепкой без буферов грузоподъёмностью 8.2 тонн (т). В 1855 построены первые 2-осные вагоны грузоподъёмностью 6.5–10 т; с 1862 стали строить вагоны-ледники для перевозки скоропортящихся пищевых продуктов; в 1872 появились цистерны 2-осной конструкции и специальные вагоны (для перевозки живой рыбы, молочных продуктов, песка и так далее). В 1892 создан грузовой вагон ‘нормального’ типа грузоподъёмностью 12.5 т. В 1905 грузоподъёмность грузовых вагонов в России была увеличена до 15 т, а в 1911 – до 16.5 т. В конце XIX века, наряду с созданием новых типов вагонов, совершенствуется конструкция кузова рессорного подвешивания, тяговых приборов, буферного устройства, тормозов и так далее. К 1917 парк грузовых вагонов в основном состоял из 2-осных вагонов и насчитывал:- крытых 67%, платформ 18%, полувагонов 5%, цистерн 6% и прочих 4%. Средняя грузоподъёмность 15.1 т. Первые пассажирские вагоны в России появились на Царскосельской железной дороге, открытой в 1837. Они имели вид карет. В 1846–51 на Александровском заводе было построено 239 различных пассажирских вагонов, а в 1865 Российский инженер К.И. Рехневский сконструировал тележку с двойным рессорным подвешиванием, обеспечивавшим плавный ход. Пассажирские вагоны были оборудованы креслами (в 1-м и 2-м классах), и только в 1866 введены первые спальные вагоны в скорых поездах Петербург–Москва (в 1867 в США созданы спальные вагоны системы Пульмана). Парк пассажирских вагонов был весьма разнообразен и состоял главным образом из 2-, 3-и 4-осных вагонов, в основном с деревянными рамами и кузовами, с печным или водяным отоплением (индивидуальное для каждого вагона) или с паровым от специального вагона-котельной; освещение преимущественно свечное, редко газовое; почти все пассажирские вагоны имели автоматические тормоза, сквозную упряжь с винтовой сцепкой и буферами. Нормализация пассажирских вагонов началась с постройкой в 1896 4-осного вагона длиной 18 метров (м). В 1906 были построены двухэтажные пассажирские вагоны с тележками системы Рыковского. За годы Советской власти вагонный парк коренным образом обновлен. В 1931 прекращено строительство старых типов вагонов и организовано производство крытых 2- и 4-осных грузовых вагонов грузоподъёмностью соответственно 20 и 50 т, платформ 20, 50 и 60 т, цистерн 24, 45, 50 м; 4-осных саморазгружающихся полувагонов грузоподъёмностью 60 т; хопперов 25, 60 и 70 т со стальной рамой и хребтовой балкой, позволяющей устанавливать автосцепку. Кузова изготовлялись с металлическим каркасом и обшивкой, выполненной из дерева или металлических листов. Вагоны оборудовались автотормозами отечественной конструкции (смотрите Тормоз Казанцева и Тормоз Матросова). С 1947 строятся цельнометаллические пассажирские вагоны длиной 23.6 м. По назначению различают вагоны пассажирские и грузовые; общесетевые и промышленные транспорта; для широкой и узкой железнодорожной колеи. Современные вагоны бывают несамоходными и самоходными (моторные электрифицированные железнодорожные, трамвайные, метрополитена, дизель-поездов, автомотрисы и другие). Пассажирские вагоны разделяются на вагоны общего назначения (для перевозки пассажиров, а также вагоны-рестораны, почтовые, багажные, электростанции и другие) и специального назначения (служебные, санитарные, лаборатории, клубы и так далее). К пассажирским относятся также вагоны трамвая и метрополитена. Пассажирские вагоны различают дальнего следования, межобластного и пригородного сообщения. Вагоны общего назначения бывают:- не купейные и купейные (мягкие или жёсткие). Вагоны строятся с цельнометаллическим кузовом несущей конструкции, индивидуальным водяным или электрическим отоплением, принудительной и естественной вентиляцией, электрическим освещением. На многих вагонах имеются установки для кондиционирования воздуха, горячего водоснабжения и охлаждения питьевой воды. Дизель- и электропоезда комплектуются из моторных и прицепных вагонов. Современные вагоны купейные мягкие имеют 24–32 места, жёсткие купейные – 38 спальных мест, не купейные 54 места (81 место для сидения), областного сообщения – 68 мест для сидения. На железных дорогах бывшего Союза Советских Социалистических Республик (СССР) перевозилось за год свыше 2.8 миллиардов пассажиров, что составляло свыше 65% пассажирских перевозок в стране (1969). В 1970 в СССР было построено 1 800 пассажирских магистральных вагонов. Грузовые (товарные) вагоны подразделяются на вагоны универсальные (крытые, полувагоны, платформы, хопперы, цистерны, вагоны изотермические) и специальные (гондолы, транспортёры, для перевозки цемента, муки, битума, живой рыбы, молока, вина, спирта, сахара-сырца) и другие. В крытых вагонах перевозят грузы, требующие защиты от атмосферных воздействий, и ценные грузы. В СССР были наиболее распространены 4-осные крытые вагоны грузоподъёмностью 60 и 62 т. К грузовым вагонам промышленного транспорта относятся думпкары, шлаковозы, чугуновозы, вагонетки и другие. Большое число промышленных вагонов узкоколейные. Основные технико-экономические параметры грузовых вагонов:- грузоподъёмность, количество осей, коэффициент тары, удельный объём кузова, удельная площадь и линейные размеры. Грузоподъёмность вагона – наибольший груз, допускаемый к погрузке. Коэффициент тары – отношение тары (собственной массы вагона) к его грузоподъёмности. Удельная площадь – отношение полезной площади пола вагона к грузоподъёмности. Коэффициент тары грузового вагона в СССР на 9–12% ниже, чем в США; среднесуточный пробег в СССР составляет около 250 километров (км), в США – 83 км. По численности и грузоподъёмности парк грузовых вагонов СССР занимал 1-е место в Европе и 2-е – в мире. На грузовые вагоны приходилось около 70% грузооборота в стране (1968). В 1970 в СССР было построено 58 500 грузовых магистральных вагонов. Вагоны имеют общие для всех типов основные элементы (узлы):- ходовые части, кузов, ударно-тяговые приборы и тормоза. Ходовые части направляют вагон по рельсовым путям, обеспечивают безопасность передвижения при требуемых скоростях, плавность хода и наименьшее сопротивление движению, а также служат основанием для кузова. Ходовые части состоят из колёсных пар, букс, рессорного подвешивания и объединяющих их

балок и рам. Основанием кузова служит рама. К ней крепятся ударно-тяговые приборы и часть тормозного оборудования. Автосцепка с поглощающим аппаратом служит для сцепления вагонов и амортизации продольных усилий. Тормоза предназначены для автоматического регулирования скорости движения и остановки вагона или поезда. Все пассажирские и часть грузовых вагонов оборудуются, кроме автоматических, ручными тормозами. Нормативный срок службы крытого грузового вагона в СССР – 41 год; полувагона, платформы и цистерны – 43 года; пассажирского вагона – 55 лет. В мире насчитывается свыше 5 миллионов грузовых и свыше 200 тысяч пассажирских вагонов (1970). Развитие вагоностроения в СССР предусматривало создание грузовых вагонов большой грузоподъёмности, снижение тары и расхода металла на постройку каждого вагона, приспособленность вагона к максимальной механизации погрузочно-разгрузочных работ, совершенствование тормозов, автосцепных устройств и ходовых частей, обеспечивающих надёжную работу вагонов в тяжеловесных поездах (6 000–10 000 т) со скоростью до 120 километров в час (км/ч), применение в конструкции вагонов высокопрочных антикоррозийных сталей, высокопрочных алюминиевых сплавов и полимерных материалов, создание пассажирских вагонов для движения со скоростями 200–250 км/ч.

(2) Wagon is a four-wheeled vehicle designed to be drawn by draft animals and known to have been used as early as the I century BC, incorporating such earlier innovations as the spoked wheel and metal wheel rim. Early examples also had such features as pivoted front axles and linchpins to secure the wheels. In its essential form, therefore, the wagon has been in common use for about 2 000 years. During the IX century several additional improvements in harness and suspension led to a marked preference for wagons over carts as a means of passenger and long-distance transportation. Wagons were heavier than carts in construction, with a boxlike body that was useful for hauling freight and agricultural produce and a smoother ride due to the inherent stability of being supported on four wheels rather than two. Wagons were produced in many sizes and types, and those used for the carrying of passengers were equipped with springs between the box and the running gear. The coach variation was a later innovation, becoming a distinct form in the XVI century. One type of wagon, the Conestoga, became famous as a freight wagon during the XVIII century, and its descendant, the prairie schooner, was the most common vehicle used by settlers in the opening of the American West.

WAGON FOR INTERMODAL TRANSPORT = ВАГОН ДЛЯ СМЕШАННОЙ ПЕРЕВОЗКИ – Wagon For Intermodal Transport is a wagon specially built or equipped for the transport of intermodal transport units (ITUs) or other goods road vehicles.

WAGON–KILOMETER = ВАГОНО–КИЛОМЕТР – Wagon-Kilometer (rail transport):- unit of measure representing any movement of a wagon loaded or empty over a distance of one kilometer. The distance to be considered is that actually run. Shunting and other similar movements are excluded. All wagon journeys are included irrespective of the ownership of the wagon. / Вагоно-Километр – показатель, характеризующий расстояния, пройденные вагонами в составе грузовых и пассажирских поездов. Рассчитывается раздельно для грузовых и пассажирских вагонов по маршрутам машиниста локомотивов, как произведение количества вагонов, включённых в состав поезда, и пройденного поездом расстояния. Вагоно-километр характеризует объём работы вагонного парка, используется для исчисления качественных показателей:- динамической нагрузки, среднесуточного пробега, коэффициент порожнего пробега и других. Вагоно-километр отражает издержки железнодорожного транспорта, связанные с перевозкой грузов и пассажиров.

WAGON TRAIN = ОБОЗ (или ВЕРЕНИЦА КРЫТЫХ ПОВОЗОК) – Wagon Train:- caravan of wagons organized by settlers in the United States for emigration to the West during the late XVIII and most of the XIX centuries. Composed of up to 100 Conestoga wagons (sometimes called Prairie Schooners), wagon trains soon became the prevailing mode of long-distance overland transportation for both people and goods. Wagon-train transportation moved westward with the advancing frontier. The XIX century saw the development of such famous roads as the Santa Fe Trail, the Oregon Trail, the Smoky Hill Trail, and the Southern Overland Mail route. It was, however, in transit westward over the Oregon-California Trail that the wagon trains attained their most highly organized and institutionalized character. Meeting in early spring at a rendezvous town, perhaps near the Missouri River, the groups would form companies, elect officers, employ guides, and collect essential supplies while awaiting favorable weather, usually in May. Those riding in the wagons were directed and protected by a few on horseback. Once organized and on their way, wagon-train companies tended to follow a fairly fixed daily routine, from 4 am rising, to 7 am leaving, 4 pm encampment, cooking and tending to chores while the animals grazed, and simple recreation before early retirement. The companies had to be prepared for such challenges as crossing rivers and mountains and meeting hostile Indians. Wagon-train migrations are more widely known and written about than wagon freighting, which also played an essential role in an expanding America. Teamsters, best known as Bullwhackers or Muleskinners, conducted commercial operations on a more or less fixed two-way schedule until replaced by the railroad and the truck.

WAI = WEEKS AFTER INCUBATION

WAI = WEEKS AFTER INOCULATION

WAINSCOT = ОБШИВКА (или (СТЕННАЯ) ПАНЕЛЬ) – Wainscot:- interior paneling in general and, more specifically, paneling that covers only the lower portion of an interior wall or partition. It has a decorative or protective function and is usually of wood, although tile and marble have at times been popular. The molding along the upper edge is called a Wainscot Cap and may serve as a chair rail. Traditionally, British wainscot was oak – imported from Russia, Germany, or Holland – and wainscot oak remains a term for especially selected, quartersawn oak for paneling. A typical use of wainscot appears in early English Renaissance mansions where oak paneling to a height of 8 or 10 feet (2.5 to 3 m) was installed and hung with paintings or armour. The French equivalent for wainscot is Boiserie. The latter term's use is generally reserved, however, for the profusely decorated paneling, often carved in low relief, of the XVII and XVIII centuries in France. Boiserie commonly covers the wall up to the ceiling and may also be painted, gilded, or, in some instances, inlaid. / Бозри (Boiserie).

WAIST = КОРСАЖ (или ЛИФ, или ПОЯСНАЯ ОДЕЖДА) – Waist is a garment or part of a garment covering the body from the neck to the waistline or just below; bodice; blouse.

WAIST GIRTH = ОБХВАТ ТАЛИИ – Waist Girth (for women):- bend to one side to find the natural crease of your waist. Measure at this point keeping tape comfortable around your waist. Waist Girth (for men):- measure your waist at the height you normally wear your pants. Waist or Waist Girth:- measure around your natural waistline, while in your underwear. Keep one finger between the tape and your body for an accurate fit. Waist Girth (for men):- measure over the waist band of the trousers (not over the belt though). Waist Girth (for men):- measure your waist at the height you normally wear your pants. Waist Girth (for women):- measure around your natural waistline keeping one finger between your body and the tape. Waist Girth (for women):- bend to one side to find the natural crease of your waist. Measure at this point keeping tape comfortable around your waist. Waist:- measure around the waist. Waist:- measured horizontally along the natural waistline. / Обхват Талии:- обхват в сантиметрах естественной линии талии между подвздошными костями и нижними рёбрами. При обмере человек дышит нормально, стоит выпрямившись с расслабленным животом. Обхват Талии – измеряется строго по линии талии. Обхват Талии – расстояние на уровне линии талии в плечевых изделиях и расстояние на уровне верхнего среза в поясных изделиях.

WAIST = ШКАФУТ (или XX) – Waist is:- (1) the part of a ship's deck between the poop and forecastle; and (2) the middle part of a sailing ship between foremast and mainmast. Waist is the portion of the deck between the forecastle and quarterdeck of a sailing vessel. / Под Шкафутом, от Нидерландского слова Schavot, означающее Стеллаж или Эшафот, понимается многозначный морской термин:- (i) Шкафут на кораблях и судах – средняя часть верхней палубы от фок-мачты до грот-мачты либо от носовой надстройки (бак) до кормовой (ют). (ii) Шкафут на деревянных парусных кораблях – широкие доски, уложенные горизонтально вдоль бортов для прохода с бака на шканцы (кватердек). (iii) Шкафут на речных металлических баржах – деревянный брус, идущий вдоль борта и служащий для установки леерных стоек.

WAISTBAND = ПОЯС – (1) Waistband (one-piece) is a single thickness of fabric that is doubled and stitched to the top of a pant.

(2) Waistband (two-piece):- when two identical pieces of fabric are placed back-to-back at the top of a pant, raw edges turned inside, and joined with two widely spaced rows of stitching. the pant body is inserted betweeen and along one edge. / втачивание (stitching).

WAISTCOAT = КОРОТКАЯ КУРТКА (или ФУФАЙКА, или XX) – Waistcoat is an ornamental garment worn under a doublet; (chiefly British) vest.

WAISTING = КОРСЕТ (или БЛУЗОЧНАЯ ТКАНЬ, или КОРСЕТНАЯ ТКАНЬ, или XX) – Mercerized Waistings:- there has developed during comparatively recent years (1914), or since the mercerization process has been permitted to be used, a class of fabrics of wide variety, but which have quite a number of prominent features in common. This class of fabrics contains those which are mercerized in the piece in the filling direction, and these materials are used extensively for women's waistings and dresses, for men's shirtings and for various other purposes which creates for them a large field for sale. These cloths are produced in plain weave and also with dobby and Jacquard figures, and the results obtained appear to many consumers to be comparable to some silk fabrics, in fact they are quite often sold as such, for the lustre obtained through such methods is permanent. Since the introduction of fast colors which are able to stand the bleaching process there has been a greater opportunity for variety than there was earlier, and it is probable that the sale of such fabrics has hurt the sale of the older style Madras shirtings to quite an appreciable extent, for shirt makers can thus purchase their cloth and convert it themselves, thereby saving quite large amounts on certain lines. There has been some criticism regarding the wear of many of these new fabrics, it being claimed that they do not wear as well as the older lines and that mercerization hurts the cloth quality, but this is not true. The trouble has been when comparing the mercerized fabric that it has not been so heavy in weight or produced of such coarse yarns as the earlier shirting fabrics, and, naturally, would not stand as much hard wear. Of course, the soft twist applied to the filling yarn does render the mercerized fabric a little bit less durable, but not enough to allow any large criticism, especially when similar weights of fabrics are considered. The newer fabrics are sold largely because of their improved appearance, and because they offer opportunities for the use of fancy weaves which the others do not, and because they can be sold at a reasonable price which never could be noted on the older style of goods. Not only does such a fabric offer the above opportunity, so far as the weave is concerned, but it also allows yarns of fine sizes to be handled at a comparatively low cost, yarns which were very seldom handled at all in the earlier fabrics for the same purposes, and besides, when they were handled, it was at prohibitive prices, so far as any large sale of the cloth was concerned. Thus it will be seen that competition has developed quite extensively between Madras and mercerized shirtings, but only because the sale of the latter eliminates some of the opportunities for the sale of the former, and not because the fabrics as sold are very similar in appearance, because they usually are not. It is quite true that mercerized waistings and similar fabrics have often been purchased in place of silk material, and for this reason, they may be said to offer a certain amount of competition to such lines. One fact worth noting is that retailers in general have not as yet shown the variety or the adaptability of such material, for comparatively few lines have been purchasable by them up to the present time, and the fabrics which they have obtained in many cases have been styles of which cutters-up bought too heavily and disposed of at second hand. For this reason, the future possibilities of such cloths have not been tried out extensively. Last year saw a large increase in the use of such cloths and the coming year will witness a still greater one. But that buyers have recognized the situation is seen from the large purchases which have been made recently from mills which are able to produce these constructions in fancy weaves. In a general way, Madras shirtings are made from bleached yarn, and many of them have a somewhat higher warp count than they do filling count, while the warp yarn is also coarser in size than the filling, although this variation is usually comparatively slight, while mercerized fabrics are usually made from grey yarns. They also have a higher, or a radically higher, count in the filling than they do in the warp, and the filling is usually a heavier size of yarn than the warp, in many instances being about half as fine. This variation in cloth construction gives a much different cloth when produced and one which is radically different when finished. Besides, the fillings in Madras shirtings, which are made from bleached yarns, are comparatively as hard twisted as the warp, so that they can be handled successfully, while for the fabric which is to be mercerized, the filling has a much lower standard of twist, this standard being often less than three times the square root of the yarn size. Another feature worth noting is that a large number of the mercerized fabrics are made from combed yarns, while the earlier fabrics were and are made largely from carded stock, which gives a cloth that not only is not likely to be so strong but will not be comparable in appearance. Not only does the better yarn used tend to make a more even fabric, but the mercerized cloths, due to the various processes of finishing, lose entirely the reed marks which often make bleached and dyed yarn fabrics very objectionable, but which cannot be eliminated, excepting at a cost which is not desirable. Certain mercerized fabrics are made with carded warp and combed filling, while there are some which are made wholly from carded stock, but the majority of such fabrics, especially those made from medium and fine yarns, are manufactured from combed material. One construction which is used extensively, and which forms the basis for many weaves and stripes, is 64 by 72, with 50s-1 warp and 30s-1 soft twist filling. The fabric which we have analyzed is about this construction in the ground, although a warp of 55s-1 has been used instead of 50s-1. Another finer construction which is used in many of the higher grade fabrics is 72 by 96, with 70s-1 or finer warp and 40s-1 soft twist filling. These two constructions give a good general idea regarding the yarns used and the sizes which render the best results and also gives a general idea regarding the constructions employed. The soft twist filling is used, because better results can be obtained when the cloth is mercerized. Soft twist in the yarn allows the various Cotton fibers to lie more nearly parallel in the yarn, thus reflecting the light and giving more lustre. In a good many fabrics Egyptian Cotton is used for the filling, because this material has been found to give better results than other kinds of Cotton. Possibly, there is more Egyptian Cotton used for filling in fabrics which are to be mercerized than there is in any other one material with the exception of knitted fabrics. Following is the analysis of the fabric considered which contains a dobby pattern with stripes of crowded yarn, and also a plain fabric of a higher construction and with finer yams. Analysis No. 1:- (i) Width of warp in reed, 29-1/2 inches; (ii) Width of fabric finished, 28 inches; (iii) Ends per inch finished (over all) 84; (iv) Ends per inch finished (ground) 68; (v) Reed 32 x 2; (vi) Ends in the warp 2/16 2,288 2/16 = 2,352, total ends; (vii) Warp yarn 55/1; (viii) Filling yarn 30/1; (ix) Picks per inch, grey, 72; (x) Warp take-up, 7%; (xi) Warp weight, grey 0.054 7; (xii) Filling weight, grey 0.084 3; (xiii) Total weight per yard, grey 0.139 0; and (xiv) Yards per pound 7.19. Analysis No. 2:- (i) Width of warp in reed, 29-1/2 inches; (ii) Width of fabric finished, 28 inches; (iii) Ends per inch finished 72; (iv) Reed 34 x 2; (v) Ends in warp 2/16 1,974 2/16 = 2,038; (vi) Warp yarn 70/1; (vii) Filling yarn 40/1; (viii) Picks per inch, grey, 96; (ix) Warp take-up, 6%; (x) Warp weight, grey 0.036 9; (xi) Filling weight, grey 0.084 3; (xii) Total weight, per yard, grey 0.121 2; and (xiii) Yards per pound, grey 8.25. Most of the fabrics which are of the construction described are made on ordinary or fancy looms, and comparatively few are made on automatic machines. This is true

partly because the mills which can produce yarns of the required quality do not contain many automatic looms and also because there is a much greater necessity for having the cloth produced contain few flaws when compared with cheap carded materials. Then it is also questionable whether there is any great advantage to be gained through the use of automatic looms when fine warp yarns are used. In any case, it is at least certain that the advantage which is obtained is not as great as it is on fabrics which are woven from rather heavy yarns. A large portion of the mercerized fabrics are made with fancy dobby or Jacquard weaves, and for these weaves the ordinary automatic arrangement is not very adaptable. In making patterns for these cloths it is almost always the practice to make the figures almost entirely of filling floats. This shows up the figures more prominently, and when the cloth is mercerized the results are more desirable. Sometimes warp floats are used in combination with filling floats so as to bring out certain effects, but they are not used extensively, because the warp is usually of much finer size than the filling and does not show up any effects very well. Stripes are sometimes operated from the same beam as the ground yarn, and this probably has been done in the cloth which we have analyzed. This method can be taken if the weave and threads per dent can be adjusted correctly, but the price of cloth and the demands of buyers often make such a thing impossible, and the stripe must be made from an extra beam. When colored stripes are being produced, even though woven with plain weave, they are practically always placed on a separate beam. We are giving the drawing-in draft and chain for Fabric No. 1 which has been analyzed. This should be entirely clear, but for various reasons, it may be well to state that the figures in the draft represent the various harnesses on which the warp threads are drawn to produce this pattern. The figures at the bottom of the draft represent the number of threads which are reeded in each dent after they have been drawn through the heddle eyes in the harnesses, while the figures to the right of the draft represent the number of heddles which are required on each harness, so that the warp can be all drawn in. In fancy cloth mills, harnesses are almost always made up previous to the drawing-in operation, so that it will not be necessary to add any heddles when the warp is partly drawn in, or take them off after the drawing-in is completed. Finishing:- As previously stated, the fabric which is being considered is treated in a radically different manner from that used on the ordinary Madras or waisting fabrics. In the first place, it is necessary to bleach the cloth because it is in its grey state when woven, and the yarns contain the cotton wax besides the dirt from handling and other foreign material which has to be eliminated before any material can be successfully dyed or finished. Some finishers use the ordinary bleach when finishing such fabrics, while others use the peroxide process, but the method employed is of little importance. The bleaching makes the fabric which is being treated white, but it does not impart any lustre to it. This is done by another process which is called Mercerization, from the man who originally discovered the process. Caustic soda when applied to Cotton cloth or yarn causes it to shrink very materially, usually about 20 per cent when the cloth is shrunk as much as possible, but when this is allowed there is no lustre imparted. The lustre is obtained when the material is held out to as nearly its grey width as possible. The Cotton fibers, which in their ordinary state are rather flat twisted tubes, seem to swell out and appear more or less like small glass rods when examined under the microscope after they have been mercerized. This smooth appearance reflects the light rays and makes the lustre which is ordinarily noted. By using filling which is soft twisted the process of mercerization is aided, for the fibres, as previously stated, lie more nearly parallel in the fabric, although it is possible to impart some lustre to even the shortest Cotton fibers, and also when they are twisted harder than ordinarily noted. This will be readily recognized by examining some of the high-class voiles which are now being sold, because the yarns which these fabrics contain are very hard twisted, but even under such conditions it has been found that mercerization adds to their finished appearance, and it is often employed. Various methods are used to obtain the lustrous results which are noted in this class of fabrics, but the main necessity in obtaining these results is to hold out the fabric tightly in the filling direction when it is being treated, and, at the same time, to allow the caustic soda solution to operate. It would naturally be supposed that results would be better if a stronger solution were to be used, but this is not true, and the use of a solution over a certain strength is only a waste of material and adds to the cost. After mercerization the fabric is washed, worked, so as to slip the threads and picks into their proper positions, calendered, folded and handled in any special way necessary, and is then ready for shipment. Quite a little of such material is sold in the white state, but there are also a good many fabrics which are printed or piece dyed in addition to being mercerized. The Price For Finishing and applying the mercerization process will vary somewhat, but to-day the quoted price is 1-1/4 cents a yard, with an allowance of 2 per cent as a working loss in yardage and 3 cents a piece for the so-called silk papers for folders. It often happens when finishing fabrics entirely in the white that this above-mentioned 2 per cent working loss does not occur. The charge for the cases in which the fabrics are shipped is usually about one-twentieth of a cent a yard. When a fabric is to be dyed in addition to bleaching and mercerizing, the price is 1-1/2 cents a yard, and the 2 per cent working loss is almost always noted because of the smaller quantities handled. For printing, in addition to bleaching and mercerizing, the price is likely to be about 2 cents a yard, although the kind of pattern desired will affect the cost somewhat. In all the above quotations the amount of cloth which is to be finished will affect the prices named for accomplishing it, that is, when a small amount is to be treated, the price is likely to be somewhat higher than when a large amount is to be done. In general, it can be said that the price for this work has decreased quite a little in recent years, and, in addition, the results obtained are very much improved, facts which have in this instance been responsible for cheaper cloth to the consumer. As previously stated, the warp in mercerized fabrics such as those described is usually of rather fine size, but in construction it is no different from the ordinary warp of the same size used in making the usual fancy cloths. For 55s-1 combed warp for cloth similar to that analyzed the Cotton used would be 1-1/4 inches in length. The rolls on the various frames should be set so that in no case will the Cotton fibers be broken, for unsatisfactory yarn will result if this is done. The 55s-1 warp might be made either by three or four processes of fly-frames, although it is likely that four processes will give much better and more satisfactory results. Two layouts for such yarn follow one produced from a 35-grain finisher drawing sliver, and with 3 processes of fly-frames and the other for a finisher drawing sliver of 48 grains with 4 processes of fly-frames. 3 Processes, Fly Frames:- (i) 1 yard of 55/1 = 0.151 5 grains; (ii) 0.97 3% contraction in spinning; (iii) 0.147 0; (iv) 10.27 spinning draft; (v) 1.514 ÷ 2 ends = 0.757 = 11 hank roving; (vi) 6.85 fine frame draft; (vii) 5.185 ÷ 2 ends = 2.59 = 3.21 hank roving; (viii) 5.75 intermediate frame draft; (ix) 14.892 ÷ 2 ends = 7.45 = 1.12 hank roving; (x) 4.70 slubber frame draft; (xi) 35 grains finisher drawing weight. 4 Processes, Fly Frames:- (i) 1 yard of 55/1 = 0.151 5 grains; (ii) 0.97 3% contraction in spinning; (iii) 0.1470; (iv) 10.27 spinning draft; (v) 1.514 ÷ 2 ends = 0.757 = 11 hank roving; (vi) 6 fine frame draft; (vii) 4.54 ÷ 2 ends = 2.27 = 3.67 hank roving; (viii) 5.2 second intermediate draft; (ix) 11.80 ÷ 2 ends = 5.90 = 1.41 hank roving; (x) 4.4 first intermediate draft; (xi) 25.96 ÷ 2 ends = 12.98 = 0.64 hank roving; (xii) 3.7 slubber frame draft; (xiii) 48 grains finisher drawing weight. The filling used in such a cloth would probably be made from 1-1/8-inch Cotton, and the rolls should be set correctly for this length of staple. It often happens that it is necessary to use a longer Cotton staple in making filling yarn which is to be used in cloth that is to be mercerized. Methods will depend somewhat on the machinery being used and largely on the amount of twist which is to be given to the yarn for filling. When the twist per inch is lowered radically, a longer staple of Cotton must be used if the yarn spins well in the spinning room, or if it be handled successfully, that is, if it is made on an ordinary spinning frame. One layout for 30s-1 filling which is to be soft twisted and produced with three fly-frame processes and with a 45-grain finisher drawing sliver is as follows:- (i) 1 yard of 30/1 = 0.277 8 grains; (ii) 0.98 2% contraction in spinning; (iii) 0.272 2; (iv) 8.45 spinning frame draft; (v) 2.30 ÷ 2 ends = 1.15 = 7.25 hank roving; (vi) 6.5 fine frame draft; (vii) 7.48 ÷ 2 ends = 3.74 = 2.23 hank roving; (viii) 5.57 intermediate frame draft; (ix) 20.83 ÷ 2 ends = 10.42 = 0.8 hank roving; (x) 4.32 slubber frame draft; (xi) 45 grains finisher drawing weight. It is not necessary to state any particular facts regarding the methods which should be used in handling Cotton in the early processes of making Cotton yarn, for they are well known, and any radical changes from them are likely to result in poor yarn and low quality cloth. The more care which is given to the preliminary processes of yarn making the

better will be the quality of the cloth and the price which can be obtained. In no case should a machine be operated at an excessive speed in order to obtain greater production, especially when the fabric which is to be produced is selling for a comparatively high price, and it is very questionable whether on the cheapest fabrics excessive speed results in any great ultimate economy. Dyeing Particulars:- (1) Orange:- (i) Toluylene fast orange L X 1-1/2%; (ii) 10–30% Glauber's salt crystals; (iii) 1–2% soda ash; (iv) Enter at the boiling point and work with the steam turned off. (2) Red:- (i) Benso fast eosine B L 2%; (ii) 20–60% Glauber's salt crystals; (iii) 1–2% soda ash; (iv) Enter at the boiling point and work with the steam turned off. WAITER = РАЗНОСЧИК – Waiter is an attendant at the London Stock Exchange or Lloyd's who carries messages:- the modern equivalent of waiters who performed these duties in the XVII-century London coffee houses in which these institutions originated. / Разносчик – вспомогательный работник Лондонской Фондовой Биржи (London Stock Exchange) и Лойда (Lloyd's), который разносит сообщения, бумагу и так далее. Название восходит к Лондонским кофейным домам XVII века, из которых и развились вышеуказанные институты, где разносчики также выполняли свои функции.

WAITING PERIOD = ПЕРИОД ОЖИДАНИЯ – (1) Waiting Period is the period of time between filing a registration statement with the US Securities and Exchange Commission (SEC) and the registration statement being declared effective by the SEC. Also known as Cooling-Off Period, and Quiet Period. This is one part of the IPO process during which the issuing company is limited in its announcements to the public. This period of time can last up to three months. The federal securities laws do not define the term Quiet Period, which is also referred to as the Waiting Period. However, a quiet period extends from the time a company files a registration statement with the SEC until SEC staff declare the registration statement 'effective'. During that period, the federal securities laws limit what information a company and related parties can release to the public. The failure to comply with these restrictions generally is referred to as 'Gun-Jumping'. On June 29, 2005, the commission voted to adopt modifications to the registration, communications, and offering processes under the Securities Act of 1933. Among many other provisions, the rules update and liberalize permitted offering activity and communications to allow more information to reach investors by revising the 'gun-jumping' provisions under the Securities Act. The cumulative effects of these rules are as follows:- (i) Well-known seasoned issuers are permitted to engage at any time in oral and written communications, including use at any time of a new type of written communication called a 'Free Writing Prospectus', subject to enumerated conditions (including, in some cases, filing with the commission); (ii) All reporting issuers are, at any time, permitted to continue to publish regularly released factual business information and forward-looking information; (iii) Non-reporting issuers are, at any time, permitted to continue to publish factual business information that is regularly released and intended for use by persons other than in their capacity as investors or potential investors; (iv) Communications by issuers more than 30 days before filing a registration statement will be permitted so long as they do not reference a securities offering that is the subject of a registration statement; (v) All issuers and other offering participants will be permitted to use a free writing prospectus after the filing of the registration statement, subject to enumerated conditions (including, in some cases, filing with the commission). Offering participants, other than the issuer, will be liable for a free writing prospectus only if they use, refer to, or participate in the planning and use of the free writing prospectus by another offering participant who uses it. Issuers will have liability for any issuer information contained in any other offering participant's free writing prospectus as well as any free writing prospectus they prepare, use, or refer to. (vi) The exclusions from the definition of prospectus are expanded to allow a broader category of routine communications regarding issuers, offerings, and procedural matters, such as communications about the schedule for an offering or about account-opening procedures; and (vii) The exemptions for research reports are expanded. A number of these rules include conditions of eligibility. Most of the rules, for example, are not available to blank check companies, penny stock issuers, or shell companies. The rules address the treatment under the Securities Act of electronic communications, including electronic road shows and information located on or hyperlinked to an issuer's website. The rules define written communication as any communication that is written, printed, a radio or television broadcast, or a graphic communication. The definition of graphic communication and, thus, electronic road show excludes communications that are carried live and in real-time to a live audience, regardless of the means of transmission. Electronic road shows for initial public offerings of common equity or convertible equity securities will have to make a bona fide electronic road show readily available to an unrestricted audience to avoid filing the electronic road show with the commission. No other road shows will be subject to filing. The effective date of the rules was December 01, 2005. Waiting Period is the time during which the Securities and Exchange Commission (SEC) studies a firm's registration statement. During this time the firm may distribute a preliminary prospectus. The Waiting Period refers to the time period between a company filing a registration statement with the US Securities and Exchange Commission (SEC) and the SEC declaring that statement to be effective. This is also referred to as the 'Quiet Period'. How it works (example):- under the SEC rules, once a company makes its SEC registration filing for its initial public offering, it must not release information about its activities or related parties to the public until the SEC approves the registration for the offering. The SEC interprets this rule broadly, even including board members, management, and employees talking about the company. In 2005, the SEC changed many provisions of the waiting period and now allows companies to continue to publish information about themselves electronically and to continue to publish and report company activities through normal company networks. Why it Matters:- the waiting period precedes the introduction of a company into the capital market. During that time, the amount of public exposure and hype must be minimized to prevent any interference with SEC efforts to evaluate the company's filings. The release of any information may cause investors to 'jump the gun' on valuations and expectations for the company. The SEC's intention is to create a level playing field for all investors in the capital market, ensuring that all have the same information about the company when it goes out for sale on the market. / Период Ожидания – период до того, как вступит в силу какое-либо правило. В отношении ценных бумаг – это период времени, установленный Комиссией по Ценным Бумагам и Биржам (Securities and Exchange Commission), который должен пройти после подачи заявления на регистрацию (registration statements) ценных бумаг и до момента, когда эти ценные бумаги будут предложены к открытой продаже. Этот период может быть продлен, если требуется более длительное время для внесения исправлений или дополнения информации в регистрационное заявление (registration statement) и проспект (prospectus). Период Ожидания – период времени, составляющий обычно 20 дней, который должен пройти с момента подачи заявки в Американскую Комиссию по Ценным Бумагам и Биржам на регистрацию новой ценной бумаги и моментом, когда ценные бумаги могут быть публично предложены.

(2) Waiting Period is the time between the filing of an insurance claim and the payments made on the claim. Also known as Elimination Period. Typically, the longer the waiting period on an insurance claim, the cheaper the policy will be for the holder. / Период Ожидания:- одним из условий страхования дохода в случае потери трудоспособности (disability income insurance) является период ожидания, который проходит с момента поступления нетрудоспособности до времени начала выплаты пособий. Период ожидания до момента предъявления страховых требований называется также период устранения (elimination period).

(3) Waiting Period is the length of time an individual must be employed by a particular employer before joining the employer's pension scheme. Identical term – Qualifying Period.

(4) Waiting Period is a period of time between the beginning of a disability and the date benefits begin.

WAITING TIME = ВРЕМЯ ОЖИДАНИЯ (или СРОК ОЖИДАНИЯ) – Waiting Time is the period of time between the moment at which one is ready for an activity to start and the moment at which this activity can actually begin. See also Queue Time.

WAIVE = ОТКАЗАТЬСЯ – Waive:- to forego; to refrain from insisting upon application of an insurance deductible under specific conditions.

WAIVER = ПЕРЕДАЧА ПРАВ (или ОТКАЗ, или ДОБРОВОЛЬНЫЙ ОТКАЗ, или ОТКАЗ ОТ ПРАВ, или ИСКЛЮЧЕНИЕ) – (1) Waiver is the voluntary action of a person or party that removes that person's or party's right or particular ability in an agreement. The waiver can either be in written form or some form of action. A waiver essentially removes a real or potential liability for the other party in the agreement. For example, in a settlement between two parties, one party might, by means of a waiver, relinquish its right to pursue any further legal action once the settlement is finalized. A waiver carried out by an action, for example, might be based on whether a party in an agreement acts on a right, such as the right to terminate the deal in the first year of the contract. If it does not terminate the deal before the first year, that party waives its right to do so in the future. Waiver is an agreement attached to a policy which exempts from coverage certain disabilities or injuries that otherwise would be covered by the policy. Waiver is the intentional or voluntary relinquishment of a known right or privilege granted under an agreement, or the failure to take advantage of some failure of performance or other wrong. For example, if a Licensee fails to complain about a series of interruptions in connecting to a Licensor's database, the Licensor may later claim that the Licensee has Waived any claim that the service interruptions constituted a breach of the License Agreement. / Под Отказом От Права понимается отмена или недействительность права. Отказ от права может быть добровольным либо произойти в результате вмешательства закона. Например, если арендатор нарушает условия договора об аренде, а арендодатель требует с него уплаты ренты, несмотря на нарушения договора, арендодатель может лишиться своего права разорвать договор об аренде.

(2) Waiver is a document used to allow cargo carriage by different flag vessels other than original destination country vessels. Also for government cargoes where vessels under certain flags cannot carry the shipments.

(3) Waiver:- under the old GATT system the Waiver was often criticized as an 'easy track' amendment process, the WTO Agreement has stiffened the waiver rules while easing the amendment rules. The waiver is temporary, may be terminated by the WTO, and is subject to a 3/4s vote (stricter than some amendment votes). The opt-out is not like an amendment, because it only avoids the treaty obligations to that specific member against whom one has opted out. The treaty obligations vis-a-vis the other members still apply. A party could avoid an amendment if it were one altering the rights and obligations of members and if the Ministerial Conference decided that members not accepting the amendment may nonetheless remain members. If the waiver applicant met the criteria for a waiver, within the judgment of the Ministerial Conference, there would be no way for a member to avoid the implications of that waiver. Similarly, there is no way to avoid an opt-out vis-a-vis a specific member. Waiver is a permission granted by WTO members allowing a WTO member not to comply with normal commitments. Waivers have time limits and extensions have to be justified. / Под Отказом или Исключением понимается законное исключение, предусмотренное GATT, согласно которому подписавшие его стороны вправе разрешить одной из сторон придерживаться практики, которая в общем противоречит её обязательствам, принятым согласно GATT.

WAIVER APPROACH = ПОДХОД ПО ОТКАЗУ (или КОНЦЕПЦИЯ ОТКАЗА) – Waiver Approach:- instead of suppressing tabular data, some agencies ask respondents for permission to publish cells even though doing so may cause these respondents' sensitive information to be estimated accurately. This is referred to as the Waiver Approach. Waivers are signed records of the respondents' granting permission to publish such cells. This method is most useful with small surveys or sets of tables involving only a few cases of dominance, where only a few waivers are needed. Of course, respondents must believe that their data are not particularly sensitive before they will sign waivers.

WAIVER CLAUSE = ОГОВОРКА ОБ ОТКАЗЕ – (1) Waiver Clause is a clause which entitles both underwriter and assured to take measures to prevent or reduce loss without prejudice to the rights of either party. / В морском страховании под Оговоркой Об Отказе понимается положение, позволяющее любой из сторон предпринимать шаги для уменьшения последствий убытка 'без ущемления прав'.

(2) Waiver Clause is a clause in a marine insurance policy which preserves the respective rights of the insurer and the insured if either takes action to preserve the insured property from loss. The clause provides that any such action shall not be construed as a waiver or acceptance of abandonment. Clause in a marine insurance policy stating that no acts of the insurer or insured in recovering, saving or preserving the property insured, shall be considered a dismissal from or acceptance of abandonment.

WAIVER OF DEMAND = ОТКАЗ ОТ ТРЕБОВАНИЯ (или XX) – Waiver Of Demand:- an agreement by the party that has endorsed a check or draft to accept legal responsibility, without being formally notified, should the original issuer of the check or draft default. The waiver of demand may be express or implied; it may also be oral or written unless oral waivers are specifically prohibited by law. The term also refers to a bank's waiver of its right to formal notification when it presents short-term negotiable debt instruments such as drafts or banker's acceptances to a Federal Reserve bank for rediscounting. In such instances, the Federal Reserve considers the bank's endorsement as a 'waiver of demand, notice and protest' if the original issuer defaults on its debt obligation. / Отказ от протеста векселя.

WAIVER OF PREMIUM = ОТКАЗ ОТ ПРЕМИИ – Waiver Of Premium:- a provision in some policies to relieve the insured of premium payments falling due during a period of continuous total disability that has lasted for a specified length of time, such as three or six months. Waiver Of Premium is a provision in a policy establishing specific conditions under which the policy will be kept in force without the policyholder's being required to continue to pay premiums. Waiver Of Premium:- if you have a waiver of premium provision in your long-term care or disability insurance policy, you may qualify to stop paying premiums once you've begun collecting benefits. A waiver of premium provision increases the cost of your insurance, but means that you won't be left without coverage if you are no longerable to pay the premiums. Waiver Of Premium is a provision in an insurance policy that allows payment of insurance premiums to be permanently or temporarily stopped in the event the policyholder becomes incapacitated. Waiver of Premium is an agreement between an insurance company and a policyholder allowing the policyholder not to pay premiums if he/she is seriously injured, ill or disabled. In general, the policyholder must pay a one-time fee for the insurer to include a waiver of premium clause in a policy. / Добровольный Отказ От Взноса:- условие страхового полиса, гласящее, что все взносы по страховому полису должны быть отменены, если владелец полиса серьёзно заболеет или станет инвалидом – либо временно, либо навсегда – и, следовательно, не сможет выплачивать взносы. Некоторые полисы автоматически включают данное условие, в то время как в других случаях это

необязательное условие, а недоплаченные взносы должны покрыться дополнительными. В течение периода отказа условие о всех выплатах, полагающихся по полису, остаётся в силе.

WAIVER OF PROBATE = ОТКАЗ ОТ УТВЕРЖДЕНИЯ ЗАВЕЩАНИЯ (или ОТКАЗ ОТ НАСЛЕДСТВА) – Waiver Of Probate:- an affidavit required for the transfer of securities from estates that have not been probated. The estate must pay a 2% surety premium for insurance on the transfer.

WAIVER OF PROTEST = ОТКАЗ ОТ ПРОТЕСТА – Waiver Of Protest is a statement signed by the endorser of a note, indicating that he or she will remain liable even if he or she is not notified that the note has not been paid when due.

WAKE = КИЛЬВАТЕР (или ПОПУТНАЯ СТРУЯ) – In fluid dynamics, a Wake may either be:- (1) the region of recirculating flow immediately behind a moving or stationary blunt body, caused by viscosity, which may be accompanied by flow separation and turbulence; or (2) the wave pattern on the water surface downstream of an object in a flow, or produced by a moving object (e.g., a ship), caused by density differences of the fluids above and below the free surface and gravity (or surface tension), or both. Wake is a vessel's track through the water. Wake is:- (1) the path left behind a ship on the surface of the water; (2) the turbulent air left behind a flying aircraft; and (3) (figuratively) the area behind something, typically a rapidly moving object. / Кильватер – строй кораблей при следовании один за другим по линии курса. Смотрите также Боевые Порядки. Кильватер – волновая струя, остающаяся позади идущего судна; например, идти, следовать в кильватер или в кильватере (о судах:- следуя друг за другом). Под Кильватером или Кильватерной Струёй, от Голландского слова Kielwater, от Kiel, означающее Киль, и Water, означающее Вода, понимается:- (1) след, остающийся позади идущего судна; (2) идти в кильватер – значит идти вслед за другим судном. Кильватер – заметный на поверхности воды след от проходящего судна, очень скоро пропадающий вместе с успокоившимися волнами.

WAL = WEIGHTED AVERAGE LIFE

WALKING BOARD = ПЕРЕМЕЩАЕМЫЙ ЩИТ – Walking Board is a plywood board, generally around 2 cm thick, often used for load securing and for interlayer dunnage or top dunnage.

WALKING DOWN = СПУСКАНИЕ – Walking Down:- the now-prohibited practice of attempting to make grain flow within or out from a grain storage facility. The practice was banned for exposing facility employees to an ever-increasing risk of engulfment as grain is eroded from underneath the surface layer.

WALKING PURCHASE = ПРИОБРЕТЕНИЕ (УЧАСТКА ЗЕМЛИ), ОТМЕРЕННОГО ШАГАМИ – Walking Purchase:- (August 25, 1737), land swindle perpetrated by Pennsylvania authorities on the Delaware Indians, who had been the tribe most friendly to William Penn when he founded the colony in the previous century. Colonial authorities claimed to have found a lost treaty, of 1686, ceding a tract of Delaware tribal land between the fork of the Delaware and Lehigh rivers that extended as far as a man could walk in 1 1/2 days – about 40 miles. William Penn's son Thomas Penn (1702–75), who was proprietor of Pennsylvania in 1737, hired the three fastest walkers in the colony and offered a large prize to the one who could cover the most land. The winner, running on a carefully cleared path, crossed more than twice the land the Delaware had anticipated – causing the tribe to lose about 1 200 square miles (3 100 square km) of their land. At Thomas Penn's request, members of the Iroquois Confederacy helped enforce this unpopular decision. In reaction to this and other frauds, the Delaware joined the French in the Ohio country and returned to ravage the Pennsylvania frontier during the last French and Indian War (1756–63). In 1758 the northern half of the purchase was relinquished to the Iroquois Confederacy; the Delaware received £400 in compensation for it four years later. / Вилъйэм Пэн (William Penn). WALK–IN REFRIGERATION UNITS = ЕДИНИЦЫ КАМЕРНОГО ОХЛАЖДЕНИЯ (или ХХ) – Walk-In Refrigeration Units:- refrigeration/freezer units within a building that are large enough to walk into. They may be portable or permanent, such as a meat storage locker in a butcher store. Walk-in units may or may not have a door, plastic strips, or other flexible covers. Walk-In Refrigerator

is a refrigerated storage room, as at a butcher shop. For example, Crestwood's walk-in refrigerator had a freezing compartment that would accommodate a side of beef. / , как в лавке мясника. Например, .

WALK–IN TRADE = ВСТРОЕННАЯ ТОРГОВЛЯ (или ЗАКУПКИ ВО ВРЕМЯ ПРОГУЛКИ) – Walk-In Trade:- customers that occasionally frequent a store to make purchases there. Walk-in trade is one of the components of goodwill. Walk-in customers differ from regular customers, who are usually and ordinarily make their purchases from a given merchant, and who are attracted by the quality of service and merchandise. Walk-in customers may be attracted by the location of the store or by an appealing display.

WALK–THROUGH TEST = СКВОЗНОЙ ТЕСТ – A Walk-Through Test is a procedure used during an audit of an entity's accounting system to gauge its reliability. Walk-though tests trace the transaction step-by-step through the accounting system from its inception to the final disposition. A walk-though test is only one of many tests performed by auditors during their evaluation of an organization's accounting controls and risk management measures. The test can reveal system deficiencies and material weaknesses that would need to be rectified by the organization at the earliest. / Сквозной Тест – аудиторская процедура, используемая для оценки надёжности бухгалтерской системы клиента; предполагает проверку всех документов по хозяйственной операции, то есть всех этапов отражения данной операции в отчётной документации. Сквозной Тест – тестирование ряда документов, связанных с цепочкой обусловивших друг друга операций. Например, калькуляция себестоимости продукции сверяется с ведомостью начисления заработной платы, которая подтверждается нарядами на выполнение работ, сопоставляемыми, в свою очередь, с табелями учёта рабочего .... Сквозная Проверка (Walk-through Test):- включает отслеживание одной или нескольких операций сквозь всю систему бухгалтерского учёта.

WALL = СТЕНКА (или ПЕРЕГОРОДКА) – Wall is the definite boundary that is part of the outer structure ofcertain cells, as a plant cell. See also Cell Wall, Exine, and Pericarp. Wall is the outer layer of a cell, esp the structure in plant cells that consists ofcellulose, lignin, etc, and gives mechanical support to the cell. / Смотрите также Клеточная Оболочка или Оболочка Клетки или Клеточная Стенка (Cell Wall), Экзина (Exine), Перикарпий (Pericarp).

WALLBOARD = НАСТЕННАЯ ОБЛИЦОВОЧНАЯ ПАНЕЛЬ (или СТЕНОВАЯ ПЛИТА) – Wallboard:- any of various large, rigid sheets of finishing material used in drywall construction to face the interior walls of dwellings and other buildings. Drywall construction is the application of walls without the use of mortar or plaster. Wallboard materials include plywood and wood pulp, asbestos-cement board, and gypsum. Wood fiber and pulp boards are made by compressing together layers or particles of wood with adhesives and are manufactured with wood grain and a variety of other surface effects. They are also available with high acoustic (sound-suppressing) and thermal (insulating) capacities. Asbestos-cement boards are formed from a mixture of portland cement and asbestos fiber that has been wetted and then pressed into a board or sheet form. Organic fibers are added to some asbestos-cement boards to promote resiliency and ease of machining, and boards can also be treated with curing agents, water-repellent admixtures, and a variety of other substances to improve their performance and the ease with which they can be worked. Thin asbestos-cement sheets are usually backed with plywood or insulating board to increase their resistance to impact. One of the most common wallboard types is the gypsum panel. Gypsum, a natural mineral in crystalline form, is a hydrous sulfate of calcium. Gypsum board contains a gypsum rock core sandwiched between two layers of special paper. In fire-resistant panels, required for many types of construction, glass fibers are mixed with the gypsum base. Panels manufactured with an aluminum backing are used for insulation. Gypsum wallboard is manufactured both unfinished and finished with a variety of vinyl and other finishes in permanent colors and textures that require no additional treatment to complete the appearance of interior wall surfaces. Gypsum boards, wood sheets, and wood pulp boards are also used as a sheathing material to cover the exterior of a building's wood superstructure.

WALLED GARDEN = ОБНЕСЁННЫЙ СТЕНОЙ САД – In media and telecoms, a Walled Garden exists when a communications service provides access to content that is restricted to a communications providers' own content. It does not allow customers to access content from third parties unless they have made an arrangement with the provider (usually paying for the privilege). Walled gardens are the opposite of open networks such as the Internet. The Internet killed many walled garden services. A few internet service providers have a limited amount of success in directing subscribers to their own services. Most attempts to set up walled garden services in this space after the advent of the internet have failed. Walled gardens continue to flourish in television (e.g., satellite and cable services), albeit subject to regulatory control. They also survive in high value niches such as financial data (e.g., Reuters and Bloomberg terminals). Telecoms companies (both mobile and fixed) are attempting to set up walled garden services for the delivery of multimedia content (films and music in particular). History suggests that they will fail, and trying to sell such services to customers now accustomed to the free access the internet gives them can only be more difficult than in the past. However, much depends on the attitudes of regulators. / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). , например терминалы Ройтас (Reuters) и Блумбёг (Bloomberg).

WALLET = БУМАЖНИК – Wallet is the something that contains a means of payment, e-commerce wallets are personal Computer software (PC software), which contain the necessary sensitive information to handle payment transactions over the Internet.

WALLFLOWER = ЖЕЛТОФИОЛЬ (или НАСТЕННЫЙ ЦВЕТОК) – Wallflower is a stock that has fallen out of favor and does not get much attention from the investment community. A wallflower will typically have very low trading volumes and may also trade at low multiples of price to earnings or price to book. A wallflower stock is usually found in an unpopular sector, and seldom in a 'hot' sector. Also known as Orphan Stock. In the social context, a wallflower is somebody who remains on the sidelines of a party for any number of reasons, including reticence, unpopularity or lack of interest from others. Similarly, in the financial context, the term 'Wallflower' may have its origins in the fact that such a stock is languishing on the fringes of the stock market. Wallflowers often do not attract much coverage from research analysts, and this lack of institutional interest translates into below-average volumes and wide bid-ask spreads, which in turn can be a deterrent to retail investors. A savage bear market can turn even best-performing stocks into wallflowers eventually, especially in cases where sector valuations have scaled absurd valuations in the preceding bull market. Examples of this phenomenon would be technology stocks after the dot-com implosion of the year 2000, and alternative energy stocks in the aftermath of the 2008–09 bear market. See also Orphan Stock. Wallflower is an out-of-favor security, company, or industry. Wallpaper is a stock that has fallen out of favor with investors; stock that tends to have a low P/E (price-to-earnings ratio). Wall Flower is a bond or stock no longer attractive to investors, because of low earnings ratio. / Ценная бумага-аутсайдер, то есть непопулярная среди инвесторов ценная бумага. WALL INSULATION = ИЗОЛЯЦИЯ СТЕНЫ – Wall Insulation:- insulating materials within or on the walls between heated areas of the building and unheated areas or the outside. The walls may separate air-conditioned areas from areas not air-conditioned.

WALLPAPER = ОБОИ (или НАСТЕННАЯ БУМАГА) – (1) Wallpaper:- ornamental and utilitarian covering for walls made from long sheets of paper that have been stenciled, painted, or printed with abstract or narrative designs. Wallpaper developed soon after the

introduction of papermaking to Europe during the latter part of the XV century. Although it is often assumed that the Chinese invented wallpaper, there is no evidence that it was in general use in Asia any earlier than the time of its appearance in Europe. The earliest wallpapers in England and France were hand painted or stenciled. During the XVII century, decorative techniques also included block printing and flocking, a process whereby powdered wool or metallic powders were scattered over paper on which the design had been drawn with a slow-drying adhesive or varnish. The oldest existing example of flocked wallpaper comes from Worcester and was created in approximately 1680. Contemporary with flock work were painted Chinese papers, which first began to arrive in Europe toward the end of the XVII century. Generally referred to as India Papers, they were produced especially for the European market. The absence of repeat, or repetitive design created when single sheets are juxtaposed on the wall, and the studied dissimilarity of detail between one length and another gave them a unique quality that was highly prized. European copies produced by etched plates or woodblocks, with color applied by hand or stencil, were usually inferior to the originals. Because of their beauty and costliness, a large number of original Chinese papers have been preserved, and fine examples can be seen at Nostell Priory, North Yorkshire, and Woburn Abbey, Bedfordshire. During the XVIII century, wallpaper manufacture developed far beyond the expectations of the early makers. From the very beginning, wallpaper had been regarded as a substitute for tapestry, painted cloth, leather, and wood paneling, and the first wallpapers were esteemed because they so cleverly and inexpensively simulated the appearance of more costly hangings. Later designs, however, expressed the decorative possibilities inherent in the medium itself. In France and England new and varied styles became available – chintz patterns, satin grounds, and stripes, to mention but a few – and technical advances were making wallpaper more widely accessible. In 1785 Christophe-Philippe Oberkampf invented the first machine for printing wallpaper, and, shortly thereafter, Louis Robert designed a process for manufacturing endless rolls. French supremacy in design and execution reached its apex during the early part of the XIX century with the flock papers and distemper-colored papers of Jean-Baptiste Réveillon and panoramic decorations by Joseph Dufour. By this time French wallpapers used not only Paysage (country landscape) designs but also simulated architectural forms, such as moldings, columns, and capitals, and narrative themes that called for special experience in hanging to match the scenes accurately. Advances in the production and design of English wallpaper reached their zenith in the mid-XIX century. Machine-printed wallpaper first appeared in 1840 at a firm of printers in Lancashire and, with the work of William Morris and the Arts and Crafts Movement, created a revolution in wallpaper design. Morris' designs for the medium, which first appeared in 1862, were characterized by flat, stylized, naturalistic patterns and rich, subdued colors. His work and the progressive designs of Walter Crane coexisted, however, with the more traditional taste expressed in the work of Augustus Welby Northmore Pugin, Owen Jones, and James Huntington, who designed wallpaper in the Gothic and Rococo styles as late as the 1860s. For the next 100 years, few advances took place in the wallpaper industry. The 1950s and 1960s, however, brought more developments in wallpaper design and manufacture than any previous period. New processes enabled designers to decorate wallpaper with photogravure, and high-speed techniques were developed for the more traditional screen printing and woodblock methods. The wallpaper industry has kept abreast of modern trends in design, producing papers that range from reproductions of William Morris' original designs to those reflecting the latest fashions in the visual arts. Improvements in the durability and maintenance of wallpaper have been achieved through the use of plastic coatings. / В 1785 Кристоф-Филип Обэркампф (Christophe-Philippe Oberkampf) изобрёл . Обои – рулонный материал для внутренней отделки помещений. Бумажные обои – традиционный отделочный материал в странах Восточной Азии (Япония, Китай); в Европе до XVIII века применялись тканевые (штофные) обои, которыми обивали стены и потолки помещений. В современном строительстве различают 3 основных вида обоев:- обычные (преимущественно бумажные), влагостойкие (полимерные) и звукопоглощающие (ворсовые).

(2) Wallpaper is slang for a security with minimal to no market value. How It Works (Example):- once a security becomes worthless, its hard documentation (for example, its stock certificate) no longer has any practical function. The term Wallpaper suggests that it be used as such. Why it Matters:- following the Internet startup bust in the early 2000s, the stock of many web-based companies turned into wallpaper in a short span of time. The term doesn't only apply to stocks. For example, the impact of hyperinflation in Germany following World War I resulted in its currency becoming wallpaper. Wallpaper is a security with no monetary value. Wallpaper is the name given to stocks, bonds and other securities that have become worthless. The securities may have lost all monetary value because of bankruptcy or for other reasons. This term implies that because the certificates are worthless, may as well wallpaper your house with them. Former dotcom companies that went bankrupt are good examples of wallpaper stocks. / Буквально Обои – обесценившиеся ценные бумаги. Смысл термина состоит в том, что сертификаты акций и облигаций обанкротившихся или заявивших о своей несостоятельности компаний могут теперь использоваться только в качестве обоев. Однако сертификаты бросовых бумаг могут иметь кое-какую ценность, поскольку существуют коллекционеры сертификатов, собирающие редкие или известные сертификаты. Коллекционирование подобного рода называется Скрипофилией (Scripophily). Обои – жаргонное выражение для ценных бумаг обанкротившегося эмитента или бумаг, потерявших свою ценность в силу каких-либо иных прискорбных обстоятельств. Обои – жаргонный термин для обозначения:- (i) фальшивых бумажных денег; и/или (ii) обесценившихся сертификатов акций и облигаций.

WALL STREET = ВОЛ СТРИТ – Wall Street is street in Manhattan and which runs though the financial center of New York. Also used figuratively to refer to the New York Stock Exchange, which is situated there, and as a general term for the financial market in New York. Also known as The Street. Wall Street:- street in the southern section of the borough of Manhattan, in New York City, which has been the location of some of the chief financial institutions of the United States. The street is narrow and short and extends only about seven blocks from Broadway to the East River. It was named for an earthen wall built by Dutch settlers in 1653 to repel an expected English invasion. Even before the American Civil War the street was recognized as the financial capital of the nation. The Wall Street, or financial, district contains the New York Stock Exchange, the American Stock Exchange, investment banks, government and municipal securities dealers, trust companies, the Federal Reserve Bank, many headquarters of utilities and insurance companies, and the International Cotton, Coffee, Sugar, Cocoa, and Commodity Exchanges. The district is the headquarters of many of the country's brokerage firms. Wall Street is a worldwide symbol of high finance and investment and, as such, has entered modern mythology. To XIX-century Populists, Wall Street was a symbol of the rapacious robber barons who exploited farmers and laborers. In prosperous times Wall Street has symbolized the route to quick riches. After the devastating stock market crash of 1929, Wall Street seemed the bastion of financial manipulators able to destabilize national economies. Wall Street is the address of the New York Stock Exchange (NYSE®) in New York, State of New York (NY). Wall Street is generally automatically associated with the New York Stock Exchange, one of the world's major securities exchanges. Wall Street is the financial district of New York City, named after and centered on the eight-block-long street running from Broadway to South Street on the East River in Lower Manhattan. Over time, the term has become

a metonym for the financial markets of the United States as a whole, the American financial sector (even if financial firms are not physically located there), or signifying New York-based financial interests. It is the home of the New York Stock Exchange, the world's largest stock exchange by market capitalization of its listed companies. Several other major exchanges have or had headquarters in the Wall Street area, including NASDAQ®, the New York Mercantile Exchange (NYMEX®), the New York Board of Trade (NYBOT®), and the former American Stock Exchange (AMEX®). Anchored by Wall Street, New York City is one of the world's principal financial centers. Wall Street is a street in New York City, in lower Manhattan, where the New York Stock Exchange and major banks are situated, regarded as the embodiment of American finance; the major financial center of the United States; the money market or the financiers of the United States. Goldman Sachs has traditionally been the highest-paying investment bank on Wall Street. Wall Street is a street in lower Manhattan that is the original home of the New York Stock Exchange. The street is the historic headquarters of the largest US brokerages and investment banks. Many have since relocated to other areas of Manhattan and the United States. Wall Street was named after the wooden wall Dutch colonists built in this area in 1653 to defend themselves from the British and Native Americans. Today, the Southern tip of Manhattan is known as New York's financial district, which covers Wall Street, the New York Stock Exchange, Battery Park, the Southstreet Seaport, Trinity Church and the Woolworth Building. Wall Street is the generic term for the securities industry firms that buy, sell, and underwrite securities. Wall Street is the collective name for the financial and investment community, which includes stock exchanges and large banks, brokerages, securities and underwriting firms, and big businesses. Some people believe that the interests of these big firms contrast those of smaller businesses, or 'Main Street'. Because of their ability to quickly raise capital through the investment community, some argue that big businesses have an unfair advantage over small businesses. Outsiders feel that Wall Street businesses are an exclusive circle made up of the powerful, greedy and corrupt. Others believe that this view is outdated. Today, there are brokerages all over the country, allowing investors free access to the same information available to Wall Street's tycoons. Wall Street, the center of New York's financial district. Word Origin and History for Wall Street:- 'US financial world', 1836, from street in New York City that is home to many investment firms and stock traders, as well as NYSE®. The street socalled because it ran along the interior of the defensive wall of the old Dutchcolonial town. The street's name is often used in reference to the activities conducted on it:- 'Stock prices fell on Wall Street'. / НАЙБЭТ® (NYBOT®). НЙФБ® или Эн.Уай.Эс.И.® (NYSE®). АМЭКС® (AMEX®). Синоним финансового капитала США. Известна также просто как Зэ Стрит или Улица (The Street). Вол Стрит, Нью Йоркский денежный рынок, Американский финансовый капитал. (1) Популярное название финансового района в южной части Мэнхэтна в Нью Йорке, где находится Нью Йоркская и Американская фондовые биржи (New York and American stock exchanges). Нью Йоркская Фондовая Биржа фактически расположена на углу Вол Стрит и Брод Стрит (Wall and Broad Streets). (2) Инвестиционная компания; выражение 'юридическая компания с Вол Стрит' означает компанию, специализирующуюся на ценных бумагах и слияниях корпораций. Вол Стрит:- (1) улица в Нью Йорке, ведущая от Бродвэя (Broadway) к побережью пролива Ист Ривер, на которой располагается Нью Йоркская Фондовая Биржа (НЙФБ); (2) сама Нью Йоркская Фондовая Биржа (НЙФБ); и (3) совокупность всех финансовых институтов Нью Йорка, включая биржу, банки, денежные рынки, сырьевые и товарные рынки и так далее. Вол Стрит – популярное название делового и финансового центра Нью Йорка. Вол Стрит – в переносном смысле – финансовое сообщество брокеров, дилеров, андеррайтеров, покупающих, продающих и гарантирующих размещение ценных бумаг. Вол Стрит:- существуют различные мнения по поводу происхождения названия улицы, но общепринятой версией является то, что название происходит от расположенной здесь в XVII веке городской стены, являвшейся границей Северной части города Новый Амстердам (старое название Нью Йорка). Этот деревянный забор из брёвен служил защитой от Английских колонистов и коренных Американских жителей. Таким образом, в 1640 стена представляла собой деревянный частокол, которая позже, по поручению Голландской Вест Индской компании, была перестроена в более существенное укрепление в виде 12-футовой (4 метра) стены. В 1685 местные жители проложили вдоль стены дорогу – будущую Вол Стрит. Вскоре на улице, в различных её местах, начинают собираться купцы и различные торговцы для покупки и продажи акций и облигаций. Со временем эти торговцы разделились на два класса – аукционеров и дилеров. На Вол Стрит также находился рынок рабов, где любой желающий мог нанять себе на день или на неделю раба. В конце XVIII века торговцы и спекулянты уже собирались в определённом месте, возле растущего в то время на улице дерева платан, где и проводили свои операции с ценными бумагами, находясь все в одном месте. В 1792 они решили узаконить и закрепить свою ассоциацию, подписав 'Платановое соглашение', ставшее началом Нью Йоркской Фондовой Биржи. Идея соглашения заключалась в стремлении сделать рынок более структурированным, без аукционных манипуляций и с фиксированной комиссией. Лица, подписавшие соглашение, брали на себя обязательства взимать друг с друга при проведении операций стандартную комиссию. Лица, не подписавшие соглашение, могли участвовать в торгах, но с более высокой ставкой комиссии. 30 Апреля 1789 в здании Фэдэрэл Хол (Federal Hall), расположенном на Вол Стрит, прошла инаугурация первого Президента США Дьжодьжа Вашингтэна (George Washington), который принял присягу на балконе здания. В первые десятилетия своего существования улица Вол Стрит превратилась в площадку, где всё время преобладала буйная торговля и появлялись новые компании и предприятия. По словам одного из очевидцев того времени, историка Эдвина Дьжи. Бороуза (Edwin G. Burrows), многие жители улицы жаловались на шум и суету, царившую здесь. Открытие Канала Ири (Erie Canal) в начале XIX века подтолкнуло к развитию бизнеса Нью Йорка, так как это был единственный крупный Восточный морской порт, имевший доступ к внутренним водным путям и к портам на Великих Озёрах. Вол Стрит стала 'денежным центром Америки'. Историк Чарлз Ар. Гэйст (Charles R. Geisst) утверждал, что между интересами бизнеса на Вол Стрит и органов власти в Вашингтоне, постоянно происходило 'перетягивание каната'. В 1840-50-е большинство жителей Вол Стрит стали переселяться на Север в центр города из-за возросшего влияния бизнеса. Гражданская Война 1861–65 между Севером и Югом привела к тому, что Северные города переживали больший экономический бум, чем Южные, и, поэтому такие Северные города как Нью Йорк, стали процветать на фоне бедных и консервативных Южных городов. В Нью Йорке стали появляться крупнейшие банки и компании. Появилось крупнейшее финансовое учреждение Дьжей.Пи.Моргэн Чэйс (JPMorgan Chase), в Нью Йорк переехала штабквартира компании Дьжона Дэйвида Рокэфэлё (John David Rockefeller) Стэндод Оил (Standard Oil). В период с 1860 по 1920 экономика США перепрофилировалась с сельскохозяйственной в промышленную и финансовую сферу, и, несмотря на это, Нью Йорк сохранил свои лидирующие позиции крупного финансового и бизнес центра страны. Он являлся вторым после Лондона в мире финансового капитала. В 1884 Американский журналист Чарлз Дау впервые начал отслеживать тенденцию изменения цен 11 крупнейших компаний страны, в основном это были железнодорожные компании, выводя при этом средний показатель, показывающий общее состояние рынка. Таким образом, появился Индекс от Дау Дьжонза, ставшим удобным ориентиром для анализа рынка и общепринятым способом взглянуть на весь фондовый рынок. В 1889 существовавший до этого биржевой отчётный журнал 'Customers' Afternoon Letter' превратился в деловую газету За Вол Стрит Дьжонэл (The Wall Street Journal) – ежедневное периодическое издание, публиковавшее финансовую отчётность. Историк Дьжон Брукс (John Brooks) рассматривает начало XX столетия как период расцвета Вол Стрит. В конце XIX – начале XX веков в Нью Йорке происходит бум строительства небоскрёбов. Крупнейшие корпорации стремились построить свои штабквартиры на Мэнхэтн, где с геологической точки зрения, твёрдая порода наиболее подходила

для высотных зданий. Непросто складывались отношения Вол Стрит с государственными властями. Много недовольства среди спекулянтов появлялось в результате неоднократных попыток правительства по введению различных налогов на проводимые операции на бирже. В Октябре 1929 многие факторы успокаивали инвесторов 'что их деньги в безопасности' на Вол Стрит. Однако через несколько дней стоимость акций упала. Крах фондового рынка в 1929 привёл к Великой Депрессии, при которой четверть всех трудящихся стали безработными. В это время развитие финансового района зашло в тупик и Вол Стрит 'заплатил высокую цену' и 'стал чем-то вроде заводи в Американской жизни'. В годы Нового курса и Второй Мировой Войны Вол Стрит переживает кризис. В эти дни при проведении операций с ценными бумагами, правительством было запрещено получение любых кредитов. Таким образом, при покупке акций, покупатель должен был оплачивать 100% стоимость, не прибегая к кредитам. Существенный подъём произошёл лишь в 1967, когда объёмы торгов поднялись до 7.5 миллионов акций в день. В дальнейшем также происходили падения и взлеты из-за различных мировых событий. В 1966 на Мэнхэтн началось строительство Всемирных Торговых Центров, но после завершения строительства встала проблема по привлечению арендаторов на новые площади. Тем не менее, многие существующие компании приобрели площади под офисы в зданиях-близнецах. В некотором отношении значимость финансового района перешла от Вол Стрит к Всемирному Торговому Центру.

WALL STREET ANALYST = АНАЛИТИК С ВОЛ СТРИТ – Wall Street Analyst is an analyst employed by a brokerage firm or another firm that manages client accounts. Unlike that of the buy-side analysts employed by mutual funds, research produced by sell-side analysts is usually available to the public. Also known as Sell-Side Analyst.

THE WALL STREET JOURNAL = ЗА ВОЛ СТРИТ ДЬЖОНЭЛ (или ЖУРНАЛ ВОЛ СТРИТ) – The Wall Street Journal (WSJ) is a New York-based English-language international daily newspaper with a special emphasis on business and economic news. It is published six days a week by Dow Jones & Company, a division of News Corp, along with the Asian and European editions of the Journal. The Journal is the largest newspaper in the United States by circulation. According to the Alliance for Audited Media, it has a circulation of about 2.4 million copies (including nearly 900 000 digital subscriptions), as of March 2013, compared with USA Today's 1.7 million. Its main rival in the business newspaper sector is the London-based Financial Times, which also publishes several international editions. The Journal primarily covers American economic and international business topics, and financial news and issues. Its name derives from Wall Street, the heart of the New York financial district. It has been printed continuously since its inception on July 08, 1889, by Charles Dow, Edward Jones, and Charles Bergstresser. The newspaper version has won the Pulitzer Prize thirty-six times, including 2007 prizes for its reporting on backdated stock options and the adverse effects of China's booming economy. In 2011,The Wall Street Journal was ranked No. 1 in BtoB's Media Power 50 for the 12th consecutive year. Its editorial pages and columns, run separately from the news pages, are highly influential in American conservative circles. As editors of the editorial page, Vermont C. Royster (served 1958–71) and Robert L. Bartley (served 1972–2000) were especially influential in providing a conservative interpretation of the news on a daily basis. Beginnings:- Dow Jones & Company's, publisher of the Journal, first product was brief news bulletins hand-delivered throughout the day to traders at the stock exchange. They were later aggregated in a printed daily summary called the Customers' Afternoon Letter. The reporters Charles Dow, Edward Jones and Charles Bergstresser converted this into The Wall Street Journal, which was published for the first time on July 08, 1889, and began delivery of the Dow Jones News Service via telegraph. In 1896, The 'Dow Jones Industrial Average' was officially launched. It was the first of several indices of stock and bond prices on the New York Stock Exchange. In 1899, the Journal's Review & Outlook column, which still runs today, appears for the first time. It initially was written by Charles Dow. Journalist Clarence Barron purchased control of the company for USD130 000 in 1902; circulation was then around 7 000 but climbed to 50 000 by the end of the 1920s. Barron and his predecessors were credited with creating an atmosphere of fearless, independent financial reporting – a novelty in the early days of business journalism. In 1921, Barron's, America's premier financial weekly, was founded. Barron died in 1928, a year before Black Tuesday, the stock market crash that greatly affected the Great Depression in the United States. Barron's descendants, the Bancroft family, would continue to control the company until 2007. The Journal took its modern shape and prominence in the 1940s, a time of industrial expansion for the United States and its financial institutions in New York. Bernard Kilgore was named managing editor of the paper in 1941, and company CEO in 1945, eventually compiling a 25-year career as the head of the Journal. Kilgore was the architect of the paper's iconic front-page design, with its 'What's News' digest, and its national distribution strategy, which brought the paper's circulation from 33 000 in 1941 to 1.1 million at the time of Kilgore's death in 1967. Under Kilgore, in 1947, that the paper won its first Pulitzer Prize, for William Henry Grimes's editorials. In 1967, Dow Jones Newswires began a major expansion outside of the United States that ultimately put journalists in every major financial center in Europe, Asia, Latin America, Australia, and Africa. In 1970, Dow Jones bought the Ottaway newspaper chain, which at the time comprised nine dailies and three Sunday newspapers. Later, the name was changed to 'Dow Jones Local Media Group'. 1971 to 1997 brought about a series of launches, acquisitions, and joint ventures, including 'Factiva', the Asian Wall Street Journal, The Wall Street Journal Europe, the WSJ.com website, Dow Jones Indexes, MarketWatch, and 'WSJ Weekend Edition'. In 2007 News Corp. acquired Dow Jones WSJ, a luxury lifestyle magazine, was launched in 2008. Internet Expansion:- a complement to the print newspaper, The Wall Street Journal Online, was launched in 1996. In 2003, Dow Jones began to integrate reporting of the Journal's print and online subscribers together in Audit Bureau of Circulations statements. In 2007, it was commonly believed to be the largest paid-subscription news site on the Web, with 980 000 paid subscribers. Since then, online subscribership has fallen, due in part to rising subscription costs, and was reported at 400 000 in March 2010. In May 2008, an annual subscription to the online edition of The Wall Street Journal cost USD119 for those who do not have subscriptions to the print edition. By June 2013, the monthly cost for a subscription to the online edition was USD22.99, or USD275.88 annually, excluding introductory offers. On November 30, 2004, Oasys Mobile and The Wall Street Journal released an application that would allow users to access content from the Wall Street Journal Online via their mobile phone. It 'will provide up-to-the-minute business and financial news from the Online Journal, along with comprehensive market, stock and commodities data, plus personalized portfolio information – directly to a cell phone'. Many of The Wall Street Journal news stories are available through free online newspapers that subscribe to the Dow Jones syndicate. Pulitzer Prize – winning stories from 1995 are available free on the Pulitzer web site. In September 2005, the Journal launched a weekend edition, delivered to all subscribers, which marked a return to Saturday publication after a lapse of some 50 years. The move was designed in part to attract more consumer advertising. In 2005, the Journal reported a readership profile of about 60 percent top management, an average income of USD191 000, an average household net worth of USD2.1 million, and an average age of 55. In 2007, the Journal launched a worldwide expansion of its website to include major foreign-language editions. The paper had also shown an interest in buying the rival Financial Times. Xxxxx. The Wall Street Journal:- daily business and financial newspaper edited in New York City and sold throughout the United States. Other daily editions include The Asian Wall Street Journal, edited in Hong Kong, and The Wall Street Journal Europe, edited in Brussels. The Wall Street Journal was founded by Charles H. Dow, of Dow Jones & Company, primarily to cover business and financial news. The first issue was published on July 08, 1889. The newspaper's accuracy and the breadth and detail of its coverage won it respect and success from the start. From its founding until early in the Great Depression, the Journal rarely ventured beyond business and economic news. Then, however, it began to carry occasional feature articles on other subjects. After World War II this trend increased, and by the 1960s the Journal regularly carried two

feature articles on page one that only occasionally addressed business subjects, and then in a whimsical or amusing way. Although perceived as favoring the interests of businesses, the Journal's opinion and editorial pages reflect a wide range of highly informed business, political, and economic opinion; readers' letters; and reviews of and comments on the arts. The long-established structure of the Journal includes complete tables reporting all financial and stock market activity for the preceding day as well as thorough reports and analyses of current business topics. Published Monday through Friday, the national, Asian, and European editions of the Journal had a combined circulation of more than two million at the turn of the XXI century. Its sister publications have included Barron's, the Far Eastern Economic Review, and SmartMoney. In 2002 the paper received its 26th Pulitzer Prize, which was awarded to the entire staff for its breaking news coverage of the attack on New York City's World Trade Center. The staff won another Pulitzer in 2003 for coverage of corporate scandals in the United States. / Корп. (Corp.). Вёман Си. Ройстё (Vermont C. Royster) (1958–71) и Робёт Эл. Бартли (Robert L. Издаётся в городе Нью Йорк, Штат Нью Йорк компанией Дау Дьжонз Энд Кампэни (Dow Jones & Company) с 1889. За Вол Стрит Дьжонэл – одно из крупнейших и влиятельнейших Американских изданий. В 2010 ежедневный тираж газеты составлял 2.1 млн экземпляров и 400 000 платных подписок в Интернете. Существуют Европейское и Азиатское издания газеты. Печатаются новости политики, экономики, финансов, аналитики, культуры. Название газеты непосредственно связано с Вол Стрит, улицей Нью Йорка и финансовым центром США. Само издание посвящено в первую очередь Американским и международным деловым и финансовым новостям. За Вол Стрит Дьжонэл является Англоязычной международной ежедневной газетой, издаваемой Дау Дьжонз Энд Кампэни (Dow Jones & Company) в Нью Йорке с Азиатским и Европейским выпусками. На 2007 её международное ежедневное обращение составляло больше, чем 2 миллиона экземпляров и приблизительно 931 000 платящих подписчиков онлайн. До Ноября 2003 у газеты был самый большой тираж в США, пока её не обошла USA Today. Её главный конкурент сегодня – находящаяся в Лондоне Файнэншэл Таймс, которая также издаёт несколько международных выпусков. За Вол Стрит Дьжонэл прежде всего освещает события в США и международный бизнес, финансовые новости и проблемы – название газеты происходит от Вол Стрит, улицы в Нью Йорке, которая является сердцем финансового района. Она печаталась непрерывно, начиная со своего основания 08 Июля 1889, Чарлзом Дау (Charles Dow), Эдводом Дьжонзом (Edward Jones) и Чарлзом Бёгстрэссёром (Charles Bergstresser). Газета выиграла Пулитцёровскую Премию тридцать три раза. Будущее За Вол Стрит Дьжонэл широко обсуждалось, начиная с приобретения Дау Дьжонза Рупертом Мердоком и его компанией Ньюз Корпорэйшэн (News Corporation). Руководящий Редактор Маркус Брочли, ветеран газеты, проработавший в ней 20 лет, и прежний иностранный корреспондент, сомневался, что Мердок сможет произвести глубокие изменения в газете. Хотя Брочли предпочёл оставаться в Ньюз Корпорэйшэн как консультант, его отказ от главной редакционной работы, которой он занимался около года, порождал различные слухи о планах Мердока. Начало:- Дау Дьжонз Энд Кампэни (Dow Jones & Company), издательство За Вол Стрит Дьжонэл, было основано в 1874 репортёрами Чарлзом Дау, Эдводом Дьжонзом и Чарлзом Бергстрессером. Дьжонз преобразовал мелкое Customers' Afternoon Letter в За Вол Стрит Дьжонэл в 1889 и начал распространять сообщения Информационной службы Дау Дьжонза через телеграф. За Вол Стрит Дьжонэл печатала Average, первый из нескольких индексов запасов и цен облигаций на Нью Йоркской Фондовой Бирже. Журналист Кларэнс Бэрон купил контрольный пакет акций компании за USD130 000 в 1902; тираж тогда приблизительно равнялся 7 000 экземпляров, но поднялся на 50 000 к концу 1920-х. Бэрону и его предшественникам приписали создание атмосферы бесстрашной, независимой финансовой отчётности – новинка в первые годы деловой журналистики. Бэрон умер в 1928, за год до Чёрного Вторника, краха фондовой биржи, который вызвал Великую Депрессию в Соединённых Штатах. Потомки Бэронов, семья Бэнькрофт, продолжили управлять компанией до 2007 года. WSJ нашла свою современную форму и выдающееся положение в 1940-х, во время индустриального расширения Соединённых Штатов и его финансовых учреждений в Нью Йорке. Бернард Килгор был назначен Руководящим Редактором газеты в 1941 и президентом компании в 1945 году, в конечном счёте сделав 25-летнюю карьеру в качестве главы За Вол Стрит Дьжонэл. Именно Килгор был зачинателем особенного дизайна первой полосы газеты с его обзором Какие новости? Его стратегия общенационального распространения газеты привела к тому, что тираж вырос от 33 000 экземпляров в 1941 до 1.1 миллиона ко времени смерти Килгора в 1967. Также благодаря Килгору в 1947 газета получила свою первую Пулитцёровскую Премию за редакторские статьи. За Вол Стрит Дьжонэл имела отличную репутацию благодаря выдающимся деловым новостям и консервативности мнений, однако тираж За Вол Стрит Дьжонэл упал в нестабильных 1990-х, отражая растущие расходы на рекламу и газету и вызывая предположения, что газете, возможно, придётся решительно измениться, или быть проданной. Расширение Интернета:- выпуск приложения к печатной версии газеты, За Вол Стрит Дьжонэл – Онлайн, был начат в 1996. В 2003 Дау Дьжонз начал объединять сообщения печатной версии и онлайн подписчиков в заявлениях Бюро по контролю за тиражами. Этот сайт считается самым большим платным новостным ресурсом в Сети, распространяющим сообщения более чем 980 000 подписчиков в середине 2007. В Мае 2008 годовая подписка на онлайн-выпуск За Вол Стрит Дьжонэл стоила USD119 для тех, кто не был подписан на печатную версию. 30 Ноября 2004 Оэзис Мобайл (Oasys Mobile) и За Вол Стрит Дьжонэл запустили приложение, которое позволило пользователям получать доступ к содержанию За Вол Стрит Дьжонэл – Онлайн через мобильный телефон. Это 'обеспечит пользователям получение самых свежих деловых и финансовых новостей от сетевой версии Дьжонэл', наряду со всесторонним анализом рынков, акций и товарных бирж, плюс персональный перечень информации – всё это непосредственно на сотовый телефон'. Платное содержание газеты есть и в свободном доступе, но на ограниченной основе – для подписчиков Службы Эй.Оу.Эл. (AOL), а также через бесплатный Congoo Netpass. Много новостей За Вол Стрит Дьжонэл доступны благодаря бесплатным онлайн-газетам, которые подписываются на новости синдиката Дау Дьжонза. Материалы, получившие Пулитцавскую Премию с 1995 находятся в свободном доступе на веб-сайте Пулитца (Pulitzer). За Вол Стрит Дьжонэл недавно сделала всё своё содержание бесплатным в виде файлов формата pdf. К ним можно получить доступ как через URL, так и через веб-приложения. Однако большая часть содержания, доступного на веб-сайте, – только для подписчиков. Эти материалы содержат заголовки и первые абзацы, но блокируют большинство статьей, если пользователь не зарегистрирован. Вообще, главные новостные материалы доступны широкой публике. В Сентябре 2005 газета начала печатать выпуск выходного дня, поставляемый всем подписчикам. Этот шаг был предпринят для того, чтобы привлечь больше потребительской рекламы. В 2005 За Вол Стрит Дьжонэл сообщил о характеристики своего среднего читателя:- приблизительно 60% входит в высшее исполнительное руководство, средний доход составляет USD191 000, а средний возраст – 55 лет. В 2007 За Вол Стрит Дьжонэл начал международное расширение своего веб-сайта, чтобы популяризировать главные выпуски на иностранном языке. Газета также проявила интерес к покупке конкурирующей Файнэншэл Таймз (Financial Times). За Вол Стрит Дьжонэл – одна из ведущих газет США, знаменитая своим освещением финансовых, фирменных и рыночных новостей.

WALL STREET REFINER = НЕФТЕПЕРЕРАБОТЧИК С ВОЛ СТРИТ – The Wall Street Refiner is a Wall Street investment firm that trades crude oil and oil products on a scale similar to large oil companies. Such firms do not own oil refineries and do not take delivery of oil. / Нефтепереработчик с Вол Стрит – инвестиционная фирма с Вол Стрит, которая торгует нефтью и нефтепродуктами в

таких же масштабах, что и крупные нефтяные компании. Такие фирмы не владеют нефтеперегонными заводами и не занимаются поставками нефти. Они продают и покупают фьючерсы на нефть и нефтепродукты, занимая на контрактном рынке позицию, схожую с позицией настоящего нефтеперерабатывающего завода на рынке реального товара.

WAL–MART = ВОЛ–МАРТ – Wal-Mart:- in full Wal-Mart Stores, Inc. is the US operator of discount stores founded by Sam Walton in Rogers, Arkansas (1962). With headquarters in Bentonville, Arkansas, Wal-Mart focused its early growth in rural areas, thereby avoiding direct competition with other American retailing giants such as Sears and Kmart. As it grew, the company developed new retail formats, including Sam's Club discount warehouses (1983) and Wal-Mart Supercenters (1988). Within a decade of opening the combination grocery and merchandise Supercenters, Wal-Mart had become one of the largest grocers in the United States. An emphasis on customer attention, cost controls, and efficiencies in its distribution networks helped Wal-Mart become the largest retailer in the United States in 1990. It moved into international markets one year later with the opening of a store in Mexico, and growth continued, either through new stores or the acquisition of established retailers, in countries such as Canada, China, Germany, and the United Kingdom. By 1999 Wal-Mart had become the world's largest private employer, and by 2001, its total sales surpassed those of Exxon Mobil, ranking Wal-Mart as the largest corporation in the world. Extreme growth has not occurred without controversy; Wal-Mart has been variously criticized for contributing to urban sprawl and for perpetuating low wages. Its merchandising practices are nonetheless emulated by other retailers, and Wal-Mart continues to gain popularity with customers around the world. / Вол-Март Стоз, Инк. (Wal-Mart Stores, Inc.). WALNUT = ОРЕХ (или ОРЕХОВОЕ ДЕРЕВО) – Walnut:- any of about 20 species of deciduous trees constituting the Genus Juglans of the family Juglandaceae, native to North and South America, southern Europe, Asia, and the West Indies. The trees have long leaves with 5 to 23 short-stalked leaflets; male and female reproductive organs are borne in different, petalless flower clusters on the same tree; the twigs contain a many-chambered pith; and the fruit is a woody nut enclosed in a thick husk. Black Walnut (Juglans Nigra) of Eastern North America and English, or Persian, Walnut (Juglans Regia), native to Iran, are valuable timber trees that produce edible nuts. The Butternut (Juglans Cinerea) of Eastern North America also produces an edible nut. See also Butternut. A Black Walnut tree usually is between 20 and 30 m (about 65 and 100 feet) tall and has a trunk about 60 to 90 cm (2 to 3 feet) in diameter, with a deeply furrowed, dark brown or grayish black bark. The leaves, about 30 to 60 cm long, consist of 15 to 23 leaflets borne on very short stalks. The nut contains a sweet, oily seed and is enclosed in a yellow-green, hairy husk. Black Walnut trees are also planted for ornament and are cultivated for the wood and for a dye found in the fruit husks. Black Walnut grows slowly, maturing on good soils in about 150 years; it may have a life span of more than 250 years. The English Walnut, cultivated for many years in England, is now grown in parts of North and South America, both as an ornamental and for commercial nut production. A tree produces fine-quality nuts only on fertile, well-drained soils of medium-heavy texture. The round-tipped leaflets have smooth margins, and the terminal leaflet is the largest. The leaflets of native North American Walnuts are largest toward the center of the leaf, and have toothed margins. The dark, fine-grained wood of English and Black Walnuts is used for furniture, panelling, and gunstocks. / Орех – Род Деревьев Семейства Ореховых. 14–15 (по другим данным, до 40) видов, преимущественно в горах Южной Европы, Азии и Америки. В бывшем СССР 3 вида:- Айлантолистный Орех, Грецкий Орех и Маньчжурский Орех. Многие виды разводят ради съедобных плодов и древесины, а также как декоративные. Айлантолистный Орех в Красной Книге СССР. Ореховые – Семейство Двудольных растений. Деревья, реже кустарники. Около 70 видов (8 родов), преимущественно в умеренном и субтропическом поясах; в бывшем СССР 2 дикорастущих рода (Лапина и Орех). Плоды Грецкого, Маньчжурского Орехов, Пекана и других используют в пищу, древесину – в производстве мебели.

WALRAS' LAW = ЗАКОН ВАЛЬРАСА – Walras' Law is an economics law that suggests that the existence of excess supply in one market must be matched by excess demand in another market so that it balances out. So when examining a specific market, if all other markets are in equilibrium, Walras' Law asserts that the examined market is also in equilibrium. Keynesian economics, by contrast, assumes that it is possible for just one market to be out of balance without a 'matching' imbalance elsewhere. Walras' law is named after French neoclassical economist Léon Walras, who created general equilibrium theory and founded the Lausanne School of economics. Walras' famous insights can be found in the book Elements of Pure Economics, published in 1874. Walras' Law:- the principle that, if all markets for all goods and services in an economy are balanced, then the market for a specific good or service must also be balanced. Walras' law is based on the idea that excess demand and supply in an economy must add to zero. Thus, if there is no excess demand or supply elsewhere in an economy, then there can be no excess in a given market. Walras' law contradicts the Keynesian notion that involuntary unemployment an exist when an economy is otherwise in equilibrium because, according to the law, the labor market must itself be balanced. Critics of the law maintain that it does not consider financial markets and their effect on the markets for goods and services. Walras's Law is the concept that a surplus in one market indicates the presence of a shortage in another. In 1844, neoclassical French economist Leon Walras posited that the existing markets of the world economy are predisposed toward equilibrium between supply and demand. In other words, a change in either supply or demand results in a proportional shift in the other, which brings the system back into equilibrium. This idea suggests that the economy is a zero-sum world in which a measurable surplus in one market must be accompanied by a comparable deficit in another market. By the early decades of the XX century, Walras's law and other examples of neoclassical theory were set aside in favor of the modern economic theories of British economist John Maynard Keynes. Under Keynesian theory, markets can function and develop independently of one another. The existence of a surplus or deficit in one market is not necessarily indicative of a respective deficit or surplus elsewhere. Walras' Law:- a zero-sum mathematical principle of developed by Leon Walrus in 1844 stating that all markets are either in equilibrium or in disequilibrium, and that it is not possible for only one market to be in disequilibrium. Where there is excess supply in one market there must be an equivalent excess demand in another market that produces a zero sum. / Дьжон Мэйнад Кэйнз (John Maynard Keynes). Закон Вальраса – закон, сформулированный Французским экономистом Мари-Эспри-Леоном Вальрасом (Marie-Esprit-Léon Walras; 1834–1910)), который устанавливает, что стоимость требуемых экономикой товаров равна стоимости продаваемых товаров. Такой вывод вытекает из простой мысли о том, что для каждого индивида его доход равен его расходам (включая его займы и сбережения). Это утверждение является важным шагом в доказательстве существования абсолютно конкурентного равновесия, которое является фактором Парето (Pareto) в теории общего равновесия (general equilibrium theory).

WALSH PRICE INDEX = ИНДЕКС ПО ЦЕНАМ ОТ ВОЛШ – Walsh Price Index is a price index defined as the weighted arithmetic average of the current to base period price relatives which uses the quantities of an intermediate basket as weights. The quantities of the intermediate basket are geometric averages of the quantities of the base and current periods. It is a symmetric index and a superlative index. Walsh Price Index is the weighted sum of the current period process divided by the weighted sum of the base period prices with the geometric average of both period quantities serving as the weighting mechanism.

WALTER'S FORMULA = ФОРМУЛА ВОЛТЁРА – Walter's Formula is a formula for determining the corporation's optimal dividend-payout ratio. P = [D + r x <E-(d)/p] / p, where P is the market price per common share, E is the earnings per share, r is the rate of return, p is the capitalization rate. Change D, we can obtain the highest P.

WAR AND CIVIL WAR RISKS EXCLUSION AGREEMENT = СОГЛАШЕНИЕ ОБ ИСКЛЮЧЕНИИ РИСКОВ ВОЙНЫ И ГРАЖДАНСКОЙ ВОЙНЫ – War And Civil War Risks Exclusion Agreement is an agreement between Lloyd's underwriters and non-marine insurance companies that they will not cover certain war and civil war risks on land. Although no longer in use, the Lloyd's Ship and Goods Form (SG Form adopted on 01 January 1779) and the Free of Capture and Seizure Clause (FC&S Clause) heralded the formal introduction of war risk exclusion into insurance policies by underwriters in London, the United Kingdom. Following its establishment in the marine market, the practice of excluding war risks was extended to other branches of non-marine insurance both in London and elsewhere. For instance, following the Spanish Civil War of 1936 in which insurance markets in London and the United States suffered heavy losses from war risks, non-marine underwriters in the London market, including Lloyd's underwriters, entered into the War and Civil War Risks Exclusion Agreement in 1936. The agreement, which is still in effect and has attained worldwide application, essentially provides that underwriters would exclude from all insurances and reinsurances loss, damage or liabilities resulting directly or indirectly from war and civil war. As a result of its implementation, all non-marine policies issued around the world must (and usually do) include a War and Civil War Exclusion Clause.

WAR CHEST = ВОЕННАЯ КАЗНА – War Chest is a fund of liquid assets (cash) set aside by a corporation to pay for a takeover or to defend against a takeover. Traders will say that a company has a war chest that it plans to use to take over another company. Or traders might say that a particular company will be difficult to take over because it has a large war chest that it can use to defend itself by buying back its stock, making an acquisition of its own, paying for legal fees to mount defenses, or taking other defensive measures. See also Takeover. War Chest:- cash kept aside for a takeover or for defense against a takeover bid. / Военная Казна:- средства в виде наличных денег или ликвидных активов, которые хранятся вне корпорации на случай попытки поглощения или для обороны от поглощения. Когда торговцы говорят, что компания имеет военную казну, то это значит, что она собирается поглотить другую компанию. Или же торговцы могут сказать, что такую-то компанию будет трудно поглотить, потому что она имеет очень большую военную казну, с помощью которой она может выкупить свои акции, оплатить легальные защитные мероприятия или принять другие меры защиты. WAR CLAUSE = ОГОВОРКА О ВОЕННЫХ ДЕЙСТВИЯХ (или ОГОВОРКА О ВОЙНЕ) – (1) War Clause is a provision in, or attached to, a life insurance policy limiting or excluding the extra risk inherent in war. Sometimes the exclusion applies only to members of the armed forces; sometimes it applies to all civilians as well. Sometimes it excludes death while war is going on; sometimes it excludes death only as a result of war. War Clause is a stipulation that releases the insurer from liability if the loss occurs as a result of an act of war. War Clause is a clause included in some life insurance policies issued during wartime that limits the insurer's liability to a return of premiums if the insured dies as a result of war or while serving in the military or naval services outside the home area. War Clause is a provision excluding liability of an insurer if a loss is caused by war. / Положение, исключающее ответственность страховщика за убытки, возникшие вследствие войны или военных действий.

(2) War Clause is a clause in the US Constitution that grants power to the President to declare war, grant letters of marque, and reprisal. The power to declare war is granted under USCS Const. Art. I, § 8, Cl 11. This clause also makes rules concerning:- (i) captures on land and water; (ii) raise and support armies; (iii) provide and maintain army; and (iv) make rules for the government and regulation of the land and naval forces.

WAR CRIME = ВОЕННОЕ ПРЕСТУПЛЕНИЕ – War Crime:- in international law, serious violation of the laws or customs of war as defined by international customary law and international treaties. Definition And Conceptual Development:- the term War Crime has been difficult to define with precision, and its usage has evolved constantly, particularly since the end of World War I. The first systematic attempt to define a broad range of war crimes was the Instructions for the Government of Armies of the United States in the Field – also known as the 'Lieber Code' after its main author, Francis Lieber – which was issued by US President Abraham Lincoln and distributed among Union military personnel in 1863. For example, the Lieber Code held that it was a 'serious breach of the law of war to force the subjects of the enemy into service for the victorious government' and prohibited 'wanton violence committed against persons in the invaded country', including rape, maiming, and murder, all of which carried the penalty of death. More recently, definitions of war crimes have been codified in international statutes, such as those creating the International Criminal Court and the war crimes tribunals in Yugoslavia and Rwanda, for use in international war crimes tribunals. In contrast to earlier definitions, modern definitions are more expansive and criminalize certain behaviours committed by civilians as well as by military personnel. Immediately following World War I, the victorious Allied Powers convened a special Commission on the Responsibility of the Authors of the War and on Enforcement of Penalties. The commission's report recommended that war crimes trials be conducted before the victors' national courts and, when appropriate, before an inter-Allied tribunal. The Allies prepared an initial list of about 900 suspected war criminals and submitted the list to Germany. Although heads of state traditionally had enjoyed immunity from prosecution, the commission's main target was Germany's Emperor (Kaiser) Wilhelm II, whom most of the Allies (though not the United States) wished to hold responsible for numerous violations of the laws of war. William, however, took refuge in The Netherlands, which refused to extradite him, and he was never tried. Most of the remaining suspected war criminals on the list similarly managed to avoid prosecution, because Germany was reluctant to turn them over to the Allies. Instead, a compromise was reached whereby the Allies permitted a small number of suspects to be tried in Germany before the Supreme Court in Leipzig. These prosecutions resulted in few convictions, with most sentences ranging from a few months to four years in prison. The Nürnberg And Tokyo Trials:- the next major attempt to prosecute war criminals occurred in Europe and Asia after World War II. Throughout the war, the Allies had cited atrocities committed by the Nazi regime of Adolf Hitler and announced their intention to punish those guilty of war crimes. The Moscow Declaration of 1943, issued by the United States, Great Britain, and the Soviet Union, and the Potsdam Declaration of 1945, issued by the United States, Great Britain, and China (and later adhered to by the Soviet Union), addressed the issue of punishing war crimes committed by the German and Japanese governments, respectively. At the war's conclusion, representatives of the United States, the United Kingdom, the Soviet Union, and the provisional government of France signed the London Agreement, which provided for an international military tribunal to try major Axis war criminals whose offenses did not take place in specific geographic locations. This agreement was supported by 19 other governments and included the Nürnberg Charter, which established the Nürnberg tribunal and categorized the offenses within its jurisdiction. The charter listed three categories of crime:- (i) crimes against peace, which involved the preparation and initiation of a war of aggression; (ii) war crimes (or 'conventional war crimes'), which included murder, ill treatment, and deportation; and (iii) crimes against humanity, which included political, racial, and religious persecution of civilians. This last category included what is commonly called Genocide. The term Genocide was coined by the Polish American legal scholar Raphael Lemkin and first appeared in print in his work Axis Rule in Occupied Europe:- Laws of Occupation, Analysis of Government, Proposals for Redress (1944). The Convention on the Prevention and Punishment of the Crime of Genocide, adopted by the General Assembly of the United Nations in 1948, defined genocide as including killing or inflicting serious physical or mental injury on members of a national, ethnic, racial, or religious group with the intention of bringing about the group's destruction, in whole or in part. The convention made genocide an international crime that could be prosecuted in the court of any country. Because the Nürnberg trials preceded the convention, however, Nazi war criminals were not prosecuted for genocide. The International Military Tribunal in Nürnberg, Germany, tried 22 Nazi leaders, including one, Martin Bormann, who was tried in absentia. The trial was conducted in four languages and lasted nearly 11 months. All but three of the defendants were convicted; 12 were sentenced to death. The remaining defendants received lengthy prison terms, which they served at Spandau Prison in West Berlin. Subsequent trials were held under the auspices of Control Council Law No. 10, which was used to prosecute accused Nazi war criminals whose crimes took place in specific locales. Japanese defendants accused of war crimes were tried by the International Military Tribunal for the Far East, which was established by a charter issued by US Army General Douglas MacArthur. The so-called Tokyo Charter closely followed the Nürnberg Charter. The trials were conducted in English and Japanese and lasted nearly two years. Of the 25 Japanese defendants (all of whom were convicted), 7 were sentenced to hang, 16 were given life imprisonment, and 2 were sentenced to lesser terms. Except for those who died early of natural causes in prison, none of the imprisoned Japanese war criminals served a life sentence. Instead, by 1958 the remaining prisoners had been either pardoned or paroled. From their outset, the war crimes trials were dismissed by critics merely as 'victor's justice', because only individuals from defeated countries were prosecuted and because the defendants were charged with acts that allegedly had not been criminal when committed. In support of the trials, the Nürnberg Tribunal cited the Kellogg-Briand Pact (1928), which formally outlawed war and made the initiation of war a crime for which individuals could be prosecuted. Post-World War II Developments:- Geneva Conventions:- after the Nürnberg and Tokyo trials, numerous international treaties and conventions attempted to devise a comprehensive and enforceable definition of war crimes. The four separate Geneva conventions, adopted in 1949, in theory made prosecutable certain acts committed in violation of the laws of war. The conventions provided for the protection of wounded, sick, and shipwrecked military personnel, prisoners of war, and civilians. Like the convention on genocide, however, the Geneva conventions specified that trials were to be arranged by individual governments. In 1977 two protocols were adopted to clarify and supplement the Geneva conventions. Recognizing that many conflicts were internal rather than international in scope, the second protocol afforded greater protection to guerilla combatants in civil wars or wars of 'self-determination'. Rwanda And Yugoslavia War Crimes Tribunals:- nearly 50 years passed between the Nürnberg and Tokyo trials and the next formal international prosecution of war crimes. In May 1993, in an attempt to prevent further acts of 'ethnic cleansing' in the conflict between states of the former Yugoslavia and to restore peace and security to the Balkan region, the United Nations Security Council established the International Criminal Tribunal for the Prosecution of Persons Responsible for Serious Violations of International Humanitarian Law Committed in the Territory of the Former Yugoslavia since 1991, commonly known as the ICTY. In November 1994 the UN responded to charges of genocide in Rwanda by creating the ICTR, formally known as the International Criminal Tribunal for the Prosecution of Persons Responsible for Genocide and Other Serious Violations of International Humanitarian Law Committed in the Territory of Rwanda and Rwandan Citizens Responsible for Genocide and Other Such Violations Committed in the Territory of Neighbouring States between 01 January and 31 December 1994. Both the ICTY and ICTR were international in composition, and neither tribunal sat in the country where the covered conflict occurred; the ICTY was located in The Hague, and the ICTR was located in Arusha, Tanzania. The tribunals had nearly identical governing statutes and a common appellate chamber. Although the Nürnberg and Tokyo tribunals were empowered to impose capital punishment, the ICTR and ICTY could impose only terms of imprisonment. However, no centralized international prison system was established to house persons

convicted of war crimes before the tribunals. The governing statutes of the ICTY and ICTR defined war crimes broadly. The ICTY was given jurisdiction over four categories of crime:- (i) grave breaches of the Geneva conventions, (ii) violations of the laws or customs of war, (iii) genocide, and (iv) crimes against humanity. Recognizing that crimes against humanity do not necessarily involve a 'nexus to armed conflict' and taking into account legislation specifically enacted by the Rwandan government, the statute of the ICTR limited the jurisdiction of the tribunal to Rwandan leaders, while lower-level defendants were to be tried in domestic courts. In both tribunals rape, murder, torture, deportation, and enslavement were subject to prosecution. The tribunals thus were among the first international bodies to recognize sexual violence formally as a war crime. Like the statutes of the Nürnberg and Tokyo tribunals, the ICTY and ICTR statutes did not consider the official position of an individual, including his position as head of state, to be a sufficient basis for avoiding or evading criminal culpability. Accordingly, in 1999 the ICTY indicted Slobodan Milošević, the Serbian (1989–97) and Yugoslav (1997–2000) president, for war crimes, and in 2001 he was arrested and extradited to The Hague. Likewise, military and civilian leaders who knew or should have known that their subordinates were committing war crimes were subject to prosecution under the doctrine of command or superior responsibility. Finally, individuals who committed war crimes pursuant to government or military orders were not thereby relieved of criminal liability, though the existence of the order could be used as a mitigating factor. Thus, the rules adopted for the Nürnberg and Tokyo trials continued to influence later efforts to bring suspected war criminals to justice. Recent Trends:- in 1993 the Belgian legislature passed a controversial law giving its courts the right to try any individual accused of a war crime anywhere in the world. The law, which resulted in lengthy prison sentences for two Rwandan nuns found guilty of genocide and in judicial complaints against many world leaders (including Israeli Prime Minister Ariel Sharon, Cuban President Fidel Castro, and Palestinian leader Yāsir Arafāt), was invalidated by the International Court of Justice in 2002. The following year the law was repealed by the Belgian government and replaced by a law requiring that either the victim of the war crime or the accused be a Belgian citizen or resident. In 1998 in Rome, some 150 countries attempted to establish a permanent international criminal court; the negotiations eventually resulted in the adoption by 120 countries of a governing statute for an International Criminal Court (ICC) to be located permanently at The Hague. The statute provided the ICC with jurisdiction for the crimes of aggression, genocide, crimes against humanity, and war crimes. The court came into existence on July 01, 2002, and by 2003 the statute had been ratified by some 90 countries; three of the permanent members of the UN Security Council (China, Russia, and the United States), however, had not yet approved it. / Вильэм . WARDIAN CASE = ТЕРРАРИЙ (или ВОРДИАНСКИЙ ЛАРЕЦ) – The Wardian Case was an early type of sealed protective container for plants, an early version of the terrarium. It found great use in the XIX century in protecting foreign plants imported to Europe from overseas, the great majority of which had previously died from exposure during long sea journeys, frustrating the many scientific and amateur botanists of the time. The Wardian case was the direct forerunner of the modern terrarium (and the inspiration for the glass aquarium), and was invented by Dr Nathaniel Bagshaw Ward (1791–1868), of London, in about 1829 after an accidental discovery inspired him. Dr Ward was a physician with a passion for botany. His personally collected herbarium amounted to 25 000 specimens. The ferns in his London garden in Wellclose Square, however, were being poisoned by London's air pollution, which consisted heavily of coal smoke and sulphuric acid. Dr Ward also kept cocoons of moths and the like in sealed glass bottles, and in one, he found that a fern spore and a species of grass had germinated and were growing in a bit of soil. Interested but not yet seeing the opportunities, he left the seal intact for about four years, noting that the grass actually bloomed once. After that time however, the seal had rusted, and the plants soon died from the bad air. Understanding the possibilities, he had a carpenter build him a closely fitted glazed wooden case and found that ferns grown in it thrived. Dr Ward published his experiment and followed it up with a book in 1842, On the Growth of Plants in Closely Glazed Cases. English botanists and commercial nurserymen had been passionately prospecting the world for new plants since the end of the XVI century, but these had to travel as seeds or corms, or as dry rhizomes and roots, as salty air, lack of light, lack of fresh water and lack of sufficient care often destroyed all or almost all plants even in large shipments. With the new Wardian cases, tender young plants could be set on deck to benefit from daylight and the condensed moisture within the case that kept them watered but protected from salt spray. The first test of the glazed cases was made in July 1833, when Dr. Ward shipped two specially constructed glazed cases filled with British ferns and grasses all the way to Sydney, Australia, a voyage of several months that found the protected plants still in good condition upon arrival. Somewhat more interesting plants made the return trip:- a number of Australian native species that had never survived the transportation previously. The plants arrived in good shape, after a stormy voyage around Cape Horn. One of Dr Ward's correspondents was William Jackson Hooker, later director of the Royal Botanic Gardens, Kew. Hooker's son Joseph Dalton Hooker was one of the first plant explorers to use the new Wardian cases, when he shipped live plants back to England from New Zealand in 1841, during the pioneering voyage of HMS Erebus that circumnavigated Antarctica. Wardian cases soon became features of stylish drawing rooms in Western Europe and the United States. In the polluted air of Victorian cities, the fern craze and the craze for growing orchids that followed owed much of their impetus to the new Wardian cases. More importantly, the Wardian case unleashed a revolution in the mobility of commercially important plants. In Wardian cases, Robert Fortune shipped to British India 20 000 tea plants smuggled out of Shanghai, China, to begin the tea plantations of Assam. After germination of imported seeds in the heated glasshouses of Kew, seedlings of the rubber tree of Brazil were shipped successfully in Wardian cases to Ceylon (Sri Lanka) and the new British territories in Malaya to start the rubber plantations. Wardian cases have thus been credited for helping break geographic monopolies in the production of important agricultural goods. Dr Ward was always active in the Society of Apothecaries of London, of which he became Master in 1854. Until very recently, the Society managed the Chelsea Physic Garden, London, the oldest botanical garden in the UK. Ward was a founding member of both the Botanical Society of Edinburgh and the Royal Microscopical Society, a Fellow of the Linnean Society and a Fellow of the Royal Society. WAREHOUSE = СКЛАД – (1) Under federal statutes, Warehouse is a building, structure, or other protected enclosure in which agricultural products are stored or handled for interstate or foreign commerce. See also Approved Warehouse Storage, and Public Warehouse. Warehouse is a place for the reception, delivery, consolidation, distribution, and storage of goods/cargo. Warehouse is a

commercial building for storage of goods. Warehouses are used by manufacturers, importers, exporters, wholesalers, transport businesses, customs, etc. They are usually large plain buildings in industrial areas of cities and towns and villages. They usually have loading docks to load and unload goods from trucks. Sometimes warehouses are designed for the loading and unloading of goods directly from railways, airports, or seaports. They often have cranes and forklifts for moving goods, which are usually placed on ISO standard pallets loaded into pallet racks. Stored goods can include any raw materials, packing materials, spare parts, components, or finished goods associated with agriculture, manufacturing and production. Historically warehouses were a dominant part of the urban landscape used from the start of the Industrial Revolution through the XIX century and into the XX century:- the building remained when their original usage had changed. There are four identifiable types of warehouses. The cotton industry was co-terminus with the development of the warehouse, and all five types were represented in Manchester, United Kingdom. Warehouses in Manchester were often lavishly decorated juxtaposing with the modern view of warehouses which are assumed to be standard industrial buildings. Warehouse is a building intended for receipt, storage and handling of goods. In the United Kingdom, Warehouse is a place approved by HM Revenue & Customs (HMRC) for the storage of goods without the payment of certain duties or taxes which would normally be due on those goods. The main types of warehouse are Customs warehouses, excise warehouses and Customs and excise warehouses. Warehouse is any building or structure used for the storage of goods. WAREHOUSING = СКЛАДИРОВАНИЕ – (1) Warehousing is an act or instance of a person or company that warehouses something. With reference to shipping, Warehousing is the business of storing, examining and sorting goods which takes place in a warehouse before they are realized into the country in question. Warehousing is those activities of holding and handling goods in a warehouse (store). It is the storage of goods on behalf of a manufacturer, distributor or retailer. Warehousing is the storing of goods/cargo. Warehousing is the performance of administrative and physical functions associated with storage of goods and materials. These functions include receipt, identification, inspection, verification, putting away, retrieval for issue, etc. Warehousing is the process of storing goods within a storage facility. Warehousing can be defined as assumption of responsibility for the storage of goods. By storing the goods throughout the year and releasing them as and when they are needed, warehousing creates time utility. Functions Of Warehousing:- (i) Storage:- this is the basic function of warehousing. Surplus commodities which are not needed immediately can be stored in warehouses. They can be supplied as and when needed by the customers. (ii) Price Stabilization:- warehouses play an important role in the process of price stabilization. It is achieved by the creation of time utility by warehousing. Fall in the prices of goods when their supply is in abundance and rise in their prices during the slack season are avoided. (iii) Risk Bearing:- when the goods are stored in warehouses they are exposed to many risks in the form of theft, deterioration, exploration, fire, etc. Warehouses are constructed in such a way as to minimise these risks. Contract of bailment operates when the goods are stored in wave-houses. The person keeping the goods in warehouses acts as boiler and warehouse keeper acts as boiler. A warehouse keeper has to take the reasonable care of the goods and safeguard them against various risks. For any loss or damage sustained by goods, warehouse keeper shall be liable to the owner of the goods. (iv) Financing:- loans can be raised from the warehouse keeper against the goods stored by the owner. Goods act as security for the warehouse keeper. Similarly, banks and other financial institutions also advance loans against warehouse receipts. In this manner, warehousing acts as a source of finance for the businessmen for meeting business operations. (v) Grading And Packing:- warehouses nowadays provide the facilities of packing, processing and grading of goods. Goods can be packed in convenient sizes as per the instructions of the owner. Importance of Warehousing In the Development of Trade and Commerce:- warehousing or storage refers to the holding and preservation of goods until they are dispatched to the consumers. Generally, there is a time gap between the production and consumption of products. By bridging this gap, storage creates time utility. There is need for storing the goods so as to make them available to buyers as and when required. Some amount of goods is stored at every stage in the marketing process. Proper and adequate arrangements to retail the goods in perfect condition are essential for success in marketing. Storage enables a firm to carry on production in anticipation of demand in future. A warehouse is a place used for the storage or accumulation of goods. It may also be defined as an establishment that assumes responsibility for the safe custody of goods. Warehouses enable the businessmen to carry on production throughout the year and to sell their products, whenever there is adequate demand. Need for warehouse arises also because some goods are produced only in a particular season but are demanded throughout the year. Similarly certain products are produced throughout the year but demanded only during a particular season. Warehousing facilitates production and distribution on a large scale. Benefits From Warehouses:- (i) Regular Production:- raw materials need to be stored to enable mass production to be carried on continuously. Sometimes, goods are stored in anticipation of a rise in prices. Warehouses enable manufacturers to produce goods in anticipation of demand in future. (ii) Time Utility:- a warehouse creates time utility by bringing the time gap between the production and consumption of goods. It helps in making available the goods whenever required or demanded by the customers. Some goods are produced throughout the year but demanded only during particular seasons, e.g., wool, raincoat, umbrella, heater, etc. on the other hand, some products are demanded throughout the year but they are produced in certain region, e.g., wheat, rice, potatoes, etc. Goods like rice, tobacco, liquor and jaggery become more valuable with the passage of time. (iii) Store Of Surplus Goods:- basically, a warehouse acts as a store of surplus goods which are not needed immediately. Goods are often produced in anticipation of demand and need to be preserved properly until they are demanded by the customers. Goods which are not required immediately can be stored in a warehouse to meet the demand in future. (iv) Price Stabilization:- warehouses reduce violent fluctuations in prices by storing goods when their supply exceeds demand and by releasing them when the demand is more than immediate productions. Warehouses ensure a regular supply of goods in the market. This matching of supply with demand helps to stabilise prices. (v) Minimisation Of Risk:- warehouses provide for the safe custody of goods. Perishable products can be preserved in cold storage. By keeping their goods in warehouses, businessmen can minimise the loss from damage, fire, theft, etc. The goods kept in the warehouse are generally insured. In case of loss or damage to the goods, the owner of goods can get full compensation from the insurance company. (vi) Packing And grading:- certain products have to be conditioned or processed to make them fit for human use, e.g., coffee, tobacco, etc. A modern warehouse provides facilities for processing, packing, blending, grading etc., of the goods for the purpose of sale. The prospective buyers can inspect the goods kept in a warehouse. (vii) Financing:- warehouses provide a receipt to the owner of goods for the goods kept in the warehouse. The owner can borrow money against the security of goods by making an endorsement on the warehouse receipt. In some countries, warehouse authorities advance money against the goods deposited in the warehouse. By keeping the imported goods in a bonded warehouse, a businessman can pay customs duty in installments. Type Of Warehouses:- there are three types of warehouses as described below:- (i) Private Warehouses:- the private warehouses are owned and operated by big manufacturers and merchants to fulfill their own storage needs. The goods manufactured or purchased by the owner of the warehouses have a limited value or utility as businessmen in general cannot make use of them because of the heavy investment required in the construction of a warehouse, some big business firms which need large storage capacity on a regular basis and who can afford money, construct and maintain their private warehouses. A big manufacturer or wholesaler may have a network of his own warehouses in different parts of the country. (ii) Public Warehouses:- a public warehouse is a specialised business establishment that provides storage facilities to the general public for a certain charge. It may be owned and operated by an individual or a cooperative society. It has to work under a license from the government in accordance with the prescribed rules and regulations. Public warehouses are very important in the marketing of agricultural products and therefore the government is encouraging the establishment of public warehouses in the cooperative sector. A public warehouse is also known as duty-paid warehouse. Public warehouses are very useful to the business community. Most of the business enterprises cannot afford to maintain their own warehouses due to huge capital Investment. In many cases the storage facilities required by a business enterprise do not warrant the maintenance of a private warehouse. Such enterprises can meet their storage needs easily and economically by making use of the public warehouses, without heavy investment. Public warehouses provide storage facilities to small manufacturers and traders at low cost. These warehouses are well constructed and guarded round the clock to ensure safe custody of goods. Public warehouses are generally located near the junctions of railways, highways and waterways. They provide, therefore, excellent facilities for the easy receipt, despatch, loading and unloading of goods. They also use mechanical devices for the handling of heavy and bulky goods. A public warehouse enables a businessman to serve his customers quickly and economically by carrying regional stocks near the important trading centres or markets of two countries. Public warehouses provide facilities for the inspection of goods by prospective buyers. They also permit packaging, grading and grading of goods. The public warehouses receipts are good collateral securities for borrowings. (iii) Bonded Warehouses:- bonded warehouses are licensed by the government to accept imported goods for storage until the payment of custom duty. They are located near the ports. These warehouses are either operated by the

government or work under the control of custom authorities. The warehouse is required to give an undertaking or 'Bond' that it will not allow the goods to be removed without the consent of the custom authorities. The goods are held in bond and cannot be withdrawn without paying the custom duty. The goods stored in bonded warehouses cannot be interfered by the owner without the permission of customs authorities. Hence the name bonded warehouse. Bonded warehouses are very helpful to importers and exporters. If an importer is unable or unwilling to pay customs duty immediately after the arrival of goods he can store the goods in a bonded warehouse. He can withdraw the goods in installments by paying the customs duty proportionately. In case he wishes to export the goods, he need not pay customs duty. Moreover, a bonded warehouse provides all services which are provided by public warehouses. Goods lying in a bonded warehouse can be packaged, graded and branded for the purpose of sale. / Под Складированием понимается хранение товаров на складе.

(2) Warehousing is a procedure whereby a company gradually builds up a holding of shares in a company it wishes to takeover in the future. The acquiring company 'warehouses' small lots of shares by holding them under the name of a nominee. Companies use the warehousing technique of share acquisition when they wish to remain anonymous or are unable to make a public tender offer. Warehousing:- the interim holding period from the time of the closing of a loan to its subsequent marketing to capital market investors. Warehousing is the illegal sale of a corporate security with a provision for its repurchase by the seller at some future date and at a prearranged price. In securities trading, Warehousing is the illegal practice of buying more stock (shares) in a firm than permitted by the stock exchange regulations. Such purchases are usually disguised by holding the stock under several nominee names. Warehousing is the accumulation of shareholdings in the name of nominees with the intention of mounting a subsequent takeover bid. / Складирование – ситуация, когда ипотечный банк финансирует портфель ипотек краткосрочным кредитом под их залог до момента продаж этих ипотек конечному инвестору. Смотрите также Склад (Warehouse). Под Складированием понимается накопление акций компании, перед тем как сделать предложение о поглощении (takeover bid), путём скупки небольших пакетов акций и 'складирование' их под именем номинального инвестора. Задача заключается в том, чтобы сохранять свою анонимность и избежать требуемой законом необходимости объявлять о своём участии в капитале компании-мишени. Подобная практика противоречит Кодексу Сити по Поглощениям и Слияниям (City Code on Takeovers and Mergers). Под Складированием понимается:- (1) временное обладание иностранной валютой, краткосрочными ценными бумагами денежного рынка или иными позициями в связи с налоговыми причинами или из-за того, что позиция по своей природе является временной. (2) Заимствование средств ипотечным банком на краткосрочной основе коммерческого банка с использованием ссуды под недвижимость в качестве обеспечения. (3) В Великобритании – накопление пакетов акций через подставных лиц с намерением в последующем сделать предложение о поглощении.

(3) Warehousing is the borrowing of funds by a retail lender on a short-term basis using permanent mortgage loans as collateral. This form of interim financing, called a Warehouse Loan, is used to raise funds to make home mortgages and carry them until the mortgages are packaged and sold 'out of the warehouse' to an investor. Proceeds from the sale are used to reduce the warehouse loan. Warehousing is the pledging as security, to a commercial bank, of a long-term mortgage for a short-term loan. Warehousing is the borrowing of funds by a mortgage banker on a short-term basis from a commercial bank using mortgage loans as security.

WAREHOUSING ACTIVITIES AND PRACTICES = СКЛАДСКИЕ ВИДЫ ДЕЯТЕЛЬНОСТИ И ПРАКТИКИ – Warehousing Activities And Practices:- any legal, operational, managerial, or financial duty that a warehouse operator has regarding any googs, e.g., agricultural product.

WAREHOUSING AGREEMENT = СОГЛАШЕНИЕ О СКЛАДИРОВАНИИ – Warehousing Agreement is a contractual agreement between the owner and the user of a warehouseman's service. See also Negotiable Warehouse Receipt, and Warehouse Receipt.

WAREHOUSING AND FORWARDING PACKAGES LOST IN LOADING, ETC CLAUSE = ОГОВОРКА О ПОТЕРЕ ПАКЕТОВ ПРИ ПОГРУЗКЕ И ТОМУ ПОДОБНОМ ВО ВРЕМЯ СКЛАДИРОВАНИЯ И ЭКСПЕДИРОВАНИЯ – Warehousing And Forwarding Packages Lost In Loading, Etc Clause provides coverage for landing, warehousing, forwarding, and special charges in the event of loss or damage recoverable under the average terms; also provides for payment of the insured value of any package or packages which may be totally lost in loading, transshipment or discharge. / при погрузке, перегрузке или разгрузке.

WAREHOUSING ENTRY = ВВОЗ ДЛЯ СКЛАДИРОВАНИЯ – Warehousing Entry is a document required by Customs authorities when goods are placed in a bonded warehouse. / Документ, требуемый таможенными органами, когда товары помещены на склад, обеспеченный обязательством.

WARFARE = ПРИЁМЫ ВЕДЕНИЯ БОРЬБЫ – Warfare:- engagement in or the activities involved in war or conflict:- guerrilla warfare ... / Приёмы Ведения Борьбы:- .

WAR FINANCE = ВОЕННЫЕ ФИНАНСЫ – War Finance:- the fiscal and monetary methods that are used in meeting the costs of war, including taxation, compulsory loans, voluntary domestic loans, foreign loans, and the creation of money. War finance is a branch of defense economics. Government efforts to finance major wars have frequently led to major changes in the tax system. In the United States, for example, the importance of the personal income tax as a revenue source increased significantly during World War II, when higher rates, lower exemptions, and a deduction-at-source system of collection were introduced. Great Britain and many other belligerents in World War II resorted to general sales taxes. Compulsory loans have been used as an alternative to taxation, but they have usually been perceived as taxes by the public. Voluntary loans, in which money is raised by selling government bonds, are of two types:- those financed by the public from its savings and those financed by bankers and others from credit created by expansion of the monetary supply. The first type of loan is generally anti-inflationary in its effects because it eliminates excess purchasing power. The second type of loan, under wartime conditions, is likely to be as inflationary as would be the printing of the same amount of new paper currency. A popular fallacy about war finance is that government borrowing transfers the war costs to future generations. The real costs in goods and services underlying the monetary costs, however, are paid by the war generation when the government uses the real resources for war, bidding them away from other uses. The most dangerous form of war finance is the printing of new paper money, resorted to when no more taxes can be collected and the government's credit has broken down. Usually the printing is not done by the government directly but by the central bank, which then lends the printed money to the government through purchases of bonds. Major wars are usually financed to some extent by inflationary measures. Inflation distributes the burden of war costs in an arbitrary manner, penalizing persons with fixed incomes. After a certain point, inflation may even lower production by placing a premium on the hoarding of raw materials and durable goods, as well as the holding of real estate and other fixed assets, thus shifting resources from productive to nonproductive uses.

WAR FINANCE CORPORATION = ВОЕННАЯ ФИНАНСОВАЯ КОРПОРАЦИЯ – The War Finance Corporation was created by the US Congress on 05 April 1918 to facilitate the extension of credit to vital war industries during World War I, primarily by making loans to financial institutions. During its six months of wartime existence, the corporation advanced USD71 387 222. In 1919 it greatly assisted the director general of railroads and railroad companies, and until 1920 it served as the chief agency through which the Treasury

purchased government obligations. With the return of peace, amendments to the corporation's charter greatly expanded its activities. After 1919 it actively financed the American agricultural and livestock industries until the Agricultural Credits Act terminated the corporation in 1924, after it had lent USD700 million. / Военная Финансовая Корпорация.

WAR LOAN = ВОЕННЫЙ ЗАЁМ – War Loan:- UK Government to repay War Loan in March 2014. The Treasury will redeem the £1.9 billion 3½% War Loan and repay all of the UK's debt from the First World War. The government has said it will redeem the £1.9 billion 31/2% War Loan as part of a move to repay all of the UK's debt from the First World War. War Loan, a popular 'perpetual' government bond that has paid a 3.5% coupon since 1932, will be bought back on 09 March next year, according to the Treasury. Computershare, the company which maintains the register of government bonds, or gilts, will contact the 120 000 holders of War Loan to make arrangements for the payment. The move follows the Treasury's announcement in October that it would repay the smaller 4% Consolidated Loan which was issued in 1927 when Winston Churchill was chancellor. This was the first repayment of an undated gilt in 67 years and raised the prospect that War Loan and the other rump perpetual gilts would soon be consigned to history. Britain has paid £5.5 billion in interest on War Loan and its predecessor loan which briefly paid a 5% coupon. Chancellor Neville Chamberlain notoriously cut the interest rate to 3.5% to reduce the costs of servicing the national debt. The Treasury kept the group of nine perpetuals running because for many years they represented a cheaper source of borrowing. More recently, however, gilt yields have fallen, making it cheaper to issue new bonds to pay off this historic debt. The move was welcomed by fund managers who will also benefit from a capital boost when the bond is bought back at par. Ian Spreadbury, bond fund manager at Fidelity, said the biggest challenge for investors was what to do with the proceeds. 'I have recycled the proceeds back into long-dated gilts, but to achieve a yield equivalent to War Loan before the announcement you have to look at single-A rated corporate bonds'. 'Fortunately, there are opportunities to switch into bonds in that area still offering an attractive yield for the small amount of credit risk. But I caution investors not to extend risk too far down the credit spectrum in their search for yield at this point in the credit cycle', he added. In a statement Chancellor George Osborne said it was a proud moment for the country to pay off its First World War debts. He also claimed it was a sign of the government's fiscal credibility, although with his Autumn Statement today expected to confirm UK debts have reached nearly £1.5 trillion, that may be stretching things too far. On 30 June 1932 Neville Chamberlain announced that the Government would be exercising its right to call in the 5% War Loan, offering a choice of taking cash or continuing the loan at 3.5%. Today (in 2015), the War Loan issued in 1917 to help finance Britain in World War 1 is finally redeemed. We've written about it repeatedly over the years as it has always fascinated us. Was its coupon cut in 1932 a form of default from the UK government? Does George Osborne's claim that it is being redeemed this year as a result of a tight grip on the public finances ring true? To commemorate this most interesting of gilts we have made a film about War Loan – one that tells the economic history of the UK through wars, default, the re-joining and leaving of the gold standard, the inflationary 1970s, the loss of the UK's AAA credit rating, and finally the deflation that has followed the Great Financial Crisis. / Винстон Чёчил (Winston Churchill). Военный Заём:- государственные ценные бумаги, выпущенные во время войны; у них нет даты погашения, они приносят только 3½% дохода и стоят менее половины указанного на них номинала.

WARM = WEIGHTED AVERAGE REMAINING MATURITY

WARM AIR FURNACE = ТОПКА (или ПЕЧЬ) С ТЁПЛЫМ ВОЗДУХОМ (или КАЛОРИФЕР) – Warm Air Furnace:- in the United States, commercial warm air furnaces are self-contained oil-fired or gas-fired furnaces that are designed to supply heated air through ducts to spaces that require it. Commercial warm air furnaces are industrial equipment and have a maximum rated input capacity of 225 000 British thermal units (Btu) an hour or more. See also Furnace. / Калорифер Воздушного Отопления

WARM GERMINATION TEST = ИСПЫТАНИЕ НА ТЁПЛОЕ ПРОРАСТАНИЕ – Warm Germination Test is the testing of seeds under ideal conditions to determine the percentage of seeds that will produce seedlings. The test uses a set number of seeds placed in optimal moisture and heat conditions and measures the resulting seedlings that emerge after seven days. See also Seed Germination Test.

WARM–SEASON GRASS = ТРАВА ДЛЯ ТЁПЛОГО СЕЗОНА – Warm-Season Grass:- grasses that undergo major growth during the spring, summer, or fall, and that are usually dormant in winter. See also Cool-Season Grass.

WARMTH TO WEIGHT RATIO = СООТНОШЕНИЕ ТЕПЛА К ВЕСУ – Warmth To Weight Ratio is a measurement used to evaluate the effectiveness of an insulated product in relation to weather conditions and the environment. The insulation with the best rating is down. Down provides the best warmth to weight ratio over almost any other insulation material, which is why you will see down garments and sleeping bags as the primary choice for use in almost every high altitude, cold weather expedition.

WARM–UP = РАЗМИНОЧНЫЙ КОСТЮМ (или ТЕЛОГРЕЙКА, или ТУЖУРКА) – Warm-Up is a suit for exercise or casual wear comprising a jacket or sweatshirt and pants. Often used in plural. Also called Warm-Up Suit or Athletic Suit or Sweat Suit.

WARNING AREA = ОБЛАСТЬ ПРЕДОСТЕРЕЖЕНИЯ – Warning Area is the airspace which may contain hazards to non participating aircraft in international airspace. / воздушное пространство, которое может содержать .

WARP = WEATHER AND RADAR PROCESSOR

WARP = КОРОБЛЕНИЕ (или ПОКОРОБЛЕННОСТЬ) – When air drying, solar drying, or kiln drying lumber, it is costly and frustrating to have high quality boards damaged by stain, warp, and checking. These defects all result from biological characteristics of wood but each may be kept at a minimum by following a few common sense recommendations. Before discussing the suggested practices, a basic understanding of these problems is needed. Warp:- Warp is distortion of a board from a flat plane caused by unequal shrinkage in different directions relative to the wood grain. Most species tend to shrink most in the direction tangential to the annual rings, somewhat less radially from pith to bark (or perpendicular to the annual rings), and a negligible amount longitudinally along the tree trunk. Thus, if a board tends to shrink unequally in any direction during drying, it will tend to warp Sometimes distortion will occur in freshly sawed hardwoods. This form of warp is caused by 'growth stresses' created by the growth characteristics of living trees and is not developed by shrinkage during drying. Warp may be reduced by proper stickering and stacking and by top weighting the lumber pile. The old axiom that 'if a board dries flat it will stay flat' best describes the logic to reducing warp. Sufficient mechanical restraint to hold a board flat during drying will eliminate warp or straighten distortion caused by growth stresses. See also Checking, and Stain. Any deviation from a true or plane surface. Warp includes bow, crook, cup and twist, and any combination of these. / развод (или потёк (stain)). Любое отклонение от правильной или гладкой поверхности. К покоробленности относятся погнутость/дуга/сгиб/продольная покоробленность, изгиб/крюк/перекос/загиб, углубление/коробление в поперечном направлении и крыловатость/скручивание, а также любая комбинация упомянутых дефектов. Покоробленность возникает при выпиловке, сушке или хранении. Наблюдаются:- (i) продольная покоробленность по пласти – покоробленность по длине плоскости, перпендикулярной пласти, которая, в свою очередь, подразделяется на (a) простую покоробленность – продольную покоробленность по пласти, характеризующаяся только одним изгибом, и (b) сложную покоробленность – продольная покоробленность по пласти, характеризующаяся несколькими изгибами; (ii) продольная покоробленность по кромке –

покоробленность по длине в плоскости, параллельной пласти; (iii) поперечная покоробленность – покоробленность по ширине; и (iv) крыловатость или, так называемая винтовая покоробленность – спиральная покоробленность по длине. Продольную покоробленность по пласти и продольную покоробленность по кромке измеряют по величине стрелы прогиба сортимента. Поперечную покоробленность измеряют по величине стрелы прогиба сортимента. Крыловатость измеряют по наибольшему отклонению поверхности сортимента от плоскости. Сложную покоробленность измеряют по величине стрелы прогиба наибольшего из составляющих её искривлений. Под Короблением Древесины понимается изменение формы пиломатериалов, заготовок и деталей при их высыхании (разбухании). Различают:- винтовое коробление, поперечное коробление и продольное коробление. Винтовое коробление древесины образуется при наличии тангенциального наклона волокон. Основная причина поперечного коробления древесины – различие в усушке (разбухании) в радиальном и тангенциальном направлениях. Продольное коробление древесины вызывается разницей усушки вдоль волокон отдельных зон доски, например, при наличии такого порока древесины, как крень. Временное коробление древесины может наблюдаться при неравномерных увлажнении или сушке пиломатериалов. Коробление древесины происходит также при механической обработке пиломатериалов или заготовок, имеющих значительные остаточные напряжения, сохранившиеся после камерной сушки. Крень – порок древесины хвойных пород, который образуется в сжатой зоне изогнутых стволов, когда годичные слои уширяются за счёт развития реактивной древесины, тёмным цветом напоминающий позднюю древесину. Различают сплошную и местную крень. Порок увеличивает усушку древесины вдоль волокон, способствует короблению, ухудшает и ряд других её свойств.

WARP = ОСНОВА – Warp:- the total number of threads or ends which make up the entire warp in the loom. The warp is always under tension. In weaving cloth, the Warp is the set of lengthwise yarns that are held in tension on a frame or loom. The yarn that is inserted over-and-under the warp threads is called the Weft, Woof, or Filler. Each individual warp thread in a fabric is called a Warp End or End. Warp means ‘that which is thrown across’ (Old English Wearp, from Weorpan, to throw, cf. German Werfen, Dutch Werpen). Very simple looms use a spiral warp, in which a single, very long yarn is wound around a pair of sticks or beams in a spiral pattern to make up the warp. Because the warp is held under high tension during the entire process of weaving, warp yarn must be strong. Yarn for warp ends is usually spun and plied fiber. Traditional fibers for warping are wool, linen and silk. With the improvements in spinning technology during the Industrial Revolution, it became possible to make Cotton yarn of sufficient strength to be used as the warp in mechanized weaving. Later, artificial or man-made fibers such as nylon or rayon were employed. Warp:- the yarns that run lengthwise in a woven or warp-knit fabric. Warp:- the set of yarn found in every fabric woven on the loom and running parallel with the selvedge, or lengthwise in the fabric, and interwoven with the weft, the two forming the various weaves according to the methods of intersection. The warp is stretched in parallel lines in the loom and certain parts of it are alternately raised and depressed at every pick, allowing the shuttle to pass between with the weft. The warp can be of the same size as the weft or of higher or lower; as a rule, however, it is stronger and often it is placed closer together than the weft. The standard twist for warp is about 4½ times the square root of the yarn size. Cotton warp, as a rule, is twisted to the right, and worsted warp yarn to the left. The fabric is usually stronger warp ways than weft ways. Warp is called also Chain or Web. See also Weft. Threads which run parallel to the loom. Any yarn that runs length-wise in cloth made on a loom. The yarn is usually stronger than the filling, since it has to withstand more friction in weaving. Warp yarn is always under tension whereas the filling is not subject to such tension since it comes off the nose of the filling bobbin which sets in the shuttle. Warp yarn usually has more twist so that it can do its work well in weaving. The yarn is wound on the warp beam which sets in sockets at the back of the loom. It is left off evenly as the fabric is being woven by the let-off motion device at the back of the loom. Newly woven cloth is governed in its course around the cloth roller by the take-up motion at the front of the loom and the action of the roller itself. Warp, in woven fabric, the yarns that run lengthwise and is interwoven with the fill (weft) yarns. Warp is:- (1) the set of yarn in all woven fabrics, that runs lengthwise and parallel to the selvage and is interwoven with the filling. (2) The sheet of yarns wound together on a beam for the purpose of weaving or warp knitting. See also Warp Sheet. Warp:- the yarns that run the length of the loom. The warp yarns are pulled through the loom as the weft or filling yarns are woven across the warp to make the fabric. Warp is the group of yarns placed first on a loom in weaving. Warp runs parallel to the selvage, forming the length of the fabric. The filling threads are interlaced over and under the warp threads in a pattern or weave. See also Selvage, and Weaving. Warp is the yarn running lengthwise in a fabric. A group of yarns in long lengths and approximately parallel. Warp:- the yarns that run the length of the loom. The warp yarns are pulled through the loom as the weft or filling yarns are woven across the warp to make the fabric. / Смотрите также Уток (Weft). уточина (filling). Найлан^{T3} (Nylon^{TM}). Продольная нить. Нити, которые расположены параллельно ткацкому станку. В ткачестве под Основой понимаются нити, идущие параллельно друг другу вдоль ткани. В процессе выработки ткани переплетаются с нитями утка, расположенными к ним обычно перпендикулярно. В ткачестве пропитывание нитей основы (в основном из натуральных волокон) клеящим раствором – шлихтой с последующим высушиванием называется шлихтованием. Шлихтование повышает износостойкость за счёт использования в шлихте смеси крахмала, синтетических препаратов и тому подобного. Основа в ткачестве – нити, расположенные параллельно друг другу и идущие вдоль ткани. Ткань на ткацком станке образуется в результате последовательного переплетения двух систем нитей – основы и утка, расположенных перпендикулярно. Нити основы в процессе ткачества подвергаются значительно большим деформациям растяжения и изгиба, а также истирающим воздействиям рабочих органов станка, чем нити утка. Поэтому для основы употребляется пряжа более прочная, с большей круткой, выработанная из волокна более высокого качества. Основа, как правило, перед ткачеством подвергается ещё дополнительной обработке клеевыми растворами – шлихтой.

WARP BANDS = ОСНОВНЫЕ ЛЕНТЫ (или ПОЛОСАТОСТЬ ПО ОСНОВЕ) – Warp Bands:- xxxxx. See also Section Marks. Fabrics defect. / Полосатость По Основе – порок ткани.

WARP BEAM = НАВОЙ ДЛЯ ОСНОВЫ – Warp Beam or Warp Roll is the roll upon which all warp ends are uniformly, snugly, and evenly wound. For certain types of weaving – double cloth, terry toweling, pile fabric weaving, etc – two or more warp beans are used on the loom. Warp Beam is a cylindrical spool at the back of the loom on which warp yarns are wound. Warp Beam is a large spool or flanged cylinder around which the warp threads, or ends, are wound in a uniform and parallel arrangement. See also Beam.

WARP–BEAM DYEING = КРАШЕНИЕ ОСНОВЫ НА НАВОЕ – Warp-Beam Dyeing is similar to Package Dyeing but more economical. Here, the yarn is wound on to a perforated warp beam and then immersed in a tank for dyeing it applying pressure.

WARP BURL = XX – (1) Defect Name:- Warp Burl. Defect Type:- warp lines, vertical lines. Fabric Type:- Denim Bottomweights – Piece Dyed. Description:- Warp Burl:- This is the result of a warp slub having been removed with a burling tool. Severity:- Major. (2) Defect Name:- Warp Burl. Defect Type:- warp lines, vertical lines. Fabric Type:- Bottomweights – Twill Derivatives. Description:- Warp Burl:- A distortion resulting from some superfluous material such as a thick slub, waste, or wild yarn being removed with a burling tool. Severity:- Minor.

WARP–DRAWING = ПРОБОРКА ОСНОВЫ – Warp-Drawing:- warp-drawn fibers may be taken up on packages other than beams. See also Draw-Warping. Warp Drawing is a process in which a number of threadlines, are orientated under essentially equal

mechanical and thermal conditions by a stretching stage using variable speed rolls, then directly wound onto the beam. This process gives uniform end to end properties.

WARP FLOAT = XX – (1) Defect Name:- Warp Float. Defect Type:- warp lines, vertical lines. Fabric Type:- Shirting and Dress Goods – Chambray. Description:- Warp Float (face view):- This is a plain weave. The defect is the result of two adjacent ends of one shed becoming attached between the harness and the reed so as to prevent the end of the other shed from passing between them. This prevents the proper interlacing of warp and filling and appears as an end out on the face of the fabric as the yarn floats to the back. Severity:- Major. (2) Defect Name:- Warp Float. Defect Type:- warp lines, vertical lines. Fabric Type:- Shirting and Dress Goods – Chambray. Description:- Warp Float (back view):- This is a plain weave. The defect is the result of two adjacent ends of one shed becoming attached between the harness and the reed so as to prevent the end of the other shed from passing between them. This prevents the proper interlacing of warp and filling and appears as an end out on the face of the fabric as the yarn floats to the back. Severity:- Major.

WARP FLOATS = XX ПО ОСНОВЕ – (1) Defect Name:- Warp Floats. Defect Type:- warp lines, vertical lines. Fabric Type:- Bottomweights – Twill Derivatives. Description:- Warp Floats:- This defect is the result of two warp ends, drawn through the same harness, becoming joined by a floating attachment of fiber between the drop wires and the harness. As the attachment approaches the harness, it restricts proper shedding and interferes with the interlacing of the warp and filling yarns. Erratically, the attachment is made to slide back on the warp ends by the build up of tension from the harness movement to again repeat the cycle. This will continue until an end breaks or the restriction is noticed by the operator. Severity:- Major. (2) Defect Name:- Warp Floats or Mat-ups. Defect Type:- warp lines, vertical lines. Fabric Type:- Shirting and Dress Goods – Chambray. Description:- Warp Floats or Mat-ups:- This defect is the result of three warp ends drawn through the same harness becoming matted together with a floating attachment of fiber between the drop wires and the harness. As the attachment approaches the harness, it restricts proper shedding and interferes with the interlacing of the warp and filling yarns. Erratically, the attachment is moved back by the build-up of tension from the movement of the harness to again repeat the cycle. This will continue until an end breaks or the restriction is noticed and removed by the operator. Severity:- Major.

WARP HOLDING PLACE = МЕСТО (или УЧАСТОК) УДЕРЖИВАНИЯ ОСНОВЫ – Warp Holding Place:- warp-faced area of a fabric where the weft yarns are predominant. Note:- this defect is caused by entanglement behind the shafts or harness, putting tension on several adjacent warp threads. See also Sticker (1).

WARPING = ВЕРПОВАНИЕ (или ПЕРЕТЯГИВАНИЕ, или ПОДТЯГИВАНИЕ) – Warping is a slow method of moving a boat in still waters or against the wind. Using ropes or cables to maneuver a ship. Warping or Kedging is a method of moving a sailing vessel, typically against the wind or out from a dead calm, by hauling on a line attached to a kedge anchor, a sea anchor or a fixed object, such as a bollard. In small boats, the anchor may be thrown in the intended direction of progress and hauled in after it settles, thus pulling the boat in that direction. / Использование канатов или тросов для маневрирования судна. Верпование:- ‘Верповать’ означает перетаскивать судно с одного место на другое или снимать с мели с помощью верпа – вспомогательного якоря, который прикрепляется к буям, другим кораблям, объектам на берегу:- деревьям, столбам и так далее. Верпы также завозят на шлюпке, сбрасывают в воду и подтягивают шпилем к ним корабль. Верпование:- передвижение (подтягивание) корабля (судна) за счёт выборки взятого на шпиль или брашпиль троса верпа.

WARPING = СНОВАНИЕ (или СНОВКА) – In textile, Warping:- in weaving, there are two different and distinct sets of yarn that are interlaced to form a cloth:- (i) the warp yarn, which is placed around the loom and extends lengthwise, and (ii) the weft yarn, which moves from side to side, alternating over and under the warp yarn. Yarn warping is the simple practice of wrapping the yarn over either end of the loom to weave through. Two types of yarn warping are used in weaving. In direct warping, the yarn is placed directly around the section beams in the loom, meaning the yarn is transferred directly from the spool onto the ends. The second is indirect warping. In this method, the warp is wound in bands onto a pattern drum and then transferred onto the beams in a separate step. Indirect warping is generally used for fancier and more complicated patterns. See also Beaming, and Wefting. The weave of the Yarn is tightened in a warp processor to give it the correct tightness for weaving of the designs to be done perfectly. Warping, shown in the drawing, is essentially the laying of the yarns in parallel order. A specified number of threads per inch are drawn from a creel and wound on a warp beam. Several ‘section’ beams are then combined to provide the designated number of threads per inch required in the fabric specification. The combination of section beams occurs during the slashing process to create the warp, or loom, beam. This entire system of parallel threads is wound on one loom beam to become the ‘warp’, or lengthwise system of threads in the fabric. / Снование Пряжи – промежуточный этап в подготовке основы ткацкого станка, которому подвергают только основную пряжу, поступающую на бобинах после перематывания в сновальный отдел. Фактически – это объединение нитей с большого числа мотальных паковок на одну сновальную паковку. В процессе снования на сновальный валик или ткацкий навой навивается определённое число нитей расчётной длины. Способы Снования:- в производстве практикуются четыре способа снования:- партионный, ленточный, секционный и полный. Снование по каждому из этих способов может быть прерывным и непрерывным. Наиболее распространённым способом снования является партионный, обеспечивающий наибольшую производительность. Также исследования и опыт работы предприятий показали, что более распространённым является прерывный вид снования. (1) Партионный:- нити основы частями навиваются на сновальные валики с определённым числом нитей, которые образуют партию с общим числом нитей, равным числу нитей на ткацком навое. Партионное снование применяется в том случае, если по условиям технологии необходимо шлихтование пряжи (для хлопчатобумажной, льняной, шерстяной гребенной пряжи, искусственных и синтетических нитей и пряжи). (2) Ленточный:- нити с большого числа мотальных паковок навиваются отдельными лентами на специальный барабан. Общее число нитей в лентах равно числу нитей на ткацком навое. Затем все ленты одновременно перевиваются со сновального валика на ткацкий навой. Ленточный способ используется:- для шерстяной аппаратной пряжи, так как она имеет высокую линейную плотность и не шлихтуется (отходы при этом процессе минимальные, а шерстяная пряжа качественнее и дороже других видов сырья); при сновании искусственного шёлка, если на навое большое число нитей (10–12 тысяч и более); при сновании цветных нитей, то есть основ с манером, в случае сложного переплетения (манер основы – последовательность цветных нитей в основе). (3) Секционный:- нити с большого числа мотальных паковок навиваются на отдельные секции (с небольшой заправочной шириной). Общее число нитей, навитое на отдельные секции, равно числу нитей на ткацком навое. Затем отдельные секции набираются на общий ствол и образуют ткацкий навой. Используется для подготовки основ технических тканей. (4) Полный:- особенностью полного способа снования является то, что основа с мотальных паковок наматывается непосредственно на ткацкий навой. Требования, предъявляемые к процессу снования:- (i) в процессе снования не должны ухудшаться физико-механические свойства пряжи или нити; (ii) натяжение снующихся нитей должно быть одинаковым и по возможности постоянным в течении всего процесса; (iii) длина снования должна быть рассчитана, из сновальных валиков должно получиться целое число ткацких навоев; (iv) форма намотки должна быть строго цилиндрической и удельная плотность намотки должна соответствовать принятому значению; и (v) производительность процесса снования должна быть максимальной, а отходы минимальными. Нити основы, сматываясь с мотальных паковок, помещённых в сновальных рамках, проходят через направляющие детали и

делительный рядок, огибают мерильный вал и навиваются на сновальный вал (барабан). Укатывающий вал служит для прессования намотки. Как видно из рисунка, ленточный способ снования отличается от партионного тем, что намотанная на барабан основа перевивается на ткацкий навой. Это приводит к излишним простоям ленточных машин (КПВ машин не превышает 0.3–0.4). С целью повышения эффективности ленточных машин сновальные барабаны делают съёмными; их направляют в шлихтовальный отдел для шлихтования с них основ. В зависимости от вида пряжи и волокна в нитепроводные схемы машин могут быть включены дополнительные устройства (баллоногасители, натяжные приборы и другое). Обрывность В Сновании:- обрывность в сновании определяется в виде числа обрывов на один миллион метров одиночной нити. Обрывность на 1 миллион метров считают по формуле:- Обрывность О = К * 1 000 000 / mcн * lcн, (обрывов на 1 миллион метров), где К – число обрывов на 1 сновальный валик или ленту; mcн – число нитей на сновальном валике или ленте; lcн – длина снования. Величина обрывности при сновании с конических бобин находится в следующих пределах на 1 миллион метров:- 4–6% (х/б пряжа средней толщины); 8–10% (шерстяная гребенная пряжа); 10–14% (шерстяная аппаратная пряжа). Обрывность кручёной пряжи примерно в 2 раза меньше. Пороки, Отходы При Сновании:- пороки снования ухудшают качество основ и будущей ткани, увеличивают угары (отходы) и снижают производительность шлихтовальных машин и ткацких станков. При сновании возможны следующие пороки:- (i) Нахлёстка:- когда конец оборванной нити не связывается с концом нити на сновальном валике, а заматывается на нём; (ii) Защип:- когда конец оборванной нити привязывается к другой нити на сновальном валике. Нахлёстка и защип вызывают образование жгутов на сновальном валике во время шлихтования, а при ткачестве сход и выход нити; (iii) Рвань На Валике:- обрыв группы нитей и связывание их пучком или в нахлёстку; (iv) Врезание Нити В Края Сновального Валика:- результат неправильной установки рядка относительно фланцев или перекос фланцев; (v) Слабина И Разное Натяжение Нити:- результат неправильного регулирования натяжных приборов или выскальзывание нити из под шайбы натяжного прибора; (v) Несоответствие Числа Нитей На Валике:- результат невнимательности ставильщицы при установке ставки на шпулярник; (vi) Слабина Края:- возникает при неравномерном прижиме укатывающего валика к сновальному; (vii) Неправильная Длина Снования:- возникает при неправильной работе счётчика; и (viii) к порокам снования относятся также большие узлы при связывании, замотка пучка, смешивание на валике разных видов пряжи. Отходы при сновании:- (1) вследствие смены ставки бобин; и (2) при обрыве нитей. Процент угаров составляет 0.02–0.15% от массы пряжи поступаемой в снование (этот процент зависит от способа снования, толщины пряжи и её качества).

WARPING BOARD or FRAME = СНОВАЛЬНАЯ МАШИНА (или СНОВАЛЬНАЯ СТАНИНА или РАМА) – Warping Board or Frame is a rectangular frame with strong pegs insered into its sides used to wind a warp. / Партионная Сновальная Машина СП-140:- Технологическая Схема:- партионная сновальная машина предназначена для снования пряжи с бобин на сновальные валы при большой скорости. По сравнению со сновáнием на ленточных машинах при сновании на партионных машинах обеспечивается большая равномерность натяжения основных нитей, лучшая форма и строение навоя, сокращаются затраты труда и снижается стоимость обработки в ткачестве. Кинематическая Схема:- от электродвигателя постоянного тока клиноременной передачей движение передаётся сновальному валу. Укатывающий валик получает движение благодаря трению о сновальный вал. Сновальный вал располагается между пинолями, которые при закреплении сновального вала или перед его съёмом могут получить движение в осевом направлении от электродвигателя. Движение от электродвигателя к пинолям передаётся посредством червячных передач, зубчатых передач и червячно-винтовых передач. Пиноли соединяются со сновальным валом с помощью шипов на концах пинолей и соответствующих пазов в муфтах дисков сновального вала. Зажим и разъединение пинолей со сновальным валиком производится до пробуксовки муфты на валу электродвигателя. От мерильного вала движение передаётся зубчатыми передачами тахогенератору и десятичному счётчику. Рядок совершает возвратно-поступательное движение на определённое расстояние, что обеспечивает рассеивание витков пряжи на сновальном вале, предотвращая врезание их в нижние слои и способствуя получению правильной цилиндрической намотки. Возвратно-поступательное движение рядку передаётся от механизма вращения сновального вала с помощью червячной передачи и кривошипно-шатунной передачи угловому рычагу, который и сообщает движение рядку. Механизм съёма наработанного сновального вала и подачи к пинолям пустого приводится в действие от реверсивного электродвигателя с помощью червячной пары, однозаходного червяка, который поворачивает зубчатый сектор, находящийся на валу. Электродвигатель включается с помощью одной из двух кнопок:- под действием одной из них производится подъём пустого вала, под действием другой – опускание полного сновального вала. На машине имеется механизм поддерживания постоянства линейной скорости снования по мере увеличения диаметра намотки сновального вала. Это осуществляется при помощи тахогенератора. При незначительном увеличении диаметра намотки основы на сновальном вале, естественно, увеличивается линейная скорость нитей, а так как мерильный вал вращается за счёт трения о него нитей то и его частота вращения увеличивается. На одном валу с мерильным валиком находится тахогенератор. Он соединён с электродвигателем. Электрический ток, вырабатываемый тахогенератором, увеличивается; проходя через магнитный усилитель, он размагничивает усилитель пропорционально силе тока. Так как мощность электродвигателя постоянна, это приводит к уменьшению напряжения, подаваемого на обмотку электродвигателя и снижению частоты вращения шкива электродвигателя. Причём уменьшение частоты вращения шкива электродвигателя происходит пропорционально увеличению диаметра намотки сновального вала. Таким образом, при увеличении диаметра намотки основы на сновальный вал его частота вращения уменьшается, за счёт чего обеспечивается постоянство линейной скорости снования. Однако при работе машины всё же наблюдаются отклонения от постоянства линейной скорости из-за нечёткой работы механизмов машины. Скорость снования устанавливается с помощью рукоятки переменного сопротивления. Машина оснащена стрелочным указателем скорости снования. От мерильного вала при помощи трёхступенчатой зубчатой передачи движение передаётся десятичному счётчику длины снования. Счётчик рассчитан на максимальную длину основы 100 000 м. Длина нити измеряется механическим путём – счётчиком, связанным с измерительным валом, вращающимся за счёт трения о движущиеся нити. В процессе снования, особенно при пуске и останове машины, наблюдается проскальзывание нитей по поверхности мерильного вала, вследствие чего возникает разница между фактической длиной нитей, навитых на сновальный вал, и показанием счётчика. Это увеличивает выход мягких концов в шлихтовании и формирование неполных основ при доработке партии. Особенно эта неточность работы сновальных машин очевидна при изготовлении основ с просновками. При наматывании на сновальный вал пряжи установленной длины машина автоматически выключается. Нити с бобин, расположенных на сновальной рамке, проходят между двумя направляющими прутками и через рядок, огибают мерильный валик и навиваются на сновальный вал, который получает движение от электродвигателя через клиноременную передачу. Уплотнение основных нитей осуществляется укатывающим валом. Рядок, распределяя равномерно основные нити между фланцами сновального вала, позволяет навивать основные нити параллельно друг другу. Ленточная Сновальная Машина СЛ-250-Ш:- Технологическая Схема:- машина СЛ-250-Ш предназначена для ленточного снования шерстяной и хлопчатобумажной пряжи с конических бобин крестовой намотки с последующим перевиванием нитей на ткацкий навой. Нити основы, сходящие с конических бобин, неподвижно установленных на бобинодержателях завозных секций сновальной рамки, проходят через натяжные приспособления – тормозки, закреплённые на стойках сновальной рамки, а затем через контактные крючки механизма контроля наличия нитей, размещённого в передней части сновальной рамки по обеим её сторонам. По выходе из сновальной

рамки нити основы проходят через направляющие валы, делительный рядок, рядок суппорта, огибают мерильный вал и направляющие валы и наматываются на сновальный барабан. Благодаря применению в сновальной рамке завозных секций сокращаются затраты времени на операцию перезаправки бобин. Поле того как бобины срабатываются, нити между бобинами и нитенатяжителями обрывают, завозные секции выдвигают по рельсам из сновальной рамки, а на их место завозят запасные секции с установленными заранее бобинами. Таким образом, перезаправка машины сводится к смене секций и связыванию концов нитей основы. Натяжные приспособления служат для создания необходимого натяжения нитей при навивании их на сновальный барабан. Механизм контроля нитей электрического действия осуществляет автоматический останов машины в случае обрыва одной или нескольких нитей. Делительный рядок является направляющим органом и одновременно разделяет нити на группы для прокладки между ними делительных шнурков (цен). В связи с этим в делительном рядке сделана пропайка зубьев и, кроме того, он снабжён подъёмным устройством. Рядок суппорта служит для равномерного распределения нитей по ширине ленты и смещения ленты вдоль образующей сновального барабана во время наматывания её на барабан. Мерильный вал соединён с десятичным счётчиком зубчатой передачей. При наработке первой ленты (в начале снования) включается десятичный счётчик и одновременно с ним – счётчик числа оборотов сновального барабана. В конце наработки первой ленты счётчик числа оборотов сновального барабана приводит в действие механизм останова машины. Остальные ленты снуются по показаниям только этого счётчика. Благодаря наличию двух счётчиков обеспечивается возможность наматывания лент одинаковой длины. При работе с одним счётчиком получить все ленты одинаковой длины невозможно вследствие разной величины скольжения нитей по мерильному валу и различного числа случаев пуска и останова машины при наработке лент. Делительный рядок, рядок суппорта, мерильный вал с десятичным счётчиком и направляющие валы закреплены на столике механизма суппорта. При навивании ленты столик механизма суппорта со всеми деталями, закреплёнными на нём, посредством ходового винта равномерно перемещается вдоль направляющих, благодаря чему обеспечивается соответствующее смещение слоёв ленты и создаётся правильная форма её сечения. В зависимости от линейной плотности пряжи и плотности ленты величина скорости перемещения суппорта изменяется. Периметр сновального барабана равен 4 м. При своём вращении барабан сообщает пряже принудительное поступательное движение. Сновальный барабан вращается также принудительно от отдельного привода. Когда на сновальный барабан будет навито заданное число лент, необходимое для образования одной основы, ленты перевивают на ткацкий навой. Для выполнения этой операции на машине имеется перевивочный станок, представляющий собой вторую половину сновальной машины. В процессе перевивки нити сматываются со сновального барабана и, пройдя через направляющие валы, навиваются на ткацкий навой. Направляющие валы служат для направления основы на ткацкий навой и являются дополнительной зоной для создания натяжения нитей. В основном заданная величина натяжения нитей основы при перевивке их на ткацкий навой создаётся путём торможения сновального барабана колодочным тормозом. В процессе перевивки основы на ткацкий навой перевивочный станок равномерно перемещается вдоль барабана под действием ходового винта. Это перемещение по величине равно перемещению суппорта, но направлено в противоположную сторону. Перемещение перевивочного станка необходимо для правильной укладки нитей основы относительно фланцев ткацкого навоя. Ткацкий навой вращается от отдельного привода. Сновальная Машина:- Обслуживание:- сновальные машины обычно обслуживают 2 человека:- сновальщица и ставильщица. Сновальщица ликвидирует обрывы, меняет сновальные валики, заправляет машину, чистит и смазывает её. Ставильщица меняет ставку бобин на запасных бобинодержателях внутри шпулярника пока с наружных бобин идёт снование. Часто работают бригадой (ставильщицы) 2–3 человека на 2–5 машин.

WARPING REEL = СНОВАЛЬНОЕ МОТОВИЛО – Warping Reel is a rotating frame that can be mounted horizontally or vertically. It's used to wind a warp and help keep the threads in order.

WARP KNIT = ОСНОВОВЯЗАНЫЙ ТРИКОТАЖ (или ПРОДОЛЬНОВЯЗАНЫЙ ТРИКОТАЖ) – Warp Knit is a type of knitted fabric construction in which the yarns are formed into stitches in a lengthwise manner. Warp knits are generally less elastic than weft knits. Common examples of warp knits are tricot knits and raschel knits. Warp Knit is a knit fabric produced by machine with the yarns running in a lengthwise direction – compare weft knit. A Warp Knit is made on a machine in which parallel yarns run lengthwise and are locked into the series of loops. It is a process that makes a more dimensionally stable fabric than weft knitting. Warp knits have a good deal of crosswise stretch. It is frequently run-resistant. Examples are tricot and Raschel. / (Raschel).

WARP KNIT FABRIC = ОСНОВОВЯЗАЛЬНАЯ ТРИКОТАЖНАЯ ТКАНЬ (или ОСНОВОВЯЗАНАЯ ТКАНЬ, или ПРОДОЛЬНОВЯЗАНЫЙ ТРИКОТАЖ) – Warp Knit Fabrics are constructed with yarn loops formed in a vertical or warp direction. All the yarns used for a width of a warp knit are placed parallel to each other in a manner similar to the placement of yarns in weaving. These fabrics can be made rapidly and in great quantity. Two common types of warp knits are tricot and raschel. Warp-Knit Fabric is a fabric that is knit with the yarns running lengthwise, e.g., tricot, milanese, and Raschel. Warp Knit Fabric is a fabric that is formed with the knitting yarns running lengthwise (warpwise).

WARP KNITTING = ОСНОВОВЯЗАЛЬНЫЙ ТРИКОТАЖ (или ПРОДОЛЬНОВЯЗАНЫЙ ТРИКОТАЖ) – Warp Knitting is a type of knitting in which the yarns generally run lengthwise in the fabric. The yarns are prepared as warps on beams with one or more yarns for each needle. Examples of this type of knitting are:- (i) milanese knitting; (ii) raschel knitting; and (iii) tricot knitting. Milanese Knitting is a type of run-resistant warp knitting with a diagonal rib effect using several sets of yarns. Raschel Knitting is a versatile type of warp knitting made in plain and Jacquard patterns; the latter can be made with intricate eyelet and lacy patterns and is often used for underwear fabrics. Raschel fabrics are coarser than other warp-knit fabrics, but a wide range of fabrics can be made. Raschel knitting machines have one or two sets of latch needles and up to thirty sets of guides. Tricot Knitting is a run-resistant type of warp knitting in which either single or double sets of yarn are used. See also Knitting, Tricot, and Weft Knitting. Warp Knitting is a type of knitting in which the yarns generally run lengthwise in the fabric. The yarns are prepared as warps on beams with one or more yarns for each needle. Examples of this type of knitting are Milanese knitting, raschel knitting, and tricot knitting. Warp Knitting is a type of knitted fabric construction in which the yarns are formed into stitches in a lengthwise manner. There are two basic types:- weft knits and warp knits. Warp knits are knitted with intermeshing loops disposed in a lengthwise or warp direction, while weft knits have their loops intermeshed in a width-wise or weft direction. Warp knits are generally less elastic than weft knits. Common examples of warp knits are tricot knits and Raschel knits. Warp Knitting:- loops are formed by needles knitting a series of warp yarns fed parallel to the direction of fabric formation. In warp knitting all needles knit simultaneously for all yarns, while in weft knitting the needles knit in sequence for each yarn. / Жакяр (Jacquard). Рашельные вязальные машины имеют один или два набора .

WARP KNITTING BEAM = НАВОЙ ДЛЯ ОСНОВОВЯЗАЛЬНОГО ТРИКОТАЖА (или НАВОЙ ДЛЯ ПРОДОЛЬНОВЯЗАНОГО ТРИКОТАЖА) – Warp Knitting Beam is a beam with a defined number of ends and length used for subsequent warp knitting operation.

WARP LOSE = ПОТЕРЯ ОСНОВЫ – Warp Lose:- Ends Down:- warp ends which have broken in weaving, thereby impeding production. Ends Out:- warp threads that have broken or snapped during weaving. They cause a light place in the cloth which is readily noted. Blemishes caused by broken ends are fixed either by the weaver or by the sewers in the dry-finishing department of the mill.

WARP PATTERN = ОСНОВНЫЙ РИСУНОК (или ОСНОВНАЯ МОДЕЛЬ) – Warp Pattern:- one repeat of the arrangement of the different counts or different colors of the warp yarns.

WARP PILE = ОСНОВНЫЙ ВОРС – Warp Pile is the extra set of warp yarns that forms the surface in a double-woven pile fabric, including types such as velvet and velour. Upholstery fabrics such as mohair, plush, and friezé are produced by this method. See also Pile, and Velvet Fabric. / фризе (friezé).

WAR PREMIUM = ВОЕННАЯ ПРЕМИЯ (или НАДБАВКА ЗА ВОЙНУ) – War Premium is a price that factors in the risk associated with war – particularly relevant for the oil market.

WARP PRINTING = НАБИВКА НА ОСНОВЕ (или ПЕЧАТАНИЕ НА ОСНОВЕ) – Warp Printing is the printing of a design on the sheet of warp yarns before weaving. The filling is either white or a neutral color, and a grayed effect is produced in the areas of the design. Warp Printing is a printing method in which only the warp yarns are printed with a design before the fabric is woven. A hazy, grayed effect is produced. The resulting fabric has a wavy, shadowy effect. It is also called Shadow Printing. / Уточина .

WARP–PRINT TAFFETA = ПЕЧАТНАЯ ПО ОСНОВЕ ТАФТА – Warp-Print Taffeta:- usually a plain weave, the warp yarns are printed before the filling is inserted. The fabric has a very fuzzy design when design is distorted as fabric is woven. / уточина .

WARP SHEET = ОСНОВНАЯ ПРОСТЫНЯ – Warp Sheet is a sheet comprising up to several thousand ends that are combined to make up the warp during preparation for weaving or warp knitting. See also Warp.

WARP SIZING = ШЛИХТОВАНИЕ ОСНОВ – Warp Sizing is a sizing of the warp yarn is essential to reduce breakage of the yarn and thus production stops on the weaving machine. On the weaving machine, the warp yarns are subjected to several types of actions, i.e. cyclic strain, flexing, abrasion at various loom parts and inter yarn friction. With sizing the strength – abrasion resistance – of the yarn will improve and the hairiness of yarn will decrease. The degree of improvement of strength depends on adhesion force between fiber and size, size penetration as well as encapsulation of yarn. Different types of water soluble polymers called textile sizing agents/chemicals such as modified starch, polyvinyl alcohol (PVA), carboxymethyl cellulose (CMC), acrylates are used to protect the yarn. Also wax is added to reduce the abrasiveness of the warp yarns. The type of yarn material (e.g., cotton, polyester, linen), the thickness of the yarn, type of weaving machinery will determine the sizing recipe. The sizing liquor is applied on warp yarn with a warp sizing machine. After the weaving process the fabric is desized (washed). See also Slashing. Warp Sizing is an essential process to coat warp yarns with elastic film and bind fibers of yarns as lowering fluff or hairiness so that yarns may be so strong that resist the mechanical strain in weaving process, and maintain or improve weaving efficiency. Quality of warp sizing is generally evaluated by the following factors:- (1) Cohesive Strength:- total strength including elasticity of sized yarn to resist such mechanical strains in weaving process as tensing, bending, rubbing, shedding, etc. Warp yarns are drawn as rubbing o thread eye of droppers, mail of healds, comb of reed, etc. How to improve cohesive strength? Use any sizing agebt with sponge effect. In weaving threads into cloth by looms, the warp must be resistant to such mechanical strains as tensing bending rubbing, shedding, etc, otherwise yarn may be broken. A number of such yarn breakages may lower weaving efficiency and quality of woven cloth. How to measure cohesive strength? Conventional Cohesion Tester (TM type yarn rubbing and cohesion tester) developed several decades ago was the most useful device. Nowadays, weavability predictor developed by Hiruta Riken Co., Ltd (Hyogo, Japan; a manufacturer of sizing agents and technical consultant on sizing) is only device with patented mechanism to simulate and apply mechanical strains of looms to yarns, and to numerically determine yarn cohesive strength. It is already approved worldwide that analysis data obtained by this device correlate to actual weavability. (2) Fluff Binding:- very important factor to prevent yarns from clinging among yarns. It is particularly required in weaving a high-density fabric or by a high-speed air jet loom. Sized yarns without fluff (of which fluff is lowered well) may be shed smoothly in weaving loom. Shedding angle of shuttle loom is usually as wide as shuttle with a specified size could move through shed warp sheets to insert weft, in which fluffs of warp sheets hardly block such movement. On the contrary, the angle of air jet loom is minimized by prioritizing the speed of shedding motion. Weft is inserted by linear air jey, but may be blocked by fluffs if they are many or long. How to reduce fluff? (i) Obtain easy divide by dividing rods of sizing machine:- (a) use any sizing agent with sponge effect; and (b) obtain 50% or more voids in the width of squeezing roller. (ii) Set cylinder dryer temperature properly:- modern sizing machines consist of two-size box and three groups of cylinder dryers. In order to reduce fluffs, temperatures of two front groups should be set higher than the rear. That is, warp is divided into two sheets of which surface are quickly dried respectively by front dryers, so that sheets might be again coupled without sticking together on the rear dryer. (3) Size Pickup (SPU):- the amount of size picked up by yarns. An ideal size pickup is pre-determined according to yarn/fabric construction, by which you can formulate a size recipe and set squeeze roll pressure and other mechanical conditions. Size must be picked up by yarn sheet evenly. Basics of ideal SPU for regular cotton woven cloth (English yarn count – SPU (±1.0%)):- 10/s – 8.0; 20/s – 9.0, 30/s – 10.0, 40/s – 12.0, 50/s – 14.0; 60/s – 15.0; 80/s – 16.0. SPU = Size Concentration x Squeezing Ratio. Squeezing Ratios (depending on machine and squezze roller conditions):- 90–120% by polyester/cotton blend; 100% or less by 100% polyester; 100–150% by 100% cotton; 120–170% by 100% rayon. (4) Smoothness and Softness:- another important factor of sized yarn as well as cohesive strength particularly in weaving high-count yarns into a high-density fabric by a high-speed air jet loom. Sizing agent and auxiliaries for smoothness/softness:- any sizing agent with sponge effect; wax; oiling agent; softener (surfactant); acrylic resin; and after waxing. Moisture regain (after drying process) for smoothness/softness (ideal amount of moisture of sized yarn):- 100% cotton – 6.5–7.0%; 65% polyester/35% cotton – 3.0–3.5%; 100% polyester – 1.0–1.5%; 100% rayon – 9.0–9.5%. (5) Size Cooking Conditions:- determine the quality of size solution in terms of viscosity, particle size, etc. In other words, a good size solution can be prepared in a good cooking process:- (i) by a high pressure cooker; or (ii) by an open cooker. Viscosity of size solution:- for better warp sizing, it is important to maintain ideal viscosity of size solution. If size solution has extreme high viscosity, it may not permeate in warp yarns well which might be rough and hard in handling touch, and be bound as a tape (two or more yarns are bound together). On the contrary, if size solution without enough viscosity is applied in warp yarns, their fluffs may not be laid down well, and/or SPU may be lower than expacted because size may be easily squeezed out. In general, ideal viscosity is between 10 and 20 seconds by 6-mm viscosity cup. (6) Sizing Machine Conditions:- in terms of size box temperature, squeeze pressure, draft, dry cylinder temperature, etc which may determine the quality of the above factors. Size box temperature:- viscosity of size solution may vary with temperatures, which may affect the appropriate SPU rate. In order to achieve a constant SPU rate, it is necessary to maintain a constant size temperature. The use of an automatic temperature control device is essential to obtain a consant temperature according to the difference of yarn kinds. Ideal size temperature for yarn kinds in greige state:- (i) 100% cotton – 90–95 °C; greige cotton yarn contains cotton waxes of which melting point is about 85 °C – size temperature for such yarn must be 90 °C or more, otherwise the yarn might not absorb size solution but retaining cotton waxes; (ii) polyester/cotton CVC – 90–95 °C; (iii) 100% rayon – 75–80 °C; rayon fiber may be broken with high temperatures; (iv) polyester/rayon – 80–90 °C. Ideal size temperature for 100% cotton dyed yarn – 75–90 °C; ideal temperature depends on dyeing condition; residual fixing agent on fiber might block the

penetration of size solution. Stretching (draft):- it is preferable for yarns to minimize draft in sizing process. Ideal stretch rate is 1.2–1.5% for 100% cotton and polyester/cotton blend. / Ко., Эл.ти.ди. (Hiruta Riken Co., Ltd). fluffs = распушенные кончики на пряже (пушок). протирание или притирка (rubbing). влагопоглощательная способность (moisture regain).

WARP SLUB = XX ПО ОСНОВЕ – (1) Defect Name:- Warp Slub. Defect Type:- warp lines, vertical lines. Fabric Type:- Bottomweights – Plain Weave Derivatives. Description:- Warp Slub:- Warp yarn with a short thick place in the yarn. Severity:- Minor. (2) Defect Name:- Warp Slub. Defect Type:- Isolated Defects. Fabric Type:- Shirting and Dress Goods – Oxford or Basket. Description:- Warp Slub:- A place where the warp end contains a slub or segment of increased diameter. Severity:- Minor.

WARP STREAKS = ПОЛОСЫ ПО ОСНОВЕ (или ПОЛОСКИ ПО ОСНОВЕ, или ПОЛОСАТОСТЬ ПО ОСНОВЕ, или ЗАТАСКИ ПО ОСНОВЕ) – Warp Streaks are narrow, bare and dense stripes running along the warp direction of the fabric. These are due to the warp yarn that differ from the adjacent warp end in material, count, filament, twist, luster, tension, colour. When the dyed fabric is viewed in reflected light the dense regions reflect more light and appear lighter in shades and vice versa. Uneven spacing of the reed dents give a continuous type of warp streak. It can be reduced by using good quality reeds. Warp Streaks are narrow, barre and dense stripes running along the warp direction. Main reasons are the variation in density of adjacent group of warp ends due to non-uniform dent spacing, wrong drawing-in, or count variations. Also, the variations in lustre, reflectance of dye pick-up of adjacent groups arising out of differences in raw materials, blend composition or yarn constructions contribute for streaks. Warp Streaks:- Fabric:- cotton-twill suiting; Construction:- (i) Count:- 106 x 52; (ii) Warp:- 26/2 combed cotton; (iii) Filling:- 30/2 combed cotton; Finish:- plain dyed khaki. Defect:- numerous short, light warp streaks. Analysis:- physical tests showed no abnormal construction or yarn composition fault which could be responsible for this defect. Examination under ultraviolet light, however, showed a marked fluorescence in the streaky sections, indicating traces of unremoved mineral oil. This defect appeared to be due to portions of the warp yarn's being badly stained with mill oil or grease. In the dyeing and finishing, the dirt was evidently removed, but enough of the oil remained to act as a resist in dyeing. Warp Streaks:- it is narrow, bare and dense strips running along the warp direction of the fabric and it is formed due to the variation in the density of adjacent groups of warp ends because of non-uniform spacing, wrong drawing-in of ends through reed, or difference in count of yarn. Warp Streak:- Fabric:- slub shirting broadcloth; Construction:- (i) Count:- 120 x 64; (ii) Warp:- 40/1 combed cotton; (iii) Filling:- 36/1 cotton slub yarn; Finish:- plain dyed light blue. Defect:- narrow warp streak throughout piece. Analysis:- the dark-appearing streak in this fabric was found to be due to a cracky open place in the warp, apparently caused by a damaged reed. As in the case of many other fabric defects, the degree or intensity of this type of imperfection may vary greatly. In some cloth constructions a slight 'reedy' condition in the gray goods may be so minimized in finishing that an experienced inspector in the weaving-mill cloth room would be justified in passing the goods as first quality. The example described in this instance, however, as disclosed in the accompanying photomicrograph, is typical of an extreme condition which would normally be detected and classified as a 'second' by the mill. Warp Streaks:- a fabric fault that shows as bands or streaks running warpwise. Warp streaks should not be confused with reed marks. Warp Streaks:- Fabric:- napped cotton soft-filled sheeting; Construction:- (i) Count:- 44 x 36; (ii) Warp:- 20/1 carded cotton; (iii) Filling:- 13/1 carded cotton; Finish:- plain dyed camel and napped. Defect:- warp streaks near one edge of fabric. Analysis:- examination of a cutting from the piece submitted showed that the warp streaks were due to differential napping of the surface. The streaks were visible on both the face and the back of the cloth. By microscopic analysis it was found that the warp yarns were unevenly spaced in those areas in a fairly regular pattern. Where the ends were closer together, the filling was apparently bound more tightly and resisted the napping. The uneven spacing of the warp yarns was due to a faulty gray-goods condition, which probably would have showed up as warp streaks in the dyed goods before napping, but the latter operation accentuated the condition. Warp Streak:- in woven fabric, a narrow band running lengthwise and characterized by apparent differences in color from adjoining ends. Compare Barré. Warp Streak:- Fabric:- striped dress goods; Construction:- (i) Count:- 96 x 72; (ii) Warp:- 40/1 combed cotton (brown) and cord made up of two ends of 20/2 combed cotton (white); (iii) Filling:- 40/1 combed cotton; Finish:- plain preshrunk. Defect:- single dark warp streak near the center of the piece. Analysis:- analysis showed that one of the white cords contained an end of 37/2 cotton and that an adjacent cord was composed of 50/3 yarns. Since these two composite yarns were finer in diameter than the normal specified 20/2, the adjoining brown ground stripes appeared to be wider in proportion and resulted in the streaky appearance. Fabrics defect. Warp Streaks:- Fabric:- three-leaf cotton-twill suiting; Construction:- (i) Count:- 106 x 56; (ii) Warp:- 36/2 combed cotton; (iii) Filling:- same as warp:- (iv) Finish:- plain dyed khaki. Defect:- numerous single warp streaks present across the entire width of the goods and running continuously throughout each piece. General appearance was one of uneven luster rather than a difference in color or shade. Analysis:- as indicated above, the warp yarns in these goods were supposed to have been two-ply 36's cotton. Analysis of a large number of consecutive ends taken from the fabric showed wide variations in the size of the single yarns. Actual size range was from 32's to 43's, with the twist varying from a low of 16 turns per inch to a high of 30 turns per inch. The ply twist was also very irregular, running from as low as 14.3 to as high as 17.6 turns per inch. The variations in yarn size and twist resulted in differences in light reflection, producing the streaky warp appearance. In this particular case, the yarns had been purchased by the weaving mill from a commission yarn spinner, who eventually assumed all responsibility. Warp Streak is a streak running in warpwise direction. This may be further qualified to indicate whether the streak is exactly parallel to the warp yarns or running at an angle, and with some comment on length of the streak. (Some technicians, particularly among our English friends, refer to warp streaks as warp 'stripes'). Warp Streaks:- Fabric:- parachute-canopy fabric; Construction:- (i) Count:- 110 x 76; (ii) Warp:- 40/13 nylon; (iii) Filling:- 60/20 nylon; Finish:- plain white. Defect:- continuous warp streaks across full width of sample. Analysis:- it was found that the streaks appeared as bright ends at intervals in a regular pattern, repeating on every eighth end. Investigation showed that this construction had been slashed from eight section beams. Physical tests on the bright-appearing warp ends indicated that they were under greater tension than the remainder of the warp and this resulted in greater light reflection. The defect was attributed to excessive tension applied to one section beam during warping. Warp Streak:- Fabric:- underwear French crêpe; Construction:- (i) Count:- 150 x 94; (ii) Warp:- 75/50 bright acetate rayon; (iii) Filling:- 75/30/35 bright viscose rayon; Finish:- plain dyed black. Defect:- single dull-appearing warp streak. Analysis:- analysis showed that the dull warp streak was due to the presence of three adjacent warp ends slightly chafed in weaving. The broken filaments resulted in reducing the luster of the damaged yarns. This type of damage might have been due to roughness of a reed dent wire, or to a rough drop wire or heddle. The use of stainless-steel reeds is considered good insurance against injury to fine rayon yarns originating from rusty wires. Warp Streaks:- Complaint:- women's all-wool dress goods, dyed dark red, showed short, light streaks in the warp and the filling. Analysis:- microscopic examination revealed that the light streaks were due to the presence of single wool fibers which apparently did not take on the dyestuff. It was impossible to eliminate this condition by any known dyeing procedure. When the single fibers were studied more closely, it was evident that they were in a damaged condition. Although the exact cause of the damage to the fibers in the finished fabric was not determined, it was assumed that a small amount of one lot of wool had suffered mildew or bacteria attack, which made the fibers resistant to normally applied wool dyestuffs. Warp Streak:- Fabric:- combination-yarn dress goods; Construction:- (i) Count:- 54 x 44; (ii) Warp:- 100/60 bright viscose-rayon crêpe plied with 150/40 dull acetate rayon; (iii) Filling:- same as warp; Finish:- plain dyed light green. Defect:- single warp streak. Analysis:- analysis revealed that the rayon-crêpe yarn in the single end in question was of the identical denier, filament count, and make as the remainder of the rayon yarns and had the proper twist, but was a semidull rayon instead of a bright rayon, dyeing slightly lighter and producing the streak as noted. Warp

Streaks:- Fabric:- lining twill; Construction:- (i) Count:- 144 x 72; (ii) Warp:- 150/40 bright acetate rayon; (iii) Filling:- same as warp; Finish:- plain dyed light gray. Defect:- dark warp streaks across the full width of the piece. Analysis:- microscopic examination showed a solid deposit on most of the warp yarns. Attempts to remove this deposit by laboratory desizing and scouring were unsuccessful. Since it was known that these goods had been warp-sized with a gelatin-base material, it was at first assumed that the sizing had been oven hied or baked on in slashing, which would make it difficult to remove. Upon checking on the warp-sizing formula used, however, it was learned that a slasher foreman who was inexperienced in the use or properties of gelatin had taken precautions to prevent the formation of mildew by the addition of formaldehyde. Chemical reaction between the gelatin and the formaldehyde resulted in the formation of an insoluble mass on the warps before weaving. Warp Streaks:- Fabric:- novelty leno-weave dress goods; Construction:- (i) Count:- 52 x 36; (ii) Warp:- 150/40 dull acetate rayon plied S with 100/40 viscose-rayon crêpe S; (iii) Filling:- same as warp; Finish:- plain dyed pink. Defect:- single warp streak throughout piece. Analysis:- analysis of the sample submitted showed that the single streak was due to the presence of a Z twist rayon-crêpe end in one of the combination yarns, instead of all-S twist as specified. Furthermore, it was observed that the particular Z-twist yarn in question had a residue of a dark-colored tint, which made it even more prominent in the dyed fabric. However, the incomplete removal of the tint was considered to be of secondary importance, since the difference in twist alone would result in the appearance of a streak. Warp Streaks:- Fabric:- spun-rayon novelty dress goods; Construction:- (i) Count:- 38 x 42; (ii) Warp:- 14/1 80% XX4-in. 1%-den. bright viscose rayon, 20% 1%-den. bright viscose rayon cut to % in. to make nubby yarn; (iii) Filling:- same as warp; Finish:- plain dyed light green. Defect:- single darker green warp streak. Analysis:- it was found that the single darker dyeing end was of a different size (32/1 instead of 14/1) and was composed of a blend of 50% 1%-inch 1% -denier bright viscose and 50% 2-inch 3-denier dull acetate, instead of as specified. Furthermore, chemical tests showed that the acetate fibers had been saponified, probably because of a causticizing treatment of the goods by the finisher, which might be considered a normal operation for what was supposed to have been an all-viscose fabric. As a result of this saponification, the foreign end became more noticeable than the off-size alone would indicate, owing to the fact that the converted acetate dyed darker than the normal all-viscose yarns. Warp Streak:- Fabric:- spun-rayon dress goods; Construction:- (i) Count:- 34 x 34; (ii) Warp:- novelty yarn composed of one end of 30/1 spun- viscose-rayon nubby yarn, ply-twisted with one end of 75/20 dull acetate rayon; (iii) Filling:- same as warp; Finish:- cross-dyed blue (viscose) and white (acetate). Defect:- single dark-dyed end in warp. Analysis:- analysis showed that the dark-dyed end was composed of two plies of all-viscose spun rayon, instead of one end of viscose and one of filament acetate, as specified. It was later determined that this was a selvage end, which had accidentally been woven into the body of the fabric. Being all viscose, it was dyed solid blue and was revealed as a dark streak. Warp Streaks:- Fabric:- spun-rayon Blub broadcloth; Construction:- (i) Count:- 102 x 52; (ii) Warp:- 30 1 1%-in. 1%-den. bright viscose rayon; (iii) Filling:- 18 1 90$ 1%-in. 1%-den. bright viscose rayon 10 % nubby rayon stock; Finish:- plain dyed light blue. Defect:- single end warp streaks across full width of several pieces. Analysis:- laboratory stripping and redyeing resulted in no improvement. Inspection under ultraviolet light showed a difference in fluorescence between the light- and dark-dyed warp ends. Further investigation revealed that the weaving mill, in an attempt to improve the running qualities of this fiber, had applied an oil to one lot, prior to opening and carding. Yarns spun from this lot were inadvertently mixed in warping with yarns spun from the same make of fiber processed as received. Although the oil was of a type used before and found to give no trouble, it was evident that previously there had been no mixing of oiled and unoiled lots, so that it was not known for certain whether the oil was not completely removable in finishing. Or it was possible that this particular oil was slightly different in its chemical properties because of oxidation or some other form of deterioration in use, resisting complete removal in scouring. Warp Streak:- Fabric:- underwear French crêpe; Construction:- (i) Count:- 150 x 94; (ii) Warp:- 75/50 acetate rayon; (iii) Filling:- 75/30 voile-twist viscose rayon; Finish:- boiled-off white. Defect:- streaky warp, presenting a dirty appearance. Analysis:- microscopic examination showed that this defect was due to traces of unremoved blue tint on a number of the warp ends. It was determined by laboratory tests that normal- soap scouring and even alkaline hydrosulphite solution were not effective in removing this discoloration completely, it being necessary to resort finally to the use of a hypochlorite bleach. Similar tests were made on cuttings of gray goods supplied by the finisher, and the laboratory findings were confirmed. Evidently the tinted yarn as used by the weaver was not fugitive in normal wet processing of the woven fabric, and it was necessary for the mill to reimburse the finisher for the additional bleaching operation. Warp Streaks:- Fabric:- pigment-taffeta dress goods; Construction:- (i) Count:- 92 x 68; (ii) Warp:- 100/60 dull viscose rayon; (iii) Filling:- 150/90 dull viscose rayon; Finish:- plain dyed light blue. Defect:- single, continuous, dark warp streaks. Analysis:- the dark streaks were confined to single warp yarns in which the denier and the twist were found to be normal. The filament counts, however, were subnormal, varying in the individual ends from 19 to 45, instead of the standard 60. It was evident, therefore, that more than one cone of the original yarn was involved. The fewer filaments are proportionately coarser and dye darker than the normal-sized filaments. This defect is usually due to clogged holes in the rayon spinnerettes through which the viscose solution is extruded in the spinning process. The defective yarns provide less cover than do the normal yarns, and in extreme cases the defect may be seen in the gray goods, presenting a 'cracky' appearance. If similar low-filament yarns are woven in the filling, they will show up in the dyed goods as dark filling bands. Warp Streaks:- Fabric:- lining twill; Construction:- (i) Count:- 112 x 68; (ii) Warp:- 150/40 bright viscose rayon; (iii) Filling:- same as warp; Finish:- plain dyed tan. Defect:- short intermittent bright warp streaks distributed throughout a number of pieces. Analysis:- microscopic examination of the cross sections of a number of the short bright places showed them to contain mostly flat or elongated-type filaments. The same warp yarns examined in areas in which there were no streaks showed comparatively uniform rounded-type cross sections. Since it is impossible for the weaving mill or the finisher to produce such an alteration in the contour of the filaments through any known processing operation, this was attributed to a rayon-yarn manufacturing fault. Although no attempt was made to advise the yarn producer of the probable cause of this imperfection, it appeared that the irregularity was introduced during the yarn-spinning operation. Warp Streaks:- Fabric:- flat-crêpe dress goods; Construction:- (i) Count:- 114 x 70; (ii) Warp:- 100/60 dull viscose rayon; (iii) Filling:- 100/60 viscose-rayon crêpe, 2 S and 2 Z; Finish:- blue-ground print. Defect:- light-dyed warp streaks running continuously throughout piece. Analysis:- single-strand breaking-strength and elongation tests showed that the light-dyeing ends were weaker than the darker-dyeing ends and had a lower elongation at the break. The differences in wet elongations were even more pronounced. Chemical tests revealed definite evidence of degradation of the cellulose in the lighter ends. Since there was no way in which the gray mill could have produced this chemical degradation, it was evident that this was a rayon-yarn manufacturing fault. It should be noted that stripping and redyeing, although impractical on printed goods, did not serve to eliminate the streaky warp condition. Warp Streaks:- Fabric:- taffeta dress goods; Construction:- (i) Count:- 112 x 52; (ii) Warp:- 150/40 bright acetate rayon; (iii) Filling:- same as warp; Finish:- plain dyed blue. Defect:- continuous warp streaks, giving a 'strained-yarn' appearance. Analysis:- there was no evidence of mixed yarns or variation in denier, twist, filament count, or yarn cross sections. Single-strand breaking-strength and elongation tests made on a large number of warp ends removed from the fabric showed appreciable differences in the load-elongation characteristics of the yarns, although the total breaking strength and elongation were very much the same. By chance, a series of spot checks made on the yarns as they were received, before warping, by the mill showed a similar condition and this confirmed the fact that the variation was not due to any fault of the weaving mill. Apparently the warp ends having this variation in elongation, when they were subjected to the same load during warping or slashing, developed differences in strains which showed up as a streaky ov tight-end condition in the finished fabric. Warp Streaks:- Fabric:- dress-goods crêpe; Construction:- (i) Count:- 160 x 68; (ii) Warp:- 75/20 bright acetate rayon; (iii) Filling:- 100/40 viscose-rayon crêpe, 2 S and 2 Z; Finish:- plain dyed dark blue. Defect:- single warp streaks

throughout the piece. Analysis:- tests of denier, filament count, single-end breaking strength and elongation, and twist revealed no difference to account for the warp streaks. Microscopic examination of the yarn cross sections showed significant variation between the normal and the light-appearing warp ends, to indicate some fault in the yarn itself. The light, streaky ends all had a preponderance of filaments with two lobes, whereas the remaining normal yarns had three or four lobes. Although no effort was made to determine whether the net effect was one of luster or of dyeing differences, it seemed reasonable to conclude that there was a basic fault in the manufacture of the acetate rayon which produced this defect. Warp Streak:- Fabric:- automobile slip-cover fabric; Construction:- (i) Count:- 80 x 46; (ii) Warp:- 300/60/3 bright medium-tenacity viscose rayon; (iii) Filling:- same as warp; Finish:- plain dyed maroon. Defect:- single dark warp streak. Analysis:- denier, filament count, and twist of the dark-dyeing end were the same as the remainder of the warp yarns. Single-strand breaking-strength and elongation tests, however, showed that end to have a lower strength and higher elongation than the normal warp yarns. These tests identified it as being a regular-tenacity viscose yarn introduced into the warp by mistake and having a different dye affinity from that of the medium-tenacity yarns of the same manufacture, size, and filament count. Warp Streaks:- Fabric:- pigment-taffeta dross goods; Construction:- (i) Count:- 72 x 56; (ii) Warp:- 100/00 dull viscose rayon; (iii) Filling:- 150/90 dull viscose rayon; Finish:- plain dyed white. Defect:- grayish-appearing single warp streaks. Analysis:- the grayish-colored ends were found to be normal in twist, denier, filament count, cross section, and tensile strength and elongation. Microscopic examination showed no evidence of any foreign matter deposited on the surface of these ends. Laboratory scouring in soap and soda-ash solution resulted in no improvement; but when the sample was subjected to a mild chlorine bleach, the streaky condition disappeared. This defect was probably due to the presence of a few ends of incompletely bleached rayon, a yarn-manufacturing fault. In this case it was possible to correct the condition in the finishing plant before delivering the goods, although it entailed a slight surcharge for the extra processing. Warp Streaks:- Fabric:- flat-crêpe dress goods; Construction:- (i) Count:- 114 x 64; (ii) Warp:- 100/60 dull viscose rayon; (iii) Filling:- 100/40 bright viscose-rayon crêpe, 2 S and 2 Z; Finish:- white polka-dot print on blue ground. Defect:- single, dark warp streak. Analysis:- analysis showed this defect to be due to a mixed warp end. The darker dyeing yarn was 100/40 bright viscose, instead of 100/60 dull as specified. Inasmuch as the weaver's supply of the 100/40 bright yarn was in the form of skeins only, and as the warp was prepared from cones, it would not have been possible for him to introduce such a mixture. It was, therefore, assumed that the yarn manufacturer was at fault in having placed a single cone of the wrong yarn in a case of the 60-filament warp yarn. Warp Streaks:- Fabric:- taffeta dress goods; Construction:- (i) Count:- 112 x 52; (ii) Warp:- 150/60 bright viscose rayon; (iii) Filling:- same as warp; Finish:- plain dyed green. Defect:- over-all warp streaks. Analysis:- independent of any tendency for the warp yarn itself to dye unevenly, or any fault of the dyer in not obtaining a more level dyeing, a certain amount of this streaky, or 'reedy', appearance may have been due to the manner in which the filaments of the individual warp yarns adhered to each other and lay in the cloth. Some viscose-rayon yarns have been found to be more circular in contour than others, presenting a somewhat rounded yarn with uniform covering power. Other yarns, though the filaments are of the same appearance and contour, tend to lie in the fabric in ribbonlike formation. Although it is sometimes possible for the weaving mill to alter the 'roundness' of single-warp ends through tension, twisting, slashing, or other means, it is generally thought that this is an inherent characteristic of certain viscose yarns, probably originating with the rayon-spinning operation. Warp Streaks:- Fabric:- nylon underwear fabric; Construction:- (i) Count:- 248 x 110; (ii) Warp:- 2 ends of 30/10 semidull nylon plied 14 turns S; (iii) Filling:- 70/34 semidull nylon; Finish:- plain dyed tea rose. Defect:- single warp streak. Analysis:- analysis revealed that this defect was due to the presence of an end of nylon yarn in the warp which had the correct number of filaments, but sized 105 denier instead of 30. Breaking strength and elongation tests showed it to be 'undrawn' nylon. In the manufacture of nylon, the finished yarn is obtained by drawing down the extruded filaments by a stretching process. Occasionally, some undrawn yardage remains in the package. While normally these undrawn portions are eliminated before the finished package is delivered to the mill, in this case it was obviously not detected during inspection. Warp Streaks:- Fabric:- panne satin dress goods; Construction:- (i) Count:- 225 x 76; (ii) Warp:- 100/26 bright acetate rayon; (iii) Filling:- 100/40 dull acetate rayon; Finish:- plain dyed white. Defect:- continuous warp streaks. Analysis:- analysis showed no physical or chemical differences between the streaky and the normal-appearing warp ends. The difference was apparently one of luster, as the condition was visible in goods finished white. Laboratory boil-off of a cutting of gray goods obtained from the mill showed the presence of the same defect. From a knowledge of the properties of some of the finish which was being used by the yarn manufacturer, it was suspected that the defect was due to the presence of some lots of yarn in this warp with differences in age, the finish on some ends affecting the luster. This suspicion was confirmed when information obtained from the weaving mill disclosed the fact that, in one warp, several cases of very old yarn had been used, along with newly delivered yarn of the same type. The yarn manufacturer assumed all responsibility, because the mill had not been cautioned about any danger in using old and new yarn together. Warp Streaks:- Fabric:- gabardine sportswear; Construction:- (i) Count:- 106 x 58; (ii) Warp:- 20/1 50% 2-in. 1%-den. dull viscose rayon 50% 2-in. 3-den. dull viscose rayon; (iii) Filling:- same as warp; Finish:- plain dyed gray. Defect:- over-all warp streakiness. Analysis:- laboratory tests on the finished goods showed the presence of unremoved starch-base warp sizing. After desizing and stripping and redyeing, the general warp streakiness was completely eliminated. There have been numerous cases in which the finisher has not removed warp sizing, so as to retain a firmer hand without adding sizing or stiffening agents in his final finishing treatment. In some constructions and in some shades, this incomplete removal of warp sizing does not necessarily result in streaky dyeing. In other instances, when the dyer has been careless in desizing and has then used a starch finish, he has assumed that it would be impossible to determine whether or not the desizing operation had been carried out before dyeing. However, such finish usually comes out in hot water alone, and the original warp sizing can still be detected by chemical test. The weaver can reasonably disclaim any responsibility for warp streakiness in cases in which there is evidence of unremoved warp sizing, especially if tests prove that such sizing is readily removable when an enzyme is used. Warp Streaks:- Fabric:- flat-crêpe dress goods; Construction:- (i) Count:- 135 x 64; (ii) Warp:- 100/34 dull acetate rayon; (iii) Filling:- 100/40 bright viscose rayon crêpe, 2 S and 2 Z; Finish:- blue-ground print. Defect:- continuous warp streaks across the full width of the piece. Analysis:- chemical tests showed that the acetate warp yarns in the sample submitted had been partially and unevenly saponified by the dyer prior to printing. The streaks were due to uneven dyeing, the amount of color picked up varying with the degree of saponification. Laboratory dyeing tests made on representative head ends of gray goods showed that the acetate warp dyed uniformly when acetate-type dyestuffs were used. While saponification of acetate rayon is fairly common practice in preparing goods for discharge printing, there are many factors which may be responsible for uneven saponification, such as normal tension variations introduced during warping, slashing, and weaving, or inadequate control by the dyer. Under the circumstances, neither the yarn manufacturer nor the weaver assumes responsibility for such a defect. Warp Streaks:- Fabric:- sharkskin-type dress goods; Construction:- (i) Count:- 112 x 50; (ii) Warp:- 150/40 dull acetate rayon; (iii) Filling:- 15/1 50% 2-in. 3-den. dull viscose rayon 50% 2-in. 3-den. dull acetate rayon; Finish:- plain dyed light blue. Defect:- irregular warpwise streaks. Analysis:- inspection of the full piece showed several irregular streaks running in a warpwise direction on one face of the cloth only and varying from % inch to 1 inch in width. Microscopic examination revealed a marked distortion of the filaments in the warp yarns in the streaky sections. Since there was no evidence of any gray-goods condition which could have been responsible for this damage, it was assumed that the defect was caused in finishing, probably by rubbing over some rough surface, but that it was not severe enough to rupture any of the yarns. Warp Streaks:- Fabric:- novelty dress goods; Construction:- (i) Count:- 90 x 64; (ii) Warp:- one end of 100/60 dull viscose rayon, alternating with one end of 100/40 dull acetate rayon; (iii) Filling:- same as warp; Finish:- cross-dyed black (viscose) and white (acetate). Defect:-

dark warp streaks. Analysis:- examination showed that the warp streaks were due to a number of the acetate warp yarns, sometimes singly and more often in groups of several adjacent ends, being slightly grayish in cast. Microscopic analysis revealed the presence of very small black particles on the yarn surface, and it was assumed that this discoloration was caused by a small amount of dyestuff adhering to certain of the acetate warp ends. The condition was corrected by treatment with a proteolytic enzyme, indicating that there had been some unremoved gelatin sizing on those warp yarns, this material being subsequently dyed by the rayon dyestuff. It was difficult to explain why certain ends had retained part of the warp sizing. This may have been due to uneven size pickup in slashing as a result of tension differences or slight variations in finish on the original yarn. Nevertheless, in view of the ease with which the residue could be removed, it was decided that the finisher was to blame for not having given the fabric a thorough boil-off and desizing, prior to dyeing. Warp Streaks:- Fabric:- sharkskin-type dress goods; Construction:- (i) Count:- 120 x 52; (ii) Warp:- 150/40 dull acetate rayon; (iii) Filling:- 300/80 dull acetate rayon; Finish:- plain dyed blue. Defect:- three narrow streaks running in a warpwise direction. Analysis:- inspection of several yards of the pieces submitted showed that the streaks did not follow the warp yarns exactly. Microscopic examination showed that the filling yarns were bruised in the streaky areas. As the streaks were dyed darker than the remainder of the fabric, it was assumed that the damage was due to a chafing before dyeing. Inasmuch as there was no indication of any such condition's having been present in the gray goods, it was decided that this defect was introduced at the finishing plant, prior to dyeing. While it is difficult to suggest where such a damage might have been inflicted, two occasions for possible chafing would be during the beaming of the piece just before putting the roll on the jig, or during the boil-off. Warp Streaks:- Fabric:- five-harness-warp sateen; Construction:- (i) Count:- 102 x 100; (ii) Warp:- 60/3 combed cotton; (iii) Filling:- same as warp; Finish:- gray goods. Defect:- warp streaks throughout several pieces. Analysis:- analysis disclosed the fact that the warp streaks in the sample submitted were due to the presence of a number of plied ends with abnormally high twist (up to 40 turns, instead of the normal 20 turns per inch). The highly twisted yarns were thinner in diameter than the normal warp ends and resulted in the appearance of warpwise cracks or streaks. / Уточина:- такая же как основа. Найлан^{T3} (Nylon^{TM}). с ненормально высокой круткой (до 40 кручений на дюйм вместо нормальных 20 кручений на дюйм). Под Полосой По Основе понимается местный порок в виде полосы по длине ткани, отличающийся от остальной поверхности интенсивностью окраски, линейной плотностью нитей, натяжением. Полосатость По Основе – порок ткани.

WARP STRIPE = ПОЛОСКА ПО ОСНОВЕ (или ПОЛОСА ПО ОСНОВЕ) – Warp Stripe:- the presence, in a piece-dyed fabric, of one or more warp yarns of the wrong color. This defect is caused by isolated yarns of different characteristics having been introduced during winding or warping and subsequently reacting differently during dyeing and finishing. / Полосатость Основы (warp stripe):- порок заключительной отделки ткани; полосы на основе полотна, которые проходят равномерно через всю или часть ткани. Примечание:- этот порок вызван отдельными видами пряжи с различными особенностями, введёнными во время накрутки или снования и, следовательно, по-разному реагирующими во время окрашивания и отделки.

WARPWISE FLOATS = ПЕРЕКРЫТИЯ (или ПОДПЛЕТИНЫ, или ПОПЛАВКИ, или ПОДНЫРКИ НИТИ, или НЕПОДРАБОТКИ НИТИ) В НАПРАВЛЕНИИ ОСНОВЫ – Warpwise Floats:- Fabric:- Chambray dress goods; Construction:- (i) Count:- 80 x 72; (ii) Warp:- 40/1 combed cotton, alternate ends dyed aqua; (iii) Filling:- 40/1 combed cotton (white); Finish:- plain bleached and preshrunk. Defect:- warp wise 'floats' along one edge of a full piece. Analysis:- examination showed that the floats ran in a straight line throughout the full piece at a distance of about 3 inches from one selvage, repeating at approximately 2-inch intervals. The floats were found to be due to the cutting of single picks in the faulty areas. From the nature of this defect, it was attributed to damage during weaving, probably produced by a faulty temple roll. / Уточина:- 40/1 гребенная хлопковая (белая). Подныpки не более 5 см. Размер порока – до 1 см. Под Подныpками понимается дефект суровой ткани, когда уточные нити на коротких участках не переплетаются с основными, а выступают в виде скобочек или петель сверху или снизу полотна; причины – нечистый зев, несвоевременный ввод уточной нити в зев, провисание нитей основы, излишне высокое или низкое расположение шпаруток и другое.

WARP YARN = ОСНОВНАЯ ПРЯЖА – Warp Yarns are the yarns that run parallel to the selvage or long dimension of a fabric.

WARR. = WARRANT

WARR = WASTE AND RELEASE REDUCTION

WARRANT = ВАРРАНТ – (1) Warrant:- in law, authorization in writing empowering a person to perform an act or to execute an office. The term is applied to a great variety of documents, most commonly judicial or quasi-judicial warrants, of which the most common are for arrest or search. A warrant is necessary if an arrest is to be considered legal, except in situations in which arrest without warrant is recognized by law or statute (see Arrest). In the ordinary case, the warrant is issued at the behest of a complainant who provides an affidavit setting forth facts sufficient to satisfy the belief that an offense has been committed and that the person accused is the guilty party. Usually the facts stated must be sworn to as within the direct knowledge of the complainant. Hearsay and facts stated on information and belief are generally not sufficient basis for issuing a warrant. The warrant must identify the person to be arrested, but, if the person's name is unknown, a fictitious name may be substituted (a so-called John Doe Warrant); in such cases a physical description of the person is required. The legality of a warrant and, hence, of the arrest may be tested by a civil suit for false imprisonment or, in common-law countries, by a habeas corpus proceeding (See Habeas Corpus). The issuance of search warrants is governed by many of the same limitations as the issuance of arrest warrants. The descriptions of the property to be seized or of the place to be searched must be so particular that the officer charged with the execution of the warrant will be left with no discretion. Statutes ordinarily define the types of property subject to seizure; many of them restrict these categories to such objects as stolen property, weapons, and gambling equipment. Other judicial warrants include escape warrants, issued for the recapture of escaped prisoners, and warrants of commitment, issued to incarcerate a prisoner either before or after trial. Other types of warrants include tax warrants, which provide the authority to collect taxes, and land warrants, transferable certificates issued by the government entitling the holder to a specific tract of public land. Warrant is a document of title issued by a warehouse or depository for a specific lot of stored commodity that meets the specifications of the corresponding exchange commodity futures contract. A commodity (e.g., Cotton, Gold, Metal, Oil, Natural Gas, etc) that is 'on warrant' is eligible for delivery against a short position on the exchange. Warrant is a security entitling the holder to buy a proportionate amount of stock at some specified future date at a specified price, usually one higher than current market price. Warrants are traded as securities whose price reflects the value of the underlying stock. Corporations often bundle warrants with another class of security to enhance the marketability of the other class. Warrants are like call options, but with much longer time spans-sometimes years. And, warrants are offered by corporations, while exchange-traded call options are not issued by firms. Certificate of physical deposit, which gives the title to physical commodity in an exchange-approved warehouse. Warrant is a securitized product issued by a specific bank or securities house and usually carrying the name of the issuer, which gives the purchaser the right to buy gold at a certain price on a specific date. They are thus not dissimilar to options, but the pricing mechanism is generally simpler. Options are a generic instrument and would not be specifically tied to one house. See also Subscription Warrant. In some countries this document has the characteristics of securities. Also known as Pledge Receipt, or Warehouse Receipt. In government accounting, Warrant is an order drawn authorizing payment to a designated payee. In securities,

Warrant is a security entitling the holder to buy a proportionate amount of stock at some specified future date at a specified price, usually one higher than current market. This 'Warrant' is then traded as a security, the price of which reflects the value of the underlying stock. Warrants are issued by corporations and often used as a 'Sweetener' bundled with another class of security to enhance the marketability of the latter. Warrants are like call options, but with much longer time spans – sometimes years. In addition, warrants are offered by corporations whereas exchange traded call options are not issued by firms. In the state, Warrant is an order issued by the Chief Financial Officer (CFO) that authorizes payment to a designated payee. Warrant is a certificate giving the buyer the right, but not the obligation, to buy a specified amount of an asset at a certain price over a specified period of time. Warrants differ from options only in that they are usually listed. Warrant is an official certificate, or legal security, authorizing a vendor to receive consideration (money). / Варрант Дьжона Доу (John Doe Warrant). Документ о праве собственности, выписываемый складом или депозитарием на конкретную партию хранимого сырья, . Под Варрантом, от Английского слова Warrant, означающее Основание или Правомочие, в гражданском праве ряда государств (Франция, Великобритания, США, Япония и другие) документ, выдаваемый владельцу товара при сдаче его на склад. Обычно состоит из двух частей – Складского Свидетельства и собственно Варранта. Является видом ценной бумаги, так как владелец товара может продать или заложить его, передав варрант покупателю по индоссаменту. Под Варрантом понимается складская квитанция, содержащая положения о доверительном управлении (трасте). Под Варрантом понимается:- (1) ценная бумага, которая обеспечивает своему владельцу право подписаться на обыкновенные акции (ordinary shares) компании в определённый день и по фиксированной цене. Сами варранты покупаются и продаются на фондовых биржах и являются аналогами фондовых опционов. Цены подписки обычно превышают рыночные цены, поэтому покупка варранта является игрой в надежде на то, что компания будет процветать. Варранты стали весьма популярными в последние годы (1980-е) в связи с тем, что компании, выпускающие их, имеют право не включать их в баланс. (2) Документ, который служит подтверждением помещения товаров на хранение на склад общественного пользования (public warehouse). Документ выписывается под конкретные товары и может передаваться посредством индоссамента. Варранты часто используются в качестве обеспечения банковского займа. Складские варранты, выдаваемые на складах, приписанных к пристани (wharf), называют доковыми варрантами (dock warrants), или варрантами начальника пристани (wharfinger's warrants).

(2) A Warrant is a legal contract which obligates the issuer to make physical shipment of the specified commodity (e.g., Barley) on demand, under the conditions and timeframes set out in the rules of the futures exchange. Warrants are issued by those who have sold futures (hold a short position), and wish to make delivery.

(3) Warrant is an issuer-based product that gives the buyer the right, but not the obligation, to buy (in the case of a call) or to sell (in the case of a put) a commodity at a set price during a specified period.

(4) Warrants are securitized options and can be regarded as options from the point of view of valuation. They may be issued by the issuer of the underlying, or by a third party. They differ from traded options in a number of ways:- (i) Warrants are securities, whereas options are (transferable in the case of traded options) contracts. This is a legal difference and not important to investors. (ii) Warrants are issued by a range of companies and banks, whereas traded options are 'issued' by the exchange on which they trade. Warrants issued by a third party (i.e. not the issuer of the underlying and usually a bank) are usually covered warrants. These are the most accessible way for most private investors to buy options. (iii) The terms of a warrant are decided by the issuer. One effect of this is that some issuers (especially companies issuing call warrants on their own shares) choose very long dates expiries, that may run into many years. (iv) Warrants are more accessible to investors to buy:- private investors can buy them in the same way was shares. They are less accessible to write, i.e. short. Warrants issued by the issuer of the underlying:- where a call warrant is issued by a listed company on its own shares, it is usual to settle through the issue of new shares at the exercise price. This means that there is a class of warrants that can cause dilution of earnings and therefore affect the value of the underlying security. This is not usually significant, but some companies have large numbers of warrants or equivalent securities (such as convertible bonds) which would have a significant impact if exercised. Such warrants are often issued together with bonds or other debt instruments. The effect of this is similar to a convertible bond issue, with the advantage that the option and pure bond elements can be sold separately. If debt holders keep the warrants, they hedge the risks of changes that benefit shareholders at the expense of debt holders. There mere existence of the hedge reduces the incentive shareholders have to do so. Warrant is an option to purchase a specified amount of securities at a specified price within a specified period. Like options, Warrants certify the right to buy (call warrant), or to sell (put warrant), a certain underlying, e.g., stocks or bonds, at a previously specified price during (American-style warrant), or at the end (European-style warrant), of a certain term. In contrast to an option, a warrant is not a standardized instrument, i.e. the warrants of various issuers – usually banks – have different features relating to, for example, the term. It is a security of a specific market value that may be exchanged for a certain share at a predetermined price. The warrant's value lies in the defference between the predetermined conversion price and the market price of the share. Warrant is a security issued by a corporation that gives the holders the option to buy a specific amount of stocks or bonds at a specified price and time. In finance, certificate that gives the holder the right to buy shares of stock at a stated price, with or without a specified time limit. Warrant is a certificate giving the holder the right to purchase securities at a stipulated price within a specified time limit or perpetually. Sometimes a warrant is offered with securities as an inducement to buy. See also Rights. Warrant is an issuer-based product that gives the buyer the right, but not the obligation, to buy (in the case of a call) or to sell (in the case of a put) a stock or a commodity at a set price during a specified period. Warrants are financial instruments issued by banks and other institutions which are traded on the Australian Securities Exchange (ASX). They are a form of derivative giving the holder the right to trade (buy or sell) or cash settle the underlying instrument with the warrant issuer for a particular price at a particular time according to the terms of issue. It is important to understand how to use warrants before you make any financial commitments. Types of warrants? There are many different forms of warrants but broadly there are two main categories of warrants:- (i) Investment Warrants:- tend to be longer dated and less freqently traded, with a lower risk/return profile than trading warrants. Can be used by investors looking for long-term leveraged exposure to the underlying instrument. May also offer other features such as entitlement to dividends, or a capital guarantee on the initial investment. Types of investment warrants include Instalments, Endowments, Self Funding Instalments and Structured Investment Products. (ii) Trading Warrants:- trading instruments that provide leverage to an underlying instrument. Can be used to help manage risk on an investment portfolio. Can be used to trade the direction of an underlying instrument over the short term, usually with a high risk/return trade off. Types of trading warrants include Calls, Puts, Equity, Index, Currency, Commodity, Knock-out and MINIs. What are the benefits? (i) Leverage:- most warrants offer some form of leverage. This means that a small percentage change in the underlying instrument means a larger percentage change in the warrant. (ii) Low Purchase Cost:- lower initial outlay than investing in a share or underlying instrument directly. Purchasing a warrant gives you the same economic ownership exposure for less cost. (iii) Self-Managed Super Fund (SMSF) Benefits:- instalment warrants are an eligible form of SMSF gearing which can provide both income and deduction benefits. (iv) Enhanced Investment Income:- instalment warrant holders are entitled to the full dividends and franking credits of the underlying shares. Percentage yield is increased due to the lower initial cost. (v) Unlocking Wealth:- holders of an existing portfolio can convert shares to instalment warrants through a process called 'Cash Extraction' which unlocks wealth to invest elsewhere. (vi) Portfolio Protection:- some types of equity and index warrants allow you to protect the value of a portfolio by locking in a

sale price. (vii) Loss Management:- some types of call and put warrants can expire worthless, however, your loss is limited to the invested capital whereas losses could be a lot higher if you held the underlying instrument. (viii) Exposure:- index warrants offer exposure to the broader market without the need to own a large portfolio. What are the risks? (i) Pricing Variables:- a warrants pricing is subject to many variables such as price of the underlying instrument, time to expiry, volatility, interest rates and dividends. Any adverse changes can have a negative effect on the warrant. (ii) Leverage:- leverage is a double edged sword, with a warrant likely to move both up and down more rapidly than the underlying instrument. (iii) Limited Life:- warrants have an expiry date and therefore a limited life. Unless the underlying share price is above the exercise price for call warrants or below the exercise price for put warrants upon expiry, the warrant will expire worthless. (iv) Time Decay:- warrants are decaying assets so it is important to monitor expiry dates and know when to exercise a warrant. In the securities underwriting, Warrant is short for the Subscription Warrant. Warrants are, in principle, like stock options. They give the holder the right to buy shares at a given price for a specified period of time. Warrants are usually issued by a company as an additional financing bonus. For example, investors buying shares at CAD5.00, may be given a warrant (or half a warrant) to buy a share at CAD5.00 (or slightly) higher for a year or two. If the stock performs, then investors get a double benefit. Warrant is an options contract often sold with another security. For instance, corporate bonds may be sold with warrants to buy common stock of that corporation. Warrants are generally detachable. Warrants (a particular form of option) are tradable instruments giving the holder the right to buy from the issuer of the warrant (usually a corporation) a certain number of shares or bonds under specified conditions for a designated of time. Warrant scan be traded apart from the underlying securities to which the warrants are linked and thus have a market value. The treatment of warrants is the same as that for other options, and the issuer of the warrant is considered, by convention, to have incurred liability, which is the counterpart of the asset held by the buyer and reflects the current cost of buying out the issuer's contingent liability. Warrants are a form of options that are treated in the financial account in the same way as other options; they are tradable instruments giving the holder the right to buy, under specified terms for a specified period of time, from the issuer of the warrant (usually a corporation) a certain number of shares or bonds. A Warrant is an option to purchase a certain number of a company's shares at a pre-determined price, within a defined time period. Warrants are frequently included in a bond issuance, so that the bond buyer acquires both the bond and its accompanying interest payments, as well as the option to profit from any increase in the company's stock price. Warrants are most commonly issued when an entity is having trouble attracting investors to a bond issuance, and must sweeten the offer in order to obtain a reasonable bond price. Warrants may also be issued to corporate outsiders as a form of compensation. This is especially common when the issuer has little cash to spare for a more traditional cash payment. Warrants to not give their holder the right to receive dividends, and have no voting rights. Warrant is an option issued by a company. The holder has the right to purchase shares at a specified price at specified times in the future. / Инвестиционный инструмент, позволяющий инвестору приобрести определённое количество активов по определённой цене, иногда в течение некоторого периода времени, но обычно для них не устанавливаются сроки. Варрант – сертификат (свидетельство), дающий его держателю право купить ценные бумаги по оговорённой цене в рамках определённого периода времени или в любое время. Иногда предлагается вместе с ценными бумагами в качестве стимула к покупке. Под Варрантом понимается публичный опцион; финансовый инструмент, предоставляющий его владельцу право на приобретение определённого количества обыкновенных акций в определённый срок по определённой цене. Выпускается для внешних участников, в то время как внутренний опцион (stock option) предоставляет такое право работникам компании. Варрант:- финансовый инструмент, предоставляющий его владельцу право на приобретение обыкновенных акций. Варрант – производная ценная бумага, дающая право её владельцу подписаться на базовый актив в определённый срок по определённой цене. Варрант (Warrant (WT)):- ценная бумага, дающая её владельцу право на покупку некоторого количества акций на определённую будущую дату по определённой цене. Обычно варранты используются при новой эмиссии ценных бумаг. Варрант торгуется как ценная бумага, цена которой отражает стоимость лежащих в его основе ценных бумаг. В отличии от опционов на покупку варранты выпускаются на более длительные сроки.

(5) In governmental accounting, Warrant is a draft on the Treasury for the payment of money. / В ведении государственного бюджета под Варрантом понимается тратта на Казначейство для оплаты денежных средств.

(6) Warrants look like cheques and clear through the banking system like cheques, but are not drawn against cleared funds in a demand deposit account. A cheque differs from a warrant in that the warrant is not necessarily payable on demand and may not be negotiable.

(7) Warrant (or Warehouse Receipt) for metals is a certificate of physical deposit, which gives title to physical metal in an exchange-approved warehouse. Warrant is a document of possession, issued by the warehouse company, for each lot of London Metal Exchange (LME)-approved metal held within an LME-approved facility. Warrants are used as the means of delivering metal under LME contracts. See also London Metal Exchange (LME).

WARRANT BOND = ОБЛИГАЦИЯ С ВАРРАНТОМ – Warrant Bonds are the bonds with an attached warrant which entitles the purchaser to a certain number of shares of the borrowing company for a certain period at a price fixed in advance. The coupon on the bond may be lower than that of comparable bonds without warrants because of the potential benefit of buying shares at an advantageous price. Warrant Bond is a bond with a warrant attached (bond with bond warrant or share warrant). Warrant Bond:- a bond with option rights is called a Warrant Bond. For a limited time, it confers the right to buy equity securities, such as shares, of the bond issuer at a predetermined price (exercise price). Warrant bonds differ from convertible bonds firstly in that the bond still exists after the option right has been exercised. Interest payments and redemption at the end of the duration are still the same as with ordinary bonds, but the option is no longer part of the bond. The second difference is that the warrant of a warrant bond can be traded separately. The following stock-exchange listings are possible:- (i) bond cum option; (ii) bond ex option; and (iii) option only. As far as the preferential subscription right, the yield and the anti-dilutive provisions are concerned, the conditions are the same as for convertible bonds. Investing in warrant bonds can offer several different benefits. On the one hand, there is the potential for price gains in the event of rising share prices, while on the other hand the price risk is limited since a warrant bond is a conventional bond with additional rights in the form of options. However, ownership of the option alone needs to be considered separately. Depending on the terms and conditions, unattached options have enormous potential both for gains and losses.

WARRANTED NO RISK AFTER DISCHARGE = РУЧАЕМСЯ БЕЗ РИСКА ПОСЛЕ ВЫГРУЗКИ – Warranted No Risk After Discharge (WNRAD (or NRAD)):- insurance ceases upon discharge from vessel or aircraft. Note:- WNRAD/NRAD can mean insurance ceases once goods are discharged by the port authorities. Check your wordings to be sure.

WARRANT INTO NEGOTIABLE GOVERNMENT SECURITIES = ВАРРАНТ НА ОБРАЩАЮЩИЕСЯ ПРАВИТЕЛЬСТВЕННЫЕ ЦЕННЫЕ БУМАГИ – Warrant Into Negotiable Covernment Securities (WINGS) is a special type of warrant which gives the holder the right to buy US Treasury bonds within a certain period at a set price. See also Bond Option. Warrant Into Negotiable Covernment Securities:- warrants for subscribing the US Treasury Bonds.

WARRANT ISSUE = ВЫПУСК ВАРРАНТА – Warrant Issue is a bond issue which bears interest throughout its terms to maturity and features a warrant which embodies the right to purchase a share or other security. The warrant may be traded separately from the bond. See also Convertible Bond.

WARRANT–LINKED BONDS, EX–WARRANTS = УВЯЗАННЫЕ С ВАРРАНТОМ (или ПРИВЯЗАННЫЕ К ВАРРАНТУ) ОБЛИГАЦИИ, БЕЗ ВАРРАНТОВ – Warrant-Linked Bonds, Ex-Warrants:- embody a precisely defined right for the holder to purchase or sell other assets during the exercise period. However, leverage makes the potential for capital gains considerably greater than for a corresponding direct investment.

WARRANT–LINKED BONDS, WITH WARRANTS = УВЯЗАННЫЕ С ВАРРАНТОМ ОБЛИГАЦИИ, С ВАРРАНТАМИ – Warrant-Linked Bonds, With-Warrants:- embody a money claim on the issuer (borrower). Depending on the market situation, these warrant-linked bonds can offer a higher return than other forms of fixed-interest investment. The warrant offers the opportunity of participating directly in the success of the company.

WARRANT PREMIUM = ПРЕМИЯ ЗА ВАРРАНТ – A Warrant Premium is the amount by which the cost of buying and exercising a warrant exceeds the cost of buying the underlying shares directly. A warrant premium is the option value of a warrant. It is calculated the same way:- price less intrinsic value.

WARRANT VALUE = СТОИМОСТЬ ВАРРАНТА – Warrant Value:- the theoretical value of a warrant consists of two components:- intrinsic value (formula value) and time value:- Warrant Value = Formula Value + Time Value. The formula value is the difference between the underlying share price and the warrant's exercise price, multiplied by the number of new shares issued on exercise. This value is either positive or zero, but can't be negative. On the other hand, the time value is the premium over formula value (this premium is known as the Price). The time value is always positive and approaches zero with the passage of time (up until the expiration date). The value of a warrant, also known as the Fair Price Of A Warrant, is also given by:- Warrant Value = $(P_C / (1+ p)) \times N$. Where:- P_C is the value of an American call option with the same exercise price and expiration date as the warrant, p is the proportionate increase in the number of shares outstanding if all the warrants were exercised, and N is the number of new shares issued if warrant is exercised. / Стоимость Варранта – теоретическая стоимость сертификата (свидетельства), получаемая при вычете цены использования из рыночной цены обыкновенных акций и перемножении полученной величины на количество акций, которое можно купить на каждый варрант.

WARRANTY = РУЧАТЕЛЬСТВО – (1) Warranty is a contract between the seller and the buyer of a product specifying the conditions under which the seller will make repairs or remedy other problems that may arise, at no additional cost to the buyer. The warranty document describes how long the warranty remains in effect, and which specific repairs will be performed at no extra charge. Warranties usually cover workmanship or the failure of the product if used normally, but not negligence on the part of the user if the product is used in ways for which it was not designed. Warranties are commonly issued for automobiles, appliances, electronic gear, and most other products. In some cases, manufacturers will offer extended warranties for several years beyond the original warranty period, at an extra charge. Consumers should consult federal and state laws for more extensive applications or interpretations of warranties. Warranty is a guarantee given to a buyer from a seller that the goods or services purchased will perform as promised, or a refund will be given, repair will be done at no charge, or an exchange made. Warranty is the written guarantee issued with new motor vehicles or related equipment. It defines the manufacturer's responsibility for the repair or replacement of defective parts and other services provided as part of the purchase price. A warranty can be nullified if the user does not follow certain stipulations of the manufacturer, such as preventive maintenance. Warranty is a guarantee by a seller to a buyer that if a product requires repair or remedy of a problem within a certain period after its purchase, the seller will repair the problem at no cost to the buyer. A Warranty is a guarantee related to the performance of non-financial assets that are owned by the party being guaranteed. A guarantee is frequently incurred in connection with the sale of goods or services to the party being guaranteed. If the warranty is related to a product, the party providing the guarantee normally replaces or repairs the product in question. If the warranty is related to a service, the party providing the guarantee usually provides a full or partial refund, or replacement services. A warranty is a contingent liability, so the party providing it should record a liability and warranty expense when it records the associated sale of goods or services. As the selling party incurs actual warranty costs, it charges them against the liability account, which therefore declines over time. If there is a history of minimal warranty expenditures, there is no need to record a contingent liability in advance of actual warranty expenses. Warranty is a seller's guarantee to purchaser that product is what it is represented to be and, if it is not, that it will be repaired or replaced. Within the context of vehicles, refers to an engine manufacturer's guarantee that the engine will meet 'certified' engine standards at 50 000 miles or the engine will be replaced. Retrofits may generally void an engine warranty. / Ручательство – гарантия качества производителя о качестве товарной продукции. Как правило, определяет условия, при которых товар подлежит ремонту или возврату из-за поломки или плохого качества. Ручательство – гарантия должника за доброкачественность чего-то в течение определённого гарантийного срока. Ручательство – письменное обязательство производителя произвести бесплатный ремонт или замену бракованного изделия в течение определённого периода с момента продажи изделия. Часто это называют Гарантией (Guarantee). Ручательство – условие в контракте. Договор между продавцом и покупателем продукта, определяющий условия, при которых продавец будет производить ремонт или решать другие проблемы, которые могут возникнуть при использовании продукта, без дополнительной оплаты со стороны покупателя. В договоре ручательства указывается, как долго ручательство будет оставаться в силе и какие меры должны быть предприняты без дополнительной оплаты. Ручательство обычно подтверждает качество продукта или обеспечивает исправление его недостатков при условии нормального использования, но не из-за его неправильного использования и эксплуатации. Обычно ручательства выдаются на автомобили, электробытовые приборы, электронное оборудование и многие другие продукты. В некоторых случаях производители продлевают ручательство на несколько лет сверх первоначально установленного срока ручательства без дополнительной оплаты. Потребители должны знать о своих правах, обеспечиваемых им соответствующим федеральным и штатовским законодательством, чтобы уметь более широко использовать и интерпретировать гарантию.

(2) Warranty:- where an insured or reassured promises that something will or will not be done during the period of cover or that a particular state of affairs exists or does not exist at the inception of cover. If the promise is untrue or is not kept then the insurer/reinsurer may disclaim all liability under the policy from the date of the breach, regardless as to whether the false declaration was material to the underwriting of the contract or causative of any loss. Warranty is a statement of fact in a contract, either expessed or implied. If it is unfullfilled the injured party cannot repudiate the contract but may be able to claim damages. The diffence between a warranty and a condition is that a condition is fundamental to a contract, whereas a warranty is not. Warranty is a statement by the assured, the truth of which determines the validity of the insurance contract. A warranty may relate to matters existing at or before the issuance of the policy (affirmative warranty). Or it may be an undertaking by the assured that something be done or omitted after the policy takes effect and during its continuance (promissory warranty). Many states have restricted by statute the common law rule that any breach of warranty voids an insurance policy. For example, under the New York law (15C) a breach of warranty to void the policy

must have 'materially increased the risk of loss, damage or injury within the coverage of the contract'. Warranty is a statement made by the insured as true. Also a very strict condition in a policy. A Warranty in a marine insurance policy is an undertaking by the assured, whereby he promises that a certain thing shall be done or shall not be done, or that some condition will be fulfilled, or whereby he affirms or negatives the existence of a particular state of facts. A warranty may be express or implied, and must be complied with literally. Failure to comply with the warranty is termed 'Breach of Warranty', which, if not excused, discharges the underwriter from all liability under the policy as from the date of the breach. Warranty is a statement made on an application for insurance, a claim, or other official correspondence that is warranted to be true in all respects. If untrue in any respect, even though the untruth may not have been known to the person giving the warranty, the contract may be voided whether or not the untruth or inexactness is material to the risk. In a contract of insurance, either (a) a promissory undertaking by the insured that some particular thing shall or shall not be done, or that some condition shall be fulfilled or that a particular state of facts is affirmed or negatived. It must be exactly complied with. A breach entitles the insurer to deny liability; or (b) a requirement by the insurer as to some limitation of cover, e.g., 'Warranted free of capture and seizure'. Warranty is a condition which goes with a policy and must be strictly complied with for a claim to be paid under the policy for example, use of a hot work permit. Warranty:- in the field of ocean marine insurance there are two general types of warranties that must be considered:- express and implied. Express warranties are promises written into the contract. There are also three implied warranties, which do not appear in written form but bind the parties nevertheless. Examples of expressed warranties are the free of capture and seizure warranty (FC&S warranty) and the strike, riot, and civil commotion warranty. The FC&S warranty excludes war as a cause of loss. The strike, riot, and civil commotion warranty states that the insurer will pay no losses resulting from strikes, walkouts, riots, or other labor disturbances. The three implied warranties relate to the following conditions:- seaworthiness, deviation, and legality. Under the first, the shipper and the common carrier warrant that the ship will be seaworthy when it leaves port, in the sense that the hull will be sound, the captain and crew will be qualified, and supplies and other necessary equipment for the voyage will be on hand. Any losses stemming from lack of seaworthiness will be excluded from coverage. Under the deviation warranty, the ship may not deviate from its intended course except to save lives. Clauses may be attached to the ocean marine policy to eliminate the implied warranties of seaworthiness or deviation. The implied warranty of legality, however, may not be waived. Under this warranty, if the voyage itself is illegal under the laws of the country under whose flag the ship sails, the insurance is void. / , от Латинского слова Affirmo, означающее Утверждаю, . Ручательство – гарантия исполнения контракта или иного обязательства в определённую дату в будущем. Условие в контракте или в соглашении. Ручательство – ясно выраженное утверждение в контракте (выраженное ручательство (express warranty)) либо ручательство, не сформулированное чётко, но понятное сторонам контракта (подразумеваемое ручательство (implied warranty)). Невыполнение ручательства не делает контракт недействительным (как это бывает при невыполнении условия самого контракта, однако даёт право требовать выплаты компенсации). Смотрите также Простое Ручательство (Floating Warranty). Ручательство – условие страхового полиса, которое подтверждает, что что-то будет сделано или не сделано или что определённая ситуация существует или не существует. Если ручательство нарушено, страховщик имеет право отказаться от выплаты страховой суммы даже при том, что наступил страховой случай, не связанный с нарушением этого ручательства. Например, если в полисе страхования домашнего имущества есть условие, требующее использования замков определённого типа на дверях и окнах дома, и выяснится, что такие замки не были установлены, страховщики могут отклонить требование выплаты страховой суммы в связи с гибелью имущества от разрыва трубы. На практике, однако, такого не случается, так как страховщики договариваются о том, что они откажутся платить, только если нарушение ручательства привело к наступлению страхового случая.

(3) Warranty is a statement or representation that the goods and/or services will perform as promised in the agreement; a guaranty. For example, a License Agreement relating to a database of samples of musical compositions may contain a Warranty that the Licensor has obtained permission from the composers and performers of the individual musical works to provide access to the database to the Licensee.

WARRANTY CONTRACTS = КОНТРАКТЫ С РУЧАТЕЛЬСТВОМ – Warranty Contracts are the gas purchase agreements for the sale of natural gas by a producer to a pipeline company wherein the producer warrants it will have available sufficient gas supplies to meet its commitments over the life of the contract. Generally, the producer does not dedicate gas reserves underlying any specific acreage, lease, or fields to the agreement. Substitution of various sources of gas supply may be permitted according to the terms of the contract. Warranty contracts, by their terms, may vary from the above. / в которых производитель ручается.

WARRANTY DEED = ДОГОВОР О РУЧАТЕЛЬСТВЕ – Warranty Deed:- this conveyance is the 'best' in the sense that the seller makes all the written promises (covenants) possible possible to the buyer. They are:- (i) Seizin (this means the seller possessed the property and had the right to transfer it); (ii) Quiet Enjoyment (the property is free of any claims to title by others); (iii) Against Encumbrances (this protects buyer against any lien or debt against the property); (iv) Further Assurances (seller will get for buyer any more documents found necessary for good title); and (v) Warranty (this means seller will defend title against claims by anyone).

WARRANTY EXPENSE = РАСХОД ПО РУЧАТЕЛЬСТВУ – Warranty Expense is the cost that a business expects to or has already incurred for the repair or replacement of goods that it has sold. The total amount of warranty expense is limited by the warranty period that a business typically allows. After the warranty period for a product has expired, a business no longer incurs a warranty liability. Warranty expense is recognized in the same period as the sales for the products that were sold, if it is probable that an expense will be incurred and the company can estimate the amount of the expense. This is called the Matching Principle, where all expenses related to a sale are recognized in the same reporting period as the revenue from the sale transaction. Follow these steps to calculate and record warranty expense:- (i) Determine the historical percentage of warranty expense to sales for the same types of goods for which the warranty is currently being determined. (ii) Apply the same percentage to the sales for the current accounting period to derive the warranty expense to be accrued. This amount may be adjusted to account for unusual factors related to the goods that were sold, such as initial indications that a recent batch of goods had an unusually high failure rate. (iii) Accrue the warranty expense with a debit to the warranty expense account and a credit to the warranty liability account. (iv) As actual warranty claims are received, debit the warranty liability account and credit the inventory account for the cost of the replacement parts and products sent to customers. Thus, the income statement is impacted by the full amount of warranty expense when a sale is recorded, even if there are no warranty claims in that period. As claims appear in later accounting periods, the only subsequent impact is on the balance sheet, as the warranty liability and inventory accounts are both reduced. It is very unlikely that actual warranty claims will exactly match the historical warranty percentage, so some adjustment of the warranty liability account to actual results will be justified from time to time. If there is a history of minimal warranty expenditures, there is no need to record a warranty liability in advance of actual warranty expenses. Instead, just record the cost associated with the few warranty claims as they are submitted by customers. Example of Warranty Expense:- ABC International sells USD1 000 000 in widgets in September. It has historically experienced a warranty expense of 0.5 percent, so ABC records the warranty expense with a debit to the warranty expense account of USD5 000 and a credit to the warranty liability account of USD5 000. In October, ABC receives a warranty claim, which it fulfills with a USD250 replacement part. The entry for this claim is a debit of USD250 to the warranty liability account and a credit of USD250 to the spare parts inventory account. Warranty Expense:-

when a sale transaction has occurred with a warranty purchase, the vendor will record this expense in the event the product needs to be repaired.

WARRANTY GUARANTEE = ГАРАНТИЯ ПО РУЧАТЕЛЬСТВУ – Warranty Guarantee supports the beneficiary's costs should the principal/applicant fail to meet his warranty obligations as per the contract terms.

WARRANTY PAYABLE = ВЫПЛАЧИВАЕМЫЕ РУЧАТЕЛЬСТВА (или К ВЫПЛАТЕ ПО РУЧАТЕЛЬСТВАМ) – Warranty Payable:- this is a projection of much it will cost to fix a product if a consumer purchased a warranty for the product. This term is also referred to as a Warranty Liability.

WAR RISK = ВОЕННЫЙ РИСК – War Risk:- insurance against loss or damage to property due to the acts of enemies at war. This coverage is freely written on marine risks, but not on property on land. During World War II, the government assumed, for a premium, war risks on land and the program was handled by insurers on the government's behalf and participated in by them. In Europe, the government paid for such damage. Insurance coverage for loss of goods resulting from any act of war. War Risk:- surcharge for covering additional insurance premium incurred by a vessel entering a war zone. Insurance against loss or damage to property as a result of war risks. War Risks ('Voywar 1950'). (1) In these clauses 'War Risks' shall include any blockade or any action, which is announced as a blockade by any Government or by any belligerent or by organized body, sabotage, piracy, and any actual or threatened war hostilities, warlike operations, civil war, civil commotion, or revolution. (2) If at any time before the vessel commences loading, it appears that performance of the contract will subject the vessel or her master and crew or her cargo to war risks at any stage of the adventure, the owners shall be entitled by letter or telegram dispatched to the charterers, to cancel this charter. Continuation (3), (4), (5), (a), (b), (6) of Clause 16 are omitted. War Risk:- the possible aggressive actions against a ship and its cargo by a belligerent government. This risk can be insured by a marine policy with a war risk clause. / хозяин (или капитан) и экипаж (или команда). Страхование на случай гибели или повреждения имущества в результате военных рисков. Надбавка или доплата (surcharge) за . Понятие Военного Риска является условным, имея в виду, что в него включается большой круг рисков, которые, строго говоря, выходят за рамки этого понятия. Военные Риски ('Войво 1950'). (1) В данных оговорках термин 'Военные Риски' подразумевает любую блокаду или любые другие действия, объявленные как блокада любым правительством, любой воюющей стороной или какой-либо организацией, саботаж, пиратство или любую реальную войну, угрозу войны, военные действия, операции военного характера, гражданскую войну, гражданские волнения и революции. (2) Если в любое время до начала погрузки будет установлено, что выполнение договора подвергнет судно, капитана, команду или груз военным рискам на любой стадии выполнения рейса, судовладельцы имеют право письмом или по телеграфу в адрес фрахтователя канцеллировать чартер. Пункты 3, 4, 5, a, b, 6 Статьи 16 опущены.

WAR RISK INSURANCE = СТРАХОВАНИЕ ВОЕННОГО РИСКА – War Risk Insurance is an insurance issued by marine underwriters against war-like operations specifically described in the policy. In former times, war risk insurance was taken out only in times of war, but currently many exporters cover most of their shipments with war risk insurance as a protection against losses from derelict torpedoes and floating mines placed during former wars, and also as a safeguard against unforeseen warlike developments. In the USA, war risk insurance is written in a separate policy from the ordinary marine insurance; it is desirable to take out both policies with the same underwriter in order to avoid the ill effects of a possible dispute between underwriters as to the cause (marine peril or war peril) of a given loss. War Risk Insurance:- separate insurance coverage against loss or damage due to acts of war (including objects left over from previous wars). War Risk Insurance is an insurance against loss or damage to property due to the acts of enemies at war with us. This coverage is freely written on marine risks, but not on property on land. During World War II, the government assumed, for a premium, war risks on land and the program was handled by insurers on the government's behalf and participated in by them. In Europe, the government paid for such damage.

WAR RISK SURCHARGE = НАДБАВКА ЗА ВОЕННЫЙ РИСК (или ДОПЛАТА ЗА ВОЕННЫЙ РИСК) – War Risk Surcharge is a surcharge for ports of countries in state of war. Freight surcharges are no longer updated by conferences. Please refer to shipping line agents or freight forwarders for their values. / надбавка или доплата (surcharge).

WAR RISK WATERBORNE AGREEMENT = СОГЛАШЕНИЕ О ВОЕННОМ РИСКЕ ПРИ ТРАНСПОРТИРОВКЕ МОРЕМ – War Risk Waterborne Agreement is a marine market agreement whereby underwriters will only cover goods against war risks whilst they are on the vessel subject to a time limit after arrival at the port of destination. There is reduced cover for offloading and transhipment at the port of destination.

WARSAW CONVENTION = ВАРШАВСКАЯ КОНВЕНЦИЯ – Warsaw Convention is the Convention for the Unification of Certain Rules Relating to International Carriage by Air, signed at Warsaw, 12 October 1929, or that Convention as amended by the Hague Protocol, 1955, stipulating obligations or parties and limitations and/or exonerations of carriers (aircargo). / Варшавская Конвенция об Унификации Некоторых Правил, Касающихся Международных Воздушных Перевозок (Гамбургские Правила), подписанная в Варшаве 12 Октября 1929, или указанная Конвенция, изменённая Протоколом, подписанным в Гааге 28 Сентября 1955, в зависимости от того, какой из этих документов может быть применён к настоящей перевозке.

WARSAW STOCK EXCHANGE = ВАРШАВСКАЯ ФОНДОВАЯ БИРЖА – Warsaw Stock Exchange (WSE) is the largest national stock exchange in the Central and Eastern Europe (CEE) and one of the fastest-growing exchanges in Europe. WSE Group offers a wide range of products and services within its trading markets of equity, derivative, fixed income and structured products; it also distributes market data. WSE is one of the most recognizable Polish financial institutions worldwide. The WSE's governing bodies are:- (i) the General Meeting; (ii) the Supervisory Board, referred to as the Exchange's Supervisory Board; and (iii) the Management Board, referred to as the Exchange's Management Board. The parent entity and the subsidiaries of the Group have two main business lines:- (i) financial market, which includes trading in equities, derivatives, fixed-income and other instruments, listing, and information services; and (ii) commodity market, which includes trading in electricity and property rights in certificates of origin, operation of a register of certificates of origin, clearing, trade and technical trade operator services. In its business in all these three segments, the Group organizes and operates trading on the following markets:- (i) Main Market (trade in equities, equity-related and other cash instruments, derivatives); (ii) NewConnect (trade in equities and equity-related instruments of small and medium-sized enterprises); (iii) Catalyst (trade in corporate, municipal, co-operative, Treasury and mortgage bonds operated by the WSE and BondSpot); (iv) Treasury BondSpot Poland (wholesale trade in Treasury bonds operated by BondSpot); and (v) poee WSE Energy Market (Daily-Hourly Electricity Market, Electricity Futures Market). As of Q1 2012, the Group additionally organizes and operates trade on the markets operated by the company Polish Power Exchange (PolPX):- (i) Energy Markets (Intra-Day Market, Day-Ahead Market, Commodity Derivatives Market, Electricity Auctions); (ii) Property Rights Market; and (iii) Emission Allowances Market. In addition, as of Q1 2012, the Group operates the Clearing House and the Settlement Institution via the company Warsaw Commodity Clearing House (WCCH) and a Register of Certificates of Origin via the company PolPX. Polish capital market traditions go back to 1817, when the Warsaw Mercantile Exchange was established. Following the overthrow of Poland's former communist regime in 1989, WSE was created as a joint-stock company on April 12, 1991 by the State Treasury pursuant to the Foundation Act for Giełda Papierów Wartościowych w

Warszawie SA (The Warsaw Stock Exchange Company). WSE was organized from its inception as a modern stock exchange, supported by electronic trading and dematerialized registration of securities, laying a foundation for ongoing development. WSE held its first trading session on April 16, 1991 with five listed companies, all of which were formerly State-owned companies that had been privatized. In 1999, Poland reformed its pension system, which contributed to an increase in domestic institutional investment, and in 2004 it joined the European Union (EU). These developments helped to boost trading volume in subsequent years. Over the years, the Group has continued to innovate and evolve to meet the needs of its clients. WSE commenced derivatives trading in 1998 and launched the WARSET trading system in 2000. The WARSET system was launched in cooperation with the Paris Stock Exchange and Euronext and enabled its continuous trading for the first time on WSE. WSE created the NewConnect exchange-regulated market for small and medium-size enterprises in 2007, and launched the Catalyst bond market, creating a platform for trading corporate, mortgage-backed, treasury and municipal bonds in 2009. In July 2010 WSE entered into the Master Agreement with NYSE Euronext to establish a framework for their strategic cooperation. In particular the Master Agreement provides for (i) acquisition by WSE of the new UTP developed by NYSE Euronext and (ii) an exclusive strategic partnership between the parties in a defined CEE region with respect to a variety of identified business initiatives. In recent years, WSE has become one of Europe's most dynamic IPO markets with 383 companies, including 23 foreign companies, listed on its Main Market, and 136 companies listed on NewConnect as at June 30, 2010. In addition, WSE's derivatives trading platform has grown to become the largest in CEE. Warsaw Stock Exchange is the major securities market of Poland. The Warsaw Stock Exchange (WSE; in Polish – Giełda Papierów Wartościowych w Warszawie SA (GPW)) was founded in 1817. The electronically regulated market, listing 231 companies with a market capitalization of EUR33 billion, was inaugurated in 1991. The WSE is the largest exchange in Central and Eastern Europe and the seventh-largest market for index futures in Europe. The WSE trades futures on three indeces – the WIG20 (the Warszawski Indeks Giełdowy 20 (WIG20) is a capitalization-weighted stock market index of the twenty largest companies on the Warsaw Stock Exchange), TechWIG (the index of high technology stocks), and MIDWIG (the index of 40 mid-cap stocks) – as well as individual stock futures and exchange rate futures on the US Dollar and the Euro. Trading is conducted Monday through Friday. Single-price auction begins at 10:00 am; continuous trading runs from 12:00 pm to 04:00 pm. The WSE has a 10% stake in the Power Exchange, founded in 1999. In 2002, the WSE signed a cross-membership and cross-access agreement with Euronext to each other's products. Interconnection of the cash trading platforms will be implemented in 2002. the WSE uses technology based on Euronext NSC cash single trading system. Links for derivative trading platforms will be launched in 2004. Website:- http://gpw.pl. Headquartered in Warsaw, Poland. / НЙФБ® или Эн.Уай.Эс.И.® (NYSE®). Гелда Паперу Вартощових в Варшавиэ Эс.А. WART = WEIGHTED AVERAGE REMAINING TERM

WART = БОРОДАВКА (или КАП, или НАРОСТ) – Wart is a small, typically round, area of callous growth on the inside of the boll wall associated with stink bug or plant bug feeding. Wart is a small, blunt-tipped, rounded outgrowth. / Под Бородавкой понимается невоспалительное узелковое образование кожи вирусной этиологии. Располагаются чаще на кистях, стопах, лице. Под Капом понимается наплыв на стволах, ветвях и корнях деревьев, возникающий в местах обильного развития побегов и разрастания тесно сидящих придаточных и спящих почек. Материал для столярных, резных и токарных изделий.

WARTY = БОРОДАВЧАТОЕ (или ХХ) – Warty (bark of mature trunks) (surface appearance):- bark with relatively small, scattered protuberances, as in Southern Hackberry (Celtis Laevigata). Compare with Checkered.

WAS = WASTING RATE

WAS = WEEKS AFTER SEEDING

WASDIS = WASTE DISPOSAL INFORMATION MESSAGE

WASH = ОТМЫВКА (или ПОЛОСКАНИЕ, или ПОРОЖНЯК, или ХХ) – Wash:- gains equal losses.

WASH = НАНОСЫ (или НАМЫВ, или АЛЛЮВИЙ) – Wash is the usually dry portion of a bed of a stream that contains water only during or after a local rainstorm or heavy snowmelt. See also Splay.

WASHABILITY = СТИРАЕМОСТЬ – Washability:- relatively new techniques have been developed to improve wool's washability by making the fiber more resistant to felting and shrinkage. One process takes place before the yarn is spun. The loose fleece or combed top is chlorinated to remove the tips of the 'scales' and then coated with an extremely fine resin. The resin masks the fiber's scales and keeps them from interlocking, which is the cause of felting and shrinkage. / Устойчивость К Стиркам или Стойкость К Мытью – способность переносить мойку без ухудшения качества.

WASHABLE = СТИРАЕМОЕ (или МОЕМОЕ) – Washable:- materials that will not fade or shrink during washing or laundering. Labels should be read by the consumer to assure proper results. Do not confuse with 'wash-and-wear'.

WASHABLE FABRIC = СТИРАЕМАЯ ТКАНЬ (или МОЕМАЯ ТКАНЬ, или СТИРКОПРОЧНАЯ ТКАНЬ) – Washable Fabric is a fabric that can be washed. The method of washing (by hand or machine) may not be designated.

WASH–AND–WEAR = СТИРАЙ–И–ОДЕВАЙ (или СТИРАЙ–И–НОСИ) – Wash And Wear is a term used to describe fabrics and garments that can be washed and then worn with little or no ironing. Originally, the fabrics were chemically treated and cured (baked). There are no standards governing its use. See also Easy Care. Wash-And-Wear:- ability of a garment to be washed by hand or in a washing machine and require little or no ironing. Also referred to as 'Easy Care'. Wash-And-Wear is a generic term applied to garments that satisfactorily retain their original neat appearance after repeated wear and home laundering with little or no pressing or ironing. A wash-and-wear garment is essentially free from undesirable wrinkles both during wear and after laundering and retains any original pressed-in creases or pleats. The garments should meet normal consumer demands for durability, color, stability, and shrinkage. The performance of a wash-and-wear fabric or garment depends on several factors, including the types and amounts (percentages) of fibers used, the fabric construction, the finishing treatment, the presence of a colored pattern (either woven or printed), and the methods used for washing and drying. These factors determine, in any specific instance, if a fabric or garment's performance will meet customer requirements. Variable conditions result in the varying behavior of a specific fabric or garment. Garments are labeled to specify the appropriate care for optimal performance. See also Durable Press, and Ease-Of-Care. 'Wash And Wear' is a term applied to any garment which can be washed, dried, and then worn again with little or no ironing. Also known as Durable Press, or Permanent Press. / Термин, применяемый к любому пошитому изделию, которое может быть выстирано, высушено, и затем снова одето после незначительной глажки (утюжки) или без неё. Известен также как Длительная Носка (Durable Press), или Постоянная Носка (Permanent Press). Ткань, не требующая утюжки после стирки.

WASHBOARD = СТИРАЛЬНАЯ ДОСКА – Washboard:- in hosiery, a ridgy effect caused by uneven tension between feeds on the knitting machine. Fabrics defect. / Wash = Взбученное.

WASHCOAT = XX (или ПОКРЫТИЕ ИЗ ПОРИСТОГО ОКСИДА) – Washcoat is a material applied to the substrate of catalytic combustor to increase and maintain surface area. Chemically inert, usually a high surface area alumina. / каталитической камеры сгорания для .

WASHED WOOL = МЫТАЯ ШЕРСТЬ (или ПЕРЕГОННАЯ ШЕРСТЬ) – Washed Wool is a wool washed in cold water while on the sheep's back before shearing (industrial term). / Перегонная Шерсть – шерсть с овец после прогона их через речку, озеро или какой-нибудь бассейн.

WASHER = ПРОМЫВНОЙ АППАРАТ – Washer:- xxxxx. / Промывной Аппарат – автоматический промывной аппарат, осуществляющий поточное промывание.

WASHER = ШАЙБА – Washer:- machine component that is used in conjunction with a screw fastener such as a bolt and nut and that usually serves either to keep the screw from loosening or to distribute the load from the nut or bolt head over a larger area. For load distribution, thin flat rings of soft steel are usual. To prevent loosening, several other types of washers are used. All act as springs to compensate for any increase in the distance between the head of a bolt and the nut, or between the head of a screw and the object being clamped. In addition to the spring action, some of these washers have teeth that bite into the workpiece and the screwhead and provide a locking action. They are called tooth or shakeproof lock washers and have teeth that are bent and twisted out of the plane of the washer face. The conical washer has spring action, but the only locking action is provided by friction. The helical spring washer is one of the most commonly used lock washers. / Под Шайбой, от Немецкого слова Scheibe, понимается диск с отверстием. Подкладывается обычно под гайку, головку болта для увеличения опорной поверхности, защиты поверхности детали от задиров при затягивании гайки, предотвращения её самоотвинчивания (обычно шайбы с поперечным разрезом). Шайба – деталь, подкладываемая под гайку или головку винта. Шайбы общего назначения применяют для увеличения площади опоры, если опорная поверхность из мягкого материала или неровная, а также если отверстие под винт продолговатое или увеличенного диаметра. Косые и сферические шайбы используют для устранения перекоса гайки или головки винта при затяжке. Быстросъёмную шайбу применяют в приспособлениях для экономии времени на снятие обработанной детали и установку новой. Уплотнительную шайбу из мягкого материала ставят под головку резьбовой пробки для обеспечения герметичности соединения. Пружинная шайба уменьшает опасность самоотвинчивания винтов или гаек благодаря силам упругости сжатой шайбы. Стопорная (запирающая) шайба путём отгибания её частей устраняет возможность поворота гайки или винта относительно опорной детали или вала. Концевые шайбы препятствуют осевому перемещению вдоль вала неподвижно закреплённых или вращающихся на валу деталей.

WASHER WRINKLES = ЗАСЕЧКИ ОТ ПРОМЫВНОЙ МАШИНЫ (или СЛАБИНЫ И НАТЯЖКИ ОТ ПРОМЫВНОЙ МАШИНЫ, или ГОФРЕННОСТЬ ОТ ПРОМЫВНОЙ МАШИНЫ, или СКЛАДКИ ПОСЛЕ МОЙКИ) – Washer Wrinkles:- xxxxx. See also Crowsfeet. Fabrics defect. / Пороки ткани:- Засечки; Слабины и Натяжки; и Гофренность.

WASHFAST ACID DYES = СТОЙКИЕ К СТИРКЕ (или СТОЙКИЕ К МОЙКЕ, или ПРОМЫВОПРОЧНЫЕ) КИСЛОТНЫЕ КРАСИТЕЛИ – Washfast Acid Dyes:- a vague term for a group of acid dyes that have good washfastness properties. This term is sometimes used by dye sellers for a group dyes selected for good washfastness properties. Often the dyes come from the premetallized, milling or reactive classes.

WASH–FAST FABRIC = СТОЙКАЯ К СТИРКЕ ТКАНЬ (или СТОЙКАЯ К МОЙКЕ ТКАНЬ) – Wash-Fast Fabric is a fabric that will not fade or shrink excessively during laundering.

WASHFASTNESS = УСТОЙЧИВОСТЬ К СТИРКАМ (или СТОЙКОСТЬ К МОЙКЕ или УСТОЙЧИВОСТЬ ОКРАСКИ К МОЙКЕ) – Washfastness is a measure of the resistance of a dye to washing out of the fiber. There are a number of industry-standard tests for washfastness, usually based on the equivalent to the home laundry process appropriate for the fiber. Washfastness tests are concerned not only with loss of dye from the colored fabric, but also transfer of dye from the wash liquor to other items. Washfastness depends to a great extent on the nature of the dye, but also on the fiber, the application process and the post-dyeing treatment. There is not necessarily any relationship between washfastness and lightfastness. Washfastness is the resistance of a dyed fabric to loss of color or change in properties during home or commercial laundering.

WASHING SODA = МОЮЩАЯ СОДА (или СТИРАЛЬНАЯ СОДА) – Washing Soda is a sodium carbonate. Washing soda, if 'pure', is usually sodium carbonate decahydrate ($Na_2CO_3 \cdot 10H_2O$). Retail washing soda may contain additives such as detergents, salt and optical brighteners, and is therefore not a good substitute for soda ash for dyeing. Washing Soda:- sodium carbonate decahydrate, efflorescent crystals used for washing, especially textiles. It is a compound of sodium. / Оптический Блескообразователь или Оптический Отбеливатель (Optical Brightener). десятиводный гидрат карбоната натрия (sodium carbonate decahydrate).

WASHINGTON GROUP = ВАШИНГТОНСКАЯ ГРУППА – The main purpose of the Washington Group on Disability Statistics is the promotion and coordination of international cooperation in the area of health statistics by focusing on disability measures suitable for censuses and national surveys which will provide basic necessary information on disability throughout the world. More specifically, the Washington Group aims to guide the development of a small set or sets of general disability measures, suitable for use in censuses, sample based national surveys, or other statistical formats, for the primary purpose of informing policy on equalization of opportunities. The second priority of the Washington Group is to recommend one or more extended sets of survey items to measure disability, or principles for their design, to be used as components of population surveys or as supplements to specialty surveys. These extended sets of survey items are intended to be related to the general measure(s). The World Health Organization (WHO) International Classification of Functioning, Disability and Health (ICF) has been accepted as the basic framework for the development of the sets. All disability measures recommended by the group, general or extended, will be accompanied by descriptions of their technical properties and methodological guidance will be given on their implementation and their applicability to all sections of the population. The Washington Group will disseminate work products globally through the World Wide Web. Xxxxx. Washington Group (WG) on Disability Statistics:- Purpose:- the main objective of the WG is the promotion and coordination of international cooperation in the area of health statistics by focusing on disability measures suitable for censuses and national surveys. The aim is to provide basic necessary information on disability which is comparable throughout the world. For the primary purpose of informing policy on equalization of opportunities, the WG has developed, tested internationally, and adopted a short set of disability measures suitable for use in censuses, sample-based national surveys, or other statistical formats. A second priority is to recommend one or more extended sets of survey items to measure disability to be used as components of population surveys or as supplements to specialty surveys. To that end, the WG has developed, tested and adopted an extended set of questions on functioning; and, in collaboration with the United Nations International Children's Emergency Fund (UNICEF), is working on survey modules that address child functioning and disability as well as inclusive education. These extended sets of survey items are intended to be related to the short set of disability measures. The World Health Organization (WHO) International Classification of Functioning, Disability, and Health (ICF) has been used as the basic framework for the development of all questions sets. The disability measures recommended by the WG, both short and

extended, are accompanied by descriptions of their technical properties, and methodological guidance is given on their implementation and their applicability to population subgroups. The WG disseminates its work products globally through the world-wide web and scientific publications. Year organized:- 2001. Participants:- representatives of national statistical offices, international organizations, and non-government organizations including international disability organizations have participated in the last 14 meetings. Current country representatives include (from national statistical offices):- Afghanistan, Albania, Argentina, Armenia, Aruba, Australia, Austria, Azerbaijan, Bangladesh, Barbados, Belgium, Bermuda, Bolivia, Botswana, Brazil, Bulgaria, Burundi, Cambodia, Canada, Chad, Chile, China, Hong Kong Special Administrative Region of China, Macao Special Administrative Region of China, Colombia, Costa Rica, Croatia, Cuba, Curacao, Cyprus, Czech Republic, Democratic Republic of the Congo, Denmark, Dominican Republic, Egypt, Estonia, Fiji, Finland, France, Gambia, Georgia, Germany, Ghana, Greece, Guatemala, Hungary, India, Indonesia, Iran, Iraq, Ireland, Israel, Italy, Ivory Coast, Jamaica, Japan, Jordan, Kazakhstan, Kenya, Korea, Kuwait, Kyrgyz Republic, Lao, Latvia, Lebanon, Lesotho, Lithuania, Luxembourg, Malawi, Maldives, Malta, Mauritius, Mexico, Micronesia, Moldova, Mongolia, Monserrat, Morocco, Mozambique, the Netherlands, New Zealand, Norway, Oman, Pakistan, Palestine, Panama, Papua New Guinea, Paraguay, Peru, Philippines, Poland, Portugal, Qatar, Romania, Rwanda, Saint Lucia, Saint Maarten, Samoa, Saudi Arabia, Serbia and Montenegro, Sierra Leone, Singapore, the Slovak Republic, Slovenia, Somalia, South Africa, Spain, Sri Lanka, Sudan, Sweden, Syria, Tanzania, Thailand, Togo, Tonga, Trinidad and Tobago, Tunisia, Turkey, Tuvalu, Uganda, United Arab Emirates, United Kingdom of Great Britain and Northern Ireland, United States of America, Uruguay, Vanuatu, Venezuela, Viet Nam, Yemen, Zambia, and Zimbabwe. WASHOUT = РАЗМЫВАНИЕ (или ВЫМЫВАНИЕ) – Washout:- when investors get heavily diluted by a subsequent round of investment especially when the investment is a down round. Also known as a Cramdown.

WASHOUT DAY = ДЕНЬ ЛИНЬКИ (или ДЕНЬ ВЫМЫВАНИЯ, или ДЕНЬ СМЫВАНИЯ) – Washout Day:- a selling climax or high volume decline that 'washes out' all the sellers and paves the way for buyers to take over. This may also take the form of a high volume Hammer after an extended decline. See also Hammer. / так что 'линяют' все продавцы и .

WASH PEN = ЗАГОН ДЛЯ МОЙКИ – Wash Pen is a corral, pen, or holding area with a solid floor and washing devices for cleaning cows prior to milking or showing.

WASH SALE = ПРОМЫВОЧНАЯ (или ФИКТИВНАЯ, или СОМНИТЕЛЬНАЯ, или ОТМЫВОЧНАЯ) ПРОДАЖА – Wash Sale is a purchase and sale of a security either simultaneously or within a short period of time. It may be done by a single investor or (where manipulation is involved) by two or more parties conspiring to create artificial market activity in order to profit from a rise in the security's price. Wash sales taking place within 30 days of the underlying purchase do not qualify as tax losses under US Internal Revenue Service rules. Under the Tax Reform Act of 1984, wash sale rules were extended to all taxpayers except those trading in securities in the normal course of business, such as securities dealers. Prior to the 1984 Act, noncorporate taxpayers engaged in a trade or business were exempt from wash sale rules. The Act also extended identical securities, or to instances where short sales are made within 30 days of closing. Tax-avoiding fake sale of shares between two brokers, which also inflates the price. It is illegal. Transactions that give the appearance of purchases and sales but which are initiated without the intent to make a bona fide transaction and which generally do not result in any actual change in ownership. Such sales are prohibited by the Commodity Exchange Act. See also Wash Trade, and Wash Trading. Wash Sale:- unloading investments that are not performing well and then repurchasing the same investments at a future date. The benefit of this transaction is to help achieve a lower tax deduction on the loss incurred by the bad investment. This is considered a legal transaction. A Wash Sale occurs if you sell shares at a loss and buy additional shares (even in another account) of the same or substantially identical security within 30 days before or after the sale. The Wash Sale Rule prevents an investor from obtaining the benefit of a tax loss without having reduced the investment. Under the rule, the loss is treated as 'washed' when the new shares are acquired. The holding period of the original shares is added to the cost basis of the reacquired shares and is deferred until the reacquired shares are sold. Wash Sale:- purchase and sale of a security either simultaneously or within a short period of time, often in order to recognize a tax loss without altering one's position. See also Tax Selling. A Wash Sale (also known as a Wash Loss) is not the same as a Wash Trade. A wash sale is a sale of a security (stock, bonds, options) at a loss and then the buy back of the same or similar stock soon afterwards (Internal Revenue Code Sec. 1091). The idea is to make an unrealised loss claimable as a tax deduction, by offsetting against other capital gains in the current or future tax years. The security is repurchased in the hope that it will regain its previous losses. In some tax codes, such as the USA and the UK, tax rules have been introduced to disallow the practice, for example, if the stock is bought within 30 days of its sale. The disallowed loss is added to the basis of the newly acquired security. Tax authorities may consider the practice illegal even in the absence of explicit regulations, on the grounds that the transaction is not genuine, but intended only to reduce tax liability. This also happens in Australia. / заслуживающий доверия или действительный (bona fide). Проявляется в том случае, когда вы продаёте акции в убыток и покупаете дополнительные акции (даже на другой счёт) той же самой или существенно идентичной ценной бумаги в течение 30 дней до или после этой продажи. Правило О. Фиктивная Продажа:- покупка и продажа ценных бумаг одновременно либо в течение короткого промежутка времени. Она может производиться одним инвестором (в этом случае имеет место манипулирование (manipulation)) либо двумя и более сторонами, стремящимися скрыть факт создания искусственной активности на рынке для того, чтобы получить прибыль вследствие роста котировок. Фиктивными считаются продажи, совершённые в течение 30 дней после соответствующей покупки в соответствии с правилами Службы Внутренних Доходов США (Internal Revenue Service), они не могут считаться

убытками. В соответствии с Актом о Налоговой Реформе от 1984 (Tax Reform Act of 1984), правила относительно фиктивных продаж могут распространяться на всех налогоплательщиков, кроме лиц, ведущих операции с ценными бумагами в ходе своей обычной коммерческой деятельности, например, дилеров по ценным бумагам. До акта 1984 налогоплательщики, не являвшиеся корпорациями и занимавшиеся торговыми операциями или коммерческой деятельностью, были исключением из правил о фиктивных продажах. Акт также расширил запрет на фиктивные закрывающие 'короткие' позиции продажи в целом идентичных ценных бумаг или на случай, когда 'короткая' продажа совершается в течение 30 дней после закрытия сделки. Смотрите также Thirty-Day Wash Rule. Фиктивная Продажа:- фиктивная сделка купли-продажи ценных бумаг или сырья, которые были проданы и куплены одним и тем же физическим лицом с целью создания впечатления активности и/или объёма сырья.

WASH SALE RULE = ПРАВИЛО О ПРОМЫВОЧНОЙ (или ФИКТИВНОЙ, или СОМНИТЕЛЬНОЙ, или ОТМЫВОЧНОЙ) ПРОДАЖЕ – The Wash Sale Rule states that a taxpayer cannot claim a loss on the sale or trade of a security if it is replaced with a substantially identical security within 30 days. This rule is intended to prevent investors from manufacturing losses for tax purposes on securities that they are essentially continuing to hold. The specifics of the wash sale rule are as follows:- (i) A wash sale is considered to be any transaction where a security is disposed of and then within 30 days is replaced or the taxpayer acquires an option or contract to replace the security. (ii) The rule applies if a spouse or an entity controlled by the individual obtains the replacement security. (iii) The 30-day rule involves 30 calendar days, not 30 business days (which would span a longer period of time). (iv) Any loss on the sale of the initial security is added to the cost basis of the replacement security. (v) The holding period of the initial security is added to the holding period of the replacement security, which likely results in a long-term holding period. (vi) Any security is subject to the wash sale rule if it has a CUSIP number (a unique identifier for stocks and bonds). The wash sale rule can be avoided by instead replacing a security with one that is similar, but not substantially identical to, the security that has been sold.

WASH TEST = ИСПЫТАНИЕ НА СТИРКУ (или ИСПЫТАНИЕ НА ПРОМЫВКУ) – Wash Test is a trial washing of an inconspicuous part of a garment to determine if the color is fast to washing.

WASH TRADE = ФИКТИВНАЯ (или СОМНИТЕЛЬНАЯ, или ОТМЫВОЧНАЯ) ТОРГОВЛЯ – A Wash Trade is not the same as a Wash Sale. A wash trade is an illegal form of stock manipulation in which an investor sells and buys shares at the same time in order to artificially increase trading volume and thus the stock price. The United States Security and Exchange Commission (SEC) defines a wash trade as 'a securities transaction which involves no change in the beneficial ownership of the security'. By artificially inflating the volume figures for a security the trader can dupe other traders into believing that interest has picked up in a security which may lead other traders to start buying or selling the security. See also Wash Sale.

WASH TRADING = ФИКТИВНАЯ (или СОМНИТЕЛЬНАЯ, или ОТМЫВОЧНАЯ) ТОРГОВЛЯ – Wash Trading:- entering into, or purporting to enter into, transactions to give the appearance that purchases and sales have been made, without resulting in market risk or a change in the trader's market position. Wash trading involving futures contracts is prohibited by the Commodity Exchange Act. Also known as Round Trip Trading, and Wash Sales. Wash Trade:- this is not the same as the methodology behind a wash sale. This practice is not legal because it deals with selling off and repurchasing investments just to create an increase on the trading market and costs to purchase stocks. See also Round-Trip Trade. 2012-May-01:- Royal Bank of Canada (RBC), Canada's largest bank, was sued by the Commodity Futures Trading Commission (CFTC) in April for alleged illegal Wash Trades tied to equities worth millions of Dollars in tax benefits. According to the CFTC, RBC made false and misleading statements about the trades from 2007 to 2010 in which affiliates traded among themselves at OneChicago in a way that circumvented competition and price discovery. 'A fundamental purpose of the futures markets is to provide an arm's-length mechanism for market participants to discover prices and shift risks associated with products traded in those markets', CFTC enforcement director David Meister said in an e-mail statement. 'RBC not only designed and executed a wash sale scheme that undermined that purpose; it went a step further and misled the exchange into believing that its conduct was lawful'. RBC defended itself in a statement:- 'Before we made a single trade, we proactively contacted the exchange to seek its guidance. These trades were fully documented, transparent and reviewed by both the CFTC and the exchanges, and for the next several years were monitored by them'. Andrew Stoltmann, securities lawyer, says many of the charges likely will come down to what was disclosed vs. what needed to be disclosed. 'A reply to the argument that (RBC) already disclosed everything to the proper regulators is built into the allegations', he says. Stoltmann suspects the CFTC has picked up enforcement action over the last couple years as a way to gain credibility in Washington. 'All of these regulators are really political organizations to a certain extent', he says. 'The CFTC wants to establish that it's not the 98 lb weakling anymore and (it) can bring a legitimate case against the largest bank in Canada. It certainly would be a good way for it to earn some respect'. A OneChicago spokesperson declined to comment. / Ройэл Бэньк оф Кэнэда (Royal Bank of Canada). Давид Майста (David Meister). Эндрю Столтмэн (Andrew Stoltmann).

WASH TRANSACTION = ТРАНЗАКЦИЯ ОТМЫВА – Wash Transaction:- selling the securities and buying them again within 30 days.

WASHWATER = ПРОМЫВОЧНАЯ ВОДА – Washwater:- when crude oil has to be desalted or dehydrated, the processes involved use high quality water which is commonly referred to as Washwater or Wash.

WASP = WATER QUALITY ANALYSIS SIMULATION PROGRAM

WASTAGE = ОТБРОС (или ОТХОД, или ПОТЕРИ) – (1) Wastage is a loss resulting from breakage, decay, handling, leakage, shrinkage, etc, of goods or material. Wastage is the action or process of losing or destroying something by using it carelessly or extravagantly:- the wastage of natural resources. Usage:- Waste and Wastage are to some extent interchangeable, but many people think that wastage should not be used to refer to lossresulting from human carelessness, inefficiency, etc; a waste (not a wastage) of time/money/effort etc. See also Scrap.

(2) Wastage is:- (1) in spinning, this refers to the loss between the weight of fiber acquired and the weight of fiber that can be used. In spinning, the amount of dirt, tag ends, and unusable fiber are all part of the wastage. (2) In weaving, this refers to the part of the warp that cannot be used, often about 24–36 inches of the total warp.

WASTE = ПУТАНКА (или ВЕТОШЬ) – On vessels, Waste is cotton yarn used for cleaning purposes. / Продукт под названием Путанка или Обтирочные Концы образуется в процессе ткацкого или прядильного производства. В любом производстве существует брак. Не являются исключением и процессы ткачества и прядения. При появлении узелков, утончений, уплотнений или других дефектов на нитях или пряже, они рвутся, и процесс ткачества или прядения останавливается. Далее происходит отбраковка деформированных нитей, которые впоследствии используются в качестве путанки. Существует несколько стандартов путанки. Короткие, до 10 см, мягкие концы относят к 36-му стандарту. К 39-му стандарту причисляют длинные мягкие концы, которые не могут быть использованы в производстве, ввиду их размеров. Шлихтованные или накрахмаленные концы относят к 40-му или 41-му стандарту. Также в процессе ткачества на готовых изделиях (если ткачество происходит на

старых станках) может образоваться так называемая кромка, которую впоследствии обрезают с готовой ткани. Эта кромка является 50-м стандартом путанки. Ветошь – это лоскуты тканей, которые используются как обтирочный материал на промышленных предприятиях. Как правило, источником происхождения для ветоши служит уже использованная одежда, либо отходы швейных производств (лоскут тканей, межлекальные выпады, обрезь тканей и тому подобное). Благодаря высоким потребительским характеристикам и низкой цене, ветошь на сегодняшний день используется практически во всех отраслях промышленности, а именно:- железные дороги, энергетика, нефтегазодобывающая и перерабатывающая, химическая, металлургия, машиностроение, автомобилестроение, судостроение, полиграфия, добывающая, обогатительная и многие другие. Ветошью вытирают масло, бензин, нефть, воду, общие загрязнения с самых разных поверхностей и деталей оборудования.

WASTE = ОТХОДЫ – (1) Waste:- unwanted materials left over from a manufacturing process. Waste:- fibers which forms the refuse during the various process of carding, spinning, weaving and finishing and which have been utilized lately, especially during and since the war because of the high price and scarcity of virgin wool, to a very large extent even in uniforms and still much more extensively in civilian cloths. (1924). Fiber and yarn by-products created in the manufacturing or processing of fibers, yarns, and fabrics. See also Cotton Waste. / Смотрите также Хлопковые Отходы (Cotton Waste). В текстильном производстве под Отходами понимаются отходы при переработке волокнистых текстильных материалов, в основном короткие волокна – очёсы, обрывки пряжи и тому подобное. Различают отходы возвратные, то есть используемые в производстве текстильных материалов, и безвозвратные, возникающие вследствие удаления пыли, влаги, рассеивания частиц волокон. Значительная часть отходов используется для выработки пряжи низких сортов, а также ваты. Когда-то Отходы текстильного производства назывались Угарами.

(2) Waste are materials and substances usually discarded as worthless to the user. Waste:- material removed, rejected, or otherwise lost in various manufacturing processes. Waste:- refuse from places of human or animal habitation. See also Biomass Waste, and Non-Biomass Waste. Waste refers to materials that are not prime products (that is, products produced for the market) for which the generator has no further use in terms of his/her own purposes of production, transformation or consumption, and of which he/she wants to dispose. Wastes may be generated during the extraction of raw materials, the processing of raw materials into intermediate and final products, the consumption of final products, and other human activities. Residuals recycled or reused at the place of generation are excluded. / Под Отходами Производства понимаются остатки основных и вспомогательных материалов, образовавшиеся в производственном процессе, – стружка, бракованные детали, изношенный инструмент, отработавшее масло, зола, шлаки, отвалы добычи полезных ископаемых, хвосты обогащения и так далее. Рациональная утилизация отходов одного производства и последующее использование их в качестве сырья в других производствах снижают себестоимость изготовляемой продукции.

WASTE AND TAR OILS = ОТХОДЫ И ГУДРОННЫЕ МАСЛА (или ОТХОДЫ (или ОТРАБОТАВШИЕ, или ОТРАБОТАННЫЕ) И ДИСТИЛЛЯТЫ КАМЕННОУГОЛЬНОЙ СМОЛЫ) – Waste and Tar Oils:- petroleum-based materials that are worthless for any purpose other than fuel use.

WASTE COAL = ОТХОДЫ УГЛЕОБОГАЩЕНИЯ (или УТИЛЬНЫЙ УГОЛЬ) – Waste Coal is the usable coal material that is a byproduct of previous processing operations or is recaptured from what would otherwise be refuse. Examples include anthracite culm, bituminous gob, fine coal, lignite waste, coal recovered from a refuse bank or slurry dam, and coal recovered by dredging. Waste Coal:- usable material that is a byproduct of previous coal processing operations. Waste coal is usually composed of mixed coal, soil, and rock (mine waste). Most waste coal is burned as-is in unconventional fluidized-bed combustors. For some uses, waste coal may be partially cleaned by removing some extraneous noncombustible constituents. Examples of waste coal include fine coal, coal obtained from a refuse bank or slurry dam, anthracite culm, bituminous gob, and lignite waste.

WASTE COLLECTION = ВЫЕМКА ОТХОДОВ (или СБОР ОТХОДОВ) – Waste Collection is the collection and transport of waste to the place of treatment or discharge by municipal services or similar institutions, or by public or private corporations, specialized enterprises or general government. Collection of municipal waste may be selective, that is to say, carried out for a specific type of product, or undifferentiated, in other words, covering all kinds of waste at the same time.

WASTE CUBE = НЕЗАПОЛНЕННАЯ КУБАТУРА (или НЕЗАПОЛНЕННЫЙ ОБЪЁМ, или ПУСТОПОРОЖНЯЯ КУБАТУРА) – Waste Cube is an empty space in a container resulting from cargo meeting the weight restrictions of the container before the container is full, or from the cargo not adequately filling or fitting the container.

WASTE DISPOSAL = УТИЛИЗАЦИЯ ОТХОДОВ – Waste Disposal:- removing and destroying or storing damaged, used or other unwanted domestic, agricultural or industrial products and substances. Disposal includes burning, burial at landfill sites or at sea, and recycling. Waste Disposal:- proper disposition of a discarded or discharged material in accordance with local environmental guidelines or laws. See also Disposal Of Waste. Waste Disposal:- techniques for disposing of a veterinary practice's, or abattoir or feedlot or milking shed wastes. By incineration, deep burial, washed away in a sewer as any other effluent or reclamation for industrial or agricultural use. Disposal of wastes from a veterinary practice or service has additional problems. There is a need for disposal of animal cadavers, kennel and pen wastes, tissue specimens, blood and milk and other samples. Much of the material is infected, some of it dangerous to humans, and therefore needs to be disposed of legally and systematically. Waste Disposal:- a removal of all potentially contaminated objects (e.g., objects soaked with saliva or blood) and placement in a secure site to prevent or decrease the risk of infection. Waste Disposal:- protocol for disposal of clinically generated waste, i.e. all clinical waste placed in 'yellow bags' and sent for incineration, via contracted arrangement with accredited waste disposal contractors; clinical waste from adomiciliary call must be transported in a yellow bag that is tied off securely and carried within a locked box. Waste Disposal:- processing and or removal to fi nal resting place or transfer to a place for re-use or recovering of waste. Waste Disposal:- the collection, processing, and recycling or deposition of the waste materials of human society. The term Waste covers both solid wastes (refuse, or garbage) and sewage (wastewater). See also Materials Salvage; Refuse Disposal System; and Sewage System.

WASTE ENERGY = ВТОРИЧНАЯ ЭНЕРГИЯ (или ВТОРИЧНЫЕ ЭНЕРГОРЕСУРСЫ, или УТИЛЬНАЯ ЭНЕРГИЯ) – Waste Energy:- municipal solid waste, landfill gas, methane, digester gas, liquid acetonitrile waste, tall oil, waste alcohol, medical waste, paper pellets, sludge waste, solid byproducts, tires, agricultural byproducts, closed loop biomass, fish oil, and straw used as fuel. Waste Energy:- garbage, bagasse, sewerage gas, and other industrial, agricultural, and urban refuse used to generate electricity.

WASTE HEAT = ОТБРОСНОЕ ТЕПЛО (или ОТХОДЯЩЕЕ ТЕПЛО, или ОТРАБОТАННОЕ ТЕПЛО, или ИСПОЛЬЗОВАННОЕ ТЕПЛО, или ВТОРИЧНОЕ ТЕПЛО, или УТИЛИЗАЦИОННОЕ ТЕПЛО) – Waste Heat is the sensible heat in non-combustible gases discharged to the environment. / Отбросное Тепло – тепло отходящих (топочных) газов.

WASTE HEAT BOILER = УТИЛИЗАЦИОННЫЙ ТЕПЛОВОЙ КОТЁЛ (или КОТЁЛ УТИЛИЗАТОР ОТХОДЯЩЕГО ТЕПЛА) – Waste Heat Boiler is a boiler that receives all or a substantial portion of its energy input from the combustible exhaust gases from a separate fuel-burning process. / Котёл Утилизатор Отходящего Тепла .

WASTE HEAT RECOVERY = РЕКУПЕРАЦИЯ ОТРАБОТАННОГО ТЕПЛА – Waste Heat Recovery:- any conservation system whereby some space heating or water heating is done by actively capturing byproduct heat that would otherwise be ejected into the environment. In commercial buildings, sources of water- heat recovery include refrigeration/air-conditioner compressors, manufacturing or other processes, data processing centers, lighting fixtures, ventilation exhaust air, and the occupants themselves. Not to be considered is the passive use of radiant heat from lighting, workers, motors, ovens, etc, when there are no special systems for collecting and redistributing heat.

WASTE IN FILLING = ОТХОДЫ В УТОЧИНЕ – Waste In Filling:- Fabric:- combination-yarn dress goods; Construction:- (i) Count:- 64 x 62; (ii) Warp:- 75/30 S bright viscose-rayon crêpe ply-twisted with 75/20 dull acetate rayon; (iii) Filling:- same as warp; Finish:- plain dyed navy. Defect:- small bunches of 'waste'. Analysis:- the bunches of so-called 'Waste' in the filling were found, by microscopic analysis, to be small bunches of opossum-fur fibers. To aid in providing satisfactory tension on rayon filling yarn as it leaves the shuttle, it is common practice to place a piece of fur along the shuttle sides and bottom. Opossum fur is one type used frequently, and the defect in this fabric was apparently due to some loose fur fibers' becoming trapped in the filling during weaving. / Уточина:- такая же как основа.

WASTELAGE = XX – Wastelage is a fermentation product produced by blending animal waste with a fermentable product and storing to ensile. When properly ensiled, wastelage is free of salmonella-type microorganisms and parasiticnematodes, free of noxious odors, palatable to livestock, and economically competitive as an animal feed. In addition, conversion of animal waste to wastelage eliminates concern of water pollution.

WASTE LOAD ALLOCATION = РАЗМЕЩЕНИЕ (или РАСПРЕДЕЛЕНИЕ) ЗАГРЯЗНЯЮЩЕЙ НАГРУЗКИ – Waste Load Allocation:- the maximum load of pollutants each discharger of waste is allowed to release into a particular waterway. Discharge limits are usually required for each water quality standard being, or expected to be, violated.

WASTE LOGISTICS = ЛОГИСТИКА ОТХОДОВ – Waste Logistics is the collection of used, damaged, or outdated products and or packaging from designated users. Synonym:- Reverse Distribution.

WASTE MANAGEMENT = УПРАВЛЕНИЕ ОТХОДАМИ (или ОБРАБОТКА ОТХОДОВ) – Waste Management:- the characteristic activities of waste management include:- (a) collection, transport, treatment and disposal of waste; (b) control, monitoring and regulation of the production, collection, transport, treatment and disposal of waste; and (c) prevention of waste production through in-process modifications, reuse and recycling.

WASTE MATERIALS = ОТХОДЫ (или ОТБРОСЫ, или ОТХОДНЫЕ МАТЕРИАЛЫ) – Waste Materials:- otherwise discarded combustible materials that, when burned, produce energy for such purposes as space heating and electric power generation. The size of the waste may be reduced by shredders, grinders, or hammermills. Noncombustible materials, if any, may be removed. The waste may be dried and then burned, either alone or in combination with fossil fuels.

WASTE OILS AND TAR = ОТРАБОТАННЫЕ МАСЛА И СМОЛА (или ОТРАБОТАВШИЕ МАСЛА И СМОЛА (или ДЁГОТЬ)) – Waste Oils And Tar:- petroleum-based materials that are worthless for any purpose other than fuel use.

WASTE OPENER = УГАРНЫЙ ПИТАТЕЛЬ–РЫХЛИТЕЛЬ – Waste Opener is the machine opens pure waste to return it to the process. The material is placed on a feed apron of 3 to 12 m length. The waste opener is loaded manually. Mixing takes place in the blending chamber, opening by an upright lattice and an opening roller. A pair of feed rollers below the feed chute ensure even production. A type of machines employed to open up varying types of cotton waste. The stock when delivered is rather fluffy and open and in this condition may be sent back to the picker machine for another run. / В прядильном производстве, машина предназначена для разрыхления чистых отходов и подачи их в технологический процесс. Эта машина разрыхляет очищенные угары (отходы) и заново подаёт их в технологический процесс. Материал укладывается на питающий столик, оснащённый транспортёром, длина которого колеблется от 3 до 12 метров. Угарный питатель-рыхлитель загружается вручную. В смесительной камере происходит смешивание, а разрыхление посредством двигающейся вверх решётки и разрыхляющего валика. Пара питающих валиков, находящихся под накопителем, обеспечивает безперебойную подачу.

WASTE SILK = УГАРНЫЙ ШЁЛК (или УТИЛЬНЫЙ ШЁЛК) – Waste Silk is another name for silk noil. Short ends of silk fibers used in making rough, textured, spun yarns or in blends with cotton or wool.

WASTE TREATMENT LAGOON = ЛАГУНА ОБРАБОТКИ ОТХОДОВ – Waste Treatment Lagoon is an impoundment made by excavation or earth fill for biological treatment of wastewater. See also Wastewater.

WASTE TREATMENT PLANT = ЗАВОД ПО ПЕРЕРАБОТКЕ ОТХОДОВ – Waste Treatment Plant is a facility containing a series of tanks, screens, filters and other processes by which pollutants are removed from water.

WASTE TREATMENT STREAM = ПОТОК ПЕРЕРАБОТКИ ОТХОДОВ – Waste Treatment Stream:- a continuous movement of waste from generator to treater and disposer. / к очистителю (или экстрактору или очистительному аппарату) и .

WASTE UTILIZATION = УТИЛИЗАЦИЯ ОТХОДОВ (или ИСПОЛЬЗОВАНИЕ ОТХОДОВ) – Waste Utilization is the use of agricultural waste or other waste on land in an environmentally acceptable manner while maintaining or improving soil and plant resources.

WASTEWATER = СТОЧНАЯ ВОДА (или СТОК) – Wastewater is a combination of liquid and water-carried pollutants from homes, businesses, industries, or farms; a mixture of water and dissolved or suspended solids. Typically, wastewater contains 98 to 99 percent water and one to two percent waste. Wastewater:- used water from a home, community, farm or industry that contains dissolved and/or suspended matter. Waste Water is used water, typically discharged into the sewage system. It contains matter and bacteria in solution or suspension. Wastewater is a water that has been used in flushing, washing, oil and gas extraction processes or manufacturing. Wastewater:- the spent or used water from individual homes, a community, a farm, or and industry that contains dissolved or suspended matter. / Под Сточными Водами понимаются воды, содержащие хозяйственно-бытовые и производственные загрязнения и примеси, а также талые и дождевые воды, удаляемые с территории населённых пунктов и предприятий через канализационную сеть. Подразделяются на:- (i) хозяйственно-бытовые (фекальные, кухонные, банно-прачечные, в 1 литре (л) их – 200–300 миллиграмм (мг) сухого остатка, в том числе 40–60 мг N, 5–10 мг P_2O_5 и 15–30 мг K_2O); и (ii) сельскохозяйственные (стоки животноводческих ферм и предприятий по переработке сельскохозяйственного сырья, содержат до 30 г/л примесей, в том числе 1.5–2.5 г/л N). Сточные воды – ценное удобрение для сельскохзяйственных растений. Для обезвреживания из применяют искусственные (отстойники, биофильтры, метантенки и другое) и естественные (земледельческие поля орошения, поля фильтрации, биологические пруды) способы очистки. Осадками сточных вод (после сбраживания или сушки и обеззараживания) также удобряют поля, их используют для приготовления компостов. Осадки,

предназначенные на удобрение, содержат (в % к сухому веществу):- органические вещества не менее 40, N – 1.6, P_2O_5 – 0.6 и K_2O – 0.2. Сброс в реки и водоёмы сточных вод, не прошедших очистку, запрещён.

WASTEWATER OPERATIONS AND MAINTENANCE = ЭКСПЛУАТАЦИЯ И ТЕХНИЧЕСКОЕ ОБСЛУЖИВАНИЕ СТОЧНЫХ ВОД – Wastewater Operations And Maintenance:- actions taken after construction to assure that facilities built to treat wastewater will be properly operated, maintained and managed to achieve efficiency levels and prescribed effluent levels in an optimum manner.

WASTE–WATER TREATMENT = ОЧИСТКА СТОЧНЫХ ВОД – Waste-Water Treatment is the process to render waste water fit to meet environmental standards or other quality norms. Three broad types of treatment may be distinguished:- mechanical, biological and advanced.

WASTEWATER TREATMENT PLANT = ЗАВОД ПО ОЧИСТКЕ СТОЧНЫХ ВОД – Wastewater Treatment Plant is a facility containing a series of tanks, screens, filters and other processes by which pollutants are removed from water.

WASTING ASSET = ИСТОЩАЮЩИЙСЯ (или ИСТОЩИМЫЙ, или ИСТЕКАЮЩИЙ) АКТИВ – Wasting Asset is:- (1) in accounting:- (i) fixed assets (excluding real estate) that has limited (though not necessarily predetermined) useful life and is, therefore, subject to depreciation; or (ii) natural resource such as coal, gas, oil, ores, timber, that diminishes in value due to depletion, extraction, or removal and is, therefore, subject to amortization. (2) In securities industry:- put option or call option whose value expires on a fixed date. Wasting Asset is an asset with an expected useful life of less than 50 years. Wasting Asset is:- (1) fixed asset, other than land, that has a limited useful life and is therefore subject to Depreciation. (2) A natural resource that diminishes in value because of extractions of oil, ores, or gas, or the removal of timber, or similar depletion and that is therefore subject to amortization. Wasting Asset is an exhaustible natural resource. (3) Wasting Asset is security with a value that expires at a particular time in the future. An option contract, for instance, is a wasting asset, because the chances of a favorable move in the underlying stock diminish as the contract approaches expiration, thus reducing the value of the option. (4) Wasting Asset is a long-option position that will decline in value, other things being equal, with the passage of time. Wasting Asset is:- (1) an exhaustible natural resource; (2) an asset with an expected useful life of less than 50 years; and (3) a long-option position that will decline in value, other things being equal, with the passage of time. Wasting Asset is an asset that has a limited life and thus decreases in value (depreciates) over time. Also applies to consumed assets, such as oil or gas, and termed 'Depletion'. / Истощимый Актив – актив, который имеет определённый срок службы, например, сданное в аренду имущество может полностью утратить свою стоимость в течение срока аренды. К истощимым активам можно также отнести машины и оборудование, которые в процессе эксплуатации изнашиваются и, следовательно, теряют свою стоимость. Истощающийся Актив – ценная бумага со стоимостью, срок которой истекает в определённое время в будущем. Истощающийся Актив (Wasting Asset):- (1) средства производства, но не земля, имеющие ограниченный полезный срок службы и поэтому подлежащие амортизации (depreciation). (2) Естественные ресурсы, ценность которых падает вследствие добычи нефти, руды или газа или рубки леса, а также иного вида истощения и которые поэтому подлежат амортизации (amortization). (3) Ценные бумаги, ценность которых истекает по наступлении определённого момента времени в будущем. Опционный контракт, например, является примером истощающихся активов, поскольку вероятность благоприятных изменений в котировках акций уменьшается по мере приближения срока исполнения контракта. Истощимый Актив:- активы, имеющие ограниченный срок 'жизни' и, как правило, теряющие стоимость с течением времени (при том что все остальные факторы остаются постоянными). В частности, опционы являются 'истощимыми' активами. Истощимые Активы (Wasting Assets) – материальные средства, стоимость и ценность которых уменьшаются по мере разработки месторождения полезного ископаемого:- запасы сырья в недрах, шахты, скважины, подъездные пути и тому подобное. Процесс отнесения стоимости использования таких активов на затраты называется учётом истощения природных ресурсов. Смотрите также Истощение или Разубоживание (Depletion). Истощимые Активы (Wasting Assets):- активы, стоимость которых в реальном выражении обычно со временем обесценивается. Примерами служат лизгольды и интересы в добывающих отраслях.

WASTING NATURAL RESOURCES = ИСТОЩАЮЩИЕСЯ ПРИРОДНЫЕ РЕСУРСЫ (или ИСТОЩИМЫЕ ЕСТЕСТВЕННЫЕ РЕСУРСЫ) – Wasting Assets are the Natural Resources in the National Income Accounts demonstrates that natural resources can be treated similarly to capital in national accounts, and it argues convincingly that these accounts should be revised.

WASTY WOOL = УГАРНАЯ ШЕРСТЬ (или УТИЛЬНАЯ ШЕРСТЬ) – Wasty Wool is a wool that is short, weak, and tangled, which often carries a high percentage of dirt or sand.

WATCH = ВАХТА – Watch:- the day at sea is divided into six four hour periods. Three groups of watchstanders are on duty for four hours and then off for eight, then back to duty. Seamen often work overtime during their off time. / Сутки на море поделены на шесть четырёхчасовых периодов. Три группы вахтенных (watchstanders) дежурят по четыре часа с последующим отдыхом в течение восьми часов, и затем снова возвращаются на дежурство. Моряки часто работают сверхурочно в течение полагающегося им времени отдыха.

WATCH CAP = СМОТРОВАЯ ШАПКА – Watch Cap is a knitted close-fitting usually navy-blue cap worn especially by enlisted men in the US navy in cold or stormy weather. Watch Cap is a canvas cover secured over a funnel when not in use. Sailor's headwear, woolen type, capable of covering the ears in cold weather.

WATCH LIST = СПИСОК ДЛЯ ПРОСМОТРА – (1) Watch List or Priority Watch List:- On New Year's Eve, the Office of the US Trade Representative (USTR) issued a Federal Register Notice announcing 2013's Special 301 Review. This is the annual process in which an interagency committee led by USTR conducts a review 'to identify countries that deny adequate and effective protection of intellectual property rights (IPR) or deny fair and equitable market access to US persons who rely on intellectual property protection'. The process ends with the publication of the Special 301 Report, which includes various countries on the 'Watch List', the 'Priority Watch List', or as 'Priority Foreign Countries'. If a country is listed as a Priority Foreign Country, this can lead to formal sanctions (though the US's membership in the WTO complicates this). As part of the process, USTR solicits written comments from all interested parties, and holds a public hearing which is open to all interested parties. This year, written comments and requests to testify at the hearing must be submitted by February 08 (with the exception of comments from foreign governments, which can be submitted until the 15th). The hearing will be on February 20. The Special 301 Report will be published 'on or about' April 30. The Special 301 Report has been a controversial exercise for a number of reasons. The United States has used it to publicly criticize countries for allegedly weak IPR policies that adhere to the international IPR norms found in the WTO's TRIPS Agreement (for instance, not issuing second-use patents). The process is routinely criticized for being nontransparent – with seemingly arbitrary listing decisions when it comes to which countries wind up on the list and which do not. There are questions of whether it is appropriate for USTR to be unilaterally calling out trading partners instead of using the multilateral trade system to settle disputes. As a WTO Member, the US can't levy sanctions against other WTO Members without bringing a dispute to a WTO Dispute Settlement Panel, but being blacklisted by the US has led countries to change laws and policies. See for instance, recent blogs on legal changes in Pakistan and the Philippines. See also Special 301. Special 301 is an annual review process led by the Office of the United States Trade Representative (USTR). The US

trade law (Special 301) requires an annual review of intellectual property protection and market access practices in foreign countries. Effective action under Special 301 by USTR has been essential in stemming the tidal wave of losses in US jobs and competitiveness that have threatened one of our country's most productive and fastest growing economic sectors. Special 301 and its leverage are a full-time process for the copyright industries which work with local private sector representatives, US government officials, and US Embassy officials to address and resolve copyright problems in scores of countries. The 'Special 301' Report is an annual review of the state of intellectual property rights (IPR) protection and enforcement in trading partners around world, which the Office of the United States Trade Representative (USTR) conducts pursuant to Section 182 of the Trade Act of 1974, as amended by the Omnibus Trade and Competitiveness Act of 1988 and the Uruguay Round Agreements Act (enacted in 1994). This Report reflects the Administration's resolve to encourage and maintain adequate and effective IPR protection and enforcement worldwide. It identifies a wide range of concerns, including troubling 'indigenous innovation' policies that may unfairly disadvantage US rights holders in China, the continuing challenges of copyright piracy over the Internet in countries such as Canada, Italy, and Russia, and other ongoing, systemic IPR enforcement issues presented in many trading partners around the world. USTR looks forward to working closely with the governments of the trading partners that are identified in this year's Special 301 Report, to address both emerging and continuing concerns, and to continue to build on the positive results that many of these governments have achieved. 2012 Special 301 List:- the 2012 Special 301 review process examined IPR protection and enforcement in 77 trading partners. Following extensive research and analysis, USTR has listed the 40 trading partners below as follows:- (i) Priority Watch List:- Algeria, Argentina, Canada, Chile, China, India, Indonesia, Israel, Pakistan, Russia, Thailand, Ukraine, Venezuela; (ii) Watch List:- Belarus, Bolivia, Brazil, Brunei Darussalam, Colombia, Costa Rica, Dominican Republic, Ecuador, Egypt, Finland, Greece, Guatemala, Italy, Jamaica, Kuwait, Lebanon, Mexico, Norway, Peru, Philippines, Romania, Tajikistan, Turkey, Turkmenistan, Uzbekistan, Vietnam; and (iii) Section 306 Monitoring:- Paraguay.

(2) Watch List is a list of securities singled out for special surveillance by a brokerage firm or an exchange or other self-regulatory organization to spot irregularities. Firms on the watch list may be takeover candidates, companies about to issue new securities, or others that seem to have attracted an unusually heavy volume of trading activity. Watch List is a list of securities selected for special surveillance by a brokerage, exchange, or regulatory organization; firms on the list are often takeover targets, companies planning to issue new securities, or stocks showing unusual activity. / Список Наблюдения – перечень ценных бумаг, выбранных для специального наблюдения брокерской фирмой или биржей или иной самоуправляющейся организацией с целью выявить нарушения. Компании, ценные бумаги которых входят в список наблюдения, могут быть кандидатурами для поглощения (takeover), или это компании, которые собираются выпустить новые ценные бумаги, или иные компании, которые, как представляется, имеют необычно высокий объём торгов. Перечень Для Наблюдения – список акций, выделенных для тщательного наблюдения брокерской фирмой, биржей или саморегулируемой организацией с целью выявления нарушений действующих правил.

WATCH MY NUMBER = СМОТРИ ЗА МОИМ НОМЕРОМ – Watch My Number:- xxxxx. / Смотри За Моим Номером – просьба одного брокера в операционном зале биржи к другому брокеру наблюдать за соответствующим номером брокерской фирмы на щите электрического сигнального нумератора, когда он будет отсутствовать в зале. Если номер брокера вспыхнет на щите, это означает, что ему предлагают зайти в помещение его фирмы на краю зала.

WATCH OFFICER = СМОТРИТЕЛЬ (или СЛУЖАЩИЙ ПО НАБЛЮДЕНИЮ) – Watch Officer is an officer taking his turn as officer of the watch.

WATCH POCKET = НАРУЖНЫЙ КАРМАН – Watch Pocket is a small pocket in the garment, typically located just below the front waistband of men's trousers and used to accomodate change or a pocket watch.

WATER = ECONOMIC ANALYSIS OF WATER SUPPLY

WATER = ВОДА – Water is a transparent, odorless, tasteless liquid, a compound of hydrogen andoxygen, H_2O, freezing at 32 °F or 0 °C and boiling at 212 °F or 100 °C, that in a more or less impure state constitutes rain, oceans, lakes, rivers, etc:- it contains 11.188 percent hydrogen and 88.812 percent oxygen, by weight. See also Waterway. Water is a substance composed of the chemical elements hydrogen and oxygen and existing in gaseous, liquid, and solid states. Water is one of the most plentiful and essential of compounds. It is vital to life, participating in virtually every process that occurs in plants and animals. Although the molecules of water are simple in structure (H_2O), the physical and chemical properties of the compound are extraordinarily complicated. See also Ice; Precipitation; Steam; and Water Resource. Water is a colorless, tasteless, and odorless liquid at room temperature. One of its most important properties is its ability to dissolve many other substances. The versatility of water as a solvent is essential to living organisms. Life is believed to have originated in the world's oceans, which are complicated solutions. Living organisms use aqueous solutions – e.g., blood and digestive juices – as mediums for carrying out biological processes. The water molecule is composed of two hydrogen atoms, each linked by a single chemical bond to an oxygen atom. Most hydrogen atoms have a nucleus consisting solely of a proton. Two isotopic forms, deuterium and tritium, in which the atomic nuclei also contain one and two neutrons, respectively, are found to a small degree in water. Deuterium oxide (D_2O), called Heavy Water, is important in chemical research and is also used as a neutron moderator in some nuclear reactors. Although its formula (H_2O) seems simple, water exhibits very complex chemical and physical properties that are incompletely understood. For example, its melting point, 0 °C (32 °F), and boiling point, 100 °C (212 °F), are much higher than would be expected by comparison with analogous compounds, such as hydrogen sulfide and ammonia. In its solid form, ice, water is less dense than when it is liquid, another unusual property. The root of these anomalies lies in the electronic structure of the water molecule. An oxygen atom has six electrons in its outer (valence) shell, which can hold a total of eight. When an oxygen atom forms a single chemical bond, it shares one of its own electrons with the nucleus of another atom and receives in return a share of an electron from that atom. When bonded to two hydrogen atoms, the outer electron shell of the oxygen atom is filled. The water molecule is not linear but bent in a special way. As a result, part of the molecule is negatively charged and part positively charged. It is thus a highly polar molecule. Hydrogen atoms in water molecules are attracted to regions of high electron density and can form weak linkages, called Hydrogen Bonds, with those regions. This means that the hydrogen atoms in one water molecule are attracted to the non-bonding electron pairs of the oxygen atom on an adjacent water molecule. As a result, water molecules associate strongly. In an ice crystal, the association is a highly ordered but loose structure. When the ice melts, this orderly arrangement breaks down partially and the molecules pack more closely together. This makes the liquid denser than the solid, which is why ice forms on top of liquid water. The associative force, however, is still strong enough to prevent water molecules from separating completely even at room temperature. This continued association in the liquid state accounts for the high boiling point of water. The structure of liquid water is believed to consist of aggregates of water molecules that form and re-form continually. This short-range order, as it is called, accounts for other unusual properties of water, such as its high viscosity and surface tension. The polarity of the water molecule plays a major part in the formation of aqueous solutions. If an ionic compound such as sodium chloride is placed in water, the polar water molecules reduce the electrostatic attraction between the positively charged sodium and negatively charged chloride ions. This helps to pull the ions apart. They then become hydrated, i.e. surrounded by water molecules. As a result, their charge is effectively dispersed over a

larger structure, and this keeps the sodium and chloride from recombining. To a limited extent, water dissociates into hydrogen (H^+) ions, which make a solution acidic, and hydroxyl (OH^-) ions, which make it alkaline (basic). Consequently, water can sometimes act as an acid or a base. Water is a liquid composed of two parts of hydrogen and sixteen parts oxygen by weight.

WATER 2000 = ВОДА 2000 – Water 2000:- launched in 1994, this US Rural Utilities Service initiative targeted resources to the estimated 2.5 million people who had some of the nation's most serious drinking water availability, dependability, and quality problems, including one million rural Americans who have no access to drinking water in their homes. The program was not retained by the George Walker Bush Administration. / Администрацией Дьжодьжа Вокёра Боша (George Walker Bush; 1946–).

WATER ACTIVITY = АКТИВНОСТЬ ВОДЫ – Water Activity (A_W) is a measure of the 'free' unbound. / Активность Воды – мера свойства несвязанной воды поддерживать рост и развитие микроорганизмов.

WATER AND ENVIRONMENTAL PROGRAMS = ПРОГРАММЫ ПО ВОДЕ И ОКРУЖАЮЩЕЙ СРЕДЕ – Water and Environmental Programs (WEP):- Rural Utilities Service program providing loans, grants, and loan guarantees for drinking water, sanitary sewer, solid waste, and storm drainage facilities in rural areas and cities and towns of 10 000 or less. Public bodies, nonprofit organizations, and federally recognized Indian tribes may qualify for assistance. WEP also makes grants to nonprofit organizations to provide technical assistance and training to assist rural communities with their water, wastewater, and solid waste problems. See also Water And Waste Disposal Grant, Water And Waste Disposal Loan (direct), Water And Waste Disposal Loan (guaranteed), and Water And Waste Technical Assistance And Training Grant.

WATER AND SEWER GRANT = ГРАНТ НА ВОДУ И СТОЧНЫЕ (КАНАЛИЗАЦИОННЫЕ) ТРУБЫ – In the United States, Water And Sewer Grant:- e.g., grants under the Clean Water Partners Infrastructure Program assist water and sewer projects addressing public health and environmental issues. Funding is currently limited for these projects. When available, grants may cover planning activities associated with infrastructure development or actual construction of water and sewer projects. Applicants may be required to document the critical need to be met. See also Water And Waste Disposal Grant. Some the US Rural Center offers grants to help rural communities pay for needed infrastructure projects. Each addresses a distinct need. In addition to water and sewer, grants may be used for natural gas, stormwater, broadband and certain transportation projects.

WATER AND WASTE DISPOSAL GRANT = ГРАНТ НА ВОДУ И УБОРКУ ОТХОДОВ – Water And Waste Disposal Grant:- Rural Utilities Service grant funds available to public, quasi-public, and nonprofit associations to reduce water and waste disposal costs to a reasonable level for rural users in the most financially needy communities. Grants may not exceed 75 percent of the eligible development costs of the project. The Farm Security and Rural Investment Act of 2002 (Sec. 6002) provided for grants for capitalizing revolving funds to provide financing for predevelopment costs and small, short-term capital costs, and extended grant authority through FY2007. See also Water And Waste Technical Assistance And Training Grant.

WATER AND WASTE DISPOSAL LOAN = ЗАЁМ НА ВОДУ И УБОРКУ ОТХОДОВ – (1) Water And Waste Disposal Loans (direct):- these loans are available to develop water and waste disposal (including solid waste disposal and storm drainage) systems in rural areas and towns with a population of 10 000 or less. Eligible entities are public groups, Indian tribes, and nonprofit corporations. Applicants must be unable to obtain sufficient credit elsewhere at reasonable rates and terms. Loan repayment terms are for not less than 40 years or the life of the facility, whichever is less.

(2) Water And Waste Disposal Loans (guaranteed):- similar to the water and waste disposal direct loans, with the exception that loans involving tax-exempt obligations and loans involving water and waste disposal grants may not be guaranteed. Normally, guarantees will not exceed 80 percent; although in exceptional circumstances, the guarantee can be as high as 90 percent. The interest rate is negotiable between the borrower and the lender.

WATER AND WASTE FACILITY GRANTS FOR NATIVE AMERICAN TRIBES = ГРАНТЫ НА ВОДУ И УБОРКУ ОТХОДОВ ДЛЯ КОРЕННЫХ АМЕРИКАНСКИХ ПЛЕМЁН – Water And Waste Facility Grants For Native American Tribes:- the Farm Security and Rural Investment Act of 2002 (Sec. 6010) authorizes USD50 million per year in grants and USD30 million per year in loans to benefit Indian tribes in constructing water and waste facilities. See also Farm Security And Rural Investment Act Of 2002.

WATER AND WASTE TECHNICAL ASSISTANCE AND TRAINING GRANT = ГРАНТ НА ТЕХНИЧЕСКУЮ ПОМОЩЬ И ОБУЧЕНИЕ В ОТНОШЕНИИ ВОДЫ И ОТХОДОВ – Water And Waste Technical Assistance And Training Grants:- funds are available for private nonprofit organizations to provide technical assistance and training on a wide range of issues relating to the delivery of water and waste disposal service to rural residents. Under the Federal Agriculture Improvement and Reform Act of 1996, not less than one percent nor more than three percent of water and waste disposal grant funds appropriated each year shall be available for this program.

WATER BANK = БАНК ВОДЫ – In the United States, Water Bank is a mechanism for holding water for eventual use. A water bank may include the use of surface water reservoirs, underground storage facilities, or a combination of these mechanisms.

WATER BANK ACT OF 1970 = АКТ О БАНКЕ ВОДЫ ОТ 1970 – Water Bank Act of 1970 (PL 91-559) is an act that authorized and directed the USDA to formulate and carry out a continuous program to prevent the serious loss of wetlands and to preserve, restore, and improve such lands. See also Water Bank Program (WBP).

WATER BANK PROGRAM = ПРОГРАММА БАНК ВОДЫ – Water Bank Program (WBP):- operated by the Natural Resources Conservation Service under authority of the Water Bank Act of 1970, as amended. The program was available to farmers or ranchers having specified types of wetlands along major migratory waterfowl flyways in designated counties. Farmers and ranchers entered into ten-year agreements in exchange for annual payments. The program was designed to preserve and improve wildlife habitat; preserve and improve wetlands; conserve surface waters; reduce runoff, soil erosion, and stream sedimentation; contribute to flood control, better water quality, and improve subsurface moisture; and accomplish related conservation and environmental objectives. No new funds were provided for FY1997, and participants holding expiring contracts were offered participation in the Wetlands Reserve Program, if qualified. / Служба Сохранения Природных Ресурсов.

WATER BAR = ВОДООХЛАЖДАЕМЫЙ КОЛОСНИК (или ВОДООТЛИВ, или СПУСКНОЙ ЖЁЛОБ) – Water Bar is a mound of soil built across a light duty road, skid trail or trail, or fireline for the purpose of diverting surface water onto porous forest soil.

WATER BEANS = ВОДЯНЫЕ БОБЫ – Water Beans are the irrigated soybeans.

WATER BED HEATER = НАГРЕВАТЕЛЬ ДЛЯ ВОДЯНОЙ КРОВАТИ – Water Bed Heater is an appliance that uses an electric resistance coil to maintain the temperature of the water in a water bed at a comfortable level.

WATER BEETLE = ВОДЯНОЙ ЖУК (или ВОДНЫЙ ЖУК, или ПЛАВУНЧИК, или ПЛАВУНЕЦ) – Water Beetle:- any of several thousand Species of Aquatic Beetles (Order Coleoptera), including members of the Families Haliplidae (Crawling Water Beetles),

Amphizoidae (Trout-Stream Beetles), Hygrobiidae (Screech Beetles), Gyrinidae (Whirligig Beetles), Noteridae (Burrowing Water Beetles), Hydrophilidae (Water Scavenger Beetles), Dryopidae (Long-Toed Water Beetles), and Dytiscidae (True Water Beetles, also known as Diving Beetles or Predaceous Diving Beetles). For additional information on groups and species of Water Beetles see Predaceous Diving Beetle; Water Scavenger Beetle; and Whirligig Beetle. / Плавунчики – Семейство Водных Жуков. Длина 2–5 миллиметров (мм). Задние ноги плавательные. Около 140 Видов. Распространены широко. В бывшем СССР около 30 Видов. Питаются Водорослями, реже мелкими беспозвоночными. Плавунчики (Haliplidae), Семейство Водных Жуков. Тело овальное, заострённое сзади, длина 2–5 мм. Задние ноги плавательные, их основные членики – тазики расширены в пластинки. Личинки продолговатые с многочисленными дыхательными выростами. Распространены широко. Около 140 видов; в бывшем Союзе Советских Социалистических Республик (СССР) – свыше 30. Жуки и личинки питаются в основном Водорослями, реже мелкими беспозвоночными. Плавунцы – Семейство Жуков. Длина от 1.5 до 50 миллиметров (мм). Около 2 500 Видов. Распространены широко, обитают в пресных, реже солоноватых водах. В бывшем СССР свыше 270 Видов. Хищники, истребляют личинок Комаров. Крупные виды вредят рыбоводству, поедая мальков рыб. Плавунцы (Dytiscidae), Семейство Водных Жуков. Тело продолговато-овальное, уплощённое, реже выпуклое, длина от 1.5 до 50 мм. Задние ноги плавательные, веслообразные, передние – хватательные. Личинки удлинённые, с плавательными ногами, большой головой и серповидными жвалами, которые пронизаны каналами для высасывания добычи. Распространены широко. Около 2 500 видов; в бывшем СССР – свыше 270. Живут в пресных, реже солоноватых водах; дышат воздухом, удерживая его под надкрыльями; по ночам жуки нередко выходят из воды и летают. Окукливаются в почве близ воды. Жуки и личинки – активные хищники, поедают различных водных беспозвоночных (в том числе личинок комаров), а крупные виды (например, Плавунец Окаймленный (Dytiscus Marginalis)) – и головастиков, а также мальков рыб, чем иногда вредят рыбоводству.

WATERBODY = ВОДНЫЙ ОБЪЕКТ – Waterbody:- any river, creek, slough, canal, lake, reservoir, pond, sinkhole, or other natural or artificial watercourse that flows within a defined channel or is contained within a discernable shoreline.

WATERBORNE AGREEMENT = СОГЛАШЕНИЕ, КАСАЮЩЕЕСЯ МОРСКОЙ ПЕРЕВОЗКИ (или СОГЛАШЕНИЕ О ВОДНЫХ ПЕРЕВОЗКАХ) – Waterborne Agreement:- a market understanding whereby underwriters cover goods against war risks only whilst they are on the overseas vessel. This rule is relaxed only in the case of goods in a transshipping port for a short period awaiting onward carriage. Waterborne Agreement is an agreement by marine insurers not to insure goods against war risk except when on board an ocean-going vessel with a time limit after arrival of port of destination. An understanding in the British marine insurance market whereby underwriters will cover goods against war risks only while they are on board an overseas vessel. Limited cover is allowed while goods are in craft en route between ship and shore and, also, during transshipment.

WATER BREAKER = АНКЕРОК (или БОЧОНОК, или ВОЛНОРЕЗ, или ВОДЯНОЙ БУРУН) – Water Breaker is a small cask carried in ship's boats for drinking purposes. / Бочонок – маленькая бочка.

WATERCOLOR = ВОДНАЯ КРАСКА (или АКВАРЕЛЬ) – Watercolor:- also spelled Watercolour, pigment ground in gum, usually gum Arabic, and applied with brush and water to a painting surface, usually paper; the term also denotes a work of art executed in this medium. The pigment is ordinarily transparent but can be made opaque by mixing with a whiting and in this form is known as Body Color, or Gouache; it can also be mixed with casein, a phosphoprotein of milk. Watercolor compares in range and variety with any other painting method. Transparent watercolor allows for a freshness and luminosity in its washes and for a deft calligraphic brushwork that makes it a most alluring medium. There is one basic difference between transparent watercolor and all other heavy painting mediums – its transparency. The oil painter can paint one opaque color over another until he has achieved his desired result. The whites are created with opaque white. The watercolorist's approach is the opposite. In essence, instead of building up he leaves out. The white paper creates the whites. The darkest accents may be placed on the paper with the pigment as it comes out of the tube or with very little water mixed with it. Otherwise the colors are diluted with water. The more water in the wash, the more the paper affects the colors; for example, vermilion, a warm red, will gradually turn into a cool pink as it is thinned with more water. The dry-brush technique – the use of the brush containing pigment but little water, dragged over the rough surface of the paper – creates various granular effects similar to those of crayon drawing. Whole compositions can be made in this way. This technique also may be used over dull washes to enliven them. / Акварель, от Французского слова Aquarelle, от Латинского слова Aqua, означающее Вода, – краски (обычно с клеем), разводимые в воде и легко смываемые ею. Основные качества живописи акварелью – прозрачность красок, сквозь которые просвечивают тон и фактура основы (чаще всего бумаги), чистота цвета.

WATER COLUMN = ВОДЯНОЙ СТОЛБ – Water Column (WC) is a measurement in inches of pressure of gas. 28 inches wc equals one psi (pound per square inch). Water Column is a vertical tubular member connected at its top and bottom to the steam and water space respectively of a boiler, to which the water gauge, water level controls, and fuel cutoff may be connected.

WATER CONDITIONS = СОСТОЯНИЕ ВОДЫ (или ХХ) – Water Conditions:- the status of the water supply and associated water in pondage and reservoirs at hydroelectric plants.

WATER CONSERVATION = СОХРАНЕНИЕ ВОДЫ (или РАЦИОНАЛЬНОЕ ВОДОПОЛЬЗОВАНИЕ, или КОНСЕРВАЦИЯ ВОДЫ) – Water Conservation refers to the preservation, control and development of water resources, both surface and groundwater, and prevention of pollution.

WATER CONSUMPTION = ВОДОПОТРЕБЛЕНИЕ (или ПОТРЕБЛЕНИЕ ВОДЫ) – Water Consumption:- So What Do 'Water Use' And 'Water Consumption' Mean? Water Use describes the total amount of water withdrawn from its source to be used. Measures of water usage help evaluate the level of demand from industrial, agricultural, and domestic users. For example, a manufacturing plant might require 10 000 gallons of freshwater a day for cooling, running, or cleaning its equipment. Even if the plant returns 95 percent of that water to the watershed, the plant needs all 10 000 gallons to operate. Water Consumption is the portion of water use that is not returned to the original water source after being withdrawn. Consumption occurs when water is lost into the atmosphere through evaporation or incorporated into a product or plant (such as a corn stalk) and is no longer available for reuse. Water consumption is particularly relevant when analyzing water scarcity and the impact of human activities on water availability. For example, irrigated agriculture accounts for 70 percent of water use worldwide and almost 50 percent of that is lost, either evaporated into the atmosphere or transpired through plant leaves. Water Consumption And Use Both Need To Be Measured:- Understanding both water use and consumption is critical to evaluating water stress. Measures of water usage indicate the level of competition and dependency on water resources. For example, domestic water use per capita in Qatar is one of the highest in the world, due in part to the free supply of water to Qatari nationals and limited rainfall. Although most of that use is non-consumptive, in an emergency, the country would only have enough water for 48 hours. Additionally, water is rarely returned to a watershed in perfect condition after being used by industry, agriculture, and other users, and change in quality contributes to water stress levels. Water consumption estimates, on the other hand, help gauge the impact of water use on downstream water availability and are essential to evaluating water shortages and scarcity at the watershed level, including impacts to aquatic ecosystems. Therefore, a holistic understanding of water stress requires analysis of both the total use and consumption of water. A Holistic Understanding Of Water Stress:- WRI's Aqueduct Water Risk Atlas accounts for

the impact of both water use and consumption by using a baseline water stress indicator. (World Resources Institute (WRI); headquartered in Washington, DC, The United States of America.) Baseline water stress measures total annual water use from municipal, industrial, and agricultural sectors expressed as a percent of the total annual available water after all upstream water consumption has been subtracted. By acknowledging both total water usage and consumption, Aqueduct users can rely on the baseline water stress indicator to evaluate overall freshwater demand and availability in specific watersheds. Already, more than 1.4 billion people live in river basins where the use of water exceeds the minimum recharge levels. In the next 12 years, water withdrawals in developing countries are predicted to increase by 50 percent. Measuring water usage and consumption is critically important for identifying areas that are at risk of water scarcity and excessive competition amongst users. After all, in order to prevent or manage water risk, we must first fully understand it. See also Water Use. / Водопотребление, расходование воды, подаваемой для удовлетворения различных нужд населения, промышленности и так далее. Различают две основные категории водопотребления:- (1) хозяйственно-питьевое и коммунальное водопотребление – потребление воды, связанное с бытовыми нуждами населения (питьё, приготовление пищи, содержание в чистоте жилищ и тому подобное) и обеспечением благоустройства населённых мест (поливка улиц, зелёных насаждений и тому подобного); (2) производственное или техническое водопотребление – потребление воды для технологических целей промышленности, энергетики, транспорта (парообразование, охлаждение, промывка продукции, гидравлический транспорт и тому подобное), на противопожарные нужды и прочее. Количество воды, расходуемое для нужд населения, зависит в основном от степени санитарно-технического оборудования жилищ (наличия канализации, ванн, душей, систем газоснабжения и горячего водоснабжения). Показателем размеров водопотребленя по этой категории служит удельный расход воды, то есть количество воды, расходуемое в среднем в сутки на одного жителя. Измерения и анализ фактических удельных расходов в населённых местах дают основания для установления норм водопотребления – величин удельных расходов, которые рекомендуется принимать при проектировании новых или реконструкции существующих водопроводов. Водопотребление – водопользование с изъятием воды из водных объектов или с забором воды из системы водоснабжения. Различают:- (i) безвозвратное водопотребление; (ii) водопотребление с частичным возвратом; и (iii) водопотребление с полным возвратом. Водопотребление – использование водных ресурсов для удовлетворения потребностей населения, коммунально-бытового сектора, промышленности и сельского хозяйства, обязательно предполагающее забор воды из водных объектов. В узком смысле под водопотреблением понимается потребление воды из систем водоснабжения. Выделяют две основные категории водопотребления:- (1) хозяйственно-питьевое и коммунальное – потребление воды для удовлетворения питьевых, бытовых и поливомоечных нужд; и (2) производственное или техническое – потребление воды для технологических нужд промышленного, энергетического и транспортного секторов, противопожарных нужд и так далее. По типам различают возвратное или оборотное водопотребление, заключающееся в многократном использовании воды, и безвозвратное водопотребление, при котором вода используется однократно. История организованного водопотребления насчитывает несколько тысяч лет – период существования развитых человеческих цивилизаций. Первые сооружения для централизованного водоснабжения и водопотребления населения появились около 3300 до Наше Эры на территории современного Ирана. Позднее инженерные сети водоснабжения появились в Египте, Иерусалиме, а также в Древнем Риме, где водоснабжением было обеспечено 2 миллиона жителей и подавалось около 1 миллиона кубических метров воды в сутки ($м^3$/сут), или примерно 500 литров в сутки (л/сут) на человека. В России первые системы водоснабжения, построенные в XVII веке в Москве и Киеве, снабжали лишь отдельные сооружения – Московский Кремль и Киевскую Духовную Семинарию. Однако уже в XX веке системы централизованного водоснабжения имелись на территории 215 крупных и больших городов России. Тем не менее, эти инженерные системы не могли обеспечить полноценного водоснабжения, и объём водопотребления в большинстве городов составляла 20–50 л/сут на человека. Лишь в Москве и Санкт-Петербурге этот показатель достигал 100–150 л/сут. Величина удельного суточного водопотребления на душу населения в современном мире колеблется от 30–80 литров на человека в сельской местности до 200–600 литров на человека в городах, в 20–250 раз превосходя первичные физиологические потребности человека, составляющие ~2.5 л/сут. С начала XX века, в связи с многократным приростом численности населения и ростом уровня жизни благодаря техническому, экономическому и социальному прогрессу, величина мирового водопотребления стала резко возрастать. В 1900–50 водопотребление населения планеты возросло в три раза, а с 1950 по 2000 – уже в семь раз. На сегодняшний день динамика роста водопотребления такова, что каждые 8–10 лет мировая потребность в воде возрастает вдвое. Величина водопотребления населения определяется рядом факторов, в том числе численностью населения, уровнем развития и состоянием жилищно-коммунального хозяйства, культуры водопотребления, климатическими условиями расположения объекта. Величина производственного водопотребления в свою очередь, зависит от структуры и мощности промышленного предприятия, технических особенностей и характеристик используемых технологий. В целом, водопотребление страны определяется общим уровнем её развития – в развитых странах на долю сельского хозяйства приходится до 50% водопотребления, на долю промышленности – до 40%, на долю коммунально-бытовых нужд – около 10%. Однако в среднем по миру величина водопотребления сельским хозяйством достигает 70–80%, а в развивающихся странах и больше. По данным на 2012 в России основная часть извлекаемой воды (60.2%) использовалась в промышленности; 15.8% – в сельском хозяйстве и для хозяйственно-питьевых нужд, в том числе на орошение – 13.7%. Оставшаяся часть – 10.3% на иные нужды. В 2011 суммарный водозабор из природных водных объектов вырос по сравнению с 2010 на 1.5% и составил 77 640.85 миллионов кубических метров ($м^3$), что составило ~2% водных ресурсов страны. Хозяйственно-Питьевое Водопотребление:- подразумевает потребление воды на приготовление пищи, мытьё посуды, на питьевые нужды, в гигиенических целях, на стирку и влажную уборку. Основная трата воды в быту приходится на работу туалета (35%) и процедуры личной гигиены (принятие ванны, душа и умывание) – 32%. На стирку уходит 12% воды, на мытьё посуды – 10%, на питьё и приготовление пищи – 3%, а на прочие расходы, включая уход за домашними животными и поливку цветов – 8%. Всемирной Организацией Здравоохранения установлена норма расхода воды – 450 л/сут на душу населения. Однако среднесуточное водопотребление в странах Европейского Союза, благодаря высокому уровню бытовой культуры населения и высокой стоимости услуг водоснабжения, значительно ниже этой нормы. Так, в Великобритании – 140 л, в Германии – 130 л, в США чуть больше – около 200 л/сут на человека. Анализ данных Евростата свидетельствует о том, что в конце первого десятилетия XXI века максимальная величина водопотребления из централизованных сетей водоснабжения в странах Европейского Союза менялась по странам от 76 до 31 кубических метров на человека в год. Этот расчёт осуществлен исходя из общей численности населения конкретных стран. При оценках на основе городского населения приведённые цифры будут более высокими. В Российской Федерации объём коммунального водопотребления за последние 20 лет неуклонно снижался. В 2012 в целом по всей стране они составляли 47–49 $м^3$/год, или 129–134 л/сут на одного человека, а по городам – 64–66 $м^3$/год, или 175–181 л/сут на одного горожанина. В 2012 67.7% населения Российской Федерации были обеспечены централизованным водоснабжением, остальные 32.3% – нецентрализованным водоснабжением или привозной водой. Водопотребление из централизованных систем водоснабжения имеет тенденцию к ежегодному снижению на 4–6%. Доля подземных вод в общем балансе хозяйственно-питьевого водоснабжения составляет ~45%, что намного ниже, чем в большинстве Европейских стран, хотя

подземные воды, вследствие лучшей защищённости подземных источников от загрязнения, можно с большей эффективностью использовать для коммунального водоснабжения. Более 60% городов и посёлков городского типа удовлетворяют потребности в питьевой воде, используя подземные воды, около 20% из них имеют смешанные источники водоснабжения. В сельской местности доля подземных вод в хозяйственно-питьевом водоснабжении достигает 80%. Техническое Водопотребление:- не существует ни одного технологического процесса, который обходился бы совсем без воды. Так, для выплавки одной тонны чугуна и перевода его в сталь и прокат расходуется 50–150 м^3 воды, для производства одной тонны меди – 500 м^3, для получения одной тонны синтетического каучука и химических волокон – от 2 000 до 5 000 м^3 воды. Наиболее водоёмкими отраслями являются теплоэнергетика, чёрная и цветная металлургия, машиностроение, нефтехимическая, химическая и целлюлозно-бумажная промышленность. Подавляющее число производств использует только пресную воду; новейшим отраслям промышленности (производству полупроводников, атомной техники, полимерных материалов и другим) необходима вода особой чистоты. Расход воды на промышленные нужды суммарно по миру увеличился более чем в 60 раз, достигнув в 2000 1 900 км^3, то время как в 1900 потреблялось всего 30 км^3, в 1950 – 190 км^3, в 1970 – 510 км^3. В России, как и в большинстве Европейских стран, самым водоёмким сектором экономики является промышленность, на долю которой приходится более половины общего объёма суммарного забора воды из природных источников. В совокупности современные промышленные предприятия и тепловые электростанции России расходуют такое количество воды, которое сопоставимо с суммарным годовым стоком рек Енисей и Лена. Удельная величина водопотребления на производственные нужды во всех отраслях экономики Российской Федерации снизилась с 71% в 1970 до 53% в середине 1990-х. Однако по мере восстановления промышленного комплекса этот показатель стал расти, достигнув 60.2% к 2012. Стабилизация водопотребления промышленностью связана с активным введением в эксплуатацию мощностей оборотного и повторно-последовательного водоснабжения, а также общей мировой тенденцией к внедрению водосберегающих технологий. При оборотном потреблении, когда отработанная вода после очистки снова используется в производстве, расход воды резко сокращается, например, тепловая станция при прямоточном водопотреблении расходует 1.5 км3/год, при оборотном – 0.12 км^3/год, то есть в 13 раз меньше. Тем не менее, использование воды в системах оборотного водоснабжения недостаточно:- в России вода осуществляет 3–4 оборота, в то время как в США – 7–8 оборотов. Сельское Хозяйство:- с 1970-х значительно изменилась величина водопотребления на нужды орошения и обводнения в России. В начале 1970-х доля использования воды на эти нужды составляла 15% суммарного водопотребления, в начале 1980-х – 23%. В дальнейшем с внедрением водосберегающих технологий, а позднее из-за резкого снижения площади поливаемых (с 4.8 до 2.5 миллионов гектаров (га)) и орошаемых (с 6.2 до 4.3 миллионов га) земель этот показатель снизился к 2012 до 13.2%. В развитых странах происходит переход на водосберегающие технологии и в сельском хозяйстве, так называемому Капельному Орошению.

WATER CONTENT = ВЛАГОСОДЕРЖАНИЕ (или СОДЕРЖАНИЕ ВОДЫ) – Water Content is the percentage of total mass of a substance that is constituted by water.

WATER CONTENT CLASS = КЛАСС СОДЕРЖАНИЯ ВЛАГИ – Water Content Class:- classification of goods in accordance with their water content.

WATER CONTROL = КОНТРОЛЬ ВОДЫ – Water Control:- to control the amount and depth of water in the ricefield during the required time necessary for crop growth.

WATER CONTROL STRUCTURE = СТРУКТУРА (или СООРУЖЕНИЕ) КОНТРОЛЯ ВОДЫ – Water Control Structure is any structure used to regulate surface water levels.

WATERCOURSE = РУСЛО (или ВОДОТОК) – Watercourse is a broad term for a channel that a flowing body of water follows, such as canals, rivers and streams. Watercourse is a way or course through which water may or does flow. / Под Водотоком понимается водный объект, характеризующийся движением воды в направлении уклона в углублении земной поверхности.

WATER COVER = ПОКРЫТИЕ ВОДОЙ (или ПОДТОПЛЕНИЕ) – Water Cover is a flooding of land by water, either to develop or restore shallow water areas for wildlife or wetlands or as a result of a natural disaster. Under the Farm Security and Rural Investment Act of 2002 (Sec. 2101), for the Conservation Reserve Program, water cover does not include ponds for the purpose of watering livestock, irrigating crops, or raising fish for commercial purposes. / сохранение (conservation). Под Подтоплением понимается подъём уровня грунтовых вод, вызванный повышением горизонтов воды в реках при сооружении водохранилищ и плотин, затоплением русл рек, потерями воды из водопроводной и канализационной сетей и прочее. При подтоплении заболачивается и засоляется почва, ухудшается санитарное состояние местности, разрушаются здания, дороги. Под Подтоплением понимается повышение уровня грунтовых вод, выванное хозяйственной деятельностью человека или естественными причинами. Подтопление происходит при сооружении водохранилищ, русловых плотин на реках, судоходных каналов и других гидротехнических сооружений; за счёт потери воды из водопроводной, канализационной и оросительной сети, заиления рек. При подтоплении заболачиваются и засоляются почвы, уменьшается продуктивность лугов и лесов, ухудшается санитарно-гигиеническое состояние местности, снижается прочность фундаментов сооружений и прочее. К подтопленным относят территории, на которых глубина залегания уровней грунтовых вод меньше допустимой для хозяйственного использования (для лугов она составляет 0.6–0.8 м, пашни – 0.8–1.4 м, садов – 1.2–1.8 м, мелких населённых пунктов – 1.5–2 м, городов – 3–4 м). Для защиты земель от подтопления подтопленные территории ограждают от избыточных поверхностных вод, притекающих с соседних возвышенностей (нагорные каналы, противофильтрационные завесы); понижают уровни грунтовых вод с применением мелиоративных мероприятий – строят осушительные системы и осуществляют дренаж сельскохозяйственных и застроенных земель (наиболее распространены глубокие горизонтальные дрены, располагаемые по границе защищаемой территории – головные дрены); организуют поверхностный сток (особенно для населённых пунктов). В бывшем Союзе Советских Социалистических Республик (СССР) для борьбы с подтоплениями были сооружены дренажи на сельскохозяйственных угодьях Костромской Низины (подтоплены Горьковским Водохранилищем), в Мургабском Оазисе (Каракумским Каналом), а также в городах Москва (Перервинской Плотиной) и Никополь (Каховским Водохранилищем) и так далее.

WATERCUT = ОБВОДНЁННОСТЬ – Watercut is a quantity of water in mixture extracted from an oil well (usually expressed as a percentage). / Под Обводнённостью понимается содержание воды в смеси продукции, откачиваемой из нефтяной скважины, и обычно выражаемой в процентах.

WATER CYCLE = ВОДНЫЙ ЦИКЛ (или ГИДРОЛОГИЧЕСКИЙ ЦИКЛ, или ВОДООБОРОТ) – The Water Cycle is the sequence of climatological events. The heat of the sun evaporates water from land and water surfaces; vapor, being lighter than air, rises until it reaches the cooler upper air level where it condenses into clouds; further condensation produces precipitation that falls to earth as rain, sleet or snow; some of the water is retained by the soil and some run-off returns to rivers, lakes and oceans.

WATER DAMAGE = ПОВРЕЖДЕНИЕ ВОДОЙ – (1) Water Damage:- the container itself is subject to a great deal of rough handling by terminal handling gear which may lead to the skin being pierced and goods becoming wet due to water ingress. The doors and wooden floor of the container have proved to be the main points of water entry when the containers have been standing in a column of water.

(2) Defect Name:- Water Damage. Defect Type:- Finishing Defects. Fabric Type:- Bottomweights – Sateen Derivatives. Description:- Water Damage:- This is the result of a fabric being wet after finishing and allowed to remain in a box or roll. The color tends to migrate leaving the fabric blotchy. Severity:- Major. Water Damage:- a stain that has a sharply defined straight or wavy edge and that fades away rapidly to normal color. Note:- this defect is caused by deposition of dye, soil or finishing compounds carried by water wicking through the fabric, and represents the furthest point of this migration. / развод (или потёк (stain)). Ущерб, Причинённый Водой (water damage):- порок ткани; пятно с чётко определяемым направлением или волнистым краем, которое быстро исчезает, возвращаясь к обычному цвету. Примечание:- этот порок вызван нанесением краски, загрязнения или отделочных составов, которые распространяются при затекании воды сквозь ткань, и обеспечивают сгон красителя к краям пятна.

WATERED CAPITAL = РАЗВОДНЁННЫЙ КАПИТАЛ – Watered Capital or Watered Stock in India represents those security issues which are not covered or backed by the value of the assets of the company. It is the excess of total capitalisation over the real value of the long-term assets of the company. Simply speaking 'water' is said to be present in the capital when a part of the capital is not represented by assets. It is considered to be as worthless as water. Watered capital arises when a company pays higher price for the assets acquired from a going concern or when the promoters' services are highly valued. It also arises when adequate consideration in the form of assets in not received for the issue of securities. The capital becomes watered to the extent of the excess price paid for the assets or the excess payment made to promoters or the inadequacy of consideration for the issue of securities. The primary test of watered stock is found in the intent of the promoters who sell the stock if there is a deliberate attempt to much the shareholders by the inflation of the value of the assets, a watered condition is the inevitable result. For example, company purchases machinery from another company for Rs. 1 lakh, but its real value is Rs. 80 000 only. In this case Rs. 20 000 is the amount of watered capital. Watered capital is one of the main causes of over-capitalisation. But it does not mean over-capitalisation in all circumstances. Water enters the capital usually in the initial period, i.e. at the time of promotion. Over-capitalisation can be observed only when the corporation has worked for a few years. A company may start with watered capital but its working may be very efficient and its earnings may justify the amount of capitalisation. In such a case, the company will not be over-capitalised even though a part of the capital is watered or not represented by an asset. It is also possible that a company is over-capitalised even though it has no watered stock. Over-capitalisation may be caused by low earnings, existence of idle capital and factors other than the existence of watered capital. See also Watered Stock. Watered Capital is called so because the flow of money can be seen at the time of promotional events only and then money flows like water with the capital in the initial period at the time of promotion whereas Over capitalization can be calculated after the company has worked for some years and at the end only. Over capitalization can be caused by watered capital whereas water capital is not caused by overcapitalization and it can be calculated at the time when the company is taking the promotional event in hand. When the stock or capital of a company is not represented by issue of equivalent value, it is termed as Watered Capital signifying presence of water in the capital of the company. Watered Capital is the value of the eroded capital on account of a company continuously incurring losses. The accumulated losses and other intangible assets are viewed as a percentage of the paid-up capital and watered capital is the residual part of the paid-up capital after accounting the amount of losses. / Разводнённый Капитал.

WATERED STOCK = РАЗВОДНЁННАЯ ДОЛЯ – Watered Stock is a stock representing ownership of overvalued assets, a condition of overcapitalized corporations, whose total worth is less than their invested capital. The condition may result from inflated accounting values, gifts of stock, operating losses, or excessive stock dividends. Among the negative features of watered stock from the shareholder's standpoint are inability to recoup full investment in liquidation, inadequate return on investment, possible liability exceeding the par value of shares, low market value because of poor dividends and possible adverse publicity, reduced ability of the firm to issue new stock or debt securities to capitalize on growth opportunity, and loss of competitive position because of the need to raise prices to provide a return acceptable to investors. To remedy the situation, a company must either increase its assets without increasing its outstanding shares or reduce outstanding shares without reducing assets. The alternatives are to increase Retained Earnings or to adjust the accounting values of assets or of stock. Watered Stock is a stock that is issued with a value much greater than the value of the issuing company's assets. Watered stock can be caused by excessive stock dividends, overvalued assets and/or large operating losses. Assets can be overvalued for several reasons, including inflated accounting values or excessive issue of stock (through a dividend or employee stock-option program). This term is thought to originate from ranchers who would feed their cattle large amounts of water before market day to make them heavier, fetching a price higher than their worth. Watered Stock is an asset with an artificially-inflated value. The term is most commonly used to refer to a form of securities fraud common under older corporate laws that placed a heavy emphasis upon the par value of stock. Stock Watering was originally a method used to increase the weight of cows before sale. It entailed forcing a cow to bloat itself with water before it was weighed for sale. Its introduction to the New York financial district is popularly credited to Daniel Drew, a cattle driver turned financier. American stock promoters in the late 1800s could inflate their claims about a company's assets and profitability, and sell stocks and bonds in excess of the company's actual value. To do so, they would contribute property to a new corporation in return for stock at an inflated par value. On the balance sheet, the property would be the corporation's only capital, and because legal capital was fixed to aggregate par value, the value of the property would go up. While the promoter had USD10 000 in stock, the corporation might only have USD5 000 worth of assets, but would still be worth USD10 000 on paper. Holders of watered stock could be personally liable if creditors foreclosed on the corporation's assets. If they had received USD10 000 in stock for a USD5 000 capital contribution, they would not only lose their USD5 000 investment but would also be personally liable for the additional USD5 000, whether they were the aforementioned promoter lying about the value of their contribution, or an innocent investor relying on par value to gauge the true value of the corporation. Because par value was such an unreliable indicator of the actual value of stock, and because high par values could create liability for investors if the corporation went belly up, corporate lawyers began advising their clients to issue stocks with low par values. The legal capital or 'stated capital' of the corporation would still be determined based on par value, but the balance sheet would include the investment over par value as a capital surplus, and everything would still balance. In 1912, New York authorized corporations to issue 'no par stock' with no par value at all, in which case the board of directors would allocate the incoming capital between stated capital and capital surplus. All other states followed suit. Thanks in large part to a proliferation of low par and no par stock, watered stock is less of an issue these days. The last major American court case dealing with watered stock was in 1956. Watered Stock:- shares of stock of a corporation which have been issued at a price far greater than true value. In this case, the actual value of all shares is less than the value carried on the books of the corporation. Watered Stock is a stock that is sold with a face value that is much greater then its actual (market) value. While watered stock may appear to be a good value, due to corporation laws, the stock holder may be exposed to liability up to the face value (rather then having their liability limited to the price paid). Watered Stock:- shares of stock of a corporation that were issued at a price greater than fair market value. The actual value of watered stock is less than the value carried on the books of the corporation. In corporate law, Watered Stock:- shares of stock that have been issued by the corporation for less than full lawful

consideration. Traditionally, par value established the consideration for which stock could be issued, and every state enacted a constitutional or statutory provision governing such consideration. However, since the enactment of the federal securities laws during the 1930's requiring the disclosure of financial information of a corporation to a potential investor, the issuance of stock at its par value has become of less importance, and stock is usually issued today with no or only nominal par value. 11 Fletcher, Cyclopedia of the Law of Private Corporations §§5199, 5207 and 5207.1 (1987). Watered Stock is a stock representing ownership in a corporation that is worth less than the actual invested capital, resulting in problems of low liquidity, inadequate return on investment, and low market value. Watered Stock:- shares issue offered to the public at prices that are highly inflated when compared with the book value of the issuer's assets. An illegal practice when it can be established that the issuer's management sanctioned it with the full knowledge of the facts, its gets its name from the cattlemen's practice of increasing the livestock's size and weight before its sale by inducing it to drink inordinate amounts of water. See also Stock Watering. Watered Stock:- a stock that is put out as if fully paid for, but that is not because some or all of the shares were sold (or given out) for less than full price. / Флэтчё (Fletcher). Разводнённый Капитал (Watered Stock) – акционерный капитал корпорации, эмитированный корпорацией под завышенную оценку принадлежащей ей собственности, или предложенный выпуск акций, за который корпорация не может получить достаточной выручки. Разводнённые Акции (Watered Stock) – акции, представляющие право владения переоценёнными (overvalued) активами, – признак капитализации корпораций с высоким уровнем. Это значит, что общая стоимость активов меньше, чем реальный объём инвестированного капитала. Эта ситуация может быть результатом убытков или необоснованно высоких дивидендов. Среди негативных признаков разводнённых акций – невозможность вернуть полную сумму своих вложений в случае ликвидации, неадекватный доход по инвестициям, возможность того, что обязательства превысят номинальную (par) стоимость акций, низкая рыночная стоимость (market value) вследствие низких дивидендов, возможно, плохая репутация и сокращение возможности выпускать новые акции или кредитные обязательства для привлечения капитала. Не исключена также потеря конкурентоспособности вследствие необходимости повышать цены на продукцию, чтобы выплачивать акционерам адекватный доход. Для исправления ситуации компания должна либо увеличить объём своих активов, не увеличивая объёма находящихся в руках акционеров (utstanding) акций, либо сократить объём находящихся на руках акций, не сокращая активов. Альтернативой является увеличение нераспределённых доходов (retained earnings) или корректировка учётных бухгалтерских оценок активов или акций.

WATER FACTOR = ВОДЯНОЙ ФАКТОР (или ВОДНОЕ ЧИСЛО) – Water Factor (WF) is a measurement of water efficiency that is calculated as gallons of water used per cubic foot of capacity. So, if a clothes washer uses 30 gallons per cycle and has a tub volume of 3.0 cubic feet, then the water factor is 10.0. The lower the WF, the more efficient the clothes washer. WF is the present water performance metric that allows the comparison of clothes washer water consumption independent of clothes washer capacity. WF is the quotient of the total weighted per-cycle water consumption, Q, divided by the capacity of the clothes washer, C. The lower the value, the more water efficient the clothes washer. The equation is:- WF = Q / C. Energy Star qualified clothes washers must have a maximum WF of 7.5.

WATERFLOODING = ЗАВОДНЕНИЕ – Waterflooding is the injection of hot water into oil beds to aid in oil recovery. / Заводнение (Waterflooding) – закачка воды в законтурную или внутриконтурную части залежи для поддержания пластового давления. Один из основных вторичных методов разработки нефтяных месторождений.

WATER FRAME = ВОДНЫЙ СТАН (или ВОДНАЯ РАМА) – Water Frame is an machine to create cotton thread first used in 1768. It was able to spin 128 threads at a time, making it an easier and faster method than ever before. It was developed by Richard Arkwright, who patented the technology in 1767. The design was partly based on a spinning machine built for Thomas Highs by clock maker John Kay, who was hired by Arkwright. See also Spinning, and Spinning Frame. The Spinning Frame or Water Frame was developed by Richard Arkwright who along with two partners patented it in 1769. The design was partly based on a spinning machine built for Thomas High by clock maker John Kay, who was hired by Arkwright. For each spindle, the water frame used a series of four pairs of rollers, each operating at a successively higher rotating speed to draw out the fiber, which was then twisted by the spindle. The roller spacing was slightly longer than the fiber length. Closer spacing caused the fibers to break while further spacing caused uneven thread. The top rollers were leather-covered and loading on them was applied by a weight that kept the twist from backing up before the rollers. The bottom rollers were wood and metal, with fluting along the length. The water frame was able to produce a hard, medium count thread suitable for warp, finally allowing 100% cotton cloth to be made in Britain. A horse powered the first factory to use the spinning frame. Arkwright and his partners used water power at a factory in Cromford, Derbyshire in 1771, giving the invention its name. Richard Arkwright is credited with a list of inventions, but these were actually developed by such people as Thomas Highs and John Kay. Arkwright nurtured the inventors, patented the ideas, financed the initiatives, and protected the machines. He created the cotton mill, which brought the production processes together in a factory, and he developed the use of power – first horse power and then water power – which made cotton manufacture a mechanized industry. / Сэр Ричад Акрайт (Sir Richard Arkwright; 1732–92). Томэс Хайз (Thomas Highs) и Дьжон Кэй (John Kay).

WATERFRONT LIQUID NATURAL GAS PLANT = ПРИМЫКАЮЩИЙ К БЕРЕГУ ЗАВОД ПО СЖИЖЕНИЮ ПРИРОДНОГО ГАЗА – Waterfront Liquid Natural Gas (LNG) Plant is an LNG plant with docks, wharves, piers, or other structures in, on, or immediately adjacent to the navigable waters of the United States or Puerto Rico and any shore area immediately adjacent to those waters to which vessels may be secured and at which LNG cargo operations may be conducted.

WATER GAS = ВОДЯНОЙ ГАЗ – Water Gas is a fuel gas containing approximately equal amounts of carbon monoxide and hydrogen, and varying smaller amounts of methane, carbon dioxide, and nitrogen, made by passing steam and air over heated coke or coal. Water Gas is of low illuminating value, but after it is carbureted it burns with a brilliant flame. Water Gas is a toxic gaseous mixture consisting chiefly of carbon monoxide and hydrogen, prepared from steam and incandescent coke:- used as anilluminant, fuel, and in organic synthesis. Water Gas is a mixture of hydrogen and carbon monoxide produced by passing steam over hot carbon, used as a fueland raw material. See also Producer Gas. / Водяной (синий, голубой) Газ (Water Gas) – разновидность генераторного газа. Газообразное топливо, получаемое в результате циклической паровоздушной обработки раскалённого кокса или угля.

WATER GAUGE = ВОДОМЕР (или ВОДОМЕРНАЯ РЕЙКА, или ВОДЯНОЙ МАНОМЕТР, или ВОДОМЕРНОЕ СТЕКЛО) – Water Gauge is an instrument that indicates the presence or the quantity of water in a tank, reservoir, or boiler feed. Also called Water Glass. Water Gauge is the gauge glass and its fittings for attachment. Water Gauge is an instrument indicating the level of water, as in a boiler, tank, reservoir, or stream.

WATER GLASS = РАСТВОРИМОЕ СТЕКЛО (или ЖИДКОЕ СТЕКЛО, или ВОДОМЕРНОЕ СТЕКЛО) – Water Glass:- also called Sodium Silicate, or Soluble Glass, crystal-like lumps that range from colorless to white or grayish white and resemble glass but can be dissolved in water to form a syrupy liquid. Some forms are slightly soluble, and some are almost insoluble; they are best dissolved by heating with water under pressure. A little water dissolves water glass more readily than much water does. The solutions are strongly alkaline. The chemical formulas Na_2SiO_3, $Na_6Si_2O_7$, and $Na_2Si_3O_7$ describe the composition of various forms of water glass. Water

glass is used as a bonding agent in manufacturing grindstones and abrasive wheels. It is a cement for glass or porcelain and is used in various industrial and certain printing processes. It was formerly used as a household preservative for eggs. / Жидкое Стекло – водный раствор силиката натрия или калия.

WATER–GLYCOL FLUID = ВОДНО–ГЛИКОЛЕВАЯ ЖИДКОСТЬ – Water-Glycol Fluid is a fluid whose major constituents are water and one or more glycols or polyglycols. Waterglycol Fluids contain from 35 to 60 percent water to provide the fire resistance, plus a glycol antifreeze such as ethylene, diethylene, or propylene which is nontoxic and biodegradable, and a thickener such as polyglycol to provide the required viscosity. These fluids also provide all the important additives such as antiwear, foam, rust, and corrosion inhibitors. Operating temperatures for waterglycol fluids should be maintained below 49 °C (120 °F) to prevent evaporation and deterioration of the fluid. To prevent separation of fluid phases or adverse effects on the fluid additives, the minimum temperature should not drop below 0 °C (32 °F). Viscosity, pH, and water hardness monitoring are very important in waterglycol systems. If water is lost to evaporation, the fluid viscosity, friction, and operating temperature of the fluid will increase. The end result is sluggish operation of the hydraulic system and increased power consumption. If fluid viscosity is permitted to drop due to excessive water, internal leakage at actuators will increase and cause sluggish operation. A thin fluid is also more prone to turbulent flow which will increase the potential for erosion of system components. Under normal use, the fluid pH can be expected to drop due to water evaporation, heat, and loss of corrosion inhibitors. The fluid pH should be slightly alkaline (i.e. above pH8) to prevent rust. However, because of their volatility and toxicity, handling of the amine additives that stabilize the pH is not recommended. Therefore, these essential additives are not usually replenished. Fluids with pH levels that drop below 8 should be removed and properly discarded. Makeup water added to the system must be distilled or soft deionized. The calcium and magnesium present in potable water will react with lubricant additives causing them to floc or come out of solution and compromise the fluids performance. When this condition occurs the fluid is permanently damaged and should be replaced. To prolong the fluid and component life, water added to the system should have a maximum hardness of 5 parts per million (ppm).

WATER HAMMER = ГИДРАВЛИЧЕСКИЙ УДАР (или ВОДЯНОЙ МОЛОТ) – Water Hammer is a sudden increase in pressure of water due to an instantaneous conversion of momentum to pressure. Water Hammer (or, more generally, Fluid Hammer) is a pressure surge or wave resulting when a fluid (usually a liquid but sometimes also a gas) in motion is forced to stop or change direction suddenly (momentum change). Water hammer commonly occurs when a valve is closed suddenly at an end of a pipeline system, and a pressure wave propagates in the pipe. It may also be known as Hydraulic Shock.

WATER HEATED IN FURNACE = ВОДА, НАГРЕТАЯ В ТОПКЕ – Water Heated In Furnace:- some furnaces provide hot water as well as heat the home. The water is heated by a coil that is part of the furnace. There is no separate hot water tank. / В топке котла.

WATER HEATER = ВОДОНАГРЕВАТЕЛЬ (или НАГРЕВАТЕЛЬ ВОДЫ, или ВОДОПОДОГРЕВАТЕЛЬ) – Water Heater is an automatically controlled, thermally insulated vessel designed for heating water and storing heated water at temperatures less than 180 degrees Fahrenheit. Water Heater is an appliance intended principally for heating domestic (or tap) water. Water Heater is an appliance for supplying hot water for purposes other than space heating or pool heating.

WATER HEATING = ВОДЯНОЕ ОТОПЛЕНИЕ (или ВОДЯНОЙ ОБОГРЕВ) – Water Heating:- Energy Efficiency program promotion to increase efficiency in water heating, including low-flow showerheads and water heater insulation wraps. Could be applicable to residential, commercial, or industrial consumer sectors. / Под Отоплением понимается искусственный обогрев помещений для поддержания температуры, отвечающей условиям теплового комфорта (например, 18–20 °C в жилых помещениях), а иногда и требованиям технологического процесса. Под отоплением понимают также системы, выполняющие эти функции. Основные виды:- водяное, воздушное, лучистое, панельное, печное, электрическое отопление. Под Отоплением понимается искусственный обогрев помещений для возмещения в них тепловых потерь и поддержания на заданном уровне температуры, отвечающей чаще всего условиям теплового комфорта для людей, а иногда требованиям технологического процесса. Наиболее распространено водяное отопление.

WATER HEATING DSM PROGRAMS = ПРОГРАММЫ УС НА ВОДЯНОЙ ОБОГРЕВ – Water Heating DSM Programs:- these are demand-side management (DSM) programs designed to promote increased efficiency in water heating, including water heater insulation wraps. / Программы Управления Спросом .

WATER HEATING EQUIPMENT = ВОДОПОДОГРЕВАТЕЛЬНОЕ ОБОРУДОВАНИЕ – Water Heating Equipment is the automatically controlled, thermal insulated equipment designed for heating and storing heated water at temperatures less than 180 degrees Fahrenheit for other than space heating purposes.

WATER–HOLDING CAPACITY = СПОСОБНОСТЬ (или ЁМКОСТЬ) УДЕРЖАНИЯ ВОДЫ – Water-Holding Capacity is the ability of a soil and crop system to hold water in the root zone. See also Soil.

WATER IMBIBITION = ВПИТЫВАНИЕ ВОДЫ (или ПОГЛОЩЕНИЕ ВОДЫ) – Water Imbibition is fundamental to both waterflood and steamdrive performance in low permeability reservoir rocks such as diatomite and chalk. Imbibition is an immiscible displacement process, whereby a non-wetting fluid within a porous medium is spontaneously expelled by wetting fluid that surrounds the medium and is drawn into the medium by capillary suction. This phenomenon is caused by the differential attraction forces between the pore walls and fluids. The rate of imbibition is primarily dependent on the rock permeability, pore structure, wettability, and the interfacial tension between the resident phase and the imbibing phase. On the macroscopic scale, capillary imbibition forces determine, in part, how rapidly and easily a hydraulically fractured water injector injects water into a low permeability formation and at what rate the injected water propagates. In naturally fractured systems with a high degree of interconnectedness, imbibition forces must be strong for a waterflood to be successful. If they are not, water will propagate through the fracture network from injector to producer and the waterflood will fail. Capillary phenomena are equally important during steam injection into diatomite or lower permeability sandstones. Steam injection, especially at short times, is accompanied by condensation and flow of the resulting hot water away from the injector. Likewise, for live steam to enter the matrix of a low permeability rock, a substantial capillary entry pressure must be overcome. Producers might also suffer from capillary effects as the formation attempts to maintain capillary equilibrium with fluids in the production hydraulic fracture and the well. Because of the importance of imbibition on oil recovery, it has been studied widely. However, our knowledge of hydrocarbon recovery and fluid displacement in porous media is less than complete. To date, much of the focus on imbibition has centered on carbonaceous rocks. This is a result of the importance of the North Sea Chalks1, the West Texas Carbonates, and the Middle Eastern Limestones. See also Imbibition. / , смачиваемость (wettability), .

WATERING DOWN EFFECT = ЭФФЕКТ РАЗМЫВАНИЯ (или ЭФФЕКТ ВЫМЫВАНИЯ) – Watering Down Effect:- loss in the value of the equity paper issued by a company due to the placement of additional stock.

WATERING PLACE = МЕСТО ЗАПРАВКИ ВОДОЙ – Watering Place is a place other than a spring or well where vessels and vehicles replenish their water supply.

WATERING–UP = ПОЛИВ – A term Watering-Up refers to irrigating after planting – a method used to establish a Cotton crop. / Под Поливом понимается искусственное увлажнение корнеобитаемого слоя почвы и приземного слоя воздуха для улучшения водного и теплового режимов. По назначению различают:- (i) Вегетационные Поливы проводятся весной и летом в период роста и развития сельскохозяйственных культур; (ii) Влагозарядковые Поливы; (iii) Удобрительные Поливы; (iv) Освежительные Поливы; (v) Посадочные Поливы; (vi) Провокационные Поливы; (vii) Предпосевные Поливы; (viii) Промывочные Поливы; и (ix) Противозаморозковые Поливы. При дождевании применяются все виды поливов; при поверхностном орошении – вегетационные, влагозарядковые, удобрительные, предпосевные и промывные; при внутрипочвенном орошении – вегетационные, влагозарядковые, удобрительные и предпосевные; при капельном орошении – вегетационные и удобрительные; при аэрозольном – удобрительные, освежительные и противозаморозковые. Поливы должны обеспечивать расчётные орошения режимы, равномерность увлажнения почвы в пределах корнеобитаемого слоя выращиваемых сельскохозяйственных культур по всему полю без непроизводительного сброса воды за его пределы и в более глубокие слои почвогрунтов (за исключением промывных поливов засолённых земель). При механизации и автоматизации полива, правильной технологии его проведения существенно повышается производительность труда поливальщиков, обеспечивается качественный полив при любых уклонах сельскохозяйственных угодий, улучшается мелиоративное состояние орошаемых и прилегающих к ним земель.

WATER INTAKE/OUTFLOW = ПРИТОК/ОТТОК ВОДЫ (или ВПУСК/ВЫПУСК ВОДЫ, или ВОДОЗАБОР/ВОДОСТОК) – Water Intake/Outflow is a structure through which water enters or exits a conduit. / или выходит из трубы.

WATER–JET LOOM = ВОДНОРЕАКТИВНЫЙ ТКАЦКИЙ СТАНОК (или ВОДОСТРУЙНЫЙ ТКАЦКИЙ СТАНОК, или ГИДРАВЛИЧЕСКИЙ ТКАЦКИЙ СТАНОК) – Water Jet Loom:- water-jet weaving machines were first developed in Czechoslovakia in the 1950s and subsequently refined by the Japanese in the 1960s. Water-jet weaving machines are not used as frequently as air jets, but they are preferred for some types of fabrics. The process is unsuitable for yarns of hydrophilic fibers because the fabric picks up too much moisture. Water-soluble warp sizings are used on most staple warp yarns. Therefore, the use of water-jet looms is restricted to filament yarns of acetate, nylon, polyester, and glass; yarns that are non absorbent, and those that do not lose strength when wet. Furthermore, these fabrics come off the loom wet and must be dried. In this technique a water jet is shot under force and, with it, a weft yarn. The force of the water as it is propelled across the shed carries the yarn to the opposite side. This machine is economical in its operation. A water jet of only 0.1 centimeter is sufficient to carry a yarn across a 48 inch shed. The amount of water required for each weft yarn is less than 2.0 cubic centimeters. Water-jet machines can reach speeds of 2 000 meters of picks per minute. The water-jet looms can produce superior high quality fabrics that have good appearance and feel. Both air and water jet weaving machines weave rapidly, provide for laying different colors in the weft direction, and produce uniform, high quality fabrics. They are less noisy and require less space than most other types of weaving machines. They cause Minimal damage to warp yarns during the weaving operation, because the air or water jets are less abrasive than moving metal parts. The speeds of shuttle less weaving machines can be compared by measuring the picks per minute (ppm) or the yards laid per minute (ypm) in weft insertion. In 1990, The top speed for a projectile weaving machine was 420 ppm with between 1 000 and 1 203 ypm weft insertion. Flexible rapier weaving machines operated at 524 ppm and rigid rapiers at 475 ppm, laying weft at upto 1 404 and 930 ypm, respectively. Air jets could lay as many as 1 200 ppm and water jets upto 1 500 ppm, laying 2 145 and 2 360 ypm, respectively. If a fabric 60 inches wide is woven on each machine at a density of 50 pice per inch, Approximately 84 yards of weft yarn would be needed to produce an inch of fabric. In theory, the projectile would produce approximately 8.4 inches of fabric per minute; the flexible rapier, 10.5 inches; the rigid rapier, 9.5 inches; the air jet, 24 inches; and the water jet, 30 inches.The slowest of the new machines could produce a yard of fabric in 4.3 minutes, and the fastest would take just 1.2 minutes. Seldom do weaving machines operate at full capacity, but even at 50 percent efficiency such machines could produce a yard of fabric every 2.5 minutes. See also Jet Loom. A Water-Jet Loom is a machine for weaving cloth (loom) which uses a jet of water to insert the weft (crosswise threads) into the warp (lengthwise threads). The new (2008) Toyota LWT710 water-jet loom is a fusion of the fundamental technologies in the LW Series water-jet looms perfected over the past 40 years, the carefully planned functioning concepts of the JAT710 air-jet loom which has achieved the major share of the global market and the needs and expectations of our customers. Through our unwavering commitment to customer satisfaction, we have created the ideal weaving machine, combining higher speed and lower vibration with a wide range of new and improved features. The new LWT710 Series Water Jet Loom has these superb features:- (i) Enhanced Operability:- the function panel offers vastly improved communications features. We have made use of the latest in electronics technology and troubleshooting, with our sights firmly set on the future of fabric mills to achieve not just great visibility, but also dramatically improved machine operation and handling. (ii) High Speed:- maximum speed – 1 250 rpm. A new beating mechanism, new frame structure, ultra-fast CPU processing speed and other design features enable operation at a maximum speed of 1 250 rpm (R/S 190, single-color, crank-shedding specifications). (iii) High Quality:- offering a short stroke and extended weft insertion time has allowed us to dramatically shorten the distance from the beating point to the heald frame. Beat-up performance is improved and shedding volume is reduced enabling the weaving of high-quality textiles while placing minimum strain on the yarn. (iv) Versatility:- use of the beating link and let-off/take-up controller from the dependable and proven JAT710, along with use of a new weft-insertion mechanism, make possible weaving that is gentle on the yarn, from light to heavy fabrics. The full complement of standard equipment, together with a diverse range of options that include our own innovative w-FIS and a ten-frame negative cam, make it easy to accomplish weaving fabrics of varying fineness, high-density fabrics, and more. (v) Low Vibration:- through 3D design and computer analysis, we have achieved optimization of the frame structure, including the cross-rail connections, along with lighter weight and optimized balance for the beating mechanism. This in turn achieves low vibration during high-speed operation. (vi) Communications Features:- the function panel enables communication in-house as well as with customers and the Toyota head office through the application of TMS or iTTCS. Water Jet Loom is a type of loom without shuttles. Method of inserting weft yarn:- a jet of water is used to insert the weft yarn. Characteristics:- High speed operation is possible. Since water is used only filament yarns (synthetic fabrics) can be woven. Water Jet Loom:- The first loom to make use of a water jet for insertion of weft was developed by Satyr.The loom was first shown at the Brussels textile Machinery Exhibition in 1995. Scope of Water Jet Loom:- (i) Weft and warp yarn must be insensitive, i.e hydrophobic in nature; (ii) Weaving of the water attractive fabric is not possible by the water jet loom; (iii) Thermoplastic yarns offer the advantages of severance of weft by a heated blade and the provision of a heat selvedge by fusing; and (iv) It has required miniature pump to feed water under pressure to the nozzle. Features of Water Jet:- New ZW8100 Water Jet Loom for the next generation. The water jet loom demonstrated at ITMA ASIA 2005 as a concept model now has debuted as the ZW8100. The new model ZW8100 inherited the basic abilities of the ZW series that has enjoyed an excellent reputation as the global standard water jet loom and has enhanced stability at high speed. The ZW8100 intends to succeed and advance the long-cultivated basic abilities of water jet looms – weaving technology, high-speed ability, quality, and energy-saving – for the next hundred years. Tsudakoma consistently emphasises the basic abilities:- high speed, quality, versatility, eco-friendliness. Tsudakoma particularly focuses on ultra high speed ability – the mission of all jet looms. Because it considers ultra high speed as the base, Tsudakoma has optimised the frame structure, the beating system and the shedding system, and employs a newly-developed nozzle. A navigation system that enjoys a good reputation for air jet looms is also employed while taking careful note on higher versatility and

better operability. To give the best answer to reply to market demands, fulfilling basic abilities is indispensable. Flexibility to woven material is also increased. True user-friendliness is attained. The ZAX9100 is well-established for its ultra-high speed ability. The ZAX9100HD is a package model that can weave heavy fabrics at high speed while keeping quality high with enhanced basic abilities and new technology. Tsudakoma's unique heavy-duty structure responds to user's strict quality demands. The exhibit demonstrated weaving quality yarn-dyed shirting at high speed. The ZAX9100 is ranked as a premium air jet loom provided with the 'Weave Navigation System'. It handles diverse responsibilities, such as being cost-competitive, quick style change, value-added fabrics, and developing new fabrics that will be required more than ever. The ESS Electronic Shedding System, 6-colour weft selection, and the PSC support weaving value-added fabrics of various kinds and thickness wefts. The PSC Programmable Speed Control controls the rpm per one pick according to weft kinds and fabric weaves in order to attain stable weaving, thus the operation efficiency is considerably increased. Fabrics formerly limited to rapier looms are woven easily keeping quality. Tsudakoma has the largest air jet terry weaving experience in the world. Many terry weavers consider Tsudakoma's air jet looms the standard. While fusing the ultra-high speed ability of the ZAX9100 with its abundant terry weaving know-how, various elaborately designed towels such as pileheight changes and pile-cycle switching between 3 to 7-picks can be woven with a pleasant texture. In combination with the electronic Jacquard motion higher value-added terry cloth can be woven. The 'Versa-Terry System' is the integration of Tsudakoma's terry weaving technology. Various systems that Tsudakoma developed especially for terry are enhanced and new technology for weaving diversified terry cloth designs is employed. The 'Versa-Terry System' inherits and advances the thorough experience of the world's largest record of air-jet terry weaving machines. Improving all of its basic abilities:- speed, versatility, quality, energy saving, operability, the ZAX9100-Terry realizes true user-friendliness. Water Jet Loom Advantages:- Water jet propulsion has many advantages over other forms of marine propulsion, such as stern drives, outboard motors, shafted propellers and surface drives. These advantages include:- (1) Excellent Maneuverability:- (i) Precise steering control at all boat speeds; (ii) 'Zero Speed' steering effect provides 360° thrusting ability for docking and holding stationary; (iii) Sideways movement possible with multiple jet installations; and (iv) High efficiency astern thrust with 'power-braking' ability at speed. (2) High Efficiency:- (i) Propulsive coefficients as good or higher than the best propeller systems achievable at medium to high planning speeds; and (ii) Flexibility when using multiple water jets may allow operators to continue to operate efficiently on fewer drives. (30 Low Drag and Shallow Draught:- (i) Absence of underwater appendages reduces hull resistance; and (ii) Shallow draught - the water jet intake is flush with hull bottom to allow access to shallow water areas and beach landings with no risk of damage to the drive. (4) Low Maintenance:- (i) No protruding propulsion gear eliminates impact damage or snags; and (ii) Minimum downtime and simple maintenance routines. (5) Smooth and Quiet:- (i) No hull vibration, no torque effect and no high speed cavitations gives maximum comfort levels on board; and (ii) Low underwater acoustic signature. (6) Total Safety:- No exposed propeller for complete safety around people in the water and marine life. (7) Maximum Engine Life:- (i) Jet unit impeller is finely matched to engine power; (ii) Power absorption is the same regardless of boat speed; and (iii) No possibility of engine overload under any conditions. (8) Simplicity:- (i) Single packaged module; and (ii) No heavy and expensive gearbox required for many installations. Simple driveline from engine to jet coupling. (9) Easy Installation:- (i) Complete factory tested package, ready to bolt in; and (ii) No difficult engine alignment problems. Comments on Water Jet:- Water jet loom is produce shed by using the high force of water. In the weaving I think that is a tremendous invention. See also Air Jet Loom. WATERLESS DYEING = БЕЗВОДНОЕ КРАШЕНИЕ – DyeCoo Waterless Dyeing:- launch of the first commercial dyeing machine that uses supercritical carbon dioxide instead of water. The textile industry is believed to be one of the biggest consumers of water. In conventional textile dyeing, large amounts of water are used both in terms of intake of fresh water and disposal of wastewater. On average, an estimated 100–150 liters of water is needed to process 1 kg of textile material, with some 28 billion kilos of textiles being dyed annually. Water is used as a solvent in many pretreatment and finishing processes, such as washing, scouring, bleaching and dyeing. Hence, the elimination of process-water and chemicals would be a real breakthrough for the textile dyeing industry, and it seems this has now come to fruition, with the launch of the world's first ever industrial dyeing machines that uses super carbon dioxide (CO_2) as a replacement for water. The manufacturer behind this system is the Dutch company, DyeCoo Textile Systems BV. Years of extensive research and development has gone into producing the novel, completely water-free dyeing process which has considerable lower operational costs compared to conventional dyeing processes. Award-winning process:- from an environmental point of view, the new dyeing machine is revolutionary. The machine was unveiled this summer and is so new it has yet to be given a name, although the technology behind the process was unveiled to the world last year when DyeCoo won the Herman Wijffels Innovation Award for the best innovative eco-based product for 2009/10. Reinier Mommaal of DyeCoo explains that the idea for water-free dyeing is nothing new. 'The principle of dyeing with CO_2 was invented in Germany twenty-five years ago. Developing a wellfunctioning machine, however, turned out to be too expensive'. DyeCoo Textile Systems' parent company, Feyecon, began tackling this issue ten years ago in partnership with the Delft University of Technology and Stork. This ultimately resulted in DyeCoo (which was formed in 2008), which literally means dyeing with CO_2. 'The benefits are huge', continues Reinier Mommaal. 'There is no water consumption, no use of chemicals, no drying and it is twice as fast. This also makes it attractive in terms of energy. It is consequently not surprising that people from around the world have shown interest in this new machine'. The disperse dyes used in the process were specially produced in cooperation with another Dutch company, Triade, responsible for the production and distribution of the CO_2 dyes, with Setex (Germany) responsible for the control system. Production machine:- the final partner of DyeCoo to make history is Tong Siang Co. Ltd (Thailand), part of the Yeh Group. The polyester textile producer will become the first textile mill to implement the commercial-scale supercritical fluid CO_2 machine into production, branding the process as DryDye. Supercritical fluid CO_2 enables polyester to be dyed with modified disperse dyes. It causes the polymer fiber to swell, allowing the disperse dye to diffuse and penetrate the pore and capillary structure of the fibers. The viscosity of the dye solution is lower, making the circulation of the dye solutions easier and less energy intensive. This deep penetration also provides effective coloration of polymers. Furthermore, dyeing and removing excess dye can be carried out in the same vessel; and residue dye is minimal and may be extracted and recycled. Currently, the process is limited to dyeing of scoured polyester fabric run in batches of 100–150 kg, although DyeCoo and its partners are developing reactive dyes for cellulosics to be available for use in this process in the not too distant future. Web-site:- http://www.dyecoo.com. See also Dyeing, and Solvent Dyeing. Dyeing with CO_2:- when carbon dioxide is heated to above 31 °C and pressurised to above 74 bar, it becomes supercritical, a state of matter that can be seen as an expanded liquid, or a heavily compressed gas. In short, above the critical point, carbon dioxide has properties of both a liquid and a gas. In this way supercritical CO_2, has liquid-like densities, which is advantageous for dissolving hydrophobic dyes, and gas-like low viscosities and diffusion properties, which can lead to shorter dyeing times compared to water. Compared to water dyeing, the extraction of spinning oils, the dyeing and the removal of excess dye can all be carried out in

one plant in the carbon dioxide dyeing process which involves only changing the temperature and pressure conditions; drying is not required because at the end of the process CO_2 is released in the gaseous state. The CO_2 can be recycled easily, up to 90% after precipitation of the extracted matter in a separator. / ДайКу Тэкстайл Систэмз Би.Фи. (DyeCoo Textile Systems BV). WATER LEVEL = УРОВЕНЬ ВОДЫ – Water Level is the elevation of the surface of the water in a boiler.

WATERLINE = ВАТЕРЛИНИЯ – Waterline is a line painted on a hull which shows the point to which a ship sinks when it is properly trimmed. Waterline is the line painted on the side of the vessel at the water's edge to indicate the proper trim. The Waterline is the line where the hull of a ship meets the surface of the water, in concept or reality. Specifically, it is also the name of a special marking, also known as the International Load Line, Plimsoll Line or Water Line (positioned amidships), that indicates the draft of the ship and the legal limit to which a ship may be loaded for specific water types and temperatures in order to safely maintain buoyancy, particularly with regard to the hazard of waves that may arise. Temperature affects the level, because warm water provides less buoyancy, being less dense than cold water, as does salinity, because fresh water is less dense than seawater. For vessels with displacement hulls, the hull speed is determined by, among other things, the waterline length. In a sailing boat, the waterline length can change significantly as the boat heels, and can dynamically affect the speed of the boat. The waterline can also refer to any line on a ship's hull that is parallel to the water's surface when the ship is afloat in a normal position. Hence, all waterlines are one class of 'ships lines' used to denote the shape of a hull in Naval Architecture plans. In aircraft design, the term 'Waterline' refers to the vertical location of items on the aircraft. This is (normally) the 'Z' axis of an XYZ coordinate system, the other two axes being the Fuselage Station (X) and Buttock Line (Y). The purpose of a load line is to ensure that a ship has sufficient freeboard (the height from the water line to the main deck) and thus sufficient reserve buoyancy. The freeboard of commercial vessels is measured between the lowest point of the uppermost continuous deck at side and the waterline and this must not be less than the freeboard marked on the Load Line Certificate issued to that ship. All commercial ships, other than in exceptional circumstances, have a load line symbol painted amidships on each side of the ship. This symbol must also be permanently marked, so that if the paint wears off it remains visible. The load line makes it easy for anyone to determine if a ship has been overloaded. The exact location of the load line is calculated and/or verified by a Classification Society and that society issues the relevant certificates. This marking was invented in the 1870s by Samuel Plimsoll. The first official loading regulations are thought to date back to maritime legislation originating with the kingdom of Crete in 2500 BC when vessels were required to pass loading and maintenance inspections. Roman sea regulations also contained similar regulations. In the Middle Ages the Venetian Republic, the city of Genoa and the Hanseatic League required ships to show a load line. In the case of Venice this was a cross marked on the side of the ship, and of Genoa three horizontal lines. The first XIX century loading recommendations were introduced by Lloyd's Register of British and Foreign Shipping in 1835, following discussions among shipowners, shippers and underwriters. Lloyd's recommended freeboards as a function of the depth of the hold (three inches per foot of depth). These recommendations, used extensively until 1880, became known as 'Lloyd's Rule'. In the 1860s, after increased loss of ships due to overloading, a British MP, Samuel Plimsoll, took up the load line cause. A Royal Commission on unseaworthy ships was established in 1872, and in 1876 the United Kingdom Merchant Shipping Act made the load line mark compulsory, although the positioning of the mark was not fixed by law until 1894. In 1906, laws were passed requiring foreign ships visiting British ports to be marked with a load line. It was not until 1930 (The 1930 Load Line Convention) that there was international agreement for universal application of load line regulations. In 1966 the International Convention on Load Lines was concluded in London which re-examined and amended the 1930 rules. The 1966 Convention has since seen amendments in 1971, 1975, 1979, 1983, 1995 and 2003, none of which have entered into force. / Лойдз (Lloyd's). Самьюэл Плимсэл (Samuel Plimsoll). Под Ватерлинией понимается линия пересечения корпусом плавающего судна поверхности воды. WATER–LOGGED = ПОДТОПЛЕННОЕ (или ПОЛУЗАТОПЛЕННОЕ) – Water-Logged:- filled with water but afloat.

WATERLOGGED FIELD = ПОДТОПЛЕННОЕ ПОЛЕ (или ПЕРЕУВЛАЖНЁННОЕ ПОЛЕ, или ЗАБОЛОЧЕННОЕ ПОЛЕ) – Waterlogged Field is a field which continuously has standing water and cannot be drained. The water level may not be deep.

WATERLOGGING = ПОДТОПЛЕНИЕ (или ПЕРЕУВЛАЖНЕНИЕ, или ЗАБОЛАЧИВАНИЕ) – Waterlogging is defined as the state of land in which the subsoil water table is located at or near the surface with the result that the yield of crops commonly grown on it is reduced well bellow for the land, or, if the land is not cultivated, it cannot be put to its normal use because of the high subsoil water table. Salinity Control is defined as the physical control, management, and use of water and related land resources in such a way as to maintain or reduce salt loading and concentrations of salt in water supplies. Drainage of irrigated land is required to reduce waterlogging and soil salinization that inevitably accompanies waterlogging in arid zones. At present, about 20–30 million hectares of irrigated land are seriously affected by salinity. Waterlogging:- impeded drainage; or soil saturated with water but not necessarily with standing water. Another problem associated with excessive irrigation on poorly drained soils is Waterlogging. This occurs (as is common for salinization) in poorly drained soils where water can't penetrate deeply. For example, there may be an impermeable clay layer below the soil. It also occurs on areas that are poorly drained topographically. What happens is that the irrigation water (and/or seepage from canals) eventually raises the water table in the ground – the upper level of the groundwater – from beneath. Growers don't generally realize that waterlogging is happening until it is too late – tests for water in soil are apparently very expensive. The raised water table results in the soils becoming waterlogged. When soils are water logged, air spaces in the soil are filled with water, and plant roots essentially suffocate – lack oxygen. Waterlogging also damages soil structure. Worldwide, as much as 10% of all irrigated land may suffer from water logging. This is an area about the size of Idaho. As a result, productivity has fallen in this area of cropland. Both waterlogging and salinization could be reduced if the efficiency of irrigation systems could be improved, and more appropriate crops (less water hungry) could be grown in arid and semi-arid regions. In addition, increasing the cost of water to more closely reflect its true value would encourage its conservation, rather than using incentives that essentially encourage wasting water, as some water rights laws in the US do (e.g., the 'use it or lose it' approaches discussed above). We can consider excessive irrigation to be another example of humanities' attempt to increase 'K' in ways that are unsustainable. For example, one could argue that the Central Valley of CA shouldn't be lush and green; it is one of the most agriculturally productive regions of the world only because of irrigation, which may not be sustainable there. Waterlogging is the natural flooding and over-irrigation that brings water at underground levels to the surface. As a consequence, displacement of the air occurs in the soil with corresponding changes in soil processes and an accumulation of toxic substances that impede plant growth. Waterlogging occurs when roots cannot respire due to excess water in the soil profile. Water does not have to appear on the surface for waterlogging to be a potential problem. Improving drainage from the inundated paddock can decrease the period at which the crop roots are subjected to anaerobic conditions. While raised beds are the most intensive management strategy, they are also the most effective at improving drainage. Waterlogged soils release increased amounts of nitrous oxide (N_2O), a particularly damaging greenhouse gas. Waterlogging occurs whenever the soil is so wet that there is insufficient oxygen in the pore space for plant roots to be able to adequately respire. Other gases detrimental to root growth, such as

carbon dioxide and ethylene, also accumulate in the root zone and affect the plants. Plants differ in their demand for oxygen. There is no universal level of soil oxygen that can identify waterlogged conditions for all plants. In addition, a plant's demand for oxygen in its root zone will vary with its stage of growth. Lack of oxygen in the root zone of plants causes their root tissues to decompose. Usually this occurs from the tips of roots, and this causes roots to appear as if they have been pruned. The consequence is that the plant's growth and development is stalled. If the anaerobic circumstances continue for a considerable time the plant eventually dies. Most often, waterlogged conditions do not last long enough for the plant to die. Once a waterlogging event has passed, plants recommence respiring. As long as soil conditions are moist, the older roots close to the surface allow the plant to survive. However, further waterlogging-induced root pruning and/or dry conditions may weaken the plant to the extent that it will be very poorly productive and may eventually die. Many farmers do not realise that a site is waterlogged until water appears on the soil surface. However, by this stage, plant roots may already be damaged and yield potential severely affected. Waterlogging occurs when the soil profile or the root zone of a plant becomes saturated. In rain-fed situations, this happens when more rain falls than the soil can absorb or the atmosphere can evaporate. Western Australia's 'Mediterranean' climate of cool and wet winters and hot dry summers produces more rain than the atmosphere can evaporate every winter. The amount of 'excess' rain is particularly large in the higher rainfall areas of the south-west. Most data on the cost of waterlogging and inundation are from the Upper Great Southern, although the problems are widespread. Cereal crop yields decrease by about 150 kg/ha for every 10 mm of rainfall in excess of the decile 5 rainfall during August in the Upper Great Southern. In the same study it was calculated that over a 10 year period in eight shires from that region, excess rainfall costs farmers about 14% in lost wheat production each year. Waterlogging and inundation slow pasture growth in winter and delay the spring flush. Pasture growth in winter is at least five times more valuable than extra production in late spring. Waterlogged legumes grow more slowly than waterlogged grasses, so waterlogged pastures become grassy and weedy. In wet years, waterlogging reduces the area that can be cropped. When paddocks are waterlogged shortly after seeding, germination and emergence are often reduced; and crops may have to be re-sown when the soil is firm enough to support machinery. Waterlogged and inundated areas contribute recharge to saline aquifers, are very susceptible to water erosion and are prone to soil structure decline if cultivated or stocked when too wet. The best way to identify problem areas is to dig holes about 40 cm deep in winter and see if water flows into them. If it does, the soil is waterlogged. Digging holes for fence posts often reveals waterlogging. Some farmers put slotted PVC pipe into augered holes. They can then monitor the water levels in their paddocks. Symptoms in the crop of waterlogging include:- (i) yellowing of crops and pastures; and (ii) presence of weeds such as toad rush, cotula, dock and Yorkshire fog grass. Low levels of oxygen in the root zone trigger the adverse effects of waterlogging on plant growth. Waterlogging of the seedbed mostly affects germinating seeds and young seedlings. Established plants are most affected when they are growing rapidly. Therefore, if a soil becomes waterlogged in July, final yields may not be greatly reduced; soils are cold, the demand for oxygen is low and plant growth is slow at this time of year. Prolonged waterlogging during the warmer spring period could be more detrimental, however the probability for this to occur is much lower than waterlogging in July. When plants are growing actively, root tips begin to die within a few days of waterlogging. The shallow root systems that then develop limit the uptake of nutrients (particularly nitrogen) and water, particularly when the soil profile starts to dry in spring. As a result plants may ripen early and grains may not fill properly. Nitrogen is lost from waterlogged soils by leaching and denitrification (degassing). Denitrification leads to the gaseous loss of nitrous oxide (N_2O) into the atmosphere, which is a major greenhouse gas. These losses, together with the lowered ability of plants to absorb nutrients from waterlogged soil, cause the older leaves to yellow. Waterlogging also directly reduces nitrogen fixation by the nodules of legume crops and pastures. Drainage can be improved on many sites and is the first thing to consider once a waterlogging problem has been identified. Options might vary from shallow surface drains (i.e. Spoon- and 'W'-drains) to more intensive drainage using wide-spaced furrows, to the intensive drainage form of raised beds. The efficiency of surface drainage increases in that order as does the degree of management. Waterlogging:- saturation of a soil with water, causing air to be displaced to the point where there is insufficient oxygen for unrestricted root activity. При подтоплении заболачиваются и засоляются почвы, уменьшается продуктивность лугов и лесов, ухудшается санитарно-гигиеническое состояние местности, снижается прочность фундаментов сооружений и прочее. К подтопленным относят территории, на которых глубина залегания уровней грунтовых вод меньше допустимой для хозяйственного использования (для лугов она составляет 0.6–0.8 метра (м), пашни – 0.8–1.4 м, садов – 1.2–1.8 м, мелких населённых пунктов – 1.5–2 м, городов – 3–4 м). Для защиты земель от подтопления подтопленные территории ограждают от избыточных поверхностных вод, притекающих с соседних возвышенностей (нагорные каналы, противофильтрационные завесы); понижают уровни грунтовых вод с применением мелиоративных мероприятий – строят осушительные системы и осуществляют дренаж сельскохозяйственных и застроенных земель (наиболее распространены глубокие горизонтальные дрены, располагаемые по границе защищаемой территории – головные дрены); организуют поверхностный сток (особенно для населённых пунктов). В бывшем Союзе Советских Социалистических Республик (СССР) для борьбы с подтоплениями были сооружены дренажи на сельскохозяйственных угодьях Костромской Низины (подтоплены Горьковским Водохранилищем), в Мургабском Оазисе (Каракумским Каналом), а также в городах Москва (Перервинской Плотиной) и Никополь (Каховским Водохранилищем) и так далее. Под Заболачиванием почвы понимается почвообразовательный процесс, развивающийся в анаэробных условиях в результате действия застойных вод. Начинается с изменения водно-воздушного режима. Приводит к избыточному увлажнению почвы, изменению состава микрофлоры, замедленному разложению растительных остатков и накоплению органического вещества (главным образом торфа), формированию заболоченных и болотных почв. Заболачивание почвы может быть вызвано атмосферными, поверхностными (склоновыми, русловыми) и грунтовыми водами, а также криогенными, биогенными и антропогенными факторами. Чаще наблюдается на тяжёлых по гранулометрическому составу почвах, при подстилании почвенных горизонтов лёгкого гранулометрического состава тяжёлыми суглинками, на мерзлотных почвах. К заболачиванию почвы приводит уничтожение лесной растительности (например, на Севере таёжной зоны), подъём уровня грунтовых вод при гидротехническом строительстве (на побережьях водохранилищ и каналов) и нарушении режима орошения. Заболачивание почвы понижает плодородие почвы, урожайность сельскохозяйственных культур, продуктивность сенокосов и пастбищ. При незначительном заболачивании проводят глубокую вспашку, бороздование и щелевание, устраивают временные каналы. Сильно заболоченные почвы осушают.

WATER MANAGEMENT = УПРАВЛЕНИЕ ВОДОЙ (или МЕЛИОРАЦИЯ) – (1) Water Management is the application of practices to obtain added benefits from precipitation, water, or water flow in any of a number of areas such as irrigation, drainage, wildlife and recreation, water supply, watershed management, and water storage in soil for crop production.

(2) Water Management (element):- for purposes of developing an area plan under the Resource Conservation and Development Program, the conservation, use, and quality of water, including irrigationand rural water supplies; the mitigation of floods and high water tables; the repair and improvement of reservoirs; the improvement of agricultural water management; and the improvement of water quality. / Программа Сохранения и Развития Ресурсов.

WATERMARK = ВОДЯНОЙ ЗНАК – Watermark is a design produced by creating a variation in the thickness of paper fiber during the wet-paper phase of papermaking. This design is clearly visible when the paper is held up to a light source. Watermarks are known to have existed in Italy before the end of the XIII century. Two types of watermark have been produced. The more common type, which produces a translucent design when held up to a light, is produced by a wire design laid over and sewn onto the sheet mold wire (for handmade paper) or attached to the 'dandy roll' (for machine-made paper). The rarer 'shaded' watermark is produced by a depression in the sheet mold wire, which results in a greater density of fibers – hence, a shaded, or darker, design when held up to a light. Watermarks are often used commercially to identify the manufacturer or the grade of paper. They have also been used to detect and prevent counterfeiting and forgery. / Водяной Знак – филигрань, видимое на просвет изображение на бумаге. Наносится валиком (эгутёром) с помощью проволочной фигуры водяного знака. Применяется для изготовления документов, денег, ценных бумаг во избежание подделок. Изучается филигранографией. В книговедении помогает датировать рукописи и старопечатные издания. Водяной Знак, или Филигрань, внутреннее, видимое на просвет изображение на бумаге, наносимое в процессе её производства. Водяные знаки на бумаге Европейского производства появились в XIII веке, в России – во 2-й половине XVII века. Изучение водяного знака, определение точного места и времени производства бумаги имеет важное значение для правильной интерпретации источника. С 1723 в России, вслед за другими Европейскими странами, водяные знаки, во избежание подделок официальных и денежных документов, наносятся на гербовую бумагу (изображение Государственного герба и слов:- 'Гербовая Бумага'). Водяные знаки обычно делаются на бумаге через определённые промежутки или по всему полю бумаги в виде однообразного рисунка или узора, что позволяет отличить настоящие деньги, ценные бумаги и документы, марки и другое от фальшивых. Водяными знаками пользуются также как средством украшения бумаги. Нанесение водяного знака производится обычно ровнителем (эгутером) или при помощи цилиндров круглосеточной машины на мокрое полотно бумаги.

WATER MARK = ОТМЕТИНА ОТ ВОДЫ (или ПРОМОЧКА) – Water Marks:- water dropping mark on fabric. Finishing defect. Water Mark:- irregular light and dark bands giving a rippled effect similar to moire. Note:- this defect is caused by the fabric having been subjected to excessive heat and/or pressure and occurs more often in fabrics having a ribbed or corded structure. / Порок или дефект заключительной отделки. Промочка – Неравномерная Окраска – тёмные и светлые пятна или продольные полосы, которые образуются вследствие плохой подготовки ткани к отбеливанию и в результате нарушения режима крашения. Водное Пятно (Water Mark):- порок ткани; неправильные светлые и тёмные полосы, дающие отражение, подобное муару. Примечание:- (1) Муар – дефект в виде нежелательного мраморного внешнего вида поверхности полотна. (2) Этот порок вызван тканью, подверженной излишне высокому нагреванию и (или) давлению, и происходит чаще всего в тканях, имеющих ластичное переплетение.

WATER MASS = ВОДНАЯ МАССА – Water Mass:- body of ocean water with a distinctive narrow range of temperature and salinity and a particular density resulting from these two parameters. Water masses are formed as the result of climatic effects in specific regions. Antarctic bottom water is an important water mass that forms on the Antarctic continental shelf as a cold, dense residual brine during the formation of sea ice. Its salinity of 34.62 parts per thousand and temperature of –1.9 °C (28.6 °F) result in a high density of 1.027 89 grams per cubic centimeter, causing it to sink and flow northward along the bottom into the southern oceans. Mediterranean water is another example of a water mass. Excessive evaporation, low rainfall, and high temperatures continually generate large volumes of warm (11.9 °C), salty (36.5 parts per thousand) water. Its density of 1.027 78 causes it to sink to the bottom of the Mediterranean and overflow across the submarine sill at the Strait of Gibraltar, whence it sinks and spreads at a depth of about 1 000 meters (3 300 feet) in the Atlantic. Plotted on temperature-salinity diagrams, samples from a single water mass tend to cluster in unique groups or elongate zones. / Водные Массы – объём воды, соизмеримый с площадью и глубиной водоёма и обладающий относительной однородностью физико-химических характеристик, формирующихся в конкретных физико-географических условиях. Основными факторами, формирующими водные массы, являются тепловой и водный балансы данного района и, следовательно, основные показатели водной массы – температура и солёность. Часто при анализе водных масс учитываются также показатели содержания в ней кислорода и других гидрохимических элементов, которые дают возможность проследить распространение водной массы из района её формирования и трансформацию. Характеристики водных масс не остаются постоянными, они подвергаются в определённых пределах сезонным и многолетним колебаниям и изменяются в пространстве. По мере распространения из района формирования водные массы трансформируются под влиянием изменений условий теплового и водного балансов и перемешиваются с окружающими водами. Различают первичные и вторичные водные массы. К первичным водным массам относятся те, отличительные признаки которых формируются под непосредственным влиянием атмосферы и характеризуются наибольшими пределами изменений в некотором объёме воды. К вторичным – водные массы, формирующиеся в результате перемешивания первичных водных масс и отличающиеся наибольшей однородностью своих признаков. В вертикальной структуре Мирового океана выделяются водные массы:- поверхностные (первичные) – до глубины 150–200 метров (м); подповерхностные (первичные и вторичные) – на глубине от 150–200 м до 400–500 м; промежуточные (первичные и вторичные) – на глубине от 400–500 м до 1 000–1 500 м, глубинные (вторичные) – на глубине от 1 000–1 500 м до 2 500–3 000 м; придонные (вторичные) – ниже 3 000 м. Границами между водными массами являются зоны фронтов Мирового океана, зоны раздела и зоны трансформации, которые прослеживаются по увеличивающимся горизонтальным и вертикальным градиентам основных показателей водных масс. В каждом из океанов имеются характерные для них водные массы. Например, в Атлантическом Океане различаются:- водные массы Гольфстрима, Северная тропическая, Южная тропическая и другие поверхностные водные массы, Северная субтропическая, Южная субтропическая и другие подповерхностные водные массы, Северная Атлантическая, Южная Атлантическая и другие промежуточные водные массы, Средиземноморская глубинная водная масса и другие; в Тихом Океане – Северная тропическая, Северная центрально-субтропическая, Южная тропическая и другие поверхностные водные массы, Северная субтропическая, Южная субтропическая и другие подповерхностные водные массы, Северная Тихоокеанская, Южная Тихоокеанская и другие промежуточные водные массы, Тихоокеанские глубинные водные массы и другие. При изучении водных масс применяется метод T, S-кривых и изопикнический метод, позволяющие установить однородность температуры, солёности и других показателей на кривой их вертикального распределения.

WATER MODE = ВОДНЫЙ РЕЖИМ – Water Mode consists of navigable rivers, canals, the Great Lakes, the St. Lawrence Seaway, the Intercoastal Waterway, ocean shipping channels; ports; commercial ships and barges, fishing vessels, urban ferries, and recreational boats. / Водный Режим – изменение во времени расходов воды рек, уровней и объёмов воды в реках, озёрах, водохранилищах и болотах. Водный режим тесно связан с сезонными изменениями климата. В районах с тёплым климатом на

водный режим основное влияние оказывают атмосферные осадки и испарение; в районах с холодным и умеренным климатом очень существенна роль температуры воздуха. Водный режим рек проявляется в виде суточных, декадных, месячных, сезонных и многолетних колебаний; слагается из ряда характерных периодов (фаз), зависящих от сезонных изменений условий питания рек. Различают следующие фазы водного режима:- половодье, паводки и межень. Режим питания рек неравномерен в течение года вследствие неравномерности выпадения атмосферных осадков, таяния снега и льда и поступления их вод в реки. Наблюдаемые колебания уровня воды вызываются в основном изменением величины расхода воды, а также действием ветра, ледовых образований, хозяйственной деятельностью человека. Водный режим озёр определяется соотношением между количеством осадков, выпадающих на зеркало озера, испарением, поверхностным и подземным притоком в озеро, поверхностным и подземным стоком воды из озера; размерами озера, его формой, закономерностью изменения площади водного зеркала при изменении уровня, деятельностью ветра, определяющей размеры волн, высоту сгонов и нагонов уровня. Колебания уровня озера могут быть сезонные, годовые и кратковременные. Водный режим болот обусловливается климатическими и гидрологическими условиями, рельефом местности, характером растительности. Хозяйственная деятельность человека вносит всё большие изменения в водный режим. Водный Режим почвы – совокупность всех явлений, определяющих поступление, передвижение, расход и использование растениями почвенной влаги. Водный режим почвы – важнейший фактор почвообразования и почвенного плодородия. Главный источник почвенной влаги – атмосферные осадки; иногда значительную роль играют также близко расположенные грунтовые воды; в районах орошаемого земледелия большое значение имеют поливы. Воды атмосферных осадков и талые воды могут частично стекать, образуя поверхностный сток, а часть воды поступает в почву и расходуется растениями. Глубокая зяблевая пахота поперёк склонов затрудняет поверхностный сток и способствует задержанию и лучшему впитыванию талых вод. Атмосферные осадки, талые и поливные воды проникают в почву вследствие её водопроницаемости (способности почвы пропускать воду). Чем больше в почве крупных (некапиллярных) промежутков, тем выше водопроницаемость. Особое значение имеет водопроницаемость для впитывания талых вод. Если осенью почва замёрзла в сильно увлажнённом состоянии, то обычно её водопроницаемость крайне незначительна. Под лесной растительностью, предохраняющей почву от сильного промерзания, или на полях с рано проведённым снегозадержанием талая вода впитывается хорошо. Поступление в почву влаги из грунтовых вод зависит от глубины их залегания и водоподъёмной способности почв и грунта. Грунтовые воды в глинистых почвах по капиллярам поднимаются на большую высоту (до 4 метров (м)), но очень медленно; в почвах лёгкого механического состава – быстрее, но на меньшую высоту. Влажность почвы, то есть содержание в ней влаги, обычно выражают в процентах от массы сухой почвы (Весовая Влажность) или от объёма почвы ненарушенного сложения (Объёмная Влажность); запас воды в почве – в кубических метрах на 1 гектар ($м^3$/га) или в миллиметрах (мм) водного слоя. Почвенная влага может находиться в парообразном, жидком и твёрдом (лёд) состояниях. Обычно содержание водяных паров в почвенном воздухе близко к полному насыщению, а их перемещение в почве происходит под влиянием разности температур – от более тёплых слоёв к более холодным. Подвижность и доступность влаги для растений зависят от связи с твёрдыми частицами почвы, величины и строения почвенных пор, степени и характера заполненности их водой. Различают воду связанную, удерживаемую сорбционными силами, и свободную, находящуюся в почвенных порах вне влияния сорбционных сил. Связанная (сорбированная) вода удерживается поверхностью почвенных частиц с очень большой силой; эта вода практически недоступна растениям. Свободная почвенная влага может быть гравитационной, передвигающейся под преимущественным влиянием силы тяжести и капиллярных сил. Над грунтовой водой залегает зона капиллярной каймы, влага которой легко перемещается под совокупным влиянием капиллярных сил и тяжести; эта влага легко доступна растениям. Содержание влаги в зоне соответствует капиллярной влагоёмкости почвы. При глубоком залегании грунтовых вод в верхней части почвы обособляется зона подвешенной влаги, максимальное содержание которой соответствует наименьшей Влагоёмкости Почвы. Часть влаги этой зоны также доступна растениям. Капиллярная и наименьшая влагоёмкость почвы имеют большое агропроизводственное значение, так как определяют максимальную величину прочного запаса почвенной влаги (Полевая Влагоёмкость). Растения могут иссушить почву до такого состояния, при котором начинается их завядание. Такую степень увлажнения принято называть Почвенной Влажностью Устойчивого Завядания Растений, почвенную влагу сверх влажности завядания – Продуктивной Влагой. Вся влага сверх наименьшей влагоёмкости просачивается до верхней границы капиллярной каймы и далее до уровня грунтовых вод, отток которых происходит по водонепроницаемому ложу-водоупору. Разность в содержании влаги при полном насыщении и наименьшей влагоёмкости называется Водоотдачей Грунта. Величина водоотдачи колеблется от 5% (в суглинистых и глинистых грунтах) до 20–25% (в песках). От содержания воды в почве зависят технологические процессы при обработке почвы, снабжение растений водой, физико-химические и микробиологические процессы, обусловливающие превращение питательных веществ в почве и поступление их с водой в растение. Поэтому одной из основных задач земледелия является создание в почве водного режима, благоприятного для культурных растений, что достигается накоплением, сохранением, рациональным расходованием почвенной влаги, а в необходимых случаях орошением или осушением земель. Водный режим почвы зависит от свойств самой почвы, условий климата и погоды, характера природных растительных формаций; на обрабатываемых почвах – от особенностей выращиваемых культурных растений и техники их возделывания. В создании благоприятного водного режима почвы большую роль играет поддержание в почве прочной мелкокомковатой структуры. Рациональному использованию запасов почвенной влаги культурными растениями способствуют не только своевременные сроки сева, но и удобрения. Установлено, что при правильном применении удобрений растение расходует меньше воды на каждый центнер сухой массы урожая, то есть с помощью удобрений можно понизить непроизводительную трату воды растениями. Полезащитные лесные полосы, умеряя силу ветра и повышая относительную влажность приземного слоя воздуха на окаймленных ими полях, также способствуют понижению непроизводительной траты почвенной влаги культурными растениями в засушливых районах. Выделяют следующие семь типов водного режима почв:- мерзлотный, промывной (пермацидный), периодически промывной, непромывной (импермацидный), десуктивно-выпотной, выпотной и ирригационный. Мерзлотный формируется на территории распространения многолетнемёрзлых горных пород. Особенность его – наличие на некоторой глубине постоянно мёрзлого слоя, над которым в тёплое время года образуется надмерзлотная верховодка. Промывной тип, при котором почва возвращает в атмосферу меньше влаги, чем её получает (избыток влаги просачивается в грунтовые воды); свойствен таёжной зоне с подзолистыми, дерново-подзолистыми и подзолисто-болотными почвами. При периодически промывном типе лишь в отдельные годы возврат влаги в атмосферу меньше её поступления; типичен для лесостепной зоны с серыми лесными почвами. Непромывной тип водного режима почвы отличается тем, что количество возвращаемой в атмосферу влаги приблизительно равно поступлению её с осадками. Осадки промачивают почву не на всю глубину; причем между промоченным слоем почвы и зоной капиллярной каймы возникает горизонт с постоянной низкой влажностью (близкой к влажности завядания), называемый Мёртвым Горизонтом Иссушения. Встречается в степной зоне (с чернозёмными и каштановыми почвами) и в полупустынях. Десуктивно-выпотной и выпотной водные режимы наблюдаются в условиях сухого климата; в почвах, которые питаются не только атмосферными осадками, но и влагой неглубоко расположенных грунтовых вод. Десуктивно-выпотной водный режим почвы возникает в тех случаях, когда поднимающаяся грунтовая влага почти

целиком перехватывается корнями растений. При выпотном режиме грунтовые воды достигают поверхности почвы и испаряются, что часто приводит к засолению земель. Ирригационный режим создаётся в условиях поливного земледелия; многократные поливы промачивают почву на всю глубину проникновения корней, а иногда (при необходимости промывки почвы от избытка солей) и глубже. Регулирование водного режима почвы преследует цель – поддерживать в корнеобитаемом слое в течение всего вегетационного периода достаточное количество продуктивной влаги. При этом очень важно, чтобы часть почвенных пор оставалась занятой воздухом, необходимым для жизни растений и нормальной деятельности микроорганизмов. Достигается это системой агротехнических и агромелиоративных мероприятий.

WATER MOLD = ВОДЯНАЯ ПЛЕСЕНЬ – Water Mold:- also spelled Water Mould any of about 150 species of Fungi belonging to the Order Saprolegniales within the Class Oomycetes. Many of them live in fresh or brackish water or wet soils. Most species are Saprobic (i.e. they live on dead or decaying organic matter), although some cause diseases in certain fishes, higher plants, algae, protozoans, and marine invertebrates. The mycelium (filaments composing the body of the fungus) is conspicuous around bits of decaying organic matter. Reproduction is by motile, asexual spores (zoospores), which may be of two types:- pear-shaped with two apical whiplike structures (flagella) or kidney-shaped with two flagella on the concave side. Zoospores are used to classify different species of water molds. In sexual reproduction, fusion of gametes (sex cells) from differentiated sex organs takes place in an oogonium.

WATER OF THE UNITED STATES = ВОДА СОЕДИНЁННЫХ ШТАТОВ – Water Of The United States:- under the Clean Water Act of 1972, navigable waters, tributaries to navigable waters, interstate waters, the oceans out to 200 miles, and intrastate waters that are used (a) by interstate travelers for recreation or other purposes, (b) as a source of fish or shellfish sold in interstate commerce, or (c) for industrial purposes by industries engaged in interstate commerce. See also Clean Water Act Of 1972.

WATER POLLUTION = ЗАГРЯЗНЕНИЕ ВОДЫ – Water Pollution:- the presence in water of enough harmful or objectionable material that may damage the water's quality. The addition of harmful or objectionable material to water in concentrations or sufficient quantities to adversely affect its usefulness or quality. Water Pollution refers to the presence in water of harmful and objectionable material – obtained from sewers, industrial wastes and rainwater run-off – in sufficient concentrations to make it unfit for use.

WATER POLLUTION ABATEMENT EQUIPMENT = ОБОРУДОВАНИЕ ПО СНИЖЕНИЮ ЗАСОРЕНИЯ ВОДЫ (или ОБОРУДОВАНИЕ ДЛЯ БОРЬБЫ С ЗАГРЯЗНЕНИЕМ ВОДЫ) – Water Pollution Abatement Equipment is an equipment used to reduce or eliminate waterborne pollutants, including chlorine, phosphates, acids, bases, hydrocarbons, sewage, and other pollutants. Examples of water pollution abatement structures and equipment include those used to treat thermal pollution; cooling, boiler, and cooling tower blowdown water; coal pile runoff; and fly ash waste water. Water pollution abatement excludes expenditures for treatment of water prior to use at the plant.

WATER POTENTIAL = ВОДНЫЙ ПОТЕНЦИАЛ – Water Potential is the potential energy of water in a system compared to pure water, when both temperature and pressure are kept the same. It can also be described as a measure of how freely water molecules can move in a particular environment or system. It is measured in kiloPascals (kPa) and is represented by the Greek letter Psi (Ψ). Water potential is never positive but has a maximum value of zero, which is that of pure water at atmospheric pressure. When it comes to impure water, or water that has solutes in it, the more solute there is, the more negative Ψ becomes, since the solute molecules will attract the water molecules and restrict their freedom to move. Movement Of Water Molecules:- Water moves from areas of where water potential is higher (or less negative), to areas where it is lower (or more negative), and we refer to this movement as osmosis. For example, in the diagram below, the solution around the cell is hypertonic, meaning that it has a higher concentration of solute, so a lower water potential, than the inside of the cell. Since the cell has a partially-permeable membrane, allowing the movement of water in and out of it, water will move from inside of the cell, where Ψ is higher, to outside of the cell, where Ψ is lower. This can lead to the death of cells in living organisms. On the other hand, a cell that is placed in a pure water solution could take up water until it bursts and dies. Therefore, cells need an environment that does not differ significantly in its solute concentrations. Water potential is what allows water to get into plant roots when there is more solute within the root cells than the water in the soil. And as we go up the plant, Ψ decreases more and more, drawing water into the stems and then the leaves, which constantly get water evaporated out of them, maintaining a high solute concentration and a low Ψ. In our bodies, solute concentration is regulated through osmoregulation, which controls and maintains water and salt concentrations to keep us alive. Water Potential Formula:- The formula used to calculate Ψ is the following:- $\Psi = \Psi_S + \Psi_P + \Psi_G + \Psi_M$. However, it is often simplified as this formula, which is also correct:- $\Psi = \Psi_S + \Psi_P$. Here, Ψ_S stands for solute potential, Ψ_P for pressure potential, Ψ_G for gravitational potential, and Ψ_M for the matric potential. The pressure potential refers to the physical pressure exerted by objects or cell membranes on water molecules, and it increases with increasing pressure. Note that pressure potential is usually maintained at a positive in plant cells in order for them to hold their shape, allowing the plant to stay rigid. In addition, matric potential takes into account forces between water molecules and surfaces or substances, such as soil or cell membranes. The matric potential is always negative and is more significant in dry systems, such as soils, because we find that the water particles are strongly attached to the soil particles. As the name implies, gravitational potential is the way earth's gravity influences the freedom of water molecules to move. Finally, solute potential depends on the amount of solute in a solution, and it decreases as the concentration of solute increases. See also Soil Water Potential. Water Potential:- Because you will be working with potato cells in the laboratory, you need to understand the concept of water potential. Biologists use this term to describe the tendency of water to leave one place in favor of another. Water always moves from an area of higher water potential to an area of lower water potential. Water potential is affected by two factors:- pressure and the amount of solute. For example, imagine a red blood cell dropped into distilled water. Water will move into the red blood cell and cause the cell to expand, stretching the flexible membrane. At some point, the pressure of the incoming water will cause the cell to pop, just like an over-filled balloon. If a plant cell is placed in distilled water, water will enter the cell and the cell contents will expand. However, the elastic cell wall exerts a back pressure, which will limit the net gain of water.

WATERPOWER = ВОДНАЯ ЭНЕРГИЯ (или ГИДРОЭНЕРГИЯ) – Waterpower:- power produced by a stream of water as it turns a wheel or similar device. The waterwheel was probably invented in the I century BC, and it was widely used throughout the Middle Ages and into modern times for grinding grain, operating bellows for furnaces, and other purposes. The more compact water turbine, which passes water through a series of fixed and rotating blades, was introduced in 1827 by Benoît Fourneyron, a French experimenter, whose first turbine developed about six horsepower. By 1832 he had perfected a turbine capable of developing 50 horsepower. Various modifications followed Fourneyron's design, notably those of James Thomson (about 1851) and James B. Francis (1855), using radial flow inward. Water turbines, used originally for direct mechanical drive for irrigation, now are used almost exclusively to generate electric power. See also Hydroelectric Power. / в 1827 Бенуа Фурнейро (Benoît Fourneyron), Французским экспериментатором, . Дьжеймз Томсэн (James Thomson) (около 1851) и Дьжеймз Би. Фрэнсис (James B. Francis) (1855).

WATERPROOF = НЕПРОМОКАЕМОЕ (или ВОДОУПОРНОЕ, или ВОДОНЕПРОНИЦАЕМОЕ) – Waterproof is a term applied to materials that are impermeable to water; waterproof fabrics have had all their pores closed and are also impermeable to air and very uncomfortable. Waterproof:- materials that are impermeable by water. Waterproof is a term applied to materials that are impermeable

to water; waterproof fabrics have all of their pores closed and are also impermeable to air making them uncomfortable to wear. Waterproof:- (chiefly British) raincoat. Waterproof is a term applied to fabrics whose pores have been closed, and therefore, will not allow water or air to pass through them.

WATERPROOF FABRIC = НЕПРОМОКАЕМАЯ ТКАНЬ (или ВОДОУПОРНАЯ ТКАНЬ, или ВОДОНЕПРОНИЦАЕМАЯ ТКАНЬ) – Waterproof Fabric is a fabric that will not permit water to penetrate it. Among methods of waterproofing are coating the fabric with rubber or plastic. True waterproof fabrics are warm and clammy to wear because their waterproof nature also prevents the evaporation of perspiration and blocks the circulation of air.

WATER PUMPING = НАКАЧИВАНИЕ ВОДЫ (или ВОДООТЛИВ) – Water Pumping:- photovoltaic modules/cells used for pumping water for agricultural, land reclamation, commercial, and other similar applications where water pumping is the main use.

WATER PURIFICATION = ВОДООЧИСТКА (или ОЧИСТКА ВОДЫ) – Water Purification:- treatment of water to make it safe and acceptable for human use. Such treatment has grown vastly in importance in the XX century because of the growth of cities and development of industry and, consequently, of pollution. The first treatment plant was built in 1829 to purify Thames River water by filtration. After the London cholera epidemic of 1854 was traced to a public well, the problem of water treatment received widespread attention. A dramatic proof of the value of treatment came in 1892, when a cholera epidemic that ravaged Hamburg was escaped by the neighbouring city of Altona, Germany, thanks to its filtration system. Cholera outbreaks soon led to development of filtration plants in most of the world's cities, beginning with Western Europe and the United States. Filtration is still the most widely used method of purification. In slow filtration, the water is allowed to pass through a deep layer of fine sand; most of the impurities are removed by the top inch or two of sand, which is removed and cleaned from time to time or, in modern plants, is washed in place by special wash water. In rapid-filtration plants, the water is treated with a coagulant, such as aluminum sulfate, ferric chloride, or ferric sulfate, which flocculates particles, carrying most suspended matter to the bottom in sedimentation tanks. After this preparation, the water is passed at a relatively rapid rate through small beds of coarse sand that are washed from time to time. Heavily polluted waters may be chlorinated both before and after filtration. Aeration (mixing air with the water) is carried out if undesirable amounts of iron and manganese are present; they are held in solution in water only in the absence of oxygen. See also Desalination; and Water Softener. / Водоочистка – комплекс технологических процессов, имеющих целью довести качество воды, поступающей в водопроводную сеть из источника водоснабжения, до установленных нормами показателей. Водоочистка – комплекс технологических процессов, имеющих целью довести качество воды, поступающей в водопровод из источника водоснабжения, до установленных показателей (об очистке сточных вод смотрите в статье Сточные Воды). Первые сведения по водоочистке содержатся в написанной в Индии около 4 000 лет назад на Санскритском языке медицинской книге 'Усрута Сангита', где говорится:- 'Хорошо держать воду в медных сосудах, выставлять её на солнечный свет и фильтровать через древесный уголь'. Древнегреческий врач и естествоиспытатель Гиппократ рекомендовал во избежание заболеваний употреблять кипячёную воду. Первая водоочистная станция с так называемыми медленными фильтрами была построена в 1829 в Лондоне, Великобритания. В России станция очистки водопроводной воды впервые была сооружена в 1888 в Петербурге, станция обеззараживания воды – в 1910 в Нижнем Новгороде. Воды поверхностных водоисточников (рек, озёр) обычно непригодны для питья из-за мутности, цветности и более высокого, чем это допустимо для питьевой воды, содержания бактерий. Поэтому до подачи воды в хозяйственно-питьевой водопровод её осветляют (удаляют взвешенные и коллоидальные частицы), обесцвечивают и обеззараживают (освобождают от болезнетворных микроорганизмов). Для осветления и обесцвечивания воды на очистных сооружениях проводят коагуляцию взвешенных и коллоидальных загрязнений сернокислым алюминием или хлорным железом; основную массу скоагулированных загрязнений задерживают в отстойниках или осветлителях, а воду 'доосветляют' на фильтрах (песчаных или двухслойных). Воду с содержанием взвеси менее 150 милиграммов на литр (мг/л) можно осветлять на контактных осветлителях с введением коагулянта непосредственно перед поступлением воды в слои фильтрующей загрузки. Для обеззараживания в исходную или фильтрованную воду вводят жидкий хлор, хлорную известь или озон. Хорошо осветлённая вода и вода подземных водоносных горизонтов может обеззараживаться ультрафиолетовыми лучами с длиной волны 2 000–3 000 Å, обладающими бактерицидным действием. Источниками ультрафиолетового излучения служат ртутно-кварцевые или аргоно-ртутные лампы. Если вода в источнике водоснабжения имеет жёсткость (суммарное содержание солей кальция и магния), большую, чем допускается по нормам, то её до подачи в водопроводную сеть умягчают. Применяют два метода умягчения воды – реагентный и катионитовый. Реагентный Метод сводится к осаждению солей жёсткости известью (устранение так называемой Карбонатной Жёсткости) и содой (Некарбонатной Жёсткости). Он позволяет снизить общую жёсткость воды до 0.5–0.7 мг-экв/л. Для более глубокого умягчения воды используют Катионитовый Метод (смотрите Иониты), снижающий жёсткость воды до 0.03 мг-экв/л. Если вода содержит более 0.3 мг/л железа, её обезжелезивают. Подземные воды обычно обезжелезивают аэрацией (обогащают кислородом воздуха, который окисляет соли двухвалентного железа в соли трёхвалентного, выпадающие в осадок в виде гидроокиси железа), поверхностные – коагулированием. Для удаления из воды других растворённых солей её опресняют (смотрите Опреснение Воды) или обессоливают на ионитах. Дегазация воды (удаление сероводорода, метана, радона, углекислого газа и других растворённых газов) производится, как правило, аэрацией. Избыток фтора (при его содержании в воде более 1.5 мг/л) удаляют фильтрованием воды через активированную окись алюминия. При наличии в воде радиоактивных веществ её подвергают дезактивации. Дезодорация воды, то есть удаление веществ, обусловливающих привкусы и запахи, достигается сорбцией их активным углём или окислением озоном, двуокисью хлора или перманганатом калия. Водоочистка является наиболее крупнотоннажным производством в народном хозяйстве страны. Только на водоочистных станциях хозяйственно-питьевого водоснабжения бывшего СССР в 1968 очистке было подвергнуто свыше 10 миллиардов кубических метров ($м^3$) воды.

WATER QUALITY = КАЧЕСТВО ВОДЫ – Water Quality (program) is the Smith-Lever 3(d) program that provides information concerning the impacts of agriculture on water quality. Monies are provided for demonstration projects, Hydrologic Unit Area projects, and other initiatives. See also Smith-Lever 3(d) (funds). Water Quality is a term used to describe the chemical, physical, and biological characteristics of water, usually in respect to its suitability for a particular purpose. Water Quality refers to the physical, chemical, biological and organoleptic (taste-related) properties of water. A classification of the quality of watercourses or water bodies according to the uses and, e.g., levels of photochemical, biological, salinity characteristics. / Смис-Ливё (Smith-Lever).

WATER QUALITY ACCOUNTS = РАСЧЁТЫ (или УЧЁТЫ) КАЧЕСТВА ВОДЫ – Water Quality Accounts are the accounts that describe the quality and changes in quality of the water bodies (watercourses) by classes of quality.

WATER QUALITY ACT OF 1987 = АКТ О КАЧЕСТВЕ ВОДЫ ОТ 1987 – Water Quality Act of 1987 (PL 100-4) enacted over a Presidential veto on February 04, 1987. The Act further amended the Clean Water Act of 1972 by focusing greater attention on toxic contaminants, nonpoint source pollution, increased state and local responsibility, and changes in aid from grants to revolving loan programs. The Act authorized measures directing states to develop and implement nonpoint source pollution management programs

(Section 319). States were encouraged to pursue groundwater protection activities as part of their overall nonpoint source pollution control efforts. Federal financial assistance was authorized to support demonstration projects and actual control activities. See also Clean Water Act of 1977.

WATER QUALITY CLAUSES = ОГОВОРКИ О КАЧЕСТВЕ ВОДЫ – Water Quality Clauses are categories of water quality that encompass the overall state of the pollution or cleanliness of water.

WATER QUALITY CRITERIA = КРИТЕРИИ КАЧЕСТВА ВОДЫ – Water Quality Criteria:- specific levels of water quality which, if reached, are expected to render a body of water suitable for its designated use. The criteria are based on specific levels of pollutants that would make the water harmful if used for drinking, swimming, farming, fish production, or industrial processes. Water Quality Criteria:- specific levels of pollutants or characteristic of water which protect a waterbody's designated use, i.e. for drinking, fishing, swimming, agriculture or industrial processes. Water Quality Criteria refer to specific levels of water quality desired for identified uses, including drinking, recreation, farming, fish production, propagation of other aquatic life, and agricultural and industrial processes.

WATER QUALITY INCENTIVES PROGRAM = ПРОГРАММА СТИМУЛИРОВАНИЯ (или ПОБУЖДЕНИЯ К) КАЧЕСТВА ВОДЫ – Water Quality Incentives Program (WQIP):- in 1990, the Food, Agriculture, Conservation, and Trade Act set up a new Agricultural Water Quality Protection Program, generally called the Water Quality Incentives Program. WQIP was a voluntary program that aimed to enroll ten million acres of farmland under agricultural water protection plans by the end of 1995. Incentive payments of up to USD3 500 per year could be provided to producers to adopt water-quality improvement practices (i.e. efficient use of crop nutrients and pesticides, and insurance of safe storage, mixing, and handling of agricultural chemicals and animal wastes) on cropland acres near wellheads, in areas inhabited by threatened species or endangered species, or where agricultural production posed a threat to underground or surface-water quality. Cost-sharing funds were also available, with priority given to producers who improved wildlife habitat. With passage of the Federal Agriculture Improvement and Reform Act of 1996 (Sec. 334), the WQIP was combined into the Environmental Quality Incentives Program, along with the Great Plains Conservation Program, the Colorado River Basin Salinity Control program, and the Agricultural Conservation Program, to be administered by the Natural Resources Conservation Serviceand the Farm Service Agency. See also Environmental Quality Incentives Program (EQIP). / сохранение (conservation).

WATER QUALITY INDEX = ИНДЕКС ПО КАЧЕСТВУ ВОДЫ – A Water Quality Index is a weighted average of selected ambient concentrations of pollutants usually linked to water quality classes.

WATER QUALITY MONITORING = НАБЛЮДЕНИЕ ЗА КАЧЕСТВОМ ВОДЫ (или МОНИТОРИНГ КАЧЕСТВА ВОДЫ) – Water Quality Monitoring:- is the long-term, standardized measurement and observation of the aquatic environment in order to define status and trends. Water quality monitoring is the foundation on which water quality management is based. Monitoring provides the information that permits rational decisions to be made on the following:- (i) describing water resources and identifying actual and emerging problems of water pollution; (ii) formulating plans and setting priorities for water quality management; (iii) developing and implementing water quality management programs; and (iv) evaluating the effectiveness of management actions. See also Monitoring (environmental).

WATER QUALITY STANDARDS = СТАНДАРТЫ КАЧЕСТВА ВОДЫ – Water Quality Standards:- we use water in a variety of ways:- (i) drinking; (ii) washing; (iii) swimming; (iv) fishing; (v) eating (fish from it); and (vi) traveling. Aquatic organisms, such as fish, snails, frogs and insects, live in water for part or all of their lives. To protect human health and aquatic life, states, territories and authorized tribes establish water quality standards. Water quality standards are provisions of state, territorial, authorized tribal or federal law approved by the US Environmental Protection Agency (EPA) that describe the desired condition of a waterbody or the level of protection or mandate how the desired condition will be expressed or established for such waters in the future. These standards form a legal basis for controlling pollution entering the waters of the United States from a variety of sources (e.g., industrial facilities, wastewater treatment plants, and storm sewers). Water quality standards consist of the following:- (i) Designated Uses of the water body; (ii) Criteria to protect designated uses; (iii) Antidegradation Requirements to protect existing uses and high quality waters; and (iv) General Policies to address implementation issues. The Water Quality Standards Regulation requires states, territories and authorized tribes to specify goals and expectations for how each water body is used. Typical designated uses include:- (i) Protection and propagation of fish, shellfish and wildlife; (ii) Recreation; (iii) Public drinking water supply; and (iv) Agricultural, industrial, navigational and other purposes. States, territories and authorized tribes adopt water quality criteria to protect the designated uses of a water body. Water quality criteria can be numeric (e.g., the maximum pollutant concentration levels permitted in a water body) or narrative (e.g., a criteria that describes the desired conditions of a water body being 'free from' certain negative conditions). States, territories and authorized tribes typically adopt both numeric and narrative criteria. One of the principal objectives of the Clean Water Act is to 'maintain the chemical, physical and biological integrity of the Nation's waters'. Antidegradation requirements provide a framework for maintaining and protecting water quality that has already been achieved. Designated uses and water quality criteria are the primary tools states and authorized tribes use to achieve the objectives and goals of the Clean Water Act, and antidegradation requirements complement these tools by providing a framework for maintaining existing uses, for protecting waters that are of a higher quality than necessary to support the Clean Water Act goals, and for protecting waters identified by states and authorized tribes as Outstanding National Resource Waters (ONRWs). Water Quality Standards (WQS) are the provisions of state or federal law that consist of a designated use or uses for the waters and water quality criteria to protect the uses. Water Quality Standards are the state-adopted and EPA approved ambient standards for water bodies. The standards cover the use of the water bode and the water quality criteria which must be met to protect the designated use or uses. / В настоящее время существует несколько всемирных организаций, занимающихся проблемами стандартизации воды. Изданы документы, в которых даны общие и главные рекомендации по качеству воды. Каждая страна также устанавливает дополнительные необходимые нормы для воды своей местности. (1) Всемирная Организация Здравоохранения (ВОЗ), основной задачей которой является решение международных проблем охраны здоровья населения. В 1984 ВОЗ выпустило основной стандарт качества – Руководство По Контролю Качества Питьевой Воды, на основании которого разрабатываются нормативы других государств. Рекомендации ВОЗ явились результатом многолетних фундаментальных исследований и основаны на понятии Переносимого Суточного Потребления (ПСП). С рекомендациями ВОЗ по питьевой воде можно ознакомиться, например, в Директиве ЕС 98/83/ЕС (питьевая), в Директиве № 2009/54/ЕС о минеральной воде. ПСП – это количество вещества в пище или воде в пересчёте на массу тела (мг/кг или мкг/кг), которое может потребляться ежедневно на протяжении всей жизни без заметного риска для здоровья. В результате исследований были получены величины ПСП по основным потенциально вредным для человека веществам. На основе этих данных с применением сложной системы поправочных коэффициентов были разработаны нормы содержания основных вредных веществ в воде. Причём, что очень важно, при определении рекомендуемых величин для воды учитывалось поступление вещества из всех источников (с пищей, дыханием и тому подобным). Такой подход гарантирует, что суммарное суточное потребление вещества из всех источников (включая питьевую воду, содержащую концентрацию этого вещества на уровне, равном или близком рекомендованной величине) не превысит переносимого суточного потребления. (2)

Европейское Сообщество (ЕС) Директива Европейского Сообщества (European Community, EC), касающаяся ‘качества воды, предназначенной для потребления населением’ (80/778/EC) была принята Европейским Советом 15 Июля 1980. Более известный под названием Директива по Питьевой Воде (Drinking Water Directive), данный документ лёг в основу водного законодательства Европейских стран-членов ЕС. В Директиве нормируются 66 параметров качества питьевой воды, разбитые на несколько групп (органолептические показатели; физико-химические параметры; вещества, присутствие которых в воде в больших количествах нежелательно; токсичные вещества, микробиологические показатели и параметры умягчённой воды, предназначенной для потребления). (3) Агентство по Охране Окружающей Среды США (US Enviropment Protection Agency (US EPA)) – правительственное учреждение США, в задачу которого входит защита здоровья населения и охрана окружающей среды. Этим агентством был разработан федеральный стандарт качества питьевой воды США. Данный стандарт включает в себя два раздела:- National Primary Drinking Water Regulations – это обязательный для соблюдения стандарт, объединяющий на сегодняшний день 79 параметров (органические и неорганические примеси, радионуклиды, микроорганизмы), потенциально опасных для здоровья человека; National Secondary Drinking Water Regulations – стандарт, носящий рекомендательный характер и включающий перечень из 15 параметров, превышение нормативов по которым может ухудшить потребительские качества воды. На сегодняшний день разработаны новые Директивы, указанные выше. С ними можно ознакомиться в Интернете. (4) Государственный Стандарт Российской Федерации (ГОСТ). Основу ГОСТов, составляют санитарные правила и нормы (СанПиН) № 214.1116-02, которые делят бутилированные воды на две категории – высшую и первую. Воды высшей и первой категории отличаются между собой содержанием биогенных элементов, определяющих физическую полноценность воды, это кальций, магний, фтор и йод. Многие производители в Российской Федерации работают по Техническим Условиям (ТУ). Согласно единому классификатору, воды, выпускаемые по ТУ, начинающиеся с номера 9185 относятся к водам минеральным, а с номера 0131 – бутилированным столовым питьевым водам (неминеральным). Стандарты стран Европейского Сообщества, Всемирной Организации Здравоохранения отличаются от в подходе от Российского тем, что воду классифицируют с учётом исходного источника и не затрагивают медико-биологические принципы важные для здоровья человека при употреблении данной воды из конкретного источника. Российские стандарты на воду жёстче, чем рекомендуется в международных документах. Специалисты этой области сверяют свои данные с зарубежными исследованиями. Если нормативы нашей страны более строгие, чем рекомендует ВОЗ, то берут за основу наши нормативы. Если же зарубежные документы предполагают более жёсткие критерии – соответственно. Все воды, которые получали свидетельство или сертификат на продукцию, должны быть зарегистрированы в Реестре Роспотребнадзора http://fp.crc.ru (его можно посмотреть в Интернете). Международные документы, регулирующие качество воды:- в международной практике нет понятия Столовая Вода, а минеральная вода:- от 50 до 1 500 мг/л солей, не рекомендуются к систематическому употреблению. (1) ФАО-ВОЗ (по ВОЗ 2004 минерализация у минеральной воды должна быть не более 600 мг/л); (2) Директива ЕС 80/777/ЕЕС, 98/83/ЕС, 2003/40/ЕС (по Директиве минерализация должна быть до 1 000 мг/л); и (3) Директива ЕС № 2009/54/ЕС Об Использовании и Размещении на Рынке Природных Минеральных Вод. Водопроводная Вода:- (1) Сан-Пин 2.1.4.1074-01 Питьевая Вода:- Гигиенические Требования к Качеству Воды Централизованных Систем Питьевого Водоснабжения. Контроль Качества от 2002. ГОСТы по оформлению этикеток на бутылях с водой:- (1) ГОСТР 51074-2003 Национальный Стандарт Российской Федерации. Продукты Пищевые. Информация Для Потребителя, Пункт 4.22. (2) ГОСТ Р 52109-2003 Вода Питьевая, Расфасованная В Ёмкости, Пункт 5.11. Для каждого вида воды разработан свой ГОСТ, так как ко всем этим водам предъявляются разные требования. Водопроводную воду сделать идеально качественной нельзя (из-за большого количества загрязнений). Минеральная вода должна прежде всего лечить. И подготавливается она по своей особой технологии, часто с использованием диоксида углерода для обеззараживания, что недопустимо для детей до 7 лет. В воде столовой часто содержится большое количество отдельных микроэлементов. А также диоксид углерода. Если вы выбираете воду для питья на каждый день, для ребенка или для особых групп граждан:- беременных, пожилых, людей с ослабленным здоровьем, работающих на вредном производстве, то за основу качества воды, безусловно, следует брать Сан-Пин По Бутилированной Воде 2.1.4.1116-02. Этот Сан-Пин и был разработан учёными для контроля качества питьевых пресных вод на каждый день. По данному Сан-Пину самой качественной считается вода детская, затем высшей категории.

WATER RECLAMATION = УЛУЧШЕНИЕ (или ОБЕЗЗАРАЖИВАНИЕ) ВОДЫ (или ОЧИСТКА ВОДЫ) – Water Reclamation is a process by which wastewater from homes and businesses is cleaned using biological and chemical treatment so that the water can be returned to the environment safely to augment the natural systems from which it came. It is used today as both an aquifer and stream enhancement strategy. Water reclamation helps decrease diverging water from sensitive eco-systems which depend greatly on the flow to improve the quality of the water. Water reclamation also decreases the pollution to bodies of water, such as oceans and rivers, by diverting the wastewater. Some of the pollutants are used for irrigation purposes, such as nitrogen, which would be harmful to these bodies of water. Another benefit is the enhancement of wetlands which benefits the wildlife dependent on that eco-system. For instance, The San Jose/Santa Clara Water Pollution Control Plant instituted a recycling program to protect the San Francisco Bay area’s natural salt water marshes. Most of the uses of water reclamation are non potable uses such as:- washing cars, flushing toilets, cooling water for power plants, concrete mixing, artificial lakes, and irrigation for golf courses and public parks. Most systems run a dual piping system to keep the recycled water separate from the potable water. Indirect water reclamation (water passing through a body of water first) will result in potable water usage. While, this is not practiced in the United States, it is in other countries such as Namibia. Aboard the International Space Station, astronauts have been able to drink recycled urine due to the introduction of the ECLSS system. The system costs USD250 million and has been working since May 2009. The system recycles wastewater and urine back into potable

water used for drinking, food preparation, and oxygen generation. This cuts back on the need for resupplying the space station as often. Alternatives to Water Reclamation:- (i) Greywater:- like water reclamation, greywater recycles used water for irrigation and other various uses. Greywater uses the same waste as water reclamation with the exception of toilet water. Unlike water reclamation, greywater does not purify the water through a biological process, but by sand filters and soil. After passing through the soil, where it is filtered like rain water, it flows into the groundwater where it will be reused again. (ii) Desalination is an energy-intensive process where salt and other minerals are removed from sea water to produce potable water for drinking and irrigation, typically through membrane filtration (reverse-osmosis), and steam-distillation. Many ships and submarines make use of this technology. The idea of desalination is a heavily researched area worldwide. Many methodologies have been developed, including nuclear-powered desalination, and solar-powered desalination. Reclamation Processes:- wastewater must pass through numerous systems before being returned to the environment. Here is a partial listing from one particular plant system:- (i) Barscreens:- barscreens remove large solids that are sent into a grinder. All solids are then dumped into a sewer pipe at a Treatment Plant. (ii) Primary Settling Tanks:- readily settable and floatable solids are removed from the wastewater. These solids are skimmed from the top and bottom of the tanks and sent to the Treatment Plant where it'll be turned into fertilizer. (iii) Biological Treatment:- the wastewater is cleaned through a biological treatment method that uses microorganisms, bacteria which digest the sludge and reduce the nutrient content. Air bubbles up to keep the organisms suspended and to supply oxygen to the aerobic bacteria so they can metabolize the food, convert it to energy, CO_2, and water, and reproduce more microorganisms. This helps to remove ammonia also through nitrification. (iv) Secondary Settling Tanks:- the force of the flow slows down as sewage enters these tanks, allowing the microorganisms to settle to the bottom. As they settle, other small particles suspended in the water are picked up, leaving behind clear wastewater. Some of the microorganisms that settle to the bottom are returned to the system to be used again. (v) Tertiary Treatment:- deep-bed, single-media, gravity sand filters receive water from the secondary basins and filter out the remaining solids. As this is the final process to remove solids, the water in these filters is almost completely clear. (vi) Chlorine Contact Tanks:- three chlorine contact tanks disinfect the water to decrease the risks associated with discharging wastewater containing human pathogens. This step protects the quality of the waters that receive the wastewater discharge. One of two procedures are then followed according to the future disposal site:- (i) Reclaimed Water Pump Station:- the pump station distributes reclaimed water to users around the City. This may include golf courses, agricultural uses, cooling towers, or in land fills. (ii) Water is passed through high level purification to be returned to the environment. Currently this means a reverse osmosis system. See also Reclamation. / пузырь (bubble).

WATER RECYCLING = РЕЦИРКУЛЯЦИЯ ВОДЫ (или ПОВТОРНОЕ ИСПОЛЬЗОВАНИЕ ВОДЫ, или ВОДНЫЙ РЕЦИКЛИНГ, или ОБОРОТНОЕ ВОДОСНАБЖЕНИЕ) – Water Recycling:- using water again for the same or another process step, after a small form of purification is applied. (1) Water Recycling Without Purification is used in certain agricultural companies (e.g., tree nurseries) and dwellings for applications where potable water is not required (e.g., garden and land irrigation, toilet flushing). It may also be used in dwellings when the greywater (e.g., from rainwater) is already fairly clean to begin with and/or has not been polluted with non-degradable chemicals such as non-natural soaps (thus using natural cleaning products instead). This water system also needs a supply of water to recycle and reuses water as well. It is also not recommended to use water that has been in the greywater filtration system for more than 24 hours or bacteria builds up affecting the water that is being reused. Water purification/decontamination systems then again are used for applications where potable water is required (e.g., to allow drinking, and/or for other domestic tasks as washing, showering). (2) Water Recycling With Purification:- for filtering the water to become potable (or near-potable), there are numerous systems based on soft processes. These include natural biological principles such as mechanical systems (sand filtration, lava filter systems and systems based on UV radiation) biological systems (plant systems as treatment ponds, constructed wetlands, living walls) and Bio reactors or compact systems as activated sludge systems, biorotors, aerobic and anaerobic biofilters, submerged aerated filters, biorolls. Finally, 'hard', direct processes, such as distillation (evaporation) or mechanical processes such as membrane filtration, (typically ultrafiltration and reverse osmosis, which are capable of treating high volumes of grey water) can create potable, or near-potable water. There seem to be no commercially available 'hard' greywater recovery devices suitable for on-site use in the individual household, even though a number of such technologies exist. In order to purify the potable water adequately, several of these systems are usually combined to work as a whole. Combination of the systems is done in two to three stages, using a primary and a secondary purification. Sometimes a tertiary purification is also added. Some municipal sewage systems recycle a certain amount of grey and blackwater using a high standard of treatment, providing reclaimed water for irrigation and other uses. See also Reclamation, and Tailwater Recovery Irrigation System.

WATER REPELLENT = ВОДООТТАЛКИВАЮЩАЯ – Water Repellent:- fabrics that have been treated with a finish which cause them to shed water and resist water penetration, but are still air-permeable. Treatments can include wax coatings, resins, silicones, and fluorine derivatives. Such treatments do not close the pours of the fabric, while waterproof finishes do. Water Repellent:- a term applied to fabrics that have been treated with a finish which causes them to shed water, but are still air-permeable. Water Repellent is a term applied to fabrics that can shed water but are permeable to air and comfortable to wear. These fabrics are produced by treating the material with a resin, wax, or plastic finish that is not completely permanent.

WATER REPELLENT = ВОДООТТАЛКИВАЮЩИЙ ПРЕПАРАТ (или ГИДРОФОБНЫЙ ПРЕПАРАТ, или ВОДНЫЙ РЕПЕЛЛЕНТ) – Water Repellent is a liquid that penetrates wood which retards changes in moisture content and in dimensions without adversely altering the desirable qualities of wood. / .

WATER REPELLENT FABRIC = ВОДООТТАЛКИВАЮЩАЯ ТКАНЬ (или ГИДРОФОБНАЯ ТКАНЬ, или ТКАНЬ С ВОДНЫМ РЕПЕЛЛЕНТОМ, или ВОДОЗАЩИТНАЯ ТКАНЬ) – Water Repellent Fabric:- the chemical treatment of a fabric to reduce its affinity for water. Pores of the fabric are open, and the degree of repellency varies. A water repellent fab ric will give protection in a shower, but not in heavy rain. Water repellency is often created with wax or silicone resin finishes that enable the pores of the fabric to stay open so that it is more comfortable to wear than waterproof fabrics. Another name for water repellent is Water Resistant. See also Waterproof Fabric.

WATER–REPELLENT PRESERVATIVE = ВОДООТТАЛКИВАЮЩЕЕ СРЕДСТВО ЗАЩИТЫ – Water-Repellent Preservative is a water repellent that contains a preservative, accomplishing the dual purpose of imparting resistance to attack by fungi or insects. It also retards changes in moisture content. / .

WATER RESERVOIR = ВОДНЫЙ РЕЗЕРВУАР (или ВОДОХРАНИЛИЩЕ) – Water Reservoir is a large inland body of water collected and stored above ground in a natural or artificial formation.

WATER RESISTANT = ВОДОСТОЙКОЕ – Water Resistant is a degree by which water is able to penetrate a fabric. Not to be confused with water-repellent. However, the terms are often used interchangeably. Water Resistant:- a fabric treated chemically to resist water or given a 'wax-coating treatment' to make it repellent. A degree by which water is able to penetrate a fabric. Not to be confused with Water-Repellent. However, the terms are often used interchangeably.

WATER RESOURCES = ВОДНЫЕ РЕСУРСЫ – Water Resources:- the water found in fresh and brackish surface water and groundwater bodies within the national territory. In the case of surface water, the volume in artificial reservoirs and watercourses is included in addition to that in natural water bodies. The water of the oceans and open seas is excluded on the grounds that the volumes involved are so enormous as to make any stock measure meaningless and that extraction for human use has no measurable impact on them. Water Resources consist of aquifers and other groundwater resources to the extent that their scarcity leads to the enforcement of ownership and/or use rights, market valuation and some measure of economic control. Water Resource:- any of the entire range of natural waters that occur on the Earth, regardless of their state (i.e. vapor, liquid, or solid) and that are of potential use to humans. Of these, the resources most available for use are the waters of the oceans, rivers, and lakes; other available water resources include groundwater and deep subsurface waters and glaciers and permanent snowfields. Human use of natural waters, particularly of freshwater resources, has increased steadily over the centuries. It is unlikely that this trend will change given the continued growth of population and the ever-widening utilization of water for agricultural, industrial, and recreational purposes. This situation has given rise to growing concern over the availability of adequate water supplies to accommodate the future needs of society. Surface-water resources are already being used to their maximum capacity in various regions of the world, as, for example, in the southwestern United States. Quantity of water is not the only concern. Overuse has resulted in the progressive deterioration of water quality. Seepage of mineral fertilizers (phosphates and nitrates), pesticides, and herbicides into surface and subsurface waters has not only rendered them unfit for human consumption but also disrupted aquatic ecosystems. Lakes and rivers also have been contaminated by the improper disposal of sewage, the discharge of untreated industrial wastes (including such toxicants as polychlorinated biphenyls, or PCBs), and the release of heated wastewater from nuclear-power plants and other industrial facilities, which results in thermal pollution and its attendant problems. Efforts are being made to curb the contamination of water resources. For example, regulatory action by the US government to reduce phosphorous input into the Great Lakes has had measurable results, as has the implementation of improved waste-purification technology by certain municipalities in the region. The latter not only helps to restore water resources but also conserves the water supply by effective recycling. Advanced sewage-treatment facilities have made it possible to obtain potable water purer than most stream water. Projects to remove salt and other dissolved solids from brackish surface water as well as from seawater have been undertaken in such countries as Australia, Kuwait, and the United States. Water from desalination plants is generally suitable for household use and for irrigation. Other procedures employed for relieving water shortages include control of runoff and the reduction of evaporation by means of agricultural-engineering measures.

WATER RETAINING CAPACITY INDICATOR = ИНДИКАТОР ВОДОУДЕРЖИВАЮЩЕЙ СПОСОБНОСТИ – The Water Retaining Capacity Indicator measures the quantity of water that can be retained in the short-term in agricultural soil, as well as on agricultural land, and by agricultural irrigation or drainage facilities. This indicator shows how much water a given area of land can hold taking into account differences in land use, soil types, management practices and other relevant factors. A decrease in water retaining capacity implies greater potential risk of flooding.

WATER'S EDGE = КРАЙ ВОДЫ (или XX) – Water's Edge is the surface of the water.

WATERSHED = ВОДОСБОР (или ВОДОРАЗДЕЛ) – Watershed:- the geographic region within which water drains to a particular river, stream or body of water. An area on the land surface within which all runoff collects in a single stream or drainage system and exits through a single mouth or outlet. Watershed is the total area from which a single river collects surface water runoff; the catchment or drainage area of a river system. Watershed is:- (1) the total land area, regardless of size, above a given point on a waterway that contributes runoff water to the flow at that point. (2) A major subdivision of a drainage basin. The United States is generally divided into 18 major drainage areas and 160 principal river drainage basins containing some 12 700 smaller watersheds. Watershed is the land area that drains into a stream. / Под Водоразделом понимается граница поверхности Земли, разделяющая сток атмосферных осадков по двум противоположно направленным склонам. Водораздел подземных вод – условная линия, разделяющая потоки подземных вод, движущихся в разных направлениях.

WATERSHED AND FLOOD PREVENTION OPERATIONS PROGRAM = ПРОГРАММА ОПЕРАЦИЙ ПО ВОДОСБОРУ И ПРЕДОТВРАЩЕНИИ НАВОДНЕНИЙ – The Watershed and Flood Prevention Operations (WFPO) Program (Watershed Operations) includes the Flood Prevention Operations Program authorized by the Flood Control Act of 1944 (PL 78-534) and the provisions of the Watershed Protection and Flood Prevention Act of 1954 (PL 83-566). The Flood Control Act originally authorizes the Secretary of Agriculture to install watershed improvement measures in 11 watersheds, also known as Pilot Watersheds, to reduce flood, sedimentation, and erosion damage; improve the conservation, development, utilization, and disposal of water; and advance the conservation and proper utilization of land. The Watershed Protection and Flood Prevention Act provides for cooperation between the Federal government and the States and their political subdivisions in a program to prevent erosion, floodwater, and sediment damage; to further the conservation, development, utilization, and disposal of water; and to further the conservation and proper utilization of land in authorized watersheds. Introduction:- there are over 1 300 active or completed watershed projects. Assistance may be provided in authorized watershed projects to install conservation practices and project measures (works of improvement) throughout the watershed project area. The planned works of improvement are described in watershed project plans and are normally scheduled to be installed over multiple years. All works of improvement, including floodwater retarding dams and reservoirs, are owned and operated by the sponsoring local organizations and participating individuals. The Watershed and Flood Prevention Operations (WFPO) Program provides technical and financial assistance to States, local governments and Tribes (project sponsors) to plan and implement authorized watershed project plans for the purpose of:- (i) watershed protection; (ii) flood mitigation; (iii) water quality improvements; (iv) soil erosion reduction; (v) rural, municipal and industrial water supply; (vi) irrigation; (vii) water management; (viii) sediment control; (ix) fish and wildlife enhancement; and (x) hydropower. Under the Watershed Program NRCS (short for the Natural Resources Conservation Service of USDA) cooperates with States and local agencies to carry out works of improvement for soil conservation and for other purposes including flood prevention; conservation, development, utilization and disposal of water; and conservation and proper utilization of land. A Locally Led Program:- project sponsors are provided assistance in installing planned land treatment measures when plans are approved. Surveys and investigations are made and detailed designs, specifications, and engineering cost estimates are prepared for construction of structural measures. Areas where sponsors need to obtain land rights, easements, and rights-of-way are delineated. Technical assistance is also furnished to landowners and operators to accelerate planning and application of needed conservation measures on their individual land units. How The Program Works:- NRCS does watershed planning in the following ways:- (i) Sponsoring local organizations can request that watershed project plans be authorized for Federal Watershed Operations funding assistance; (ii) Watershed plans involving Federal contributions in excess of USD5 000 000 for contribution, or construction of any single structure having a capacity in excess of 2 500 acre feet, require Congressional approval; (iii) Other plans can be authorized for Federal funding by the Chief of NRCS; and (iv) After approval, technical and financial assistance can be provided for installation of works of improvement specified in the plans, subject to annual appropriations, through Watershed Operations. Technical and Financial Assistance:- Watershed and Flood Prevention Operations provides technical and financial assistance in authorized watershed projects which have public sponsors who:- (i) Conduct public meetings to assure local involvement; (ii) Obtain all land and

water rights and permits required for the installation of works of improvement; (iii) Provide local share of funds to install works of improvement; and (iv) Operate and maintain works of improvement. Eligibility Authorized Watershed Projects:- Criteria include:- (i) Public sponsorship; (ii) Watershed projects up to 250 000 acres; and (iii) Benefits that are directly related to agriculture, including rural communities, that are at least 20 percent of the total benefits of the project. Funds for Watershed Projects:- funds that may be available for watershed projects are subject to the following:- (i) Annual Congressional appropriations; (ii) State and national resource priorities; (iii) Acquisition of land and water rights, permits; (iv) Local funding established for specific project measures; (v) Completion of structural, agronomic, and vegetative designs for project measures; (vi) NRCS and the project sponsor approval of an Operation and Maintenance Agreement involving the measures to be installed. See also PL 566, and Watershed Protection and Flood Prevention Act of 1954.

WATERSHED DEGRADATION = ДЕГРАДАЦИЯ ВОДОСБОРА (или ДЕГРАДАЦИЯ ВОДОРАЗДЕЛА) – Watershed Degradation is a marked deterioration in the hydrological behavior of a river system which reduces the potential of land and water by causing a water flow of inferior quality, quantity and timing.

WATERSHED PLANS = ПЛАНЫ В ОТНОШЕНИИ ВОДОСБОРОВ – The US Watershed Plans are the plans to coordinate investigation of the physical, environmental, social, and economic conditions specific to a watershed. The plans display the benefits and opportunities for conservation, development, and management of land, water, and related resources. / сохранение (conservation).

WATERSHED PROTECTION = ЗАЩИТА ВОДОСБОРОВ – Watershed Protection is a combination of complementary practices of land treatment and structural works to maintain or improve total yield, quality, stability of flow of surface and subsurface water, and to prevent damage and loss due to excessive and uncontrolled runoff, flooding, salination, and siltation.

WATERSHED PROTECTION AND FLOOD PREVENTION ACT OF 1954 = АКТ О ЗАЩИТЕ ВОДОСБОРА И ПРЕДОТВРАЩЕНИИ НАВОДНЕНИЙ ОТ 1954 – The US Watershed Protection And Flood Prevention Act of 1954 (P.L. 83-566) (16 USC §§ 1001-1009):- signed into law August 04, 1954, and amended in 1956, 1958, 1960, 1961, 1962, 1965, 1968, 1972, 1977, 1981, 1986, 1990, 1994, 1996, and 2002. The Natural Resources Conservation Serviceadministers watershed projects for the USDA under this Act. These projects help urban and rural communities, tribal governments, and other federal agencies protect, improve, and develop the water and land resources of watersheds of up to 250 000 acres. Benefits include reduced erosion, siltation, and flooding; improved water quality; increased water supply; recharge of groundwater reservoirs; and improved fish and wildlife resources. See also PL 566. / сохранение (conservation).

WATERSHED REHABILITATION PROGRAM = ПРОГРАММА РЕАБИЛИТАЦИИ ВОДОСБОРОВ – The US Watershed Rehabilitation Program is a program authorized by the Grain Standards and Warehouse Improvement Act of 2000 (Sec. 313) to provide cost-sharing for the rehabilitation of aging small watershed structures. Local communities have constructed more than 11 000 small flood control dams in 47 states since 1948, with assistance from the Natural Resources Conservation Service. Small watershed projects provide flood control, municipal and irrigation water supply, recreation, erosion control, water quality improvement, wetland development, and wildlife habitat enhancement on more than 130 million acres across the country. Many of these dams are approaching the end of their designed life. Under the Farm Security and Rural Investment Act of 2002 (Sec. 2505) both mandatory and discretionary funding for the program was authorized. / Служба Сохранения Природных Ресурсов.

WATER SOFTENER = УМЯГЧИТЕЛЬ ВОДЫ (или ВОДОУМЯГЧИТЕЛЬ) – Water Softener is a chemical compound added to the rinse water or to the soap and the rinse water if the water is very hard. Its purpose is to prevent the formation of soap film that tends to gray the fabric. Water Softener removes hardness ($CaCO_3$) from water through an ion exchange of sodium with calcium and magnesium. Water Softener:- device for removing calcium and magnesium from water; water so treated will not form insoluble scale in pipes and tanks and will not form a precipitate with soaps or interfere with other cleaners. Water softeners usually consist of zeolite or an ion-exchange resin in a tank connected directly into the water system. The zeolite or resin contains sodium ions that change places with the calcium and magnesium ions dissolved in the water. When the zeolite or resin becomes exhausted (when most of its exchangeable sodium is replaced with calcium and magnesium), it can be regenerated by washing with a strong solution of common salt, which removes the calcium and magnesium and replaces them once again by sodium. Indispensable in many industries, water-softening units are also used in homes in a number of countries.

WATERS OF THE US = ВОДЫ США – Waters Of The US:- the territorial seas; coastal and inland waters, lakes, rivers, and streams that are navigable waters of the United States (US), including adjacent wetlands; tributaries to navigable waters of the United States, including adjacent wetlands (man-made non-tidal drainage and irrigation ditches excavated on dry land are not considered to be tributaries); interstate waters and their tributaries, including adjacent wetlands; all other waters of the United States such as isolated wetlands and lakes, intermittent streams, prairie potholes, and other waters that are not part of a tributary system to interstate waters or to navigable waters of the United States, the degradation or destruction of which could affect interstate commerce.

WATER SOLUBILITY = РАСТВОРИМОСТЬ В ВОДЕ – Water Solubility is the maximum concentration of a chemical compound which can result when it is dissolved in water. If a substance is water soluble it can very readily disperse through the environment.

WATER SOLUBLE FIBER = ВОДОРАСТВОРИМОЕ ВОЛОКНО – Water Soluble Fiber is a food fiber (e.g., Oat fiber, Barley fiber, Carob fiber, Soybean fiber, Guar gum fiber) that dissolves in water. It apparently absorbs low-density lipoproteins (LDLP) in the intestine, before the fiber passes from the body; plus it inhibits absorption of LDLP by the body's intestinal walls due to increasing the viscosity of the intestine's contents. Those two effects thus lower the amount of 'bad' cholesterol (i.e. LDLP can lead to hardening/blockage of arteries) in the body and thereby coronary heart disease (CHD). Additional to those two effects, water soluble fiber also absorbs/binds bile acid and causes it to be excreted along with that water soluble fiber. That helps to lower cholesterol levels in the body (bloodstream), because the liver synthesizes ('manufactures') more bile acids (to replace those absorbed & removed by the fiber) from cholesterol. / Водорастворимое Волокно:- растворимые в воде овсяные, ячменные, рожковые и соевые волокна.

WATER SOURCE HEAT PUMP = ТЕПЛОВОЙ НАСОС С ВОДОЙ В КАЧЕСТВЕ ИСТОЧНИКА – Water Source Heat Pump is a type of (geothermal) heat pump that uses well (ground) or surface water as a heat source. Water has a more stable seasonal temperature than air thus making for a more efficient heat source.

WATER SPOTS = ВОДЯНЫЕ ПЯТНА (или ВОДНЫЕ ПЯТНА) – Water Spots:- usually caused by wet fabric being allowed to remain too long before drying:- color migrates leaving blotchy spots. Machinery defects, and namely – Pressing Equipment. Water Spot:- an unwanted pale area in a piece-dyed fabric. Note:- this defect is caused by contamination with water prior to tinting or dyeing on a pad mangle, which results in a reduction of uptake of dye liquor. Water Spots:- caused by leaks in pressing unit or improper steam. Water Spots:- Garment:- woman's iridescent taffeta dress; Fabric Construction:- (i) Count:- 160 x 68; (ii) Warp:- 100/40 bright viscose rayon dyed blue; (iii) Filling:- 150/40 bright viscose rayon (while). Complaint:- the dress became stained from water spots. Analysis:- laboratory tests confirmed the fact that water spots stained this fabric and tiiat dry-cleaning solvents did not eliminate the stains.

Analysis disclosed the fact that the garment was made of gray goods in which the warp sizing had not been removed, in order that, without finishing, the goods might present a stiff effect. The warp sizing, being water-soluble, was partially dissolved when it came into contact with water (as it would from any water-containing liquid – fruit juices, soft drinks, milk, etc). At the same time, the wretted warp yarns shrank when wet, producing a puckered effect, as w r ell as a spotted area. Similar iridescent taffeta fabrics made of cellulose acetate rayon warps and viscose-rayon filling, cross-dyed in the piece, did not present this problem, because they contained no water-soluble stiffener. The type of fabric used in the stained garment could have been dry-cleaned, if handled very carefully, but wet cleaning would so alter the hand and appearance that it could be employed only at the owner's risk. / Уточина:- 150/40 . развод (или потёк (stain)). Порок или дефект от машинного оборудования. Пятна От Высохших Капель Воды (water spot):- порок заключительной отделки ткани; нежелательный светлый участок в куске окрашенной ткани. Примечание:- этот порок вызван уменьшением поглощения красильного раствора.

WATERSPOUT = ВОДЯНОЙ СМЕРЧ (или ВОДНЫЙ СМЕРЧ) – Waterspout:- a small-diameter column of rapidly swirling air in contact with a water surface. Waterspouts are almost always produced by a swiftly growing cumulus cloud. They may assume many shapes and often occur in a series, called a Waterspout Family, produced by the same upward-moving air current. Waterspouts are closely related to other atmospheric phenomena such as tornadoes, whirlwinds, and fire storms. It is only in recent years that some of the workings of waterspouts have been unraveled, though waterspouts have been known and remarked upon since ancient times. For much of history, they have been subjects of mystery, speculation, and fear. A few intense waterspouts have caused deaths when they moved inland over populated areas, and they certainly constitute a threat to small craft; however, there are few authentic cases of large ships being destroyed by a spout. The superstition that firing a cannonball or other projectile into a spout can 'break it up' has no scientific foundation. Contrary to popular opinion, a waterspout does not 'suck up' water to great heights, though it may lift the water level a meter or so at its point of contact with the surface. It is suspected, but remains unproven, that waterspouts sometimes draw fish and frogs into its vortex and then drop them onto land, thus accounting for the reported falls of such objects. Modern scientific interest in waterspouts began with the appearance of a particularly large and persistent spout on August 19, 1896, off the coast of Massachusetts, where thousands of vacationers and several scientists observed it. Its height was estimated to be 1 095 meters (3 593 feet, or almost 0.7 mile) and its width, 256 meters (840 feet) at the crest, 43 meters (141 feet) at the center, and 73 meters (240 feet) at the base. The shroud of spray surrounding the central funnel was about 200 meters (656 feet) wide near the water surface and 120 meters (394 feet) high. The spout's circulation persisted for at least 35 minutes, as the visible funnel disappeared and re-formed three times. Most waterspouts are smaller than this one, with much shorter lives. This exceptional spout is an example of one that apparently was spawned by thunderstorm-squall conditions similar to those that produce tornadoes over land. There is much confusion in classifying waterspouts. For many years, they were called Tornadoes Over Water, a definition still in wide use. However, as tornado researchers have learned more about atmospheric vortices, it has become clear that several mechanisms can give rise to a strong vortex pendant from a cloud (see Tornado for a discussion of vortex formation). All of these mechanisms require the following elements:- warm, moist, unstable air rising and being replaced at the surface by horizontal convergence of the surrounding air; a rapidly growing cloud aloft; and sufficient rotation in the atmosphere that can be localized and concentrated to produce a vortex. Most waterspouts closely resemble weak tornadoes, some of which are called Landspouts because of this similarity. The rotation occurs at low levels in the atmosphere, so the resulting vortex does not extend very far up into the cloud. Indeed, the rotation is not often detectable by radar, another indication that waterspouts are a phenomenon largely confined to the region below cloud base. Observations from aircraft indicate that most waterspouts have a five-stage life cycle:- (i) the dark-spot stage, with a circular, raised patch of water marking the point of contact of the vortex core with the water surface; (ii) the spiral-pattern stage, where a spiral is made visible by differences in waves on the water surface; (iii) the spray-ring stage, where the dark spot is surrounded by a sheath of water droplets ripped from the water surface by the swirling winds; (iv) the mature or spray-vortex stage, where both the spray vortex and the funnel cloud are at their maximum size and intensity; and (v) the decay stage, where the waterspout dissipates. The main visible feature of a waterspout – the classic inverted cone or funnel – consists mostly of freshwater droplets produced locally by condensation of water vapor. The funnel appears to develop downward from the base of the parent cloud, reaching toward the water surface. The condensation funnel usually appears toward the end of stage 2, as the spiral pattern in the surface water waves wraps tightly around the dark spot marking the center of the vortex. Frequently the descent of the condensation funnel is followed by the rising of the spray ring from the turbulent water surrounding the dark spot. This sheath often surrounds the lower portion of the funnel. Funnel diameters range from a few meters to 100 meters (328 feet) or more. In recent years, efforts have been made to measure the wind speeds in waterspouts. Most researchers have used small airplanes or helicopters to get close to their subjects. By filming or videotaping the swirling condensation funnel or spray sheath, they have been able to track the movement of cloud tag and small clumps of droplets using photogrammetric techniques (measuring the speed of objects recorded on film and assuming that the objects are moving at the same velocity as the wind). Doppler lidar, a device similar to radar but using light rather than radio waves, has also been used to measure winds in waterspouts. The consensus of these measurements indicates these vortices have winds in the range 15 to 85 meters per second (49 to 279 feet per second), with most spouts having their maximum winds toward the low end of this range. On the Fujita Scale of tornado intensity, most waterspouts would thus rate as F0. That is, almost all waterspouts have intensities similar that those of weak tornadoes. Measurements of the forward speeds of waterspouts are scarce. Estimates vary from a few kilometers per hour to as high as 64 to 80 km per hour (40 to 50 miles per hour). Many waterspouts leave a narrow spiral wake of disturbed water as they move along; how this wake, or tail, forms remains unknown. Waterspouts are most common between late spring and early fall, but they may appear at any time of the year or of the day or night. Lifetimes of typical waterspouts average 5 to 10 minutes, but occasionally a large waterspout may persist for up to one hour. The worldwide distribution of waterspouts is difficult to determine because most of them occur over oceans, so their detection depends on chance observations from coasts or from ships or airplanes. They are most frequent over tropical and subtropical waters during the warm season. To form, waterspouts require warm surface water in addition to the necessary atmospheric conditions discussed above. Many waterspouts have been observed over the Gulf of Mexico, off the coast of Florida and the Bahamas, and over the Gulf Stream. Indeed, more are reported in the lower Florida Keys than in any other place in the world. Waterspouts are also reported frequently off the west coast of Africa near the Equator and off the coasts of China and Japan. Though they are uncommon at higher latitudes, they have also appeared in places such as the Grand Banks of Newfoundland, on the Great Lakes, and near Seattle, Washington. / Смерч – атмосферный вихрь, возникающий в грозовом облаке и затем распространяющийся в виде тёмного рукава или хобота по направлению к поверхности суши или моря; в верхней части имеет воронкообразное расширение, сливающееся с облаками. Когда смерч опускается до земной поверхности, нижняя часть его тоже становится расширенной, похожей на опрокинутую воронку. Высота смерча может достигать 800–1 500 метров (м). Воздух в нём вращается обычно против часовой стрелки, причём одновременно он поднимается по спирали вверх, втягивая пыль или воду; скорость вращения – несколько десятков м в секунду (сек). В связи с тем, что внутри вихря давление воздуха уменьшается, там происходит конденсация водяного пара; это вместе со втянутой частью облака, пылью и водой делает смерч видимым. Диаметр смерча над морем измеряется десятками м, над сушей – сотнями м. Смерч возникает обычно в тёплом секторе циклона, чаще перед холодным фронтом и движется в том же направлении, в котором перемещается циклон (скорость перемещения 10–20 м/сек). За время своего существования смерч проходит путь длиной 40–

60 километров (км). Образование смерча связано с особо сильной неустойчивостью стратификации атмосферы. Смерч сопровождается грозой, дождём, градом и, если достигает поверхности земли, почти всегда производит большие разрушения, всасывая в себя воду и предметы, встречающиеся на его пути, поднимая их высоко вверх и перенося на значительные расстояния. Смерч на море представляет большую опасность для судов. Смерчи над сушей иногда называют Тромбами, в США их называют Торнадо.

WATER SUPPLIER = ПОСТАВЩИК ВОДЫ – Water Supplier is a person who owns or operates a public water system.

WATER SUPPLY = ПРЕДЛОЖЕНИЕ ВОДЫ (или ВОДООБЕСПЕЧЕНИЕ, или ВОДОСНАБЖЕНИЕ, или ОБВОДНЕНИЕ) – Water Supply:- available water provided to fulfill a particular need; if the need is domestic, industrial, or agricultural, the water must fulfill both quality and quantity requirements. Water supplies can be obtained by numerous types of water resources projects, such as wells, dams, or reservoirs. See also Water Resource. / Водоснабжение – совокупность мероприятий по обеспечению водой различных потребителей – населения, промышленных предприятий и других. Комплекс инженерных сооружений и устройств, осуществляющих водоснабжение (в том числе получение воды из природных источников, её очистку, транспортирование и подачу потребителям), называемых Системой Водоснабжения или Водопроводом. Водоснабжение – совокупность мероприятий по обеспечению водой различных её потребителей – населения, промышленных предприятий, транспорта и других (смотрите Водопотребление). Комплекс инженерных сооружений, осуществляющих задачи водоснабжения, называется Системой Водоснабжения или Водопроводом. Все современные системы водоснабжения населённых мест являются централизованными:- каждая из них обеспечивает водой большую группу потребителей. В зависимости от назначения обслуживаемых объектов современные водопроводы подразделяются на коммунальные и производственные (промышленные или сельскохозяйственные). Наиболее крупные потребители воды – предприятия металлургической, химической, нефтеперерабатывающей промышленности, а также ТЭС. Некоторые мероприятия, связанные с использованием воды, по своей классификации не относятся к водоснабжению. Например, подача воды для полива сельскохозяйственных полей представляет собой специальную отрасль водного хозяйства – орошение, подача воды по турбинам ГЭС относится к гидроэнергетике. Для целей водоснабжения используются природные источники воды:- поверхностные – открытые водоёмы (реки, водохранилища, озёра, моря) и подземные (грунтовые и артезианские воды и родники). Для нужд населения наиболее пригодны подземные воды. Однако для снабжения водой больших населённых мест подземных источников часто оказывается недостаточно, а получение из них значительного количества воды экономически невыгодно. Поэтому для водоснабжения крупных городов и промышленных объектов используют преимущественно поверхностные источники пресной воды. Для получения воды из природных источников, её очистки в соответствии с нуждами потребителей и для подачи к местам потребления служат следующие сооружения:- водоприёмные сооружения (смотрите Водозаборное Сооружение); насосные станции первого подъёма, подающие воду к местам её очистки; очистные сооружения; сборные резервуары чистой воды; насосные станции второго или последующих подъёмов, подающие очищенную воду в город или на промышленные предприятия; водоводы и водопроводные сети, служащие для подачи воды потребителям. Общая схема водоснабжения может видоизменяться в зависимости от конкретных условий. Если, например, вода источника не требует очистки, из схемы выпадают очистные и связанные с ними сооружения. При расположении источника на более высоких отметках, чем снабжаемый водой объект, вода может быть подана самотёком, и поэтому нет необходимости в устройстве насосных станций. Расположение водонапорных башен и резервуаров зависит от рельефа местности. В некоторых системах используется несколько источников водоснабжения, что ведёт к увеличению числа основных сооружений. При большой разности отметок на территории объекта иногда устраивают так называемое Зонное Водоснабжение, то есть отдельные сети для районов города, расположенных на разных отметках, с отдельными насосными станциями. Иногда сооружают повысительные насосные станции, забирающие воду из основной сети города и подающие её в возвышенные районы. Водоприёмные сооружения имеют различное устройство в зависимости от вида источников водоснабжения и местных условий. Для приёма поверхностных вод используются речные, водохранилищные, озёрные, морские водоприёмники. Для приёма подземных вод в зависимости от глубины залегания водоносных пластов применяются трубчатые (буровые) колодцы, горизонтальные водосборы, представляющие собой дренажные трубы или галереи, укладываемые в пределах водоносного пласта. Родниковые воды собираются при помощи каптажных сооружений (каменных резервуаров, приёмных камер и других), располагаемых в месте наиболее интенсивного выхода родниковой воды. Вода поднимается из подземных источников в большинстве случаев центробежными насосами. Весьма эффективны погружные насосы, опускаемые под уровень воды в колодец вместе с электродвигателем, заключённым в водонепроницаемый кожух. При использовании артезианских (напорных) вод после сооружения колодца уровень воды в нём устанавливается над водоносным пластом. Иногда давление в пласте столь велико, что вода самоизливается из колодца на поверхность земли. Для городских водопроводов, использующих подземные воды, обычно сооружают группу колодцев. Вода из них поступает в сборный резервуар и оттуда подаётся потребителям насосной станцией. Шахтные колодцы применяют при относительно неглубоком залегании подземных вод. В зависимости от глубины шахтных колодцев подъём воды из них может быть осуществлён обычными или погружными насосами. В системах водоснабжения населённых мест водоприёмные сооружения всех типов включаются в зону санитарной охраны. Насосные станции современных систем водоснабжения оборудуются, как правило, центробежными насосами с электрическим приводом, а также регулирующей, предохранительной и контрольно-измерительной аппаратурой. Многие насосные станции имеют телеуправление и полностью автоматизированы. Очистные сооружения обрабатывают природную воду с целью придания ей качеств, соответствующих требованиям потребителей (смотрите Водоочистка). Очищенная вода подаётся к объекту по водоводам и разводится по его территории водопроводной сетью. К уличной сети присоединяются домовые ответвления, по которым вода вводится в здания. Внутри зданий устраивается сеть внутреннего водопровода, подводящая воду к точкам её разбора через различные водоразборные устройства (краны). В благоустроенных жилых домах и в некоторых общественных зданиях устраиваются также системы, снабжающие потребителей горячей водой (смотрите Горячее Водоснабжение). В производственных зданиях вода подводится к различным технологическим агрегатам, машинам, аппаратам, котлам и так далее. Разбор воды осуществляется частично и из наружной (уличной) сети через водоразборные колонки (краны). Подача воды для тушения пожаров осуществляется из наружных пожарных гидрантов, располагаемых на уличной сети. Внутренние пожарные краны устанавливаются в общественных и производственных зданиях, а также в жилых домах выше 11 этажей. Для промышленных предприятий (в определённых условиях) применяют так называемые Оборотные Системы Водоснабжения, а также системы с последовательным использованием воды. Оборотные системы служат для предотвращения нерационального использования природных вод и их загрязнения. В таких системах воду после надлежащей обработки (охлаждения или осветления) снова подают потребителям. Для охлаждения воды в оборотных системах применяются градирни, бассейны брызгальные, охладительные пруды. При этом из источника подаётся вода только для восполнения её потерь при охлаждении и безвозвратных её расходов в производстве. Таким образом, количество воды, забираемой из источника, при оборотной системе значительно меньше, чем при обычной прямоточной системе. Это позволяет иногда использовать природный источник, который при прямоточной системе был бы недостаточным для данного

потребителя. Системы с последовательным использованием воды применяют в тех случаях, когда вода, сбрасываемая одним производственным потребителем, может употребляться другим. Это также уменьшает количество воды, которое надо забирать из источника водоснабжения. Вследствие значительного роста водопотребления в населённых местах (в результате роста числа жителей, а также при наличии всех видов благоустройства) и промышленности в некоторых районах местные природные источники оказываются недостаточными для удовлетворения потребностей в воде. В такие районы вода подаётся из удалённых источников. Так, одним из источников водоснабжения Москвы является Река Волга, из которой вода поступает по каналу на расстояние 128 километров (км); в центральные районы Донбасса вода подводится каналом и водоводами на расстояние 130 км. Санитарный Надзор:- качество подаваемой населению воды (на всём пути её транспортирования от водопроводной станции до потребителя) подвергается строгому санитарному контролю. Санитарный надзор, осуществляемый районными и городскими санэпидстанциями, распространяется на все системы хозяйственно-питьевого водоснабжения населённых мест и другие системы, подающие воду питьевого качества. Органами Государственного Санитарного Надзора в бывшем СССР утверждено ‘Положение о проектировании зон санитарной охраны централизованного водоснабжения и водных источников’, обязательное для всех организаций, проектирующих и строящих системы водоснабжения, и для всех водопроводных предприятий. На территории, входящей в зону санитарной охраны, устанавливается режим, обеспечивающий надёжную защиту источника водоснабжения от загрязнения и сохранение требуемых качеств воды. Проект зон санитарной охраны составляет неотъемлемую часть каждого проекта водоснабжения, без которой он не может быть утверждён. История водоснабжения насчитывает несколько тысячелетий. Ещё в Древнем Египте для получения подземных вод строились весьма глубокие колодцы, оборудованные простейшими механизмами для подъёма воды, использовались гончарные, деревянные и даже металлические (медные и свинцовые) трубы. В античном Риме имелись уже довольно крупные централизованные системы водоснабжения; сохранились акведуки, служившие для перехода самотёчных водопроводных каналов через овраги и долины. При раскопках в Новгороде был обнаружен водопровод из деревянных труб, время постройки которого относится к концу XI – началу XII веков. Имеются сведения о самотёчном водопроводе из гончарных труб, построенном в Грузии в XIII веке. В XV веке был сооружён родниковый водопровод для Московского Кремля. В первой половине XVIII века были построены водопроводные сооружения в Петербурге, Петергофе, Царском Селе. В 1804 закончено сооружение первого Московского (Мытищинского) водопровода, а в 1861 – Петербургского городского водопровода. В 1902 вступил в действие новый водопровод Москвы с приёмом воды из Москвы Реки у Деревни Рублёво. Всего в дореволюционной России централизованные системы водоснабжения имелись в 215 городах (около 20% общего их числа). За годы Советской власти водоснабжение получило большое развитие как по числу водопроводов и протяжённости водопроводных линий, так и по количеству воды, подаваемой населению и другим потребителям. К 1968 в СССР число городов, имеющих централизованное водоснабжение, составляло 1 600, а рабочих посёлков – 2 520, протяжённость водопроводных линий выросла в 34 раза, а общее количество подаваемой в городские водопроводы воды – приблизительно в 40 раз. Обводнение – обеспечение водой безводных и маловодных районов путём освоения местных ресурсов воды и переброски её по каналам и трубопроводам с других территорий. При обводнении строят различные водозаборные сооружения, водохранилища, каналы, водопроводы, водопойные пункты и тому подобное. В бывшем СССР из общей площади 291 миллион гектаров (га) пастбищ, используемых сельским хозяйством, в 1984 было обводнено около 190 миллионов га. Обводнение развито также в Австралии, Новой Зеландии, США и других. Обводнение – комплекс мероприятий, главным образом гидротехнических, проводимых в безводных и маловодных районах для обеспечения их водой. Обводнение – первый этап строительства систем водоснабжения и орошения в местах, где нет водных источников или они малодебитны, либо имеют непригодную воду. При обводнении в первую очередь осваивают местные водные ресурсы (подземные воды, реки, озёра, атмосферные осадки), для чего строят водозаборные сооружения (колодцы, каптажи, кяризы, водозаборы на реках и тому подобное), водохранилища для аккумулирования местного стока, регулирующие водохранилища на реках и другое. Если они недостаточны, отсутствуют или неравномерно распределены на местности, то выявляют внешние водные источники, из которых воду по каналам и трубопроводам обводнительных систем подают на обводняемую территорию и распределяют по ней. Состав обводнительных мероприятий зависит от хозяйственного использования обводняемой территории. При обводнении пастбищ строят шахтные и трубчатые колодцы, водоёмы с водопойными пунктами. В районах богарного земледелия для снабжения хозяйств водой сооружают групповые водопроводы, которые совмещают функции обводнительных и водоснабжающих сооружений. На территории, где имеются возможности для развития выборочного орошения (в основном в районах возделывания овощных и кормовых культур), строят обводнительно-оросительной системы:- по обводнительным каналам воду подают для водоснабжения и полива. В бывшем СССР проводили большие работы по обводнению. Площадь обводнённых пастбищ к 1974 составила более 220 миллионов гектаров (га) (общая площадь нуждающихся в обводнении пастбищ – около 300 миллионов га; 58 миллионов га обводнено в 1956–1960, 44 миллиона га – в 1961–65, 33 миллиона га – в 1966–1970), в том числе в Казахстане более 110 миллионов га, в Средней Азии более 60 миллионов га. Для ценных пастбищ (горных и других) используют водопроводы; протяжённость их свыше 4 300 километров (км) (по данным на 1972), наиболее крупные на Кавказе и в Средней Азии. Водопровод на пастбищах Джейранчёль (Азербайджанская ССР) обводнял около 200 тысяч га, обеспечивая водой 400 000 овец и 20 000 голов крупного рогатого скота. Групповые водопроводы распространены в Казахстане, Сибири, на Кавказе в Крыму. Например, Ишимский групповой сельскохозяйственный водопровод (Казахстан) охватывал 2.2 миллиона га безводных земель, подавал воду в 195 поселков:- протяжённость его водоводов 1 750 км. Обводнительно-оросительные системы были построены на Северном Кавказе, Юге Украины, в Прикаспийской Низменности; наиболее крупные:- Терско-Кумская (площадь обводнения 1.3 миллиона га, орошения 53 тысячи га), Правоегорлыкская (соответственно 1.5 миллиона га и 32 тысячи га), Кубань-Калаусская (300 тысяч га и 198 тысяч га). В 9-й пятилетке (1971–75) сооружались обводнительно-оросительные системы в зонах Терско-Кумского, Северо-Крымского и Каракумского Каналов, всего должно было быть обводнено 41 миллион га пастбищ. За рубежом обводнительные работы проводят в США, Австралии и других странах.

WATER SUPPLY SYSTEM = СИСТЕМА ВОДОСНАБЖЕНИЯ (или СИСТЕМА ПОДАЧИ ВОДЫ) – Water-Supply System:- arrangement for transporting water from areas of abundance to an area of shortage. This includes works for the collection, transmission, treatment, storage, and distribution of water for homes, commercial establishments, industry, and irrigation, as well as for such public needs as fire fighting and street flushing. There is much archaeological evidence to indicate that ancient peoples were concerned with their water supply. Wells were sufficient for small communities, and rivers provided enough water for civilizations along the Tigris and Euphrates, the Nile, and the Indus rivers; but as populations grew, wells had to be dug deeper, and water had to be brought in from more distant sources. These ancient systems included storage reservoirs at water sources, canals and aqueducts for water conveyance to points of use, and water-distribution systems. Highly advanced systems appeared about 2500 BC and reached their peak in the system supplying ancient Rome. The outstanding features of this system were the 11 aqueducts totalling 359 miles (578 kilometers) in length – of which 30 mi were supported on stone arches – that delivered some 50 000 000 gallons (189 000 000 liters) of water to the city daily. The water was distributed from large storage cisterns to public fountains and baths by an elaborate system of lead pipes. During the Middle Ages, water supplies were largely neglected, and epidemics caused by waterborne organisms

were common. In the XVII and XVIII centuries, distribution systems utilizing cast-iron pipes, aqueducts, and pumps were installed in London and Paris. During the XIX century the pollution of most water supplies became so serious that slow-sand filtration was initiated; and by the end of the century the realization that diseases could be transmitted by water led to the use of sterilizing chemicals, usually chlorine compounds. Water sources for modern supply systems include wells, rivers, lakes, and man-made reservoirs. When points of use are near sources, direct intake can be used. Offshore intakes are sometimes built in lakes to obtain water of better quality and to avoid freezing problems in winter. Reservoirs are formed usually by constructing dams near the collection point of mountain-water runoff or across rivers. Dams provide a way of regulating water collection and flow so that the supply remains constant. Modern aqueducts – comprising canals, closed tunnels, and large pipelines – deliver water by means of gravity in some cases, but usually some method of pressurization is used. After the water reaches collection points it is normally given some kind of treatment to improve its quality to a usable level. Most important is the purification process, which destroys harmful bacteria and deactivates viruses. Liquid chlorine is the most common chemical used in modern treatment plants and is usually applied before other treatment and as a final treatment before distribution. In some plants, ozone and ultraviolet light are used as disinfectants. Water-treatment works employ a variety of other treatment processes, which include long-period storage, aeration, coagulation, sedimentation, softening, and filtration; these processes are used in varying combinations, depending primarily on the characteristics of the water but also on its intended use. Long-period storage, usually in reservoirs or setting basins, gives particulates a chance to settle out, and filtration through beds of fine sand or through crushed anthracite coal can trap the suspended matter. Different chemical additives cause particles to coagulate and thus to settle. Aeration mixes air with water either by spraying the water into the air or by forcing small air bubbles through the water and is used primarily to reduce unpleasant odors and tastes. Softening is the process of removing calcium and magnesium from the water either by chemical precipitation or by ion exchange. In parts of the world where there is little or no fresh water, plants that desalt seawater, wastewater, and highly mineralized groundwater have been constructed. The methods used to remove salt from water include distillation, in which salt water is evaporated and fresh water is condensed; crystallization, where salt water is frozen in such a way that salt-free ice is formed and then thawed; and a membrane process, where the membrane filters the salt ions from the water. The first large desalting plant was built in Kuwait in 1949. Subsequent technological advances have allowed for larger, more efficient plants to be built. One plant near Tijuana, Mexico, has a daily capacity of 7 500 000 gal. After treatment, water is pumped either directly into the distribution system or to an elevated storage location, such as a water tank. For adequate distribution, water systems must operate under pressure. In some cases, the gravity drop of water from its elevated storage location provides enough pressure; otherwise, it is supplied by a pumping station. Adequate pressures range between 30 and 100 pounds per square inch (2 and 7 kilograms per square centimeter). Many communities base water-pressure requirements on what is thought to be adequate to fight fires, where pressures of up to 75 pounds per square inch are sometimes necessary. Materials used in transporting water to homes and industries include pipes of cast iron, steel, concrete, and asbestos cement. Meters record water usage at the site of consumption, and charges are levied to help pay for operation and maintenance of the system. Water Supply System:- the collection, treatment, storage and distribution of potable water from source to consumer. A Water Supply System is a system for the collection, transmission, treatment, storage and distribution of water from source to consumers, for example, homes, commercial establishments, industry, irrigation facilities and public agencies for water-related activities (fire-fighting, street flushing and so forth).

WATER TABLE = УРОВЕНЬ ГРУНТОВЫХ ВОД (или ЗЕРКАЛО ГРУНТОВЫХ ВОД) – Water Table is the upper limit of the soil or underlying rock material that is wholly saturated with water. See also Soil. Water Table is the level of ground water. Water Table:- also called Groundwater Table, upper level of an underground surface in which the soil or rocks are permanently saturated with water. The water table separates the groundwater zone that lies below it from the capillary fringe, or zone of aeration, that lies above it. The water table fluctuates both with the seasons and from year to year because it is affected by climatic variations and by the amount of precipitation used by vegetation. It also is affected by withdrawing excessive amounts of water from wells or by recharging them artificially. See also Aquifer. Water Table is the upper surface of ground water and the level below it where the soil is saturated with water. Watertable:- upper surface of groundwater, below which the layers of soil, rock, sand or gravel are saturated with water.

WATERTIGHT = ВОДОНЕПРОНИЦАЕМОЕ (или НЕПРОМОКАЕМОЕ) – Watertight:- capable of keeping out water.

WATER TRANSPORTATION = ВОДНАЯ ПЕРЕВОЗКА (или ПЕРЕВОЗКА ВОДНЫМ ТРАНСПОРТОМ) – Water Transportation includes establishments engaged in freight or passenger transportation on the open seas or inland waters, and establishments that provide incidental services such as lighterage, towing, and canal operation. Also includes excursion, sightseeing, water taxis, and cargo handling.

WATER TRANSPORTATION OF FREIGHT = ВОДНАЯ ПЕРЕВОЗКА ГРУЗОВ – Water Transportation Of Freight (not elsewhere classified):- establishments primarily engaged in transporting freight on all inland waterways, including the intracoastal waterways on the Atlantic and Gulf coasts.

WATER TRANSPORTATION OF PASSENGERS = ВОДНАЯ ПЕРЕВОЗКА ПАССАЖИРОВ – Water Transportation Of Passengers (not elsewhere classified):- establishments primarily engaged in furnishing water transportation of passengers, not elsewhere classified, such as airboats (swamp buggy rides), excursion boat operations, and sightseeing boats.

WATER TREATMENT = ВОДОПОДГОТОВКА (или ОБРАБОТКА ВОДЫ, или ОЧИСТКА ВОДЫ) – Water Treatment refers to:- (1) (prior to first use) process to render water withdrawn from any source suitable for first use; and (2) Waste-water treatment by mechanical, biological and advanced procedures.

WATER TUBE = ВОДЯНОЙ ПАТРУБОК (или КИПЯТИЛЬНАЯ ТРУБА, или ВОДОПРОВОДНАЯ ТРУБА) – Water Tube is a tube in a boiler having the water and steam on the inside and heat applied to the outside.

WATER TURBINE = ВОДЯНАЯ ТУРБИНА (или ГИДРОТУРБИНА) – Water Turbine is a turbine that uses water pressure to rotate its blades; the primary types are the Pelton wheel, for high heads (pressure); the Francis turbine, for low to medium heads; and the Kaplan for a wide range of heads. Primarily used to power an electric generator. / ковшовая турбина Пэлтона (Pelton); радиально-осевая турбина Фрэнсиса (Francis); поворотно-лопастная турбина Каплэна (Kaplan).

WATER USE = ВОДОПОЛЬЗОВАНИЕ (или ПОЛЬЗОВАНИЕ ВОДАМИ) – So What Do ‘Water Use’ And ‘Water Consumption’ Mean? Water Use describes the total amount of water withdrawn from its source to be used. Measures of water usage help evaluate the level of demand from industrial, agricultural, and domestic users. For example, a manufacturing plant might require 10 000 gallons of freshwater a day for cooling, running, or cleaning its equipment. Even if the plant returns 95 percent of that water to the watershed, the plant needs all 10 000 gallons to operate. Water Consumption is the portion of water use that is not returned to the original water source after being withdrawn. Consumption occurs when water is lost into the atmosphere through evaporation or incorporated into a product or plant (such as a corn stalk) and is no longer available for reuse. Water consumption is particularly relevant when analyzing water scarcity and the impact of human activities on water availability. For example, irrigated agriculture accounts for 70 percent of water use worldwide and almost 50 percent of that is lost, either evaporated into the atmosphere or transpired through plant leaves.

Water Consumption And Use Both Need To Be Measured:- Understanding both water use and consumption is critical to evaluating water stress. Measures of water usage indicate the level of competition and dependency on water resources. For example, domestic water use per capita in Qatar is one of the highest in the world, due in part to the free supply of water to Qatari nationals and limited rainfall. Although most of that use is non-consumptive, in an emergency, the country would only have enough water for 48 hours. Additionally, water is rarely returned to a watershed in perfect condition after being used by industry, agriculture, and other users, and change in quality contributes to water stress levels. Water consumption estimates, on the other hand, help gauge the impact of water use on downstream water availability and are essential to evaluating water shortages and scarcity at the watershed level, including impacts to aquatic ecosystems. Therefore, a holistic understanding of water stress requires analysis of both the total use and consumption of water. A Holistic Understanding Of Water Stress:- WRI's Aqueduct Water Risk Atlas accounts for the impact of both water use and consumption by using a baseline water stress indicator. (World Resources Institute (WRI); headquartered in Washington, DC, The United States of America.) Baseline water stress measures total annual water use from municipal, industrial, and agricultural sectors expressed as a percent of the total annual available water after all upstream water consumption has been subtracted. By acknowledging both total water usage and consumption, Aqueduct users can rely on the baseline water stress indicator to evaluate overall freshwater demand and availability in specific watersheds. Already, more than 1.4 billion people live in river basins where the use of water exceeds the minimum recharge levels. In the next 12 years, water withdrawals in developing countries are predicted to increase by 50 percent. Measuring water usage and consumption is critically important for identifying areas that are at risk of water scarcity and excessive competition amongst users. After all, in order to prevent or manage water risk, we must first fully understand it. See also Water Consumption Water Use refers to use of water by agriculture, industry, energy production and households, including in-stream uses such as fishing, recreation, transportation and waste disposal. Domestic Water Use:- of course some of the most important uses for water are at our homes. Domestic water use is water used for indoor and outdoor household purposes – all the things you do at home:- drinking, preparing food, bathing, washing clothes and dishes, brushing your teeth, watering the yard and garden, and even washing the dog. Water generally gets to our homes in one of two ways. Either it is delivered by a city/county water department (or maybe from a private company), or people supply their own water, normally from a well. Water delivered to homes is called Public-Supplied Deliveries' and water that people supply themselves is called Self Supplied, and is almost always from groundwater. The majority of America's population gets their water delivered from a public-supply system. This makes sense, as America's population now largely live in urban centers. The trend over the last 70 years is of people moving to urban centers and is reflected in the shrinking numbers of self-supplied people in the Nation. / Водопользование (юридическое), пользование водами (водными объектами), состоящими в исключительной собственности государства. В Советском законодательстве виды водопользования определялись:- целями использования вод (водопользование хозяйственно-питьевое, промышленное, сельскохозяйственное, транспортное, энергетическое и прочее); способом пользования (путём добычи – забора воды источника, пользование водными объектами в качестве водного пути, источника гидроэнергии и тому подобным, а также для сброса в водоёмы сточных вод); техническими условиями (водопользование общее, без применения гидротехнических сооружений или устройств, влияющих на состояние вод, и специальное, с применением таких сооружений или устройств); условиями предоставления водных объектов в пользование (совместное – если водный объект не закреплён за конкретной организацией или лицом, и обособленное – если водный объект предоставлен определённой организации или лицу), а также основаниями возникновения права пользования водами (первичное – если водный объект предоставлен в пользование непосредственно государством, и вторичное – если он предоставлен первичным водопользователем). С учётом приведённой классификации определялся правовой режим различных водных объектов, а также права и обязанности водопользователей. Например, общее водопользование (купание, водопой скота и тому подобное) осуществляется бесплатно и без разрешений государственных органов на всех водоёмах, за исключением изъятых из хозяйственного пользования, состоящих в обособленном пользовании. Для специального водопользования во всех случаях требуется предварительное разрешение государственных органов, в ряде случаев оно может быть возмездным. Все водопользователи вправе пользоваться водами в пределах, предусмотренных законодательством, и в соответствующих случаях – разрешениями государственных органов; они обязаны выполнять требования рационального использования и охраны вод и другое. Наиболее жёсткие требования предъявляются в отношении охраны вод от загрязнения производственными и бытовыми отходами. Правовыми актами установлено, что при проектировании и строительстве предприятий, зданий, сооружений и других хозяйственных объектов должны быть приняты все меры к тому, чтобы исключить сброс в водоёмы загрязнённых сточных вод и других отходов. В этих целях предписано внедрять в производство безводные технологические процессы, повторное использование воды на предприятиях, а также эффективные системы очистки сточных вод. Государственными приёмочным комиссиям было запрещено принимать в эксплуатацию новые и реконструированные предприятия, цехи и агрегаты, деятельность которых не удовлетворяла требованиям охраны водоёмов от загрязнения. Пользование водными объектами для сброса промышленных коммунально-бытовых, дренажных и других сточных вод могло производиться только с разрешения органов по регулированию использования и охране вод после согласования с органами государственного санитарного надзора, охраны рыбных запасов и другими. Сброс сточных вод допускался только, если он не приводил к увеличению содержания в водном объекте загрязняющих веществ свыше установленных норм, и при условии очистки водопользователем сточных вод до установленных специальными органами пределов. Если указанные требования нарушались, сброс сточных вод должен был быть ограничен, приостановлен или запрещён – вплоть до прекращения деятельности отдельных промышленных установок, цехов, предприятий, организаций, учреждений. В случаях, угрожающих здоровью населения, органы государственного санитарного надзора были вправе приостанавливать сброс сточных вод вплоть до прекращения эксплуатации производственных и других объектов с уведомлением об этом органов по регулированию использования и охране вод. Сброс в водные объекты производственных, бытовых и других отходов и отбросов запрещался. Была установлена система требований по водопользованию, касающаяся охраны вод от загрязнения отходами водного транспорта, лесосплава, сельского хозяйства и других. За несоблюдение указанных требований виновные привлекались к дисциплинарной, уголовной или административной ответственности. Смотрите также Государственный Водный Фонд.

WATER USE EFFICIENCY = ЭФФЕКТИВНОСТЬ ВОДОПОЛЬЗОВАНИЯ (или ЭФФЕКТИВНОСТЬ ПОЛЬЗОВАНИЯ ВОДАМИ) – Water Use Efficiency:- (1) expressed in terms of dry matter or harvested portion of the crop produced per unit of water consumed; or (2) ratio of the water used for evapotranspiration, seepage, and percolation to the sum of rainfall and irrigation supply. Water Use Efficiency is a measure of the efficiency of conversion of water into plant products. For Cotton, crop water use efficiency (CWUE) is a measure of lint yield per millimeter of water obtained from stored reserves in the soil, irrigation and rain. Calculation of irrigation efficiency (IE) is similar, but it takes into account water losses in the storage and distribution system.

WATER VAPOR = ВОДЯНОЙ ПАР – Water Vapor is a water in a vaporous form, especially when below boiling temperature and diffused, e.g., in the atmosphere. Water Vapor:- water is constantly cycling through the atmosphere. Water evaporates from the Earth's surface and rises on warm updrafts into the atmosphere. It condenses into clouds, is blown by the wind, and then falls back to the Earth as rain or snow. This cycle is one important way that heat and energy are transferred from the surface of the Earth to the

atmosphere, and transported from one place to another on our planet. Water vapor is also the most important greenhouse gas in the atmosphere. Heat radiated from Earth's surface is absorbed by water vapor molecules in the lower atmosphere. The water vapor molecules, in turn, radiate heat in all directions. Some of the heat returns to the Earth's surface. Thus, water vapor is a second source of warmth (in addition to sunlight) at the Earth's surface. These maps show the average amount of water vapor in a column of atmosphere in a given month. The units are given in centimeters, which is the equivalent amount of water that could be produced if all the water vapor in the column were to condense. The lowest amounts of water vapor (0 centimeters) appear in white, and the highest amounts (6 centimeters) appear in dark blue. Areas of missing data appear in shades of gray. The maps are based on data collected by the Moderate Resolution Imaging Spectroradiometer (MODIS) sensor on NASA's Aqua satellite (The US National Aeronautics and Space Administration (NASA)). The most noticeable pattern in the time series is the influence of seasonal temperature changes and incoming sunlight on water vapor. In the tropics, a band of extremely humid air wobbles north and south of the equator as the seasons change. This band of humidity is part of the Intertropical Convergence Zone, where the easterly trade winds from each hemisphere converge and produce near-daily thunderstorms and clouds. Farther from the equator, water vapor concentrations are high in the hemisphere experiencing summer and low in the one experiencing winter. Another pattern that shows up in the time series is that water vapor amounts over land areas decrease more in winter months than adjacent ocean areas do. This is largely because air temperatures over land drop more in the winter than temperatures over the ocean. Water vapor condenses more rapidly in colder air. Water Vapor is a synonym for steam, usually used to denote steam of low absolute pressure. Water vapor is water that is in the form of a vapor, or gas. It is a part of the water cycle. When liquid water is heated to boiling point, 100 degrees Celsius (212 F), it turns into vapor. Water vapor can also be produced directly from ice; this is called Sublimation. Steam is water vapor, but clouds are liquid water. Water vapor affects weather conditions. Water vapor is found in most of the air. In the cold, breathing out causes the water vapor in the breath to freeze. Water vapor weighs less than air, thus slightly reduces the lift produced by an aircraft wing. Water vapour is transparent. The small droplets that look white like mist are actually liquid. Water vapour is a big cause of the greenhouse effect. Water vapor is invisible but when it condenses it makes visible water. See also Steam, Sublimation, and Vapor. / Водяной Пар, газообразное состояние воды. Водяной пар получают в процессе парообразования (испарения) при нагревании воды в паровых котлах, испарителях и других теплообменных аппаратах. Водяной пар служит рабочим телом в паросиловых установках, теплоносителем в системах вентиляции, тепло- и водоснабжения; используется также в технологических целях. Если при давлении, равном 101.325 килоНьютонов на кубический метр (кН/м^3) (760 миллиметров ртутного столба (мм рт.ст.)), воду нагреть до 100 °С, то она закипает (смотрите Кипение) – начинает образовываться пар, имеющий ту же температуру, но существенно больший объём. До тех пор пока остаётся некоторое количество воды, температура системы, несмотря на непрекращающийся подвод теплоты, постоянна. Состояние, при котором вода и пар находятся в равновесии, называется Состоянием Насыщения (смотрите Насыщенный Пар), характеризующегося давлением насыщения и температурой насыщения. Только после превращения всей воды в пар, объём которого при 100 градусах Цельсия (°С) в 1 673 раза больше объёма воды при 4 °С, температура может начать вновь повышаться. При этом пар из насыщенного переходит в перегретое состояние (смотрите Перегретый Пар). Если процесс испарения проводить при различных давлениях, то температура испарения меняется в зависимости от давления. Теплоту, затраченную на нагревание 1 килограмма (кг) воды от 0 °С до температуры насыщения, называют Энтальпией Воды, а теплоту, затраченную на превращение 1 кг воды с температурой насыщения в сухой насыщенный пар, – Теплотой Парообразования (Испарения). При давлении, равном критическому (смотрите Критическое Состояние), теплота парообразования равна 0, а если проводить нагрев при более высоких давлениях, то при подводе теплоты происходит непрерывное изменение температуры, сопровождающееся непрерывным приращением объёма без разделения вещества на жидкую и газообразную фазу. Такой подогрев водяного пара при давлениях выше критического (критические параметры воды:- давление 22.1 МегаНьютонов на квадратный метр (МН/м^2) (225.65 килограмм-силы на квадратный сантиметр (кгс/см^2)), температура 374.15 °С, плотность 303 кг/м^3) иногда осуществляется в паровых котлах. В паровых машинах и турбинах применяется, как правило, не насыщенный, а перегретый пар, так как коэффициент полезного действия (кпд) машин, работающих перегретым паром (иногда его называют острым паром), выше. В бывшем Союзе Советских Социалистических Республик (СССР) и за рубежом в мощных паросиловых установках применялся водяной пар с давлением 25 МН/м^2 (255 кгс/см^2) и температурой 545 °С. Для целей нагревания (например, отопительных приборов) экономически оправдано использование насыщенного водяного пара, так как коэффициент теплоотдачи от конденсирующегося насыщенного водяного пара значительно больше, чем от перегретого. Изучение свойств водяного пара началось в XVI–XVII веках. В начале XVII века в работах Итальянского учёного Джямбаттиста дэля Порта (Giambattista della Porta; 1535–1615) исследовался удельный объём водяного пара, тогда же Французским учёным С. де Ко были рассмотрены вопросы конденсации пара. В конце XVIII века были исследованы отдельные свойства водяного пара:- зависимость температуры парообразования от давления (Французский физик Дёни Папа (Denis Papin); 1647–1714), теплота парообразования (Шотландский физик и химик Дьжосиф Блэк (Joseph Black; 1728–1799), Английский изобретатель Дьжеймз Вот (или Уатт; James Watt; 1736–1819)), удельный объём пара при давлении 0.1 Мн/м^2 (Дьжеймз Вот). Изучение свойств пара как рабочего тела паровых машин было начато в 1840-х Французским физиком и химиком Ори-Виктором Рэньо (Henri-Victor Regnault; 1810–1878). В 1904 Немецкий учёный теплотехник Рихяд Молье (Richard Mollier; 1863–1935) предложил график энтальпии-энтропии (enthalpy-entropy chart), известный также как h–s диаграмма (h–s chart или Mollier diagram) состояния водяного пара. В России в XIX веке над изучением свойств водяного пара работали учёные Л. Г. Богаевский, Б. Б. Голицын, А. И. Надеждин и другие. В бывшем СССР Профессором Иваном Ивановичем Новиковым (1916–2014) было выведено теоретическое уравнение состояния перегретого пара (реального газа). Широкие экспериментальные исследования термодинамических и физических свойств воды и водяного пара проводили Профессор Михаил Петрович Вукалович (1898–1969), Профессор Натан Борисович Варгафтик (1904–1994), Академик Владимир Алексеевич Кириллин (1913–1999), Профессор Дмитрий Львович Тимрот (1902–1992) и другие. На основании исследований Советских учёных в бывшем СССР были составлены таблицы и диаграммы термодинамических свойств воды и водяного пара при давлениях до 100 Мн/м^2 и температурах до 1 000 °С. В 1963 в Нью Йорке (США) на 4-й Международной Конференции По Свойствам Водяного Пара были приняты международные скелетные таблицы свойств водяного пара.

WATERWAY = ВОДНЫЙ ПУТЬ – Waterway:- river, canal, lake or other stretch of water which by natural or man-made features is suitable for navigation. Waterways of a maritime character (waterways designated by the reporting country as suitable for navigation primarily by sea-going ships) are included. Waterways also include river estuaries; the boundary being that point nearest the sea where the width of the river is both less than 3 km at low water and less than 5 km at high water. Waterway is a natural or artificially constructed course for the concentrated flow of water. Waterway is a river, channel, canal, or other navigable body of water used for travel or transport. WATER WEEVIL = ВОДЯНОЙ ДОЛГОНОСИК (или ВОДЯНОЙ СЛОНИК) – Rice Water Weevil (Scientific Name:- Lissorhoptrus Oryzophilus). Description Of The Pest:- the Rice Water Weevil adult (about 0.125 inch or 4 mm long) has a prominent beak and is gray with a dark marking on its back from the base of its head to the middle of its wing covers. It is distributed throughout the Sacramento Valley, the upper San Joaquin Valley, and central San Joaquin Valley (Merced County). It overwinters as an adult at the base of grass clumps, in weedy debris on levees and ditch banks, or in soil crevices. When daytime temperatures rise above 70 °F (21 °C) in late winter or early spring, rice water weevil adults begin feeding on grasses to build up their wing muscles. On calm, warm evenings (sunset to midnight), they fly in search of plant hosts growing in water. They are attracted to flooded rice fields and begin feeding on emerged rice or grasses in water along the levee banks. Longitudinal scars on the upper leaf surface indicate their presence in the field, if they are not directly observed. No males occur in California and females reproduce without mating. After arriving in a field and feeding for a few days, they lay their eggs singly under water in the leaf sheath tissue above the plant crown. One female may lay over 200 elongated eggs (0.03 inch or less than 1 mm long) over a period of several weeks. The adults that initially infest a field prefer to feed and lay their eggs in areas of the field adjacent to the levee margins. About 7 days after being laid, the eggs hatch. Small larvae mine the leaf sheath for about a day and then move to the soil to feed on the roots, where they stay through four larval instars. The legless larvae are milky white with light brown heads and have spinelikeprojections on their backs to pierce the roots and obtain oxygen. When their growth is completed, larvae pupate in mud-coated cocoons that they attach to the roots of rice, sedges, or various grasses. Adults emerge from the pupalcells from July until September. They feed on rice leaves, but by this time most plants are growing vigorously and are not adversely affected by this late adult feeding. A few of these adults will lay eggs in July or August but most enter a resting stage called Diapause. They fly to overwintering sites and remain at the base of plants, particularly perennial grasses, or debris through the winter. The life cycle from egg to adult takes about 78 days in the laboratory at 73 °F (23 °C) with approximately 7 days in the egg stage, 50 days as larvae, and 21 days for pupation. The minimum time for development in the field is about 60 to 65 days. Damage:- Rice Water Weevil is the most economically damaging of the invertebrate pests found in California. Root pruning by larvae is the major cause of reduced yields. Plants with damaged roots may become stunted and lose yield through reduction of tillers and panicles or because maturity is delayed. Reduced tilleringand slower growth also allow weeds to become better established. The heaviest infestations and most serious damage can be expected to occur between late May and July within 15 to 20 feet of the margins of the fields and levees, where weevils are concentrated; moderate damage can occur in areas 20 to 35 feet from levees. Adult feeding appears as linear slits of varying length on the upper surface of the leaves but generally does not cause economic losses. High populations of adults feeding on young rice seedlings just as they emerge through shallow water may kill some seedlings, but such injury is uncommon. Management:- management of Rice Water Weevil may be enhanced by weed control in areas around the rice field, drill seeding, and winter flooding, depending upon current management strategies for other pests. In fields with chronic, damaging populations of rice water weevil, a preventive treatment may be advisable with application limited to the field edges. Cultural Control:- Rice water weevil adults have shown a preference in California for the areas adjacent to levees and field edges during the critical period of infestation at the beginning of the season. Large, laser-leveled fields generally have less land per acre associated with levees and field edges and, therefore, large fields will have less area per acre subject to infestation. Removing weedy vegetation on the levees in spring near the time of seeding can reduce rice water weevil infestations in fields and subsequent larval populations. Drill seeding involves seeding the dry Rice field, irrigating the soil to germinate the seed, and keeping the soil moist for 6 to 8 weeks, at which time the field is then flooded. By the time the field is flooded, rice plants are more tolerant to rice water weevil injury. This method of control reduces or eliminates exposure of susceptible plants to weevil populations but may not compatible with current weed management strategies. Winter flooding of the field to enhance straw breakdown and provide waterfowl habitat can help with weevil control and reduce populations by about 50%. Aquatic weeds are strong competitors of Rice for nutrients and space, particularly during the tilleringstage. Because the rice water weevil larvae prune roots and reduce tillering, it is particularly important to have early and effective weed control to maximize recovery from water weevil injury. Organically Acceptable Methods:- cultural control methods including weed control and increasing field size are acceptable for use on organically certified Rice. Monitoring and Treatment Decisions:- treatment decisions for Rice Water Weevil are primarily based on past history of a particular field, proximity to weevil overwintering sites (ditch banks, riparian areas, weedy canal banks, etc) and economics. A new sampling method has been developed to aid in decision-making for post-flood insecticide applications. A floating barrier trap can be used and placed in fields immediately after flooding. If one rice water weevil adult per trap per day is collected during the first 7 days after flooding, that is indicative that damaging larval populations will likely develop and that a post-flood insecticide application should be considered. After the first 7 days after flooding and especially after seedling establishment, the trap does not efficiently sample adults and should not be used. Lambda-cyhalothrin (Warrior), zeta-cypermethrin(Mustang), and diflubenzuron (Dimilin) are foliar treatments applied after flooding; these products control rice water weevil adults by disrupting their life cycle but have no toxicity against the weevil larvae, which is the primary damaging stage. Warrior and Mustang work by killing the adults, therefore reducing the number of eggs deposited and the resulting larval population. Rice plants are protected by the reduction of larval populations. Dimilin functions by sterilizing adult females, causing them to lay nonviable eggs, thus reducing the larval populations. It also is toxic to newly laid eggs, i.e. those that are less than 4 days old. Lambda-cyhalothrin (Warrior) is also registered for a preflood application. In areas that have a history of rice water weevil infestations, this application should be considered. Applications can be made within 5 days of flooding and light incorporation is recommended to improve efficacy. Because there is only one generation a year, timing is critical with these products. If they are applied too late, the eggs and larvae may already be present and the product will have little effect. Also, they are fairly short-lived products in water; if they are applied too early, they will dissipate before the adults are present in the field and have minimal effect. Research has shown that applications of these products to only the 30 to 50 feet adjacent to the levees can provide acceptable Rice Water Weevil control in most conditions. This is the area with the most significant Rice Water Weevil infestation, and the insecticide applied only to this area persists in an adequate concentration long enough to affect the adult weevils. Water Weevil is a major insect pest of Rice. Water weevil larvae feed on the roots of Rice plants. See also Pest. Common Name:- Rice Water Weevil. Scientific Name:- Lissorhoptrus oryzophilus Kuschel. Order:- Coleoptera. Description:- adult weevils are small (1/8 inch), grayish-black snout beetles which may have a darker brown V-shaped area on their backs. Life Cycle:- adults spend winter hibernating (diapausing) in clump grasses, field trash and Spanish moss. Female weevils insert white eggs into leaf sheaths under water. In 4 to 9 days, tiny (1/32 inch), white, slender, legless, C-shaped larvae or grubs hatch from eggs and develop through four stages (instars) for about 27 days until they are about 1/3 inch long. They then pupate within a water-tight, oval mud cell attached to the roots and emerge 5 to 7 days later. Adults emerge throughout the reproductive stage of rice development and feed on leaves before leaving the field in late summer and fall. Development from egg to adult normally occurs within 35 days. Two generations and possibly a partial third can occur annually. Habitat and Food Source(s):- mouthparts are for chewing. In spring (April through May), when Rice plants have emerged and are being flooded, they fly into Rice fields and feed on the upper layer of cells (epidermis) of leaves, producing long, narrow window-like (skeletonized) slits along the leaf called Feeding ‘Scars’. Upon reaching host plants, flight muscles of adults degenerate. Larvae chew on roots of developing rice and obtain oxygen from the host plant by means of a paired hooks on the upper surface of their

second through seventh abdominal segments. Adults are most active during the evening and night. Alternate host plants include aquatic grasses and sedges that occur in and around Rice fields. Pest Status, Damage:- larval stages feed on roots of developing Rice plants, causing yield reduction when they occur in large numbers; medically harmless.The root damage caused by high numbers of larvae reduces yield.

WATER WELL = ВОДЯНАЯ СКВАЖИНА – Water Well is a well drilled to (1) obtain a water supply to support drilling or plant operations, or (2) obtain a water supply to be used in connection with an improved recovery program. See also Well. Water Well:- a bored, drilled or driven shaft or dug hole whose depth is greater than the largest surface dimension and whose purpose is to reach underground water supplies.

WATER WHEEL = ВОДЯНОЕ КОЛЕСО – Water Wheel is a wheel that is designed to use the weight and/or force of moving water to turn it, primarily to operate machinery or grind grain. Waterwheel is a mechanical device for tapping the energy of running or falling water by means of a set of paddles mounted around a wheel. The force of the moving water is exerted against the paddles, and the consequent rotation of the wheel is transmitted to machinery via the shaft of the wheel. The waterwheel was perhaps the earliest source of mechanical energy to replace that of humans and animals, and it was first exploited for such tasks as raising water, fulling cloth, and grinding grain. The combination of waterwheel and transmission linkage, often including gearing, was from the Middle Ages usually designated a mill. Of the three distinct types of water mills, the simplest and probably the earliest was a vertical wheel with paddles on which the force of the stream acted. Next was the horizontal wheel used for driving a millstone through a vertical shaft attached directly to the wheel. Third was the geared mill driven by a vertical waterwheel with a horizontal shaft. This required more knowledge and engineering skill than the first two, but it had much greater potential. Vertical waterwheels were also distinguished by the location of water contact with the wheel; first, the undershot wheel; second, the breast wheel; and third, the overshot wheel. These waterwheels generally used the energy of moving streams, but tidal mills also appeared in the XI century. Each type of mill had its particular advantages and disadvantages. Relatively little is known of their development before the Middle Ages, but certain of their characteristics suggest an order of appearance within the context of the complexity of construction and the possibilities for utilization. The simple vertical wheel required little extra structure, but the force and rate of power takeoff were dependent upon stream characteristics and wheel diameter. Since change of power direction was not involved, this wheel proved most useful in raising water, utilizing, for instance, a string of pots worked by a chain drive. The horizontal-wheel mill (sometimes called a Norse or Greek Mill) also required little auxiliary construction, but it was suited for grinding because the upper millstone was fixed upon the vertical shaft. The mill, however, could only be used where the current flow was suitable for grinding. The geared vertical-wheel mill was more versatile. Construction was relatively simple if the wheel were of the undershot kind, for the wheel paddles could be simply dipped in the stream flow, whether it was river, tide, or man-built millrace. A millwright could choose his gear ratio to match power utilization with rate of stream flow, and the wheel could be mounted in a bridge arch or on a barge anchored in midstream. Vitruvius described the first geared vertical wheel for which we have good evidence. This mill is also of major significance because it was the first application of gearing to utilize other than muscle power. This mill had an undershot wheel and, unlike the breast or overshot wheels, did not make use of the weight of falling water. Mills with geared breast and overshot wheels required more auxiliary construction, but they allowed the most generalized exploitation of available water power. A major construction problem was locating a mill where the fall of water would be suited to the desired diameter of the wheel. Either a long millrace from upstream or a dam could be used. Little is known of the details of geared-mill development between the time of Vitruvius and the XII century. An outstanding installation was the grain mill at Barbegal, near Arles, Fr., which had 16 cascaded overshot wheels, each 7 feet (2 meters) in diameter, with wooden gearing. It is estimated that this mill could meet the needs of a population of 80 000. Even though the highly adaptable, geared mill, with its widely diversified stream-flow conditions, was used in the Roman Empire, historical evidence suggests that its most dramatic industrial consequences occurred during the Middle Ages in Western Europe. After the XIII century the overshot waterwheel appears to have become more common than the undershot wheel. The geared mill of the Middle Ages was actually a general mechanism for the utilization of power. The power from a horse- or cattle-powered mill was small compared to that from overshot water-wheels, which usually generated two to five horsepower.

WATT = BATT – Watt is the unit of power in the International System of Units (SI) equal to one Joule of work performed per second, or to 1/746 horsepower. An equivalent is the power dissipated in an electrical conductor carrying one Ampere current between points at one Volt potential difference. It is named in honor of James Watt (1736-January-19–1819-August-25; Scottish instrument maker and inventor whose steam engine contributed substantially to the Industrial Revolution; he was elected fellow of the Royal Society of London in 1785). One thousand Watts equal one kiloWatt. Most electrical devices are rated in Watts. Watt is the unit of power equal to the rate of work represented by a current of one Ampere under a pressure of one Volt. Named after the Scottish engineer James Watt, 1819. Watt is the electrical unit of power. The rate of energy transfer equivalent to 1 Ampere flowing under a pressure of 1 Volt at unity power factor. Abbreviation:- W. The unit of electrical power equal to one Ampere under a pressure of one Volt. A Watt is equal to 1/745.7 horsepower. The SI unit of power. Power is the rate at which work is done, or (equivalently) the rate at which energy is expended. One Watt is equal to a power rate of one Joule of work per second of time. This unit is used both in mechanics and in electricity, so it links the mechanical and electrical units to one another. In mechanical terms, one Watt equals about 0.001 341 02 horsepower (hp) or 0.737 562 foot-pound per second (lbf/s). In electrical terms, one Watt is the power produced by a current of one Ampere flowing through an electric potential of one Volt. The name of the unit honors James Watt (1736–1819), the British engineer and inventor who built the first practical steam engines. Watt (W) is the unit of electrical power equal to one Ampere under a pressure of one Volt. A Watt is equal to 1/745.7 horsepower (hp). Watt is a unit of measure of electric power at a point in time, as capacity or demand. One Watt of power maintained over time is equal to one Joule per second. Some Christmas tree lights use one Watt. The Watt is named after Scottish inventor James Watt and is capitalized when shortened to W and used with other abbreviations, as in kWh. Watt:- the base unit of power, a Watt, is a measure of the rate at which work is being done. / Единица электрической энергии, эквивалентная одному Амперу при одном Вольте. 1 Ватт равен 1/745.7 или 0.001 341 02 лошадиной силы (лс). Ватт – универсальная единица мощности в Международной Системе Единиц СИ. Названа в честь Шотландского изобретателя Дьжеймза Вота (или Дьжеймса Уатта; James Watt; 1736–1819). Обозначение:- Вт. 1 Ватт равен:- (i) мощности, при которой за время 1 с совершается работа в 1 Дж; (ii) активной мощности электрической цепи, эквивалентной механической мощности 1 Вт; (iii) тепловому потоку, эквивалентному механической мощности 1 Вт. 1 Вт = 10^7 эрг/с = 0.102 кгс·м/с = $1.36 \cdot 10^{-3}$ лс. Применяют Ватт также в качестве единицы звуковой мощности, потока звуковой энергии, потока энергии ионизирующего

излучения и так далее. В технике широко используют кратные и дольные единицы от Ватта, такие как килоВатт (1 кВт = 10^3 Вт), МегаВатт (1 МВт = 10^6 Вт) и ГигаВатт (1 ГВт = 10^9 Вт) и другие. Ватт – единица мощности, входит в Международную Систему Единиц. Обозначается Вт или W. Ватт – мощность, при которой за время 1 секунда (сек) совершается работа, равная 1 Джоулю (Дж). Ватт как единица электрической (активной) мощности равен мощности неизменяющегося электрического тока силой 1 Ампер при напряжении 1 Вольт. 1 Вт = 10^7 эрг/сек = 0.102 кгс·м/сек = $1.36 \cdot 10^{-3}$ лошадиных сил (л.с.). Ввиду малости размера Ватт в технике обычно применяются кратные единицы:- килоВатт (1 кВт = 1 000 Вт) и МегаВатт (1 МВт = 1 000 000 Вт).

WATTHOUR = ВАТТ–ЧАС – Watthour is a common metric unit of work or energy, representing the energy delivered at a rate of one Watt for a period of one hour. This is equivalent to exactly 3.6 kiloJoules (kJ) of energy, or about 3.412 141 Btu, 0.859 846 (kilogram) Calories, or about 2 655 foot pounds. The electrical energy unit of measure equal to one Watt of power supplied to, or taken from, an electric circuit steadily for one hour. Watthour (Wh) is the electrical energy unit of measure equal to one watt of power supplied to, or taken from, an electric circuit steadily for one hour. Watt-Hour:- one Watt of power expended for one hour. One thousandth of a kiloWatt-hour. Watthour (Wh) is an electrical energy unit of measure equal to one Watt of power supplied to, or taken from, an electric circuit steadily for one hour. A unit of energy equivalent to one thousandth of a kiloWatthour. / 1 Ватт-Час равен 3 600 Джоулей (Дж). Ватт-час является внесистемной единицей работы и энергии. Обозначение:- Вт·ч (Wh). 1 Вт·ч = 3 600 Дж; 1 кВт·ч = $3.6 \cdot 10^6$ Дж.

WATT–HOUR METER = ВАТТ–ЧАС МЕТР (или ЭЛЕКТРИЧЕСКИЙ СЧЁТЧИК) – Watt-Hour Meter is a device that measures and records over time the electric power flowing through a circuit. Although there are several different types of Watt-hour meters, each consists essentially of a small electric motor and a counter. A precise fraction of the current flowing in the circuit is diverted to operate the motor. The speed at which the motor turns is proportional to the current in the circuit, and, therefore, each revolution of the motor's rotor corresponds to a given amount of current flowing through the circuit. The counter is connected to the rotor and adds and displays the amount of power the circuit has carried based on the number of revolutions of the rotor. The counter is usually marked in kiloWatt-hours (1 000 Watt-hours). Mercury-type and commutator-type Watt-hour meters measure power in direct-current circuits. Induction-type meters measure power in alternating-current circuits and are the type commonly seen on the outside of houses. Specialized Watt-hour meters include totalizing meters, which record the power used in more than one circuit, and highly accurate portable meters, which are used for testing installed Watt-hour meters. / Электрический Счётчик – прибор для учёта расхода (потребления) электрической энергии в сетях переменного или постоянного тока. В механических электрических счётчиках подвижная часть вращается во время потребления электрической энергии, расход которой (обычно в кВт·ч или А·ч) определяется по показаниям счётного механизма. Электрический Счётчик – электроизмерительный прибор для учёта электроэнергии, отдаваемой станцией в сеть или получаемой потребителем от сети за определённый промежуток времени. По характеру выполняемого измерения электрические счётчики относятся к интегрирующим измерительным приборам. В цепях постоянного тока применяют электрические счётчики магнитоэлектрических, ферродинамических, электролитических и электродинамических систем, а в цепях переменного тока – преимущественно индукционные (для учёта как активной, так и реактивной энергии). Электрические счётчики всех систем, кроме электролитических, представляют собой микроэлектродвигатели, поэтому их часто называют Моторными. Основное отличие электрического счётчика от показывающих приборов со стрелочным или световым указателем состоит в том, что его подвижная часть не связана пружиной и может свободно вращаться, причём каждому её обороту соответствует определённое значение измеряемой величины. Электрический счётчик имеет цепи тока и напряжения с последовательным и параллельным включением в контролируемую цепь. Протекающие по цепям токи создают в электромагнитах переменные магнитные потоки Φ_U (поток, создаваемый током в цепи напряжения (параллельной нагрузке)) и Φ_I (поток, создаваемый током нагрузки) в результате взаимодействия потока Φ_U с вихревыми токами, индуктируемыми в диске потоком Φ_I, возникает вращающий момент, пропорциональный мощности P. Количество оборотов подвижной части за время t пропорционально энергии $W = \int^2_0 Pdt$. Результат измерения (обычно в килоВатт-часах) определяют по показаниям счётного механизма, соединённого червячной передачей с осью диска. Электрический счётчик постоянного тока применяют для учёта расхода электроэнергии на подвижном составе электрифицированного железнодорожного транспорта, на электролизных установках (в условных единицах – Вольт-часах), для измерения количества электричества (в Ампер-часах), прошедшего через аккумуляторную батарею при её зарядке. Электрические счётчики переменного тока применяют как квартирные счётчики электроэнергии и для учёта расхода электроэнергии в электроприводах, осветительных сетях, коммунальном хозяйстве и тому подобном. Погрешность измерения электрического счётчика 1–2.5%.

WATTLE = БОРОДКА (или ПЛЕТЕНЬ) – Wattle(s) (cattle) is a type of cattle ownership identification mark. Wattles are used in colder climates where longer winter hair growth makes brand recognition difficult. This form of identification is made by surgically separating both layers of skin from the connective tissue on the neck or the jaw by pinching up a quantity of skin and cutting it. When the cut is healed, a hanging flap is left with an approximate distance of two to four inches. See also Brand(ing), and Freeze Brand(ing). / строчка с защипами (pinching) – порок.

WAVE = WATER ALLIANCES FOR ENVIRONMENTAL EFFICIENCY

WAVE = ВОЛНА – Wave:- on a body of water, a ridge or swell on the surface, normally having a forward motion distinct from the oscillatory motion of the particles that successively compose it. The undulations and oscillations may be chaotic and random, or they may be regular, with an identifiable wavelength between adjacent crests and with a definite frequency of oscillation. In the latter case, the waves may be progressive, in which the crests and troughs appear to travel at a steady speed in a direction at right angles to themselves. Alternatively, they may be standing waves, in which there is no progression. In this case, there is no rise and fall at all in some places, the nodes, while elsewhere the surface rises to a crest and then falls to a trough at a regular frequency. There are two physical mechanisms that control and maintain wave motion. For most waves, gravity is the restoring force that causes any displacements of the surface to be accelerated back toward the mean surface level. The kinetic energy gained by the fluid returning to its rest position causes it to overshoot, resulting in the oscillating wave motion. In the case of very short wavelength disturbances of the surface, i.e. ripples, the restoring force is surface tension, wherin the surface acts like a stretched membrane. If the wavelength is less than a few millimeters, surface tension dominates the motion, which is described as a Capillary Wave. Surface gravity waves in which gravity is the dominant force have wavelengths greater than approximately 10 cm (4 in.). In the intermediate length range, both restoring mechanisms are important. The mathematical theory of water wave propagation shows that for waves whose amplitude is small compared to their length, the wave profile can be sinusoidal, and there is a definite relationship between the wavelength and the

wave period, which also controls the speed of wave propagation. Longer waves travel faster than shorter ones, a phenomenon known as Dispersion. If the water depth is less than one-twentieth of the wavelength, the waves are known as Long Gravity Waves, and their wavelength is directly proportional to their period. The deeper the water, the faster they travel. For capillary waves, shorter wavelengths travel faster than longer ones. The energy of the waves is proportional to the square of the amplitude, i.e. the maximum displacement of the surface above or below its rest position. Mathematical analysis shows that a distinction must be made between the speed of the troughs and crests, called the Phase Speed, and the speed and direction of the transport of energy or information associated with the wave, termed the group velocity. For non-dispersive long waves the two are equal, whereas for surface gravity waves in deep water the group velocity is only half the phase speed. Thus, in a train of waves spreading out over a pond after a sudden disturbance at a point, the wave front travels at only half the speed of the crests, which appear to run through the packet of waves and disappear at the front. For capillary waves, the group velocity is one and one-half times the phase speed. Waves whose amplitude is large compared to their length cannot be so readily described by mathematical theory, and their form is distorted from a sinusoidal shape. The troughs tend to flatten and the crests sharpen toward a point, a shape known as a Conoidal Wave. In deeper water the limiting height of a wave is one-seventh of its length. As it approaches this height the pointed crests break to form whitecaps. In shallow water the long-amplitude waves distort, because crests travel faster than troughs to form a profile with a steep rise and slow fall. As such waves travel into shallower water on a beach, they steepen until breaking occurs. Waves on the sea surface are generated by the action of the wind. During generation the disturbed sea surface is not regular and contains many different oscillatory motions at different frequencies. Wave spectra are used by oceanographers to describe the distribution of energy at different frequencies. The form of the spectrum can be related to wind speed and direction and the duration of the storm and the fetch (or distance upwind) over which it has blown, and this information is used for wave prediction. After the storm has passed, the waves disperse, the longer-period waves (about 8 to 20 seconds) propagating long distances as well, while the shorter-period waves are damped out by internal friction. / Волна – возмущение, распространяющееся с конечной скоростью в пространстве и несущее с собой энергию без переноса вещества. Волны – изменения состояния среды (возмущения), распространяющиеся в этой среде и несущие с собой энергию. Морские Волны – волны на поверхности моря или океана. Благодаря большой подвижности частицы воды под действием разного рода сил легко выходят из состояния равновесия и совершают колебательные движения. Причинами, вызывающими появление волн, являются приливообразующие силы Луны и Солнца, ветер, колебание атмосферного давления, подводные землетрясения и деформации дна. В соответствии с этим морские волны подразделяются на приливные (смотрите Приливы И Отливы), ветровые, барические (смотрите Сейши) и сейсмические (смотрите Цунами). В большинстве случаев волновые движения отличаются неправильностью формы. Следует различать перемещение частиц в волне и видимое движение формы волны, заключающееся в передвижении в пространстве её профиля. Частицы в волне совершают перемещение по замкнутым или почти замкнутым траекториям. Основные характеристики морских волн – их высота, равная расстоянию по вертикали между гребнем и подошвой волны, длина волны – расстояние по горизонтали между двумя смежными вершинами или подошвами волн, скорость перемещения формы волны, или фазовая скорость, период волны. Период ветровых морских волн не превосходит 30 секунд (сек), барические и сейсмические морские волны имеют период, исчисляемый минутами, десятками минут и часами. Периоды приливных волн измеряются часами. В зависимости от преобладающей роли сил, участвующих в формировании волновых движений, волны подразделяются на гравитационные и капиллярные (смотрите Волны На Поверхности Жидкости). Волны, продолжающие существовать после окончания действия сил, их вызвавших, называются Свободными Волнами, в отличие от Вынужденных Волн, поддерживаемых непрерывным притоком энергии. Ветровые Волны – вынужденные волны, образующиеся за счёт энергии ветра, передаваемой волнам путём непосредственного давления воздушного потока на наветренные склоны гребней и его трения о поверхность волны. Развитие ветровых волн начинается с образования ряби, являющейся капиллярными волнами. Возрастая, капиллярные волны превращаются в гравитационные, которые постепенно увеличиваются по длине и высоте. В начальной стадии развития волны бегут параллельными рядами, которые затем распадаются на обособленные гребни (трёхмерное волнение). Взволнованная ветром поверхность воды приобретает весьма сложный рельеф, непрерывно изменяющийся во времени. На поверхности моря всегда существуют ветровые волны самые разнообразные по своим размерам (иногда достигая длины до 400 метров (м), высоты 12–13 м и скорости распространения 14–15 м/сек). В глубоком море размеры волн и характер волнения определяются скоростью ветра, продолжительностью его действия, ‘разгоном волн’, то есть расстоянием от подветренного берега в направлении ветра до точки наблюдения, а также структурой ветрового поля и конфигурацией береговой черты. В мелком море дополнительным фактором, влияющим на процесс образования волн, является глубина моря и рельеф дна; малые глубины ограничивают рост волн. Если ветер, вызвавший волнение, стихает, то ветровые волны постепенно преобразуются в свободные волны, называемые Зыбью, волны которой имеют более правильную форму, чем ветровые волны, и большую длину гребней. Наиболее часто встречается смешанное волнение, при котором одновременно наблюдаются зыбь и ветровые волны. Изучение морских волн представляет большой практический интерес в связи с многочисленными проблемами мореплавания, морского гидротехнического строительства, кораблестроения и так далее и требует детальных теоретических и экспериментальных исследований с помощью различных инструментов, устанавливаемых на судах и на берегу. Приборами для наблюдения за ветровыми волнами являются волномерные рейки или вехи, волномеры и волнографы различных систем. Стереофотосъёмка позволяет регистрировать состояние поверхности моря на большой площади. Регистрация длиннопериодных морских волн (например, приливных волн) производится приборами, называемыми Мареографами.

WAVELENGTH = ДЛИНА ВОЛНЫ – Wavelength (y):- of an electromagnetic wave, the distance in the direction of propagation between nearest points at which the electric vector has the same phase; the distance as expressed in nanometers (nm, billionth of a meter) of the wavelength period or frequency (peak to peak or trough to trough) of the wavelength in question. The visible spectrum spans 400–700 m. Wavelength is a distance between corresponding points of two consecutive waves. ‘Corresponding Points’ refers to two points or particles in the same phase, i.e. points that have completed identical fractions of their periodic motion. Usually, in transverse waves (waves with points oscillating at right angles to the direction of their advance), wavelength is measured from crest to crest or trough to trough; in longitudinal waves (waves with points vibrating in the same direction as their advance), it is measured from compression to compression or rarefaction to rarefaction. Wavelength is usually denoted by the Greek letter Lambda (λ); it is equal to the speed (v) of a wave train in a medium divided by its frequency (f):- $\lambda = v / f$. / распространение или продвижение (propagation).

WAVELLITE = ВЭЙВЭЛИТ (или ВАВЕЛЛИТ) – Wavellite:- hydrated aluminum phosphate ($Al_3(PO_4)_2(OH)_3 \cdot 5H_2O$), a common phosphate mineral that typically occurs as translucent, greenish, globular masses in crevices in aluminous metamorphic rocks, in limonite and phosphate-rock deposits, and in hydrothermal veins. Occurrences include Zbiroh, Czech Republic; Montebras, France; Barnstaple, Devon, England, the United Kingdom, where it was first found; Llallagua, Bolivia; and Dunnellon, State of Florida, the United States. Named by William Babington in 1805 in honor of Dr. William Wavell (20 December 1750 England – 15 May 1829 Barnstaple, England, England), a physician, botanist, historian, and naturalist in Harwood Parish, Devonshire, England, who discovered the mineral. Lustre:- vitreous, greasy, pearly. Diaphaneity (Transparency):- transparent, translucent. Color:- green to yellowish-green and yellow, greenish white, yellowish-brown, brown, brownish-black, blue, white and colorless; colorless in transmitted

light; coloration may be zoned. Hardness (Mohs):- 3.5-4. Density:- 2.36 g/cm^3 (measured) and 2.37 g/cm^3 (calculated). For detailed physical properties, See Phosphate Mineral (table). / Вильэм Бэбиньтчэн (William Babington). Доктор Вильэм Вэйвэл (Dr. William Wavell). Вавеллит – минерал, который по своим характеристикам близок к бирюзе и варциситу. Свое название камень получил в честь учёного Вильяма Вэйвэла, именно он впервые обнаружил вавеллит в Англии. Вавеллит является водным фосфатом алюминия. Его химическая формула – $Al_2(PO_4)_2(OH)_3 \cdot 5H_2O$. Цвет вавеллита бывает желтоватым, голубоватым, зелёным. Сам минерал состоит из множества микрокристаллов, которые преломляют солнечные лучи, из-за чего камень выглядит разноцветным. В кислотах растворяется без остатка, хрупкий. Основные физические свойства:- твёрдость – 3.5–4; плотность – 2.3–2.5 грамма на кубический сантиметр (г/см^3); блеск – стеклянный; прозрачность – просвечивает до прозрачного. Месторождения:- чаще всего вавеллит залегает в виде сферолитов, которые состоят из множества мелких игольчатых кристаллов. Диаметр сферолитов редко превышает 3 сантиметра (см), их поверхность однотонного цвета, а на срезе переливается разными оттенками. В России вавеллит добывают в районе горного кряжа Пай-Хой и в Забайкалье. Мировыми поставщиками этого минерала являются США (Арканзас), Бразилия (Вилла-Рика, Минас-Жерайс), Чехия (Богемия), Германия (Лангенштригис), Англия (Барнстэтс). Применение:- Вавеллит является ценным коллекционным минералом. Особенно ценятся Российские ярко-жёлтые образцы и голубые образцы из Бразилии. Широко применяется в сельскохозяйственной промышленности. Благодаря высокому содержанию оксида фосфора (до 32%) из этого минерала делают недорогое минеральное удобрение.

WAVEMETER = ВОЛНОМЕР (или ЧАСТОТОМЕР) – Wavemeter is a device for determining the distance between successive wavefronts of equal phase along an electromagnetic wave. The determination is often made indirectly, by measuring the frequency of the wave. Although electromagnetic wavelengths are different in different propagation media, wavemeters are conventionally calibrated on the assumption that the wave is moving in free space, i.e. at 299 792 458 meters per second. Wavelength can then be determined according to an equation in which wavelength (λ) is equal to the speed of propagation (c) divided by the frequency of vibration (f), given in Hertz. Frequencies of between 50 kHz and 1 000 MHz are usually measured by means of a tuned inductance-capacitance circuit. Values of inductance (L) and capacitance (C) being calibrated, frequency can be determined using the formula $1/2\pi\sqrt{LC}$. For measuring higher frequencies, wavemeters make use of such devices as coaxial lines or cavity resonators as tuned elements. One of the simplest is the Lecher wire wavemeter (Austrian physicist Ernst Lecher; 1856–1926), a circuit containing a sliding (moving) short circuit. By finding two points at which the short circuit gives maximum absorption of the signal, it is possible to measure directly a distance equal to one-half of a wavelength. / Австрийский физик Эрнст Лехя (Ernst Lecher; 1856–1926). Частотомер – прибор для измерения частоты периодических процессов (колебаний). Например, частоту механических колебаний измеряют вибрационным и электрическим частотомерами (в сочетании с преобразователями механических колебаний в электрические), частоту электромагнитных колебаний измеряют электрическим частотомером (в диапазоне звуковых частот) и электронными частотомерами, называемых также Волномерами (в диапазоне радиочастот).

WAVE PICKING = ВОЛНОВОЕ КОМПЛЕКТОВАНИЕ (или ВОЛНОВАЯ КОМПЛЕКТАЦИЯ) – Wave Picking is a method of picking for multiple item orders where all zones are picked simultaneously and the product is sorted later. This method of picking is often used when picking shipments for specific carriers so that the product for each carrier is in the same place and can be sorted after it is picked.

WAVINESS = ВОЛНИСТОСТЬ – Waviness is a damage as a result of moisture affecting, for instance paper plies or veneered boards. / Повреждение, возникшее в результате воздействия влаги, например на слоёную бумагу или фанерованную древесно-волокнистую плиту.

WAVY CLOTH = ВОЛНИСТОЕ ПОЛОТНО (или ВОЛНИСТАЯ ТКАНЬ) – Wavy Cloth is a cloth that will not lie flat on a cutting table. Synonym:- Baggy Cloth. Compare Tight Pick. See also Baggy Cloth. Defect Name:- Wavy Cloth. Defect Type:- weft lines, horizontal lines. Fabric Type:- Denim Bottomweights – Piece Dyed. Description:- Wavy Cloth:- This condition is the result of the loom beam let-off not working properly, causing alternate tightness and slackness of the warp yarn. This results in thick and thin places in the fabric. Severity:- Major. / Под Волнистостью Полотна понимается распространённый порок в виде неровностей поверхности полотна, вызывающих его неполное прилегание к плоскости.

WAVY FACE = ВОЛНИСТАЯ ЛИЦЕВАЯ ПОВЕРХНОСТЬ (или ВОЛНИСТЫЙ ФОН, или ВОЛНИСТАЯ ЛИЦЕВАЯ ЧАСТЬ) – Wavy Face is a surface condition characterized by a considerable variation in yarn diameter. Wavy Face:- Fabric:- Alpaca-type dress goods; Construction:- (i) Count:- 64 x 60; (ii) Warp:- 30/1 cotton; (iii) Filling:- 150/40 bright viscose rayon; Finish:- brown-dyed ground print. Defect:- wavy-face appearance. Analysis:- this condition was prevalent in gray goods and in boiled-off and bleached goods, as well as in the finished printed sample submitted. Examination proved it to be due to the presence of very unevenly spun warp yarns, the very thin ends sizing as fine as 38/1 and the very coarse ends as heavy as 27/1. On the gray goods' being wetted out, an almost crepe like effect was produced, resulting in the so-called 'Wavy' Face. / Уточина:- 150/40 .

WAVY SEAMS ON STRETCH DENIM = ВОЛНИСТЫЕ ШВЫ НА РАСТЯГИВАЮЩЕМСЯ ДЭНИМЕ – Wavy Seams On Stretch Denim:- where the seam does not lay flay and is wavy due to the fabric stretching as it was sewn or during subsequent laundering and handling operations. Recommended Solutions for wavy seams on stretch garments:- (1) use minimum presser foot pressure; (2) instruct sewing operators to use proper handling techniques and not stretch the fabric as they are making the seam; (3) where available, use differential feed to compensate for the stretch of the fabric. Fabrics defect.

WAVY SELVAGE = ВОЛНИСТАЯ КРОМКА – Wavy Selvage:- too strong temples may cause Curly or Wavy Selvage. This defect may be overcome by adjusting the position of the temple and the selvages, and by allowing the selvage to run a little oblique. Tension of ground and selvage ends must always remain uniform to minimize selvage defects. See also Slack Selvage.

WAX = ВОСК – Waxes:- solid or semisolid material derived from petroleum distillates or residues. Waxes are light-colored, more or less translucent crystalline masses, slightly greasy to the touch, consisting of a mixture of solid hydrocarbons in which the paraffin series predominates. Included are all marketable waxes, whether crude scale or fully refined. Waxes are used primarily as industrial coating for surface protection. Wax:- any of a class of pliable substances of animal, plant, mineral, or synthetic origin that differ from fats in being less greasy, harder, and more brittle and in containing principally compounds of high molecular weight (e.g., fatty acids, alcohols, and saturated hydrocarbons). Waxes share certain characteristic physical properties. Many of them melt at moderate temperatures (i.e. between about 35 and 100 °C, or 95 and 212 °F) and form hard films that can be polished to a high gloss, making them ideal for use in a wide array of polishes. They do share some of the same properties as fats. Waxes and fats, for example, are soluble in the same solvents and both leave grease spots on paper. Notwithstanding such physical similarities, animal and plant waxes differ chemically from petroleum, or hydrocarbon, waxes and synthetic waxes. They are esters that result from a reaction between fatty acids and certain alcohols other than glycerol, either of a group called Sterols (e.g., cholesterol) or an alcohol containing 12 or a larger even number of carbon atoms in a straight chain (e.g., cetyl alcohol). The fatty acids found in animal and vegetable waxes are almost always saturated. They vary from lauric to octatriacontanoic acid ($C_{37}H_{75}COOH$). Saturated alcohols from C_{12} to C_{36} have been identified in various waxes. Several dihydric (two hydroxyl groups) alcohols have been separated, but they do not form a large

proportion of any wax. Also, several unidentified branched-chain fatty acids and alcohols have been found in minor quantities. Several cyclic sterols (e.g., cholesterol and analogues) make up major portions of wool wax. Only a few vegetable waxes are produced in commercial quantities. Carnauba wax, which is very hard and is used in some high-gloss polishes, is probably the most important of these. It is obtained from the surface of the fronds of a species of palm tree native to Brazil. A similar wax, candelilla wax, is obtained commercially from the surface of the candelilla plant, which grows wild in Texas and Mexico. Sugarcane wax, which occurs on the surface of sugarcane leaves and stalks, is obtainable from the sludges of cane-juice processing. Its properties and uses are similar to those of carnauba wax, but it is normally dark in color and contains more impurities. Other cuticle waxes occur in trace quantities in such vegetable oils as linseed, soybean, corn (maize), and sesame. They are undesirable because they may precipitate when the oil stands at room temperature, but they can be removed by cooling and filtering. Cuticle wax accounts for the beautiful gloss of polished apples. Beeswax, the most widely distributed and important animal wax, is softer than the waxes mentioned and finds little use in gloss polishes. It is used, however, for its gliding and lubricating properties as well as in waterproofing formulations. Wool wax, the main constituent of the fat that covers the wool of sheep, is obtained as a by-product in scouring raw wool. Its purified form, called Lanolin, is used as a pharmaceutical or cosmetic base because it is easily assimilated by the human skin. Sperm oil and spermaceti, both obtained from sperm whales, are liquid at ordinary temperatures and are used mainly as lubricants. About 90 percent of the wax used for commercial purposes is recovered from petroleum by dewaxing lubricating-oil stocks. Petroleum wax is generally classified into three principal types:- (i) Paraffin (see Paraffin Wax), (ii) Microcrystalline, and (iii) Petrolatum. Paraffin is widely used in candles, crayons, and industrial polishes. It is also employed for insulating components of electrical equipment and for waterproofing wood and certain other materials. Microcrystalline wax is used chiefly for coating paper for packaging, and petrolatum is employed in the manufacture of medicinal ointments and cosmetics. Synthetic wax is derived from ethylene glycol, an organic compound commercially produced from ethylene gas. It is commonly blended with petroleum waxes to manufacture a variety of products. Wax is a diverse group of naturally-occurring greasy, hard, or soft and moldable high molecular weight solid substances of animal, plant or mineral origin. Wax may contain saturated hydrocarbons, esters of higher fatty acids, and higher alcohols. Most natural waxes contain a wide range of molecular sizes and therefore soften over a wide temperature range instead of melting at a specific temperature, as do substances of a uniform molecular size. Wax is a solid or semi-solid material derived from petroleum distillates or residues by such treatments as chilling, precipitating with a solvent, or de-oiling. It is a light-colored, more-or-less translucent crystalline mass, slightly greasy to the touch, consisting of a mixture of solid hydrocarbons in which the paraffin series predominates. Includes all marketable wax, whether crude scale or fully refined. The three grades included are microcrystalline, crystalline-fully refined, and crystalline-other. The conversion factor is 280 pounds per 42 US gallons per barrel. Wax is a natural, oily or greasy substance consisting of hydrocarbons or esters of fatty acids that are insoluble in water but soluble in non-polar organic solvents, such as benzene. Wax is a solid or semi-solid material at 77 degrees Fahrenheit consisting of a mixture of hydrocarbons obtained or derived from petroleum fractions, or through a Fischer-Tropsch type process, in which the straight-chained paraffin series predominates. This includes all marketable wax, whether crude or refined, with a congealing point (ASTM D 938) between 80 (or 85) and 240 degrees Fahrenheit and a maximum oil content (ASTM D 3235) of 50 weight percent. American Society for Testing and Materials (ASTM). / Американское Общество по Испытаниям и Материалам (АОИМ). Фиша-Тропш (Fischer-Tropsch; в честь Немецких химиков Франца Фиша (Franz Fischer; 1877–1947) и Ханса Тропша (Hans Tropsch; 1889–1935), осуществивших этот процесс в 1925). Под Восками понимаются продукты различного происхождения, напоминающие по свойствам пчелиный воск. Природные воски (тпл 40–90 °C) – животные (ланолин, пчелиный, спермацет) и растительные (карнаубский) – состоят главным образом из сложных эфиров высших жирных кислот и одноатомных спиртов, ископаемые (озокерит, церезин) – из предельных углеводородов. Искусственные воски получают, например, из нефтяных парафинов, полимеризацией этилена. Применяют в быту, косметике, медицине, технике.

WAX STREAKS = ВОСКОВЫЕ ПОЛОСЫ – Wax Streaks:- waxing is done during beaming to reduce hairiness and warp breakage. Because of excess waxing warp way and weft way, wax bands observed on fabric called wax streaks. Weaving defect. Wax Streaks:- (i) at warping if Wax Licking roller movement is not proper; (ii) higher or lower intermediate speed of wax roller; (iii) stopping during beaming; (iv) contact points of wax roller; (v) improper viscosity of wax; (vi) flag, fluff on wax roller accumulation; and (vii) beam and warp alignment. / Порок или дефект ткачества.

WAXY CORN = ВОСКОВИДНАЯ КУКУРУЗА (или ХХ КУКУРУЗА) – Waxy Corn refers to Corn (Maize) hybrids that produce kernels in which the starch that is contained within those kernels is at least 99% amylopectin, versus the average of 72–76% amylopectin in traditional Corn starch. / Восковидная Кукуруза – Zea Mays conv. Ceratina, гибридная Кукуруза с повышенным содержанием амилопектинов.

WAXY ENDOSPERM = ВОСКОВОЙ ЭНДОСПЕРМ – Waxy Endosperm:- glutinous or waxy type of starchy endosperm, in which the starch fraction is composed of nearly 100% amylopectin, 0–2% amylose, stains reddish brown with weak potassium iodide-iodine solution. Waxy Endosperm (syn. Glutinous Rice) is a starchy endosperm in which the starch fraction is composed almost entirely of amylopectin. It stains reddish brown with weak potassium iodide-iodine solution. Waxy endosperm has an opaque appearance. It is 'glutinous' in character, i.e. it becomes pasty and sticky when cooked. However, the waxy type of endosperm does not contain gluten. Rice pastries and high-quality Rice wine are made from milled waxy Rice. / развод (или потёк (stain)). Под Эндоспермом понимается запасающая ткань семени растений, в которой откладываются питательные вещества, необходимые для развития зародыша. Эндосперм хорошо развит у злаков, зонтичных, паслёновых и некоторых других растений.

WAXY (GLUTINOUS) RICE = ВОСКОВОЙ (ГЛЮТИНОЗНЫЙ) РИС – Waxy, Sweet or Glutinous Rice grown in the United States is short and plump with a chalky white, opaque kernel. When cooked, this Rice loses its shape and is very glutinous. Waxy Rice is more often used in commercial product formulations. The starch and flour from waxy Rice is used in frozen products as a binder for gravies, sauces, and fillings because it is resistant to breakdown during freezing and thawing, unlike some corn or wheat starches. Waxy (Glutinous) Rice is a milled Rice with negligible or no amylose in the grain. See also Glutinous Rice, and Sweet Rice. Waxy (Glutinous) Rice differs from nonwaxy (nonglutinous) Rice principally in having almost no amylase (fraction A) in its starch, which is essentially entirely amylopectin (fraction B). Some other differences in kernel composition between waxy and nonwaxy cereals may be considered as attributes of the waxy character. Since composition is affected by environmental conditions and variety, materials suitable for the study of this effect of the waxy gene on kernel composition are samples of similar genetic stock grown under identical conditions. Brown Rice samples of three pairs of isogenic lines differing in the waxy gene, which had been grown under identical conditions, were studied for their content and quality of fat, protein, and starch. Brown Rice was chosen instead of milled Rice because the composition of milled Rice would be affected by the degree of milling, which is difficult to control. / В России, к Глютинозным относят зёрна Риса однородные по цвету, плотного строения, консистенции молочного стекла, в разрезе стеаринообразные без мучнистого или стекловидного вкрапления. Глютинозный Рис:- обработанные зёрна Риса особых глютинозных сортов. От обыкновенного Риса они отличаются тем, что при варке образуют сплошную клейкую массу. Поэтому могут негативно повлиять на качество блюда,

особенно если есть желание приготовить Рис рассыпчатым. Глютинозные зёрна плотные, на разрезе с консистенцией молочного стекла, стеаринообразные, однородные по цвету, без мучнистых или стекловидных вкраплений.

WAXY WHEAT = ВОСКОВИДНАЯ ПШЕНИЦА (или ХХ ПШЕНИЦА) – Waxy Wheat refers to Varieties of Wheat (Triticum Aestivum) which produce a higher amylopectin content, and thus a lower amylose content in the starch within their seeds; than traditional Varieties of Wheat. For example, bread flour made from Waxy Wheat would contain 0–3% amylose; versus 24–27% amylose in bread flour made from traditional Varieties of Wheat. Because bread made from such waxy (i.e. lower amylose) Wheat becomes firm at a much slower rate than bread made from traditional Wheat Varieties, bread made from Waxy Wheats would probably require less shortening (added to the flour) to keep that bread soft.

WAY = ПУТЬ (или НАПРАВЛЯЮЩИЕ) – Way is a longitudinal surface that guides the reciprocal movement of a machine part. Way is movement of a ship through water such as headway, sternway or leeway.

WAYBILL = НАКЛАДНАЯ – A Waybill (WB) is a non-negotiable receipt issued by the carrier. It is most common in the container trade either where the cargo is likely to arrive before the formal documents or where the shipper does not insist on separate bills for every item of cargo carried, e.g., because this is one of a series of loads being delivered to the same consignee. Delivery is made to the consignee who identifies himself. It is customary in transactions where the shipper and consignee are the same person in law making the rigid production of documents unnecessary. See also Air Waybill, Bill Of Lading, Consignment Note, and Seawaybill. A ‘Way Bill’ or a ‘Waybill’ is another term to describe a ‘Bill Of Lading’. Waybill is a document prepared by a transportation line at the point of a shipment, showing the point of the origin, destination, route, consignor, consignee, description of shipment and amount charged for the transportation service. It is forwarded with the shipment or sent directly by mail to the agent at the transfer point or waybill destination. A detailed description of the shipment sent to the transfer point. Abbreviation is WB. Unlike a bill of lading, a waybill is not a document of title. Waybill is the non-negotiable transport document evidencing the contract for cargo transportation from one point to another. Waybill is the document covering a shipment and showing the forwarding and receiving stations, the name of consignor and consignee, the car initials and number, the routing, the description and weight of the commodity, instructions for special services, the rate, total charges, advances and waybill reference for previous services, and the amount prepaid. A WayBill is a description of goods sent with a common carrier freight shipment. Waybill (WB) is a document issued by a carrier that contains the same information as a bill of lading, but unlike the latter, does not represent a contract between the shipper and the carrier or a document of the title to the goods. It is generally a document used for tracking items sent for distribution or for transfer between warehouses. A Waybill is a written list detailing goods included in a shipment by rail or road. Unlike a Bill Of Lading, it does not have the status of a security. Waybill is a document prepared by a transportation line at the point of origin of a shipment, showing the point of origin, destination, route, consignor, consignee, description of shipment, and amount charged for the transportation service, and forwarded with the shipment, or directly by mail, to the agent at the transfer point or waybill destination. Waybill is a document, issued by a shipping line to a shipper, which serves as a receipt for the goods and evidence of the contract of carriage. Waybill is a document (that looks like a bill of lading) issued by a carrier that describes the goods to be transported and that details the shipping particulars. Waybills are issued by both air carriers (Air Waybills) and ship lines (Sea Waybills). They merely indicate that the stated goods were received by the carrier for transport, they do not convey title. Waybill is a consignment note; generally speaking, document covering dispatch of goods. Waybill is a document covering a shipment and showing the forwarding and receiving station, the names of consignor and consignee, the car initials and number, the routing, the description and weight of the commodity, instructions for special services, the rate, total charges, advances and waybill reference for previous services and the amount prepaid. / , например, . накладная не является документом права собственности. Обозначение:- WB. Накладная – товаросопроводительный, а не товарораспорядительный документ, сопровождающий груз. В зависимости от контекста под Накладной понимается:- (i) товарная накладная – первичный бухгалтерский документ, оформляющий операции по отпуску и приёму товарно-материальных ценностей; или (ii) транспортная накладная – основной документ, которым оформляется перевозка грузов по железнодорожным, внутренним водным путям, воздушным и автомобильным транспортом. Под Накладной понимается документ об отправке груза с указанием грузоотправителя, грузополучателя, маршрута, тарифа и веса. Используется перевозчиком для внутренней отчётности. Накладная (Waybill) – документ, которым оформляется отпуск и приём различных товаров, а также перевозка грузов. Регулирует отношения между отправителем, перевозчиком и получателем груза.

WAYBILL DESTINATION = НАЗНАЧЕНИЕ ПО НАКЛАДНОЙ – A Waybill (WB) Destination:- the place designated as the end; written directions for finding some lacation; written on letters or packages that are to be delivered to that location. / Назначение По Накладной – пункт назначения, указанный в транспортной накладной.

WAYBILL (NOT NEGOTIABLE) = НАКЛАДНАЯ (НЕОБОРОТНАЯ (или НЕОБРАЩАЕМАЯ, или БЕЗ ПРАВА ПЕРЕДАЧИ)) – Waybill (Not Negotiable):- a written list detailing goods included in a shipment by rail or road. Unlike a bill of lading, it does not have the status of a security.

WAYD = WHAT ARE YOU DOING?

WAY LUBRICANT = ПУТЕЙНАЯ СМАЗКА – Way Lubricant is a lubricant for the sliding ways of machine tools such as planers, grinders, horizontal boring machines, shapers, jig borers, and milling machines. A good way lubricant is formulated with special frictional characteristics designed to overcome the stick-slip motion associated with slow-moving machine parts. See also Lubricant.

WAYPORT CARGO = СКВОЗНОЙ ГРУЗ (или ПОПУТНЫЙ ГРУЗ, или ГРУЗ ДЛЯ ПОРТОВ НА ПУТИ МАРШРУТА) – Wayport Cargo is cargo using Maersk Line’s mother vessels, e.g., AE1, AE3, AE5, AE6, AE8, AE9, AE11, TP1, TP2, TP3, TP5, TP6, TP8, etc, within only 1 region. It includes transshipment cargoes. AE1 is an abbreviation for Asia-Europe Service Loop-1, AE3 – Asia-Europe Service Loop-3, and so forth. TP1 is an abbreviation for Transpacific Service Loop-1, and so forth. For example, Maersk’s Transpacific Service Loop-3 or Transpacific-3 or TP3 is all-water weekly service from Kobe, Japan via Chinese and Taiwan ports to US East Cost (Port Elizabeth, NJ) via Panama Canal with seven vessels deployed; 37 days of transit. Below are all wayport cargoes:- (i) booked OAK/SIN via HKG (routing:- OAK-HKG-SIN : 2 vessels) this shipment will be called Wayport between HKG-SIN if it uses a mother vessel such as AE1 for HKG-SIN leg; and (ii) booked YAT/SIN (routing:- YAT-SIN:- 1 vessel) if booked on mother vessel such as AE1, this is also called a Wayport Cargo. The above abbreviation is used to determine the following ports:- OAK – Port of Oakland, the US; HKG – Port of Hong Kong, China; SIN – Port of Singapore, Singapore; and YAT – Port of Yantian, China. / К Сквозному Грузу или Попутному Грузу относится груз, перевозимый материнскими судами Мэрск Лайн (Maersk Line), например, судами AE1, AE3, AE5, AE6, AE8, AE9, AE11, TP1, TP2, TP3, TP5, TP6, TP8 и так далее, но в пределах только одного региона. В такой тип груза входят перегружаемые грузы. Обозначение AE1 образуется по первым буквам типичного маршрута Азия-Европа Обслуживаемая Ветка № 1 (Asia-Europe Service Loop-1), AE3 – Азия-Европа Обслуживаемая Ветка № 3 (Asia-Europe Service Loop-3) и так далее. Обозначение TP1 образуется по первым буквам типичного маршрута Транстихоокеанская Обслуживаемая Ветка № 1 (Transpacific Service Loop-1) и так далее. Например, Транстихоокеанская Обслуживаемая Ветка № 3 или Транстихоокеанская № 3 или TP3 (Transpacific Service Loop-1 или Transpacific-3 или TP3) является всеводной

еженедельной обслуживаемой веткой из Кобе, Япония через Китайские и Тайваньские порты к Восточному Побережью США (в Порт Элизабет, Штат Нью Джерси) через Панамский Канал (Panama Canal) семью оборачивающимися судами; 37 суток в пути. Далее приводятся все сквозные грузы этой транспортной линии:- (i) забронированный OAK/SIN через HKG (маршрут:- OAK-HKG-SIN: обслуживаемый 2 судами) (booked OAK/SIN via HKG (routing:- OAK-HKG-SIN:- 2 vessels)) эта грузовая партия будет называться Сквозной между HKG-SIN, если она будет перевозиться материнским судном, таким как AE1 для участка HKG-SIN; и (ii) забронированный YAT/SIN (маршрут:- YAT-SIN: обслуживаемый 1 судном) (booked YAT/SIN (routing:- YAT-SIN: 1 vessel)) в том случае, когда забронирован под перевозку материнским судном, таким как AE1, он также называется Сквозным Грузом. Вышеперечисленные обозначения используются в морском судоходстве для профессионального обозначения следующих портов:- OAK – Порт Оклэнд, США (Port of Oakland, the US); HKG – Порт Гон Конг, Китай (Port of Hong Kong, China); SIN – Порт Сингапур, Сингапур (Port of Singapore, Singapore); и YAT – Порт Янтьян, Китай (Port of Yantian, China).

WAYS AND MEANS = СПОСОБЫ И СРЕДСТВА – Ways And Means:- provision of funds to meet a government's budgeted expenditure and demands of its economic policies, through imposition of taxes and raising of loans.

WAYS AND MEANS COMMITTEE = КОМИТЕТ ПО СПОСОБАМ И СРЕДСТВАМ – Ways And Means Committee is a permanent committee of the United States House of Representatives that makes recommendations to the US House on all bills that would raise revenue. The Committee on Ways & Means handles tax, health care, trade, welfare, and social security. The US Constitution requires that all bills regarding taxation originate in the House, and all bills regarding taxation must go through this committee. Born:- January 07, 1802. Headquartered in Washington, District of Columbia (DC), the United States. Ways And Means Committee is a committee concerned with all matters associated with raising a government's funds. The Committee of Ways and Means is a government body that is charged with reviewing and making recommendations for government budgets. The term 'Ways and Means' originated with the English Parliament (later the British Parliament and UK Parliament) and refers to the provision of revenue to meet national expenditure requirements and to forward the objectives of economic policy. Ways and Means are principally provided by the imposition of taxation. In Britain, budget resolutions, upon which the Finance Bill is based, are in fact Ways and Means resolutions. Ways and Means resolutions are also used to make provision for an increase or decrease in national debt (through the Consolidated Fund or the National Loans Fund). The Committee of Ways and Means, in effect between 1641 and 1967, was the body responsible for proposing changes in taxation to Government. Any Minister could make proposals to the committee. The Chairman of Ways and Means, an appointed role, presided over the Committee. The Committee of Ways and Means was abolished in 1967 and the responsibility for all fiscal matters, including taxation, now rests with the Chancellor of the Exchequer. However, the position of Chairman of Ways and Means still exists since the Chairman may take the place of the Speaker in that individual's absence. Traditionally, the title of Chairman of Ways and Means is conferred on the Deputy Speaker of the House. It was formerly an appointed position resulting from a motion tabled at the beginning of each Parliament by the Leader of the House. Following the 06 May 2010 General Election, the Chairman of Ways and Means and his two deputies were elected by ballot. The Chairman of Ways and Means has two deputies:- the First and Second Deputy Chairman of Ways and Means; thus there are three Deputy Speakers who may take the place of the Speaker. The Speaker and his deputies are considered independent, do not normally vote, and are not included in the figures of party strengths within the House of Commons. Upon retirement from the service of the House, it is usual for each of these Members to be elevated to a peerage and the House of Lords. The current Chairman of Ways and Means is Lindsay Hoyle. The First Deputy Chairman is Nigel Evans and the Second Deputy Chairman is Dawn Primarolo. The United States House Committee on Ways and Means is a committee in the United States House of Representatives similar to that same committee in the United Kingdom House of Commons. Unlike its UK counterpart, the US committee still meets and has jurisdiction over all taxation, tariffs, and other revenue-raising measures, as well as Social Security, Medicare, and a number of other programs. The Canadian federal government, which follows the British Parliamentary System, also adopted the term 'Ways and Means' within its tax system. For example, the Minister of Finance introduces changes to its fiscal plan via a Ways and Means Motion to Amend the Income Tax Act. The Minister tables the motion in Parliament and then presents the budget highlights in a formal budget speech. Only after a federal budget is tabled may the government's detailed taxation plans be made public. The current federal Minister of Finance is Jim Flaherty. / Линдзи Хойл (Lindsay Hoyle). Найджел Эвэнз (Nigel Evans) и Дон Праймирэло (Dawn Primarolo). Текущий федеральный Министр Финансов Дьжим Флаэрти (Jim Flaherty).

WEAK = СЛАБОЕ – Weak (seed cone armature) (strength):- with armature that tends to break easily.

WEAK ACID = СЛАБАЯ КИСЛОТА – A Weak Acid is an one that does not fully ionize in solution. Some of the acid remains in molecular form, rather than completely ionizing. If HA represents the acid, some would remain in solution as HA, and some would ionize to H^+ and A^-. Acetic acid and citric acid are commonly used weak acids. An acid may be technically weak, but still capable of causing serious skin burns. See also Acid, and Strong Acid. See also Weak Base for more discussion of pH effects surrounding 'weakness' (remembering that more acid lowers pH). / Смотрите также Кислота (Acid), Сильная Кислота (Strong Acid), и Слабое Основание (Weak Base).

WEAK BASE = СЛАБОЕ ОСНОВАНИЕ – A Weak Base does not fully ionize in solution. Some of a weak base remains in solution in molecular form. If BOH represents the base, some would remain in solution as BOH, and some would ionize to B^+ and OH^-. This makes for something of a 'reservoir' action – if some of the OH^- ions are used up in reactions, more of the BOH will ionize. Because of this, the pH of a solution of a weak base will change by less than one for a change in concentration of the base by a factor of 10 (for a strong base, which ionizes completely to B^+ and OH^-, increasing the concentration by a factor of 10 will increase the pH by 1). pH, unless very accurately measured, is a poor indication of how much of a weak base is in solution. Sodium carbonate and sodium bicarbonate are examples of weak bases (note that neither actually contains OH, but rather they hydrolyze to yield OH^-). See also Base, and Strong Base. / Слабое Основание. Бикарбонат Натрия или Двууглекислый Натрий или Кислый Углекислый Натрий (Sodium Bicarbonate). WEAK BASIS = СЛАБЫЙ БАЗИС – Weak Basis is a condition in which the spot price is significantly below the futures indicating a low demand. See also Wide Basis.

WEAK DOLLAR = СЛАБЫЙ ДОЛЛАР – Weak Dollar:- a situation where the US Dollar's value is decreasing relative to one or a basket of foreign currencies. Essentially, a weak Dollar means that a US Dollar can exchange for fewer amounts of foreign currency. The Dollar may weaken due to changes in the interest rate and outlook on the US economy's future. Depending on the type of transaction that a party is participating in, possessing a weak Dollar is not necessarily a bad situation. For example, a weak Dollar may be bad news for US citizens wishing to vacation in foreign countries, but it could be good news for US tourist attractions, as it also means that the US would be more inviting as a destination for foreign vacationers. Weak Dollar is the depreciated Dollar with respect to other currencies, meaning that more Dollars are needed to buy a unit of foreign currency. Weak Dollar is a Dollar that can be exchanged for only a small or decreasing amount of foreign currency. A weak Dollar means that the US Dollar cannot buy very much of another currency. The strength of the Dollar has an impact on imports and exports because goods and services from a foreign nation are usually purchased in the currency of the producing nation. A weak Dollar usually leads to high exports and low imports. The opposite of Strong Dollar. Weak Dollar is the US Dollar when it is worth less relative to other currencies. Because the Dollar is a floating currency, its value varies according to market trends. When one Dollar trades for fewer units of one or more other currencies, it is known as a Weak Dollar. See also Exchange Rate, and Strong Dollar. Weak Dollar is a Dollar that has relatively little purchasing power abroad and that can be exchanged only for a relatively small amount of foreign currency, such as the Japanese Yen, the Euro or

the Canadian Dollar. A weak Dollar signifies that imports are increasingly expensive and that exports are inexpensive. Thus, the level of exports tends to rise while imports decline. The Dollar may weaken because of government actions, or in response to declining economic conditions, large trade and budget deficits, inflation, or unattractive investment opportunities in the US relative to other countries. A strong Dollar, on the other hand, can be used to purchase a larger amount of other currencies and generally makes exporting more difficult. Weak Dollar is a depreciated Dollar with respect to other currencies, meaning that more dollars are needed to buy a unit of foreign currency. Antithesis of Strong Dollar. Weak Dollar is a Dollar that is of smaller value relative to foreign currencies. A weak Dollar exchanges for fewer units of other currencies compared with the units for which it could have been exchanged in the past. A weak Dollar tends to help US firms that rely heavily on foreign sales because the firms' products will cost less in terms of the foreign currencies. A weak Dollar hurts consumers of foreign goods because these goods cost more in terms of US Dollars. / Слабый Доллар – падающий Доллар, стоимость которого сокращается по отношению к курсам иностранных валют. Это означает, что держатели Долларов будут получать в обмен за них меньше Фунтов Стерлингов, Йен, или других валют. Слабый Доллар облегчает вывоз (или экспорт) товаров Американским производителям, поскольку иностранным покупателям они обходятся дешевле. Доллар может ослабеть из-за несоблюдения правительством США требований денежно-кредитной политики (эмитирования слишком большого количества Долларов) и утраты доверия к правительству США, большого внешнеторгового и бюджетного дефицита, непривлекательных процентных ставок на деноминированные в Долларах инвестиции по сравнению с доходностью инвестиций, деноминированных в других валютах, и по другим причинам.

WEAKENING BASIS = ОСЛАБЛЯЮЩИЙСЯ БАЗИС – A Weakening Basis occurs when the difference between the cash market price of a given commodity and the futures price of the same commodity widens. This happens when the cash market price increases more slowly relative to the futures price or the cash price decreases faster relative to the futures price. The basis then, becomes more negative or less positive. Weakening Basis is a basis movement over time that occurs when the cash price is declining relative to the futures price. / Ослабляющийся Базис:- движение базиса за какой-то срок, которое происходит, когда цена за наличный расчёт снижается относительно цены фьючерса.

WEAK–FORM EFFICIENCY = ЭФФЕКТИВНОСТЬ СЛАБОЙ ФОРМЫ – Weak-Form Efficiency:- a pricing theory that the price of a security reflects the past price and trading history of the security. Theory implies that security prices follow a random walk. Related:- Semistrong-Form Efficiency, and Strong-Form Efficiency.

WEAK HANDS = СЛАБЫЕ РУКИ – (1) Weak Hands:- when used in connection with delivery of commodities on futures contracts, the term Weak Hands usually means that the party probably does not intend to retain ownership of the commodity. See also Strong Hands. / Смотрите также Сильные Руки (Strong Hands). Слабые Руки – собирательный термин, применяемый для указания на тех инвесторов, которые спешно избавляются от своих бумаг при краткосрочных падениях их курсовой стоимости.

(2) Weak Hands:- when used in connection with futures positions, the term usually means positions held by small speculators.

WEAK HOLDINGS = СЛАБЫЕ УДЕРЖАНИЯ (или СЛАБЫЕ АВУАРЫ) – Weak Holdings:- xxxxx. / Слабые Пакеты Акций (Weak Holdings) – акции, сохраняемые на марже спекулянтами, которые хотят использовать любую причину для их продажи.

WEAK INTERACTION = СЛАБОЕ ВЗАИМОДЕЙСТВИЕ – Weak Interaction:- the forces between atoms that are less strong than the forces involved in a covalent (chemical) bond (between two atoms). Weak interactions include ionic (chemical) bonds, hydrogen bonds, and Van der Waals forces. / Слабое Взаимодействие – взаимодействие между атомами, слабее, чем ковалентное (водородное, ионное и Ван дер Ваальсовое).

WEAK LONGS = ИСТОЩЁННЫЕ ПОКУПАТЕЛИ (или СЛАБЫЕ ПОКУПАТЕЛИ) – Weak Longs are the traders holding long positions in the market that are at risk of liquidating. This can be in order to avoid the delivery process, or be due to mounting losses and/or margin calls that force the longs to cover. The small trader is thought to be a weak long during periods of excessive price retracements.

WEAK MARKET = ИСТОЩЁННЫЙ РЫНОК (или СЛАБЫЙ РЫНОК) – Weak Market is a market in which sellers outnumber buyers. Weak Market is a market with few buyers and many sellers and a declining trend in prices. Weak Market is a market for one or more securities in which there are few buyers and many sellers. A weak market comes about due to declining prices, and it is sometimes associated with high trading volume. See also Bear Market, and Panic Sell. Weak Market is a market where sellers far outnumber buyers and prices are in a general state of decline. Technically Week Market is a market in which open interest is increasing and prices are decreasing, or in which open interest is decreasing and prices are increasing. A market in which trading volume does not correspond to price where increasing volume accompanies decreasing prices or decreasing volume accompanies increasing prices. Also known as Technically Weak. Technical analysts are concerned only with the price movements of securities. Unlike fundamental analysts, they do not care about the characteristics of the company that has issued the security. Technical analysts follow trends in a security's supply and demand, as shown on price charts, to choose the most profitable times to buy and sell. / Слабый Рынок:- ситуация, характеризующаяся преобладанием продавцов над покупателями и общей тенденцией к спаду цен. Слабый Рынок:- ситуация, характеризующаяся большим спросом на продажу, чем на покупку.

WEAKNESS = СЛАБОСТЬ – A term 'Weakness' refers to the market's ability to move lower as well as stay under pressure during periods of brief price strength. / Слабость – состояние снижения цен на ценные бумаги или сырьё.

WEAK SLIDER BODIES = СЛАБЫЕ ТЕЛА БЕГУНКОВ – (1) Weak Slider Bodies:- can best be determined with proper testing equipment. However, manifests itself by slider becoming compressed or crushed under minimum pressure or becoming distorted enough to create hard operation. Closure defects, and namely – Zippers:- Slider Defects. / Порок или дефект застёжки.

(2) Weak Slider Bodies:- same as for metal zippers. Can best be determined with proper testing equipment. However, manifests itself by slider becoming compressed or crushed under minimum pressure or becoming distorted enough to create hard operation. Closure defects, and namely – Nylon Spiral Zipper:- Slider Defects. / Порок или дефект застёжки. Найлан^{T3} (Nylon^{TM}).

WEAK SPOTS = СЛАБЫЕ ПЯТНА – Weak Spots:- Article:- white pillowcase; Fabric Construction:- (i) Count:- 68 x 72; (ii) Warp:- 30/1 carded cotton; (ii) Filling:- 40/1 carded cotton. Complaint:- customer returned a single new pillowcase to the retailer because of weak spots. Analysis:- physical tests showed tendering of the cotton in several spots at one end of the pillowcase and chemical tests indicated the presence of oxycellulose in those places. The condition was found to exist on both sides of a seam, with no noticeable tendering of the cotton sewing thread at the seam. Test for starch in the pillowcase was positive, but none was found in the sewing thread or the attached cotton identification label. This was considered proof of the fact that the customer had not laundered the pillowcase. It was concluded that the defect was caused by some damage in the original finished sheeting before it was cut and sewed, probably the result of overbleaching by the finisher. / Уточина:- 40/1 кардная хлопковая.

WEAK SUSTAINABILITY = СЛАБАЯ УСТОЙЧИВОСТЬ – Weak Sustainability:- all forms of capital are more or less substitutes for one another; no regard has to be given to the composition of the stock of capital. Weak sustainability allows for the depletion or degradation of natural resources, so long as such depletion is offset by increases in the stocks of other forms of capital, for example, by investing royalties from depleting mineral reserves in factories.

WEAK WEB = СЛАБЫЙ ХОЛСТ (или СЛАБАЯ ВАТКА, или СЛАБЫЙ ПРОЧЁС) – Weak Web is a web of fiber that, when being transferred from the card doffer to the calendar rolls to form sliver, does not have sufficient strength from fiber cohesion or clinging entanglement to hold itself together while forming a continuous bridge in processing.

WEAK YARN = СЛАБАЯ ПРЯЖА – Weak Yarn is the yarn that is found to be either below standard breaking specifications or to be weak enough to cause an abnormally high degree of stops in textile processing.

WEALTH = БОГАТСТВО – Wealth is:- (1) in general:- tangible or intangible thing that makes a person, family, or group better off. (2) In accounting:- a value of an entity's accumulated tangible cash, land, building, etc) and intangible (copyright, patents, trademarks, etc) saleable possessions minus liabilities. (3) In economics:- total of all assets of an economic unit that generate current income or have the potential to generate future income. It includes natural resources and human capital but generally excludes money and securities because the represent only claims to wealth. Two common types of economic wealth are:- (i) Monetary Wealth:- anything that can be bought and sold, for which there is market and hence a price. The market price, however, reflects only the commodity price and not necessarily its value. For example, water is essential for human existence but is usually very cheap. (ii) Non-Monetary Wealth:- things which depend on scarce resources, and for which there is demand, but are not bought and sold in a market and hence have no price. Examples are education, health, and defense. Wealth:- net assets, both tangible and intangible, of an individual or legal entity, or of a group, such as a family, a nation, etc. Wealth is the abundance of valuable resources or material possessions. The word wealth is derived from the old English Weal, which is from an Indo-European word Stem. An individual, community, region or country that possesses an abundance of such possessions or resources is known as Wealthy. The concept of wealth is of significance in all areas of economics, and clearly so for growth economics and development economics yet the meaning of wealth is context-dependent. At the most general level, economists may define wealth as 'anything of value' which captures both the subjective nature of the idea and the idea that it is not a fixed or static concept. Various definitions and concepts of wealth have been asserted by various individuals and in different contexts. Defining wealth can be a normative process with various ethical implications, since often wealth maximization is seen as a goal or is thought to be a normative principle of its own. The United Nations definition of inclusive wealth is a monetary measure which includes the sum of natural, human and physical assets. Natural capital includes land, forests, fossil fuels, and minerals. Human capital is the population's education and skills. Physical (or 'manufactured') capital includes such things as machinery, buildings, and infrastructure. Definitions of 'Wealth':- Adam Smith, in his seminal work The Wealth of Nations, described wealth as 'the annual produce of the land and labour of the society'. This 'produce' is, at its simplest, that which satisfies human needs and wants of utility. In popular usage, wealth can be described as an abundance of items of economic value, or the state of controlling or possessing such items, usually in the form of money, real estate and personal property. An individual who is considered wealthy, affluent, or rich is someone who has accumulated substantial wealth relative to others in their society or reference group. In economics, net wealth refers to the value of assets owned minus the value of liabilities owed at a point in time. Wealth can be categorized into three principal categories:- personal property, including homes or automobiles; monetary savings, such as the accumulation of past income; and the capital wealth of income producing assets, including real estate, stocks, bonds, and businesses. All these delineations make wealth an especially important part of social stratification. Wealth provides a type of social safety net of protection against an unforeseen decline in one's living standard in the event of job loss or other emergency and can be transformed into home ownership, business ownership, or even a college education. A term 'Wealth' refers to some accumulation of resources (net asset value), whether abundant or not. The opposite of wealth is Destitution. A term 'Richness' refers to an abundance of such resources (income or flow). A wealthy individual, community, or nation thus has more accumulated resources (capital) than a poor one. The opposite of richness is Poverty. The term implies a social contract on establishing and maintaining ownership in relation to such items which can be invoked with little or no effort and expense on the part of the owner. The concept of wealth is relative and not only varies between societies, but varies between different sections or regions in the same society. A personal net worth of USD10 000 in most parts of the United States would certainly not place a person among the wealthiest citizens of that locale. However, such an amount would constitute an extraordinary amount of wealth in impoverished developing countries. Concepts of wealth also vary across time. Modern labor-saving inventions and the development of the sciences have enabled the poorest sectors of today's society to enjoy a standard of living equivalent if not superior to the wealthy of the not-too-distant past. This comparative wealth across time is also applicable to the future; given this trend of human advancement, it is likely that the standard of living that the wealthiest enjoy today will be considered impoverished by future generations. Industrialization emphasized the role of technology. Many jobs were automated. Machines replaced some workers while other workers became more specialized. Labour specialization became critical to economic success. However, physical capital, as it came to be known, consisting of both the natural capital and the infrastructural capital, became the focus of the analysis of wealth. Adam Smith saw wealth creation as the combination of materials, labour, land, and technology in such a way as to capture a profit (excess above the cost of production). The theories of David Ricardo, John Locke, John Stuart Mill, in the XVIII century and XIX century built on these views of wealth that we now call classical economics. Marxian economics distinguishes in the Grundrisse between material wealth and human wealth, defining human wealth as 'wealth in human relations'; land and labor were the source of all material wealth. In economics, Wealth in a commonly applied accounting sense is the net worth of a person, household, or nation, that is, the value of all assets owned net of all liabilities owed at a point in time. For national wealth as measured in the national accounts, the net liabilities are those owed to the rest of the world. The term may also be used more broadly as referring to the productive capacity of a society or as a contrast to poverty. Analytical emphasis may be on its determinants or distribution. Economic terminology distinguishes between wealth and income. Wealth is a stock variable, that is, measurable at a date in time, for example the value of an orchard on December 31 minus debt owed on the orchard. For a given amount of wealth, say at the beginning of the year, income from that wealth, as measurable over say a year is a flow variable. What marks the income as a flow is its measurement per unit of time, such as the value of apples yielded from the orchard per year. In macroeconomic theory the 'wealth effect' may refer to the increase in aggregate consumption from an increase in national wealth. One measure of it is the wealth elasticity of demand. It is the percentage change in the amount demanded of consumption for each one-percent change in wealth. Wealth may be measured in nominal or real values, that is in money value as of a given date or adjusted to net out price changes. The assets include those that are tangible (land and capital) and financial (money, bonds, etc). Measurable wealth typically excludes intangible or nonmarketable assets such as human capital and social capital. In economics, 'Wealth' corresponds to the accounting term 'Net Worth'. But analysis may adapt typical accounting conventions for economic purposes in social accounting (such as in national accounts). An example of the latter is generational accounting of social security systems to include the present value projected future outlays considered to be liabilities. Macroeconomic questions include whether the issuance of government bonds affects investment and consumption through the wealth effect. Environmental assets are not usually counted in measuring wealth, in part due to the difficulty of valuation for a non-market good. Environmental or green accounting is a method of social accounting for formulating

and deriving such measures on the argument that an educated valuation is superior to a value of zero (as the implied valuation of environmental assets). Wealth is a measure of the value of all of the assets of worth owned by a person, community, company or country. Wealth is the found by taking the total market value of all the physical and intangible assets of the entity and then subtracting all debts. Essentially, wealth is the accumulation of resources. People are said to be wealthy when they are able to accumulate many valuable resources or goods. Wealth is expressed in a variety of ways. For individuals, net worth is the most common expression of wealth, while countries measure by gross domestic product (GDP) or GDP per capita. / Дэвид Рикадо (David Ricardo), Дьжон Лак (John Locke), Дьжон Стюарт Мил (John Stuart Mill). Чистые активы, как материальные, так и нематериальные, физического или юридического лица, или группы лиц, такой как семья, нация и тому подобной. Под Богатством или Благосостоянием понимается стоимость активов, принадлежащих конкретному лицу или группе лиц. Экономическая наука началась с изучения природы богатства, например, труд Эдэма Смиса (или Адама Смита) 'Богатство Наций' (Adam Smith's 'The Wealth of Nations'), и того, как оно меняется в течение данного периода. Кейнсианская теория стремилась сделать основной упор на доход, рассматривая его как главный объект исследования в макроэкономике, однако сейчас считается, что доход всего лишь оказывает влияние на поведение лиц, равно как и на их благосостояние.

WEALTH CAPITAL STOCK = ЗАПАС КАПИТАЛА СОСТОЯНИЯ – The Wealth Capital Stock is a synonym for the 'net capital stock'. The term is widely used in North America. Wealth Capital Stock is the appropriate measure of the market value of capital. Wealth capital stock in addition is adjusted for future declines in efficiency. The concept of wealth capital stock can be expanded upon by noting that the purchase price paid by an individual for an asset depends on the current and future stream of services expected from the asset. The purchase price is determined by a present value calculation which recognizes that an individual would pay more for an asset returning USD100 in services today as compared to an asset returning USD100 in services two years from today. As wealth capital stock depends upon the current and future efficiency of an asset, construction of a wealth capital stock from an efficiency function requires an assumed interest rate or discount rate to calculate present value.

WEALTH EFFECT = ЭФФЕКТ БОГАТСТВА (или ЭФФЕКТ СОСТОЯНИЯ) – The Wealth Effect is the premise that when the value of stock portfolios rises due to escalating stock prices, investors feel more comfortable and secure about their wealth, causing them to spend more. For example, economists in 1968 were baffled when a 10% tax hike failed to slow down consumer spending. Later this continued spending was attributed to the wealth effect. While disposable income fell as a result of increased taxes, wealth was rising sharply as the stock market moved up. Undaunted, consumers continued their spending spree. The wealth effect helps to power economies during bull markets. Big gains in people's portfolios can make them feel more secure about their wealth and their spending. However, the relationship between spending and stock market performance is a double-edged sword as poor stock prices in bear markets hurt economic confidence. Wealth Effect:- changes in aggregate demand caused by change in the value of assets such as stocks, bonds, gold, property. Increase in the market value of these assets induces a feeling of being 'richer' in their owners (even if no additional cash is realized) and often tends to encourage spending and to dampen savings. The Wealth Effect is an increase in consumer spending directly proportional to strong portfolio performance. The wealth effect is a behavioral economic theory which posits that consumer spending increases significantly when overall portfolio performance is high. During a bull market, portfolio values rise to high levels. Portfolio holders, consequently, perceive themselves as more affluent. Psychologically associating higher net worth with having more disposable income, consumers increase their spending. The wealth effect is believed by many economic analysts to be the reason why significant interest rate and tax increases associated with bull markets have, historically, had little effect on levels of consumer spending. The psychological components of the wealth effect can inversely affect a bear market as consumers engage in lower spending. This comes as a result of consumers feeling they do not have enough money due to significantly lower portfolio values. Wealth Effects are effects on private spending arising from a change in wealth. Wealth effects are usually associated with changes in the value of equity, bonds and real estate. The Pigou Effect is an economics term that refers to the stimulation of output and employment caused by increasing consumption due to a rise in real balances of wealth, particularly during deflation. Real wealth was defined by Arthur Cecil Pigou as the sum of the money supply and government bonds divided by the price level. He argued that Keynes' General Theory was deficient in not specifying a link from 'real balances' to current consumption and that the inclusion of such a 'wealth effect' would make the economy more 'self correcting' to drops in aggregate demand than Keynes predicted. An economy in a liquidity trap cannot use monetary stimulus to increase output because there is little connection between personal income and money demand. John Hicks thought that this might be another reason (along with sticky prices) for persistently high unemployment. However, the Pigou Effect creates a mechanism for the economy to escape the trap:- as unemployment rises the price level drops which raises real balances and thus consumption rises. Finally, the economy moves to the new equilibrium, at full employment. Pigou concluded that an equilibrium with employment below the full employment rate (the classical natural rate) could only occur if prices and wages were sticky. The Pigou effect was criticized by Michał Kalecki because 'The adjustment required would increase catastrophically the real value of debts, and would consequently lead to wholesale bankruptcy and a confidence crisis'. / Арсур Сисл Пигу (Arthur Cecil Pigou). Кэйнз (Keynes). Дьжон Хикс (John Hicks). Михал Калецки (Michał Kalecki). Эффект Богатства или Эффект Пигу (Pigou Effect):- изменение стоимости активов, принадлежащих индивиду, в результате изменения уроня цен (инфляции или дефляции). Английский экономист Дьжон Мэйнад Кэйнз (John Maynard Keynes) утверждал, что падение цен ведёт к сокращению совокупного спроса (aggregate demand) и создаёт условия для роста безработицы. Однако, если существует эффект богатства, падение цен приводит к росту стоимости денег и, следовательно, увеличивает совокупный спрос при условии, что влияние денег на экономику является нейтральным. WEANED CATTLE = ОТЛУЧЁННЫЙ КРУПНЫЙ РОГАТЫЙ СКОТ (или ОТЛУЧЁННЫЙ КРУПНОРОГАТЫЙ СКОТ) – Weaned Cattle:- beef or dairy breeds maintained on pasture and receiving the majority of their diet from grazing. The term Pasture Cattle is intended to refer to cattle considered to be stockers, feeders and/or slaughter cattle. Parenthetical reference to Stocker, Feeder, or Slaughter Cattle is typically included in drug labeling. See also Feeders, Slaughter Cattle, and Stockers.

WEANED PIG = ОТЛУЧЁННАЯ СВИНЬЯ – A Weaned Pig (the separation of a suckling pig from the breeding female) that is removed from the farrowing unit, but that has yet to be placed in a nursery; the principle product of a breeding herd.

WEANER = ОТЛУЧЁННЫЙ – Weaners are pigs that were recently weaned (taken) from their sow. Piglets and Shoats are young pigs. Feeders are pigs at any stage from weaning to slaughter. See also Shoat. Weaner:- from about one to eight weeks after birth. Also Sows with litters from birth until mating. A Sow is a breedable female; a Gilt is a young female. A Boar is a breedable male; a Barrow, a castrated young male; and a Stag is an old castrated male. Weaner is an adolescent sheep that no longer requires liquid feed.

WEANING = ОТЛУЧЕНИЕ – Weaning is a removal of calves from their mothers so that they can no longer drink milk. Weaning:- to move animals to food other than the mother's milk.

WEAN LITTER = ОТЛУЧЁННЫЙ ПОМЁТ – Wean Litter (swine) is the total number of pigs weaned from a breeding female during one lactation. See also Birth Litter, and Nurse Litter.

WEAPON = ОРУЖИЕ (или СРЕДСТВА САМОЗАЩИТЫ) – Weapon is a tool used to injure or kill in fighting or hunting. An example of a weapon is a gun. / Средства Самозащиты – у животных и насекомых.

WEAPONIZATION = ВООРУЖЕНИЕ – Weaponization or Weaponisation is the act of making something into a weapon or making more effective as a weapon. / Доводка До Требований, предъявляемых к оружию.

WEAPONIZE = ВООРУЖАТЬ – Weaponize:- to adapt for use as a weapon of war. / Вооружение – создание или использование оружия.

WEAPON OF MASS DESTRUCTION = ОРУЖИЕ МАССОВОГО ПОРАЖЕНИЯ – Weapon Of Mass Destruction is a nuclear, radiological, chemical, biological or other weapon that can kill and bring significant harm to a large number of humans or cause great damage to human-made structures (e.g., buildings), natural structures (e.g., mountains), or the biosphere. / Оружие Массового Уничтожения (ОМП):- .

WEAR = ИЗНОС – Wear is the attrition or rubbing away of the surface of a material as a result of mechanical action. See also Abrasive Wear; Adhesive Wear; Delamination Wear; and Surface Fatigue Wear. Wear is the removal of material from a solid surface as a result of mechanical action exerted by another solid. Wear chiefly occurs as a progressive loss of material resulting from the mechanical interaction of two sliding surfaces under load. Wear is such a universal phenomenon that rarely do two solid bodies slide over each other or even touch each other without a measurable material transfer or material loss. Thus, coins become worn as a result of continued contact with fabrics and human fingers; pencils become worn after sliding over paper; and rails become worn as a result of the continued rolling of train wheels over them. Only living things (such as bone joints) are in some sense immune to the permanent damage caused by wear, since they have the property of regrowth and healing. There are four basic types of wear:- Abrasive Wear, Adhesive Wear, Corrosive Wear, and Surface-Fatigue Wear. Abrasive wear occurs when a hard, rough surface slides over a softer one, producing grooves on the latter. It also can be caused by loose, abrasive particles rolling between two soft sliding surfaces or by particles embedded in one of the opposing surfaces. Abrasive fragments borne by a stream of liquid or gas may wear down a surface if they strike the surface at high speeds. Since abrasive wear takes place when the abrading material is rough and harder than the surface to be abraded, it can be prevented either by eliminating the hard, rough constituent or by making the surface to be protected harder still. The most common type, adhesive wear, arises from the strong adhesive forces that are generated at the interface of two solid materials. When solid surfaces are pressed together, intimate contact is made over a number of small patches or junctions. During sliding, these junctions continue to be made and broken, and, if a junction does not break along the original interface, a wear particle is formed. These particles eventually break away. Adhesive wear is undesirable for two reasons:- first, the loss of material will eventually lead to a deterioration in the performance of the mechanism; and second, the formation of large wear particles in closely fitted sliding members may cause the mechanism to seize at an early stage in its productive life. Adhesive wear is many times greater for unlubricated than for effectively lubricated metal surfaces. Corrosive wear occurs whenever a gas or liquid chemically attacks a surface left exposed by the sliding process. Normally, when a surface corrodes, the products of corrosion (such as patina) tend to stay on the surface, thus slowing down further corrosion. But, if continuous sliding takes place, the sliding action removes the surface deposits that would otherwise protect against further corrosion, which thus takes place more rapidly. A surface that has experienced corrosive wear generally has a matte, relatively smooth appearance. Surface-fatigue wear is produced by repeated high stress attendant on a rolling motion, such as that of metal wheels on tracks or a ball bearing rolling in a machine. The stress causes subsurface cracks to form in either the moving or the stationary component. As these cracks grow, large particles separate from the surface and pitting ensues. Surface-fatigue wear is the most common form of wear affecting rolling elements such as bearings or gears. For sliding surfaces, adhesive wear usually proceeds sufficiently rapidly that there is no time for surface-fatigue wear to occur. Though the wear process is generally thought of as harmful, and in most practical situations is so, it has some practical uses as well. For example, many methods of producing a surface on a manufactured object depend on abrasive wear, among them filing, sanding, lapping, and polishing. Many writing instruments, principally the pencil, crayon, and chalk, depend for their effect on adhesive wear. Another use is seen in the wear of the incisor teeth of rodents. These teeth have a hard enamel covering along the outer curved surface but only soft dentine on the inner surface. Hence, abrasive and adhesive wear, which occurs more rapidly on the softer side, acts to maintain a sharp cutting edge on the teeth. / Смотите также Абразивный Износ (Abrasive Wear); Адгезивный Износ или Износ При Заедании (Adhesive Wear); Расслаивание Износ (Delamination Wear); и Контактно-Усталостный Износ или Усталостный Износ Поверхности или Износ, вызванный Усталостью Поверхности (Surface Fatigue Wear). Под Износом понимается изменение размеров, формы, массы или состояния поверхности изделия вследствие разрушения (изнашивания) поверхностного слоя изделия при трении. Износ изделий – деталей машин, элементов строительных конструкций, частей одежды и другого – зависит от условий трения и свойств материала изделия. Различают абразивный, кавитационный, контактно-усталостный и другие виды износа. Износ приводит к снижению качества изделий и их ценности. WEARING = ИЗНАШИВАНИЕ. Под Износом понимается изменение размеров, формы, массы или состояния поверхности изделия вследствие разрушения (изнашивания) микрообъёмов поверхностного слоя изделия при трении. Износ деталей машин, элементов строительных конструкций (например, ступеней лестниц) или предметов, одежды и другого зависит от условий трения, свойств материала и конструкции изделия. Износ можно рассматривать как механический процесс, осложнённый действием физических и химических факторов, вызывающих снижение прочности микрообъёмов поверхностного слоя. По условиям внешнего воздействия на поверхностный слой различают:- Абразивный Износ, Кавитационный Износ, Эрозионный Износ и другие. Износ приводит к снижению функциональных качеств изделий и к потере их потребительской ценности. Увеличению износостойкости изделий способствуют как применение материалов с высокой износостойкостью, так и конструктивные решения, обеспечивающие компенсацию износа, резервирование износостойкости и прочие, общее улучшение условий трения (применение высококачественных смазочных материалов, защиты от абразивного воздействия и прочее).

WEAR = СНАШИВАНИЕ (или ИЗНАШИВАНИЕ, или НОШЕНИЕ, или НОСКА) – Wear in textile materials is one of a limited number of fault factors in which an object loses its usefulness and the economic implication can be of enormous value to the industry. The terms wear and abrasion are sometimes confused. Wear is a very general term covering the loss of material by virtually any means. As wear usually occurs by rubbing together of two surfaces, abrasion is often used as a general term to mean wear. Some commonly referred to wear mechanisms include:- adhesive wear, abrasive wear, surface fatigue, fretting wear, and erosive wear. Adhesive, abrasive wear and surface fatigue mechanism play an important role in the abrasion mechanism of the yarns and fabrics. (1) Adhesive Wear occurs between surfaces during frictional contact and generally refers to unwanted displacement and attachment of wear debris and material compounds from one surface to another. The adhesive wear and material transfer due to direct contact and plastic deformation are the main issues in adhesive wear. The asperities or microscopic high points or surface roughness found on each surface, define the severity on how fragments of oxides are pulled off and adds to the other surface. This is partly due to strong adhesive forces between atoms, but also due to accumulation of energy in the plastic zone between the asperities during relative motion. (2) Abrasive Wear occurs when a hard rough surface slides across a softer surface. ASTM (American Society for Testing and

Materials) defines it as the loss of material due to hard particles or hard protuberances that are forced against and move along a solid surface. Abrasive wear is commonly classified according to the type of contact and the contact environment. The type of contact determines the mode of abrasive wear. The two modes of abrasive wear are known as Two-Body and Three-Body Abrasive Wear. Two-body wear occurs when the grits or hard particles remove material from the opposite surface. The common analogy is that of material being removed or displaced by a cutting or plowing operation. Three-body wear occurs when the particles are not constrained, and are free to roll and slide down a surface. (3) Fatigue Wear of a material is caused by a cycling loading during friction. Fatigue occurs if the applied load is higher than the fatigue strength of the material. Fatigue cracks start at the material surface and spread to the subsurface regions. The cracks may connect to each other resulting in separation and delamination of the material pieces. One of the types of fatigue wear is fretting wear caused by cycling sliding of two surfaces across each other with small amplitude (oscillating). The friction force produces alternating compression-tension stresses, which result in surface fatigue. / Американское Общество по Испытаниям и Материалам (АОИМ).

WEAR AND TEAR = СНАШИВАНИЕ И ПОРЧА (или ИЗНАШИВАНИЕ И РАЗРЫВАНИЕ) – (1) Wear And Tear:- a loss or deterioration resulting from ordinary use. Wear And Tear is damage that naturally and inevitably occurs as a result of normal wear or aging. It is used in a legal context for such areas as warranty contracts from manufacturers, which usually stipulate that damage due to wear and tear will not be covered. Wear and tear is a form of depreciation which is assumed to occur even when an item is used competently and with care and proper maintenance. For example, repeated impacts may cause stress to a hammer's head. In the normal use of a hammer for its designed task, this stress is impossible to prevent, and any attempt to eliminate it would make the hammer useless. At the same time, it is expected that the normal use of a hammer will not break it beyond repair until it has gone through a certain amount of use. The phenomenon of tear and wear is a good demonstration of the Second Law of Thermodynamics in action – roughly speaking, objects will get messier and more worn down over time (they are said to have higher entropy), unless energy from the outside world is used to fix them. A company which supports a warranty on a product with the possibility of tear and wear will usually limit the warranty to a period of time where its tear and wear will probably not be enough to impede the use of the product significantly. Other factors such as the willingness of a customer to replace a product through warranty will affect how long the company offers it. Loss and/or deterioration resulting from ordinary utilization. Popular and legal term for depreciation. Wear and tear is the decrease in value of an item due to deterioration through normal use rather than through accident or negligence. Wear And Tear is a synonym for Physical Deterioration. Wear And Tear:- an allowance that is tax deductible for the cost of furniture and fittings provided in dwelling houses which are let out furnished. / Снашивание И Порча – нормальная порча активов в ходе их полезной эксплуатации, которая приводит к переоценке их стоимости в сторону уменьшения (если не были приняты меры к восстановлению активов).

(2) Wear And Tear:- the amount deducted from a claims payment in recognition of the depreciation of the property insured through usage of it over time. Where cover is provided on a 'new for old basis', i.e. where the insurer agrees to replace an old item with a similar new one, no such deduction is made. Wear And Tear is the gradual deterioration of an asset which results naturally from use and/or age. Normal Wear-And-Tear is the inevitable physical decline of the condition of a property from time and usage. Normal wear-and-tear increases over the useful life of any property or asset. It results from normal usage by its occupants as well as from weather and other natural forces that surround it. Normal wear-and-tear cannot be avoided, only slowed in various ways through maintenance. Of course, this can reduce the value of the property over time, although not enough to prevent the owner from making a profit on the sale in most cases. In terms of landlords and tenants, normal wear-and-tear may or may not be deducted from the damage deposit. This usually depends on the nature of the lease and the period of time that the tenant rented the property for. For corporate properties, wear-and-tear is factored into depreciation. Wear And Tear is a lessening of asset value due to loss, damage, or depreciation resulting from ordinary use and exposure.

WEAR DEBRIS = ОСТАТКИ ИЗНОСА (или ПРОДУКТЫ ИЗНОСА) – Wear Debris:- particles that are detached from machine surfaces as a result of wear and corrosion. Also known as Wear Particles.

WEAR INHIBITOR = ИНГИБИТОР ИЗНОСА (или ЗАМЕДЛИТЕЛЬ ИЗНОСА) – Wear Inhibitor is an additive which protects the rubbing surfaces against wear, particularly from scuffing, if the hydrodynamic film is ruptured. See also Inhibitor.

WEAR TEST = ТЕСТ НА ИЗНАШИВАНИЕ – Wear Test is a test for fabric wear, abrasion, flexibility, washing, crushing, creasing, etc, in which the fabric is made into a garment, worn for a specific time, then assessed for performance. / тест на изнашивание, истирание, , ткани и так далее, в котором ткань превращена в швейное изделие, . WEATHER = ПОГОДА – Weather is the day-to-day or sometimes even instantaneous changes of atmospheric conditions over a given place or area. In contrast, climate encompasses the statistical ensemble of all weather conditions during a long period of time over that place or area. Atmospheric conditions are measured by the meteorological parameters of air temperature, barometric pressure, wind velocity, humidity, clouds and precipitation. Weather:- state of the atmosphere at a particular place during a short period of time. It involves such atmospheric phenomena as temperature, humidity, precipitation (type and amount), air pressure, wind, and cloud cover. Weather differs from climate in that the latter is the synthesis of weather conditions that have prevailed over a given area during a long time period – generally 30 years. For a full discussion of the elements and origins of weather, see Climate. Weather occurs in the troposphere, the lowest region of the atmosphere that extends from the Earth's surface to 6–8 km (4–5 miles) at the poles and to about 17 km (11 miles) at the Equator. Although weather is largely confined to the troposphere, phenomena of the higher regions of the atmosphere such as jet streams and upper-air waves significantly affect sea-level atmospheric-pressure patterns – the so-called Highs And Lows – and thereby the weather conditions at the terrestrial surface. Geographic features, most notably mountains and large bodies of water (e.g., lakes and oceans), also affect weather. Recent research, for example, has revealed that ocean-surface temperature anomalies are a potential cause of atmospheric temperature anomalies in successive seasons and at distant locations. One manifestation of such weather-affecting interactions between the ocean and the atmosphere is what scientists call the El Niño/Southern Oscillation (ENSO). It is believed that ENSO is responsible not only for unusual weather events in the equatorial Pacific region (e.g., the exceedingly severe drought in Australia and the torrential rains in western South America in 1982–83) but also for those that periodically occur in the mid-latitudes (as, for example, the record-high summer temperatures in western Europe and unusually heavy spring rains in the central United States in 1982–83). The ENSO phenomenon appears to influence mid-latitude weather conditions by modulating the position and intensity of the polar-front jet stream (see Jet Stream). Generally speaking, the changeability of weather varies widely in different parts of the world. It is most pronounced in the mid-latitude belts of the westerly winds, where a continuous procession of traveling high- and low-pressure centers produces a constantly shifting weather pattern. In tropical regions, by contrast, weather varies little from day to day or from month to month. Weather has a tremendous influence on human settlement patterns, food production, and personal comfort. Extremes of temperature and humidity cause discomfort and may lead to the transmission of disease; heavy rain can cause flooding, displacing people and interrupting economic activities; thunderstorms, tornadoes, hail, and sleet storms may damage or destroy crops, buildings, and transportation routes and vehicles.

Storms may even kill or injure people and livestock. At sea and along adjacent coastal areas, tropical cyclones (hurricanes, typhoons, and willy-willies) can cause great damage through excessive rainfall and flooding, winds, and wave action to ships, buildings, trees, crops, roads, and railways, and they may interrupt air service and communications. Heavy snowfall and icy conditions can impede transportation and increase the frequency of accidents. The long absence of rainfall, by contrast, can cause droughts and severe dust storms when winds blow over parched farmland, as with the 'dustbowl' conditions of the US Plains states in the 1930s. The variability of weather phenomena has resulted in a long-standing human concern with predictions of future weather conditions and weather forecasting. In early historical times, severe weather was ascribed to annoyed or malevolent divinities. Since the mid-XIX century, scientific weather forecasting has evolved, using the precise measurement of air pressure, temperature, humidity, and wind direction and speed to predict changing weather. The development of radar has enabled meteorologists to track the movement of cyclones and anticyclones (depressions and highs) and their associated fronts and storms. The use of advanced radar and computers in the second half of the XX century has enabled weather patterns to be tracked worldwide. These developments have improved the accuracy of local forecasts and have led to extended and long-range forecasts, although the high variability of weather in the mid-latitudes makes these longer-range forecasts less accurate. In tropical regions, by contrast, daily weather variations are minor, with regularly occurring phenomena and perceptible change associated more with seasonal cycles (dry weather and monsoons); tropical cyclones are the main variable. / Погода:- состояние атмосферы в данной местности или над обширным пространством, влияющее на человеческую деятельность. Погода относится к краткосрочным состояниям (дни и недели), в противоположность Климату – долгосрочному и регулярно повторяющемуся состоянию. Атмосферные характеристики, составляющие погоду:- температура, давление, влажность, осадки, облачность, ясность, видимость и сила ветра.

WEATHER DERIVATIVE = ПРОИЗВОДНЫЙ ИНСТРУМЕНТ НА ПОГОДУ (или ПОГОДНЫЙ ДЕРИВАТИВ) – Weather Derivative is an instrument used by companies to hedge against the risk of weather-related losses. The investor who sells a weather derivative agrees to bear this risk for a premium. If nothing happens, the investor makes a profit. However, if the weather turns bad, then the company who buys the derivative claims the agreed amount. This is not the same as insurance, which is for low-probability events like hurricanes and tornados. In contrast, derivatives cover high-probability events like a dryer-than-expected summer. Even in our advanced, technology-based society, we still live largely at the mercy of the weather. It influences our daily lives and choices, and has an enormous impact on corporate revenues and earnings. Until recently, there were very few financial tools offering companies' protection against weather-related risks. However, the inception of the weather derivative – by making weather a tradeable commodity – has changed all this. Here we look at how the weather derivative was created, how it differs from insurance and how it works as a financial instrument. Weather:- Risky Business:- it is estimated that nearly 20% of the US economy is directly affected by the weather, and that the profitability and revenues of virtually every industry – agriculture, energy, entertainment, construction, travel and others – depend to a great extent on the vagaries of temperature. In a 1998 testimony to Congress, former commerce secretary William Daley stated, 'Weather is not just an environmental issue; it is a major economic factor. At least USD1 trillion of our economy is weather-sensitive'. The risks businesses face due to weather are somewhat unique. Weather conditions tend to affect volume and usage more than they directly affect price. An exceptionally warm winter, for example, can leave utility and energy companies with excess supplies of oil or natural gas (because people need less to heat their homes). Or, an exceptionally cold summer can leave hotel and airline seats empty. Although the prices may change somewhat as a consequence of unusually high or low demand, price adjustments don't necessarily compensate for lost revenues resulting from unseasonable temperatures. Finally, weather risk is also unique in that it is highly localized, cannot be controlled and despite great advances in meteorological science, still cannot be predicted precisely and consistently. Temperature as a Commodity:- until recently, insurance has been the main tool used by companies' for protection against unexpected weather conditions. But insurance provides protection only against catastrophic damage. Insurance does nothing to protect against the reduced demand that businesses experience as a result of weather that is warmer or colder than expected. In the late 1990s, people began to realize that if they quantified and indexed weather in terms of monthly or seasonal average temperatures, and attached a Dollar amount to each index value, they could in a sense 'package' and trade weather. In fact, this sort of trading would be comparable to trading the varying values of stock indices, currencies, interest rates and agricultural commodities. The concept of weather as a tradeable commodity, therefore, began to take shape. 'In contrast to the various outlooks provided by government and independent forecasts, weather derivatives trading gave market participants a quantifiable view of those outlooks', noted Agbeli Ameko, managing partner of energy and forecasting firm EnerCast. In 1997 the first over-the-counter (OTC) weather derivative trade took place, and the field of weather risk management was born. According to Valerie Cooper, former executive director of the Weather Risk Management Association, an USD8 billion weather-derivatives industry developed within a few years of its inception. In Contrast to Weather Insurance:- in general, weather derivatives cover low-risk, high-probability events. Weather insurance, on the other hand, typically covers high-risk, low-probability events, as defined in a highly tailored, or customized, policy. For example, a company might use a weather derivative to hedge against a winter that forecasters think will be 5 °F warmer than the historical average (a low-risk, high-probability event). In this case, the company knows its revenues would be affected by that kind of weather. But the same company would most likely purchase an insurance policy for protection against damages caused by a flood or hurricane (high-risk, low-probability events). CME Weather Futures and Options on Futures:- in 1999, the Chicago Mercantile Exchange (CME) took weather derivatives a step further and introduced exchange-traded weather futures and options on futures – the first products of their kind. OTC weather derivatives are privately negotiated, individualized agreements made between two parties. But CME weather futures and options on futures are standardized contracts traded publicly on the open market in an electronic auction-like environment, with continuous negotiation of prices and complete price transparency. Broadly speaking, CME weather futures and options on futures are exchange-traded derivatives that – by means of specific indexes – reflect monthly and seasonal average temperatures of 15 US and five European cities. These derivatives are legally binding agreements made between two parties, and settled in cash. Each contract is based on the final monthly or seasonal index value that is determined by Earth Satellite (EarthSat) Corp, an international firm that specializes in geographic information technologies. Other European weather firms determine values for the European contracts. EarthSat works with temperature data provided by the National Climate Data Center (NCDC), and the data it provides is used widely throughout the over-the-counter weather derivatives industry as well as by CME. Weather Derivatives are the weather-risk management contracts. Weather Derivatives are financial instruments that can be used by organizations or individuals as part of a risk management strategy to reduce risk associated with adverse or unexpected weather conditions. The difference from other derivatives is that the underlying asset (rain/temperature/snow) has no direct value to price the weather derivative. Farmers can use weather derivatives to hedge against poor harvests caused by failing rains during the growing period, excessive rain during harvesting, high winds in case of plantations or temperature variabilities in case of greenhouse crops; theme parks may want to insure against rainy weekends during peak summer seasons; and gas and power companies may use heating degree days (HDD) or cooling degree days (CDD) contracts to smooth earnings. A sports event managing company may wish to hedge the loss by entering into a weather derivative contract because if it rains the day of the sporting event, fewer tickets will be sold. Heating degree days are one of the most common types of weather derivative. Typical terms for an HDD contract could be:- for the November to March period, for each day where the temperature rises above 18 degrees Celsius keep a cumulative count of the difference between 18 degrees and the average daily temperature. Depending upon whether the option is a put option or a call option, pay out a set amount per heating degree day that

the actual count differs from the strike. See also Exotic Derivatives. The first weather derivative deal was in July 1996 when Aquila Energy structured a dual-commodity hedge for Consolidated Edison Co. The transaction involved ConEd's purchase of electric power from Aquila for the month of August. The price of the power was agreed to, but a weather clause was embedded into the contract. This clause stipulated that Aquila would pay ConEd a rebate if August turned out to be cooler than expected. The measurement of this was referenced to Cooling Degree Days measured at New York City's Central Park weather station. If total CDDs were from 0 to 10% below the expected 320, the company received no discount to the power price, but if total CDDs were 11 to 20% below normal, Con Ed would receive a USD16 000 discount. Other discounted levels were worked in for even greater departures from normal. After that humble beginning, weather derivatives slowly began trading over-the-counter in 1997. As the market for these products grew, the Chicago Mercantile Exchange introduced the first exchange-traded weather futures contracts (and corresponding options), in 1999. The CME currently trades weather derivative contracts for 25 cities in the United States, nine in Europe, six in Canada and two in Japan. Most of these contracts track cooling degree days or heating degree days, but recent additions track frost days in the Netherlands and monthly/seasonal snowfall in Boston and New York. A major early pioneer in weather derivatives was Enron Corporation, through its EnronOnline unit. In an Opalesque video interview, Nephila Capital's Barney Schauble discusses how some hedge funds have now begun focusing on weather derivatives as an investment class. Counterparties such as utilities, farming conglomerates, individual companies and insurance companies are essentially looking to hedge their exposure through weather derivatives, and funds have become a sophisticated partner in providing this protection. There has also been a shift over the last few years from primarily fund of funds investment in weather risk, to more direct investment for investors looking for non-correlated items for their portfolio. Weather derivatives provide a pure non-correlated alternative to traditional financial markets. Valuation:- there is no standard model for valuing weather derivatives similar to the Black-Scholes (BS) formula for pricing European style equity option and similar derivatives. That is due to the fact that underlying asset of the weather derivative is non-tradeable which violates a number of key assumptions of the BS Model. Typically weather derivatives are priced in a number of ways:- (i) Business Pricing:- requires the company utilizing weather derivative instruments to understand how its financial performance is affected by adverse weather conditions across variety of outcomes (i.e. obtain a utility curve with respect to particular weather variables). Then the user can determine how much he is willing to pay in order to protect his/her business from those conditions in case they occurred based on his/her cost-benefit analysis and appetite for risk. In this way a business can obtain a 'guaranteed weather' for the period in question, largely reducing the expenses/revenue variations due to weather. Alternatively, an investor seeking certain level or return for certain level of risk can determine what price he is willing to pay for bearing particular outcome risk related to a particular weather instrument. (ii) Historical Pricing (Burn analysis):- the historical payout of the derivative is computed to find the expectation. The method is very quick and simple, but does not produce reliable estimates and could be used only as a rough guideline. It does not incorporate variety of statistical and physical features characteristic of the weather system. (iii) Index Modelling:- this approach requires building a model of the underlying index, i.e. the one upon which the derivative value is determined (for example monthly/seasonal cummulative heating degree days). The simplest way to model the index is just to model the distribution of historical index outcomes. We can adopt parametric or non-parametric distributions. For monthly cooling and heating degree days assuming a normal distribution is usually warranted. The predictive power of such model is rather limited. A better result can be obtained by modelling the index generating process on a finer scale. In the case of temperature contracts a model of the daily average (or min and max) temperature time series can be built. The daily temperature (or rain, snow, wind, etc) model can be built using common statistical time series models (i.e. autoregressive-moving-average (ARMA) or Fourier transform in the frequency domain) purely based only on the features displayed in the historical time series of the index. A more sophisticated approach is to incorporate some physical intuition/relationships into our statistical models based on spatial and temporal correlation between weather occurring in various parts of the ocean-atmosphere system around the world (for example we can incorporate the effects of El Niño on temperatures and rainfall). (iv) Physical Models of the Weather:- we can utilize the output of numerical weather prediction models based on physical equation describing relationships in the weather system. Their predictive power tends to be less or similar to purely statistical models beyond time horizons of 10–15 days. Ensemble forecasts are especially appropriate for weather derivative pricing within the contract period of a monthly temperature derivative. However, individuals members of the ensemble need to be 'dressed' (for example with gaussian kernels estimated from historical performance) before a reasonable probabilistic forecast can be obtained. (v) Mixture of Statistical and Physical Models:- a superior approach for modelling daily or monthly weather variable time series is to combine statistical and physical weather models using time-horizon varying weight which are obtained after optimization of those based on historical out-of-sample evaluation of the combined model scheme performance. Weather Derivative is a derivative whose payoff is based on a specified weather event, for example, the average temperature in Chicago in January. Such a derivative can be used to hedge risks related to the demand for heating fuel or electricity. Weather Derivatives are the forward instruments used to hedge against or speculate on weather. Virtually all of the instruments are based on degree-days, though precipitation swaps and sunshine options are among other possible instruments. WEATHER EYE = ПОГОДНОЕ ОКО (или ПОГОДНЫЙ ГЛАЗ, или БДИТЕЛЬНОСТЬ) – Weather Eye:- to keep a weather eye is to be on the alert (heads up).

WEATHER FORECASTING = ПРОГНОЗИРОВАНИЕ ПОГОДЫ – Weather Forecasting:- the prediction of the weather through application of the principles of physics, supplemented by a variety of statistical and empirical techniques. In addition to predictions of atmospheric phenomena themselves, weather forecasting includes predictions of changes on the Earth's surface caused by atmospheric conditions, e.g., snow and ice cover, storm tides, and floods. General Considerations:- Measurements And Ideas As The Basis For Weather Prediction:- with few other scientific enterprises are observations so vital as in the case of weather forecasting. From the days when early humans ventured from caves and other natural shelters, perceptive individuals in all likelihood became leaders by being able to detect nature's signs of impending snow, rain, or wind, indeed of any change in weather. With such information they must have enjoyed greater success in the search for food and safety, the major objectives of that time. In a sense, weather forecasting is still carried out in basically the same way as it was by the earliest humans – namely, by making observations and predicting changes. The tools used to measure temperature, pressure, wind, and humidity in the late XX century would certainly amaze them, and the results obviously are better. Yet, even the most sophisticated numerically calculated forecast made on a supercomputer requires a set of measurements of the condition of the atmosphere – an initial picture of temperature, wind, and other basic elements, somewhat comparable to that formed by our forebears when they looked out of their cave dwellings. The primeval approach entailed insights based on the accumulated experience of the perceptive observer, while the modern technique consists of solving equations. Although seemingly quite different, there are underlying similarities between both practices. In each case the forecaster asks 'What is?' in the sense of 'What kind of weather prevails today?' and then seeks to determine how it will change in

order to extrapolate what it will be. Because observations are so critical to weather prediction, an account of meteorological measurements and weather forecasting is a story in which ideas and technology are closely intertwined, with creative thinkers drawing new insights from available observations and pointing to the need for new or better measurements, and technology providing the means for making new observations and for processing the data derived from measurements. It tells of the theories of the ancient Greek philosophers, Renaissance scientists, and the scientific revolution of the XVII and XVIII centuries and of the creativity of XX-century atmospheric scientists and meteorologists. Likewise, it tells of the development of the 'synoptic' idea – that of characterizing the weather over a large region at exactly the same time in order to organize information about prevailing conditions. In synoptic meteorology, simultaneous observations for a specific time are plotted on a map for a broad area whereby a general view of the weather in that region is gained. (The term Synoptic is derived from the Greek word meaning 'General or Comprehensive View'.) The so-called Synoptic Weather Map came to be the principal tool of XIX-century meteorologists and continues to be used today in weather stations and on television weather reports around the world. Since the mid-XX century, digital computers have made it possible to calculate changes in atmospheric conditions mathematically and objectively, i.e. in such a way that anyone can obtain the same result from the same initial conditions. The widespread adoption of numerical weather prediction models brought a whole new group of players – computer specialists and experts in numerical processing and statistics – to the scene to work with atmospheric scientists and meteorologists. Moreover, the enhanced capability to process and analyze weather data stimulated the long-standing interest of meteorologists in securing more observations of greater accuracy. Technological advances since the 1960s have led to a growing reliance on remote sensing, particularly the gathering of data with specially instrumented Earth-orbiting satellites. By the late 1980s, forecasts of weather were largely based on the determinations of numerical models integrated by high-speed supercomputers, except some shorter-range predictions, particularly of local weather conditions, which were made by specialists directly interpreting radar and satellite measurements. Practical Applications Of Weather Forecasting:- systematic weather records were kept after instruments for measuring atmospheric conditions became available during the XVII century. Undoubtedly these early records were employed mainly by those engaged in agriculture. Planting and harvesting obviously can be planned better and carried out more efficiently if long-term weather patterns can be estimated. In the United States, national weather services were first provided by the Army Signal Corps beginning in 1870. These operations were taken over by the Department of Agriculture in 1891. By the early 1900s free mail service and telephone were providing forecasts daily to millions of American farmers. The US Weather Bureau established a Fruit-Frost (forecasting) Service during World War I, and by the 1920s radio broadcasts to agricultural interests were being made in most states. Weather forecasting became an important tool for aviation during the 1920s and '30s. Its application in this area gained in importance after Francis W. Reichelderfer was appointed chief of the US Weather Bureau in 1939. Reichelderfer had previously modernized the navy's meteorological service and made it a model of support for naval aviation. During World War II the discovery of very strong wind currents at high altitudes (the jet streams, which can affect aircraft speed) and the general susceptibility of military operations in Europe to weather led to a special interest in weather forecasting. The most famous wartime forecasting problem was for Operation Overlord, the invasion of the European mainland at Normandy by Allied forces. An unusually intense June storm brought high seas and gales to the French coast, but a moderation of the weather that was successfully predicted by Colonel J.M. Stagg of the British forces (after consultation with both British and American forecasters) enabled General Dwight D. Eisenhower, supreme commander of the Allied Expeditionary Forces, to make his critical decision to invade on June 06, 1944. The second half of the XX century has seen unprecedented growth of commercial weather-forecasting firms in the United States and elsewhere. Marketing organizations and stores commonly hire weather-forecasting consultants to help with the timing of sales and promotions of products ranging from snow tires and roofing materials to summer clothes and resort vacations. Many oceangoing shipping vessels as well as military ships use optimum ship routing forecasts to plan their routes in order to minimize lost time, potential damage, and fuel consumption in heavy seas. Similarly, airlines carefully consider atmospheric conditions when planning long-distance flights so as to avoid the strongest head winds and to ride with the strongest tail winds. International trading of foodstuffs such as wheat, corn (maize), beans, sugar, cocoa, and coffee can be severely affected by weather news. For example, in 1975 a severe freeze in Brazil caused the price of coffee to increase substantially within just a few weeks, and in 1977 a freeze in Florida nearly doubled the price of frozen concentrated orange juice in a matter of days. Weather-forecasting organizations are thus frequently called upon by banks, commodity traders, and food companies to give them advance knowledge of the possibility of such sudden changes. The cost of all sorts of commodities and services, whether they are tents for outdoor events or plastic covers for the daily newspapers, can be reduced or eliminated if reliable information about possible precipitation can be obtained in advance. Forecasts must be quite precise for applications that are tailored to specific industries. Gas and electric utilities, for example, may require forecasts of temperature within one or two degrees of the mean a day ahead of time, or ski-resort operators may need prior estimates of nighttime relative humidity on the slopes within 5 to 10 percent in order to schedule snow making. History Of Weather Forecasting:- Early Measurements And Ideas:- the Greek philosophers had much to say about meteorology, and many who subsequently engaged in weather forecasting no doubt made use of their ideas. Unfortunately, they probably made many bad forecasts, because Aristotle, who was the most influential, did not believe that wind is air in motion. He did believe, however, that west winds are cold because they blow from the sunset. The scientific study of meteorology did not develop until measuring instruments became available. Its beginning is commonly associated with the invention of the mercury barometer by Evangelista Torricelli, an Italian physicist-mathematician, in the mid-XVII century and the nearly concurrent development of a reliable thermometer. (Galileo had constructed an elementary form of gas thermometer in 1607, but it was defective; the efforts of many others finally resulted in a reasonably accurate liquid-in-glass device.) A succession of notable achievements by chemists and physicists of the XVII and XVIII centuries contributed significantly to meteorological research. The formulation of the laws of gas pressure, temperature, and density by Robert Boyle and Jacques-Alexandre-César Charles, the development of calculus by Isaac Newton and Gottfried Wilhelm Leibniz, the development of the law of partial pressures of mixed gases by John Dalton, and the formulation of the doctrine of latent heat (i.e. heat release by condensation or freezing) by Joseph Black are just a few of the major scientific breakthroughs of the period that made it possible to measure and better understand theretofore unknown aspects of the atmosphere and its behavior. During the XIX century, all of these brilliant ideas began to produce results in terms of useful weather forecasts. The Emergence Of Synoptic Forecasting Methods:- Analysis Of Synoptic Weather Reports:- an observant person who has learned nature's signs can interpret the appearance of the sky, the wind, and other local effects and 'foretell the weather'. A scientist can use instruments at one location to do so even more effectively. The modern approach to weather forecasting, however, can only be realized when many such observations are exchanged quickly by experts at various weather stations and entered on a synoptic weather map to depict the patterns of pressure, wind, temperature, clouds, and precipitation at a specific time. Such a rapid exchange of weather data became feasible with the development of the electric telegraph in 1837 by Samuel F.B. Morse of the United States. By 1849 Joseph Henry of the Smithsonian Institution in Washington, DC, was plotting daily weather maps based on telegraphic reports, and in 1869 Cleveland Abbe at the Cincinnati Observatory began to provide regular weather forecasts using data received telegraphically. Synoptic weather maps resolved one of the great controversies of meteorology – namely, the rotary storm dispute. By the early decades of the XIX century, it was known that storms were associated with low barometric readings, but the relation of the winds to low-pressure systems, called Cyclones, remained unrecognized. William Redfield, a self-taught meteorologist from Middletown, State of Connecticut, the United States, noticed the pattern of fallen trees after a New England hurricane and suggested in

1831 that the wind flow was a rotary counterclockwise circulation around the center of lowest pressure. The American meteorologist James P. Espy subsequently proposed in his Philosophy of Storms (1841) that air would flow toward the regions of lowest pressure and then would be forced upward, causing clouds and precipitation. Both Redfield and Espy proved to be right. The air does spin around the cyclone, as Redfield believed, while the layers close to the ground flow inward and upward as well. The net result is a rotational wind circulation that is slightly modified at the Earth's surface to produce inflow toward the storm center, just as Espy had proposed. Further, the inflow is associated with clouds and precipitation in regions of low pressure, though that is not the only cause of clouds there. In Europe the writings of Heinrich Dove, a Polish scientist who directed the Prussian Meteorological Institute, greatly influenced views concerning wind behavior in storms. Unlike the Americans, Dove did not focus on the pattern of the winds around the storm but rather on how the wind should change at one place as a storm passed. It was many years before his followers understood the complexity of the possible changes. Establishment Of Weather-Station Networks And Services:- routine production of synoptic weather maps became possible after networks of stations were organized to take measurements and report them to some type of central observatory. As early as 1814, US Army Medical Corps personnel were ordered to record weather data at their posts; this activity was subsequently expanded and made more systematic. Actual weather-station networks were established in the United States by New York University, the Franklin Institute, and the Smithsonian Institution during the early decades of the XIX century. In Britain, James Glaisher organized a similar network, as did a Dutch chemist and meteorologist Christoph Hendrik Diederik Buys-Ballot (or Christophorus Henricus Diedericus Buys Ballot; 1817–1890) in The Netherlands. Other such networks of weather stations were developed near Vienna, Paris, and St. Petersburg. It was not long before national meteorological services were established on the Continent and in the United Kingdom. The first national weather service in the United States commenced operations in 1871, with responsibility assigned to the US Army Signal Corps. The original purpose of the service was to provide storm warnings for the Atlantic and Gulf coasts and for the Great Lakes. Within the next few decades, national meteorological services were established in such countries as Japan, India, and Brazil. The importance of international cooperation in weather prognostication was recognized by the directors of such national services. By 1880 they had formed the International Meteorological Organization (IMO) for this end. The proliferation of weather-station networks linked by telegraphy made synoptic forecasting a reality by the close of the XIX century. Yet, the daily weather forecasts generated left much to be desired. Many errors occurred as predictions were largely based on the experience that each individual forecaster had accumulated over several years of practice, vaguely formulated rules of thumb (e.g., of how pressure systems move from one region to another), and associations that were poorly understood, if at all. Progress During The Early XX Century:- an important aspect of weather prediction is to calculate the atmospheric pressure pattern – the positions of the highs and lows and their changes. Modern research has shown that sea-level pressure patterns respond to the motions of the upper-atmospheric winds, with their narrow, fast-moving jet streams and remarkable waves that flow through the air and pass air through themselves (see above Upper-air waves). Frequent surprises and errors in estimating surface atmospheric pressure patterns undoubtedly caused XIX-century forecasters to seek information about the upper atmosphere for possible explanations. The British meteorologist Glaisher made a series of ascents by balloon during the 1860s, reaching an unprecedented height of nine kilometers. At about this time investigators on the Continent began using unmanned balloons to carry recording barographs, thermographs, and hygrographs to high altitudes. During the late 1890s meteorologists in both the United States and Europe used kites equipped with instruments to probe the atmosphere up to altitudes of about three kilometers. Notwithstanding these efforts, knowledge about the upper atmosphere remained very limited at the turn of the century. The situation was aggravated by the confusion created by observations from weather stations located on mountains or hilltops. Such observations often did not show what was expected, partly because so little was known about the upper atmosphere and partly because the mountains themselves affect measurements, producing results that are not representative of what would be found in the free atmosphere at the same altitude. Fortunately, a large enough number of scientists had already put forth ideas that would make it possible for weather forecasters to think three-dimensionally, even if sufficient meteorological measurements were lacking. Henrik Mohn, the first of a long line of highly creative Norwegian meteorologists, Wladimir Köppen, the noted German climatologist (see above), and Max Margules, an influential Russian-born meteorologist, all contributed to the view that mechanisms of the upper air generate the energy of storms. In 1911 William H. Dines, a British meteorologist, published data that showed how the upper atmosphere compensates for the fact that the low-level winds carry air toward low-pressure centers. Dines recognized that the inflow near the ground is more or less balanced by a circulation upward and outward aloft. Indeed, for a cyclone to intensify, which would require a lowering of central pressure, the outflow must exceed the inflow; the surface winds can converge quite strongly toward the cyclone, but sufficient outflow aloft can produce falling pressure at the center. Meteorologists of the time were now aware that vertical circulations and upper-air phenomena were important, but they still had not determined how such knowledge could improve weather forecasting. Then, in 1919, the Norwegian meteorologist Jacob Bjerknes introduced what has been referred to as the Norwegian Cyclone Model. This theory pulled together many earlier ideas and related the patterns of wind and weather to a low-pressure system that exhibited fronts – rather sharp sloping boundaries between cold and warm air masses. Bjerknes pointed out the rainfall/snowfall patterns that are characteristically associated with the fronts in cyclones:- the rain or snow occurs over large areas on the cold side of an advancing warm front ahead of advancing low pressure. Here, the winds are from the south and the warm air, being light, glides up over a large region of cold air. Widespread, sloping clouds spread ahead of the cyclone; barometers fall as the storm approaches, and precipitation from the rising warm air falls through the cold air below. Where the cold air advances to the rear of the storm, squalls and showers mark the abrupt lifting of the warm air being displaced. Thus, the concept of fronts focused attention on the action at air mass boundaries. The Norwegian cyclone model could be called the frontal model, for the idea of warm air masses being lifted over cold air along their edges (fronts) became a major forecasting tool. The model not only emphasized the idea but it also showed how and where to apply it. In later work, Bjerknes and several other members of the so-called Bergen School of Meteorology expanded the model to show that cyclones grow from weak disturbances on fronts, pass through a regular life cycle, and ultimately die by the inflow filling them. Both the Norwegian cyclone model and the associated life-cycle concept are still used today by weather forecasters. While Bjerknes and his Bergen colleagues refined the cyclone model, other Scandinavian meteorologists provided much of the theoretical basis for modern weather prediction. Foremost among them were Vilhelm Bjerknes, Jacob's father, and Carl-Gustaf Rossby. Their ideas helped make it possible to understand and carefully calculate the changes in atmospheric circulation and the motion of the upper-air waves that control the behavior of cyclones. Modern Trends And Developments:- Upper-Air Observations By Means Of Balloon-Borne Sounding Equipment:- once again technology provided the means with which to test the new scientific ideas and stimulate yet newer ones. During the late 1920s and '30s, several groups of investigators (those headed by Yrjö Väisälä of Finland and Pavel Aleksandrovich Molchanov of the Soviet Union, for example) began using small radio transmitters with balloon-borne instruments, eliminating the need to recover the instruments and speeding up access to the upper-air data. These radiosondes, as they came to be called, gave rise to the upper-air observation networks that still exist today. Approximately 75 stations in the United States and more than 500 worldwide release, twice daily, balloons that reach heights of 30 000 meters or more. Observations of temperature and relative humidity at various pressures are radioed back to the station from which the balloons are released as they ascend at a predetermined rate. The balloons also are tracked by radar in order to ascertain winds from their drift. Forecasters are able to produce synoptic weather maps of the upper atmosphere twice each day on the basis of radiosonde observations. While new methods of upper-air measurement have been developed, the

primary synoptic clock times for producing upper-air maps are still the radiosonde-observation times – namely, 00:00 (midnight) and 12:00 (noon) Greenwich Mean Time (GMT). Furthermore, modern computer-based forecasts use 00:00 and 12:00 GMT as the starting times from which they calculate the changes that are at the heart of modern forecasts. It is, in effect, the synoptic approach carried out in a different way, intimately linked to the radiosonde networks developed during the 1930s and '40s. Application Of Radar:- as in many fields of endeavor, weather prediction experienced several breakthroughs during and immediately after World War II. The British began using microwave radar in the late 1930s to monitor enemy aircraft, but it was soon learned that radar gave excellent returns from raindrops at certain wavelengths (five to 10 centimeters). As a result it became possible to track and study the evolution of individual showers or thunderstorms, as well as to 'see' the precipitation structure of larger storms. The photograph shows an image of the rain bands (not clouds) in a hurricane. Since its initial application in meteorological work, radar has grown as a forecaster's tool. Virtually all tornadoes and severe thunderstorms over the United States and in some other parts of the world are monitored by radar. Radar observation of the growth, motion, and characteristics of such storms provide clues as to their severity. Modern radar systems use the Doppler principle of frequency shift associated with movement toward or away from the radar transmitter/receiver to determine wind speeds as well as storm motions. Using radar and other observations, the Japanese-American meteorologist Tetsuya T. Fujita discovered many details of severe thunderstorm behavior and of the structure of the violent local storms common to the Midwest region of the United States. His Doppler-radar analyses of winds revealed 'microburst' gusts. These gusts cause the large wind shears (differences) associated with strong rains that have been responsible for some plane crashes. Other types of radar have been used increasingly for detecting winds continuously, as opposed to twice a day. These wind-profiling radar systems actually pick up signals 'reflected' by clear air and so can function even when no clouds or rain are present. Meteorological Measurements From Satellites And Aircraft:- a major breakthrough in meteorological measurement came with the launching of the first meteorological satellite, the TIROS (Television and Infrared Observation Satellite), by the United States on April 01, 1960. The impact of global quantitative views of temperature, cloud, and moisture distributions, as well as of surface properties (e.g., ice cover and soil moisture), has already been substantial. Furthermore, new ideas and new methods may very well make the XXI century the 'age of the satellite' in weather prediction. Medium-range forecasts that provide information five to seven days in advance were impossible before satellites began making global observations – particularly over the ocean waters of the Southern Hemisphere – routinely available in real time. Global forecasting models developed at the US National Center for Atmospheric Research (NCAR), the European Centre for Medium Range Weather Forecasts (ECMWF), and the US National Meteorological Center (NMC) became the standard during the 1980s, making medium-range forecasting a reality. Meteorological satellites travel in various orbits and carry a wide variety of sensors. They are of two principal types:- the low-flying polar orbiter, and the geostationary orbiter. The first type circle the Earth at altitudes of 500–1 000 kilometers and in roughly North-South orbits. They appear overhead at any one locality twice a day and provide very high-resolution data because they fly close to the Earth. Such satellites are vitally necessary for much of Europe and other high-latitude locations because they orbit near the poles. These satellites do, however, suffer from one major limitation: they can provide a sampling of atmospheric conditions only twice daily. The geostationary satellite is made to orbit the Earth along its equatorial plane at an altitude of about 36 000 kilometers. At that height the eastward motion of the satellite coincides exactly with the Earth's rotation, so that the satellite remains in one position above the Equator. Satellites of this type are able to provide an almost continuous view of a wide area. Because of this capability, geostationary satellites have yielded new information about the rapid changes that occur in thunderstorms, hurricanes, and certain types of fronts, making them invaluable to weather forecasting as well as meteorological research. One weakness common to virtually all satellite-borne sensors and to some ground-based radars that use UHF/VHF waves is an inability to measure thin layers of the atmosphere. One such layer is the tropopause, the boundary between the relatively dry stratosphere and the meteorologically active layer below. This is often the region of the jet streams. Important information about these kinds of high-speed air currents is obtained with sensors mounted on high-flying commercial aircraft and is routinely included in global weather analyses. Numerical Weather Prediction (NWP) Models:- thinkers frequently advance ideas long before the technology exists to implement them. Few better examples exist than that of numerical weather forecasting. Instead of mental estimates or rules of thumb about the movement of storms, numerical forecasts are objective calculations of changes to the weather map based on sets of equations called Models. Shortly after World War I a British scientist named Lewis F. Richardson completed such a forecast that he had been working on for years by tedious and difficult hand calculations. Although the forecast proved to be incorrect, Richardson's general approach was accepted decades later when the electronic computer became available. In fact, it has become the basis for nearly all present-day weather forecasts. Human forecasters may interpret or even modify the results of the computer models, but there are few forecasts that do not begin with numerical-model calculations of pressure, temperature, wind, and humidity for some future time. The method is closely related to the synoptic approach (see above). Data are collected rapidly by a Global Telecommunications System for 00:00 or 12:00 GMT to specify the initial conditions. The model equations are then solved for various segments of the weather map – often a global map – to calculate how much it will change in a given time, say, 10 minutes. With such changes added to the initial conditions, a new map is generated (in the computer's memory) valid for 00:10 or 12:10 GMT. This map is treated as a new set of initial conditions, probably not quite as accurate as the measurements for 00:00 and 12:00 GMT but still very accurate. A new step is undertaken to generate a forecast for 00:20 or 12:20. This process is repeated step after step. In principle, the process could continue indefinitely. In practice, small errors creep into the calculations, and they accumulate. Eventually, the errors become so large by this cumulative process that there is no point in continuing. Global numerical forecasts are produced regularly (once or twice daily) at the ECMWF, the NMC, and the US military facilities in Omaha, State of Nebraska, the United States, and Monterey, State of California, the United States, as well as in Tokyo, Japan, Moscow, Russia, and Melbourne, Australia. In addition, specialized numerical forecasts designed to predict more details of the weather are made for many smaller regions of the world by various national weather services, military organizations, and even a few private companies. Finally, research versions of numerical weather prediction models are constantly under review, development, and testing at NCAR and at the Goddard Space Flight Center in the United States and at universities in several nations. The capacity and complexity of numerical weather prediction models have increased dramatically since the mid-1940s when the earliest modeling work was done by the mathematician John von Neumann and the meteorologist Jule Charney at the Institute for Advanced Study in Princeton, State of New Jersey, the United States. Because of their pioneering work and the discovery of important simplifying relationships by other scientists (notably Arnt Eliassen of Norway and Reginald Sutcliffe of Britain), a joint US Weather Bureau, Navy, and Air Force numerical forecasting unit was formed in 1954 in Washington, DC. Referred to as JNWP, this unit was charged with producing operational numerical forecasts on a daily basis. The era of numerical weather prediction thus really began in the 1950s. As computing power grew, so did the complexity, speed, and capacity for detail of the models. And as new observations became available from such sources as Earth-orbiting satellites, radar systems, and drifting weather balloons, so too did methods sophisticated enough to ingest the data into the models as improved initial synoptic maps. Numerical forecasts have improved steadily over the years. The vast Global Weather Experiment, first conceived by Charney, was carried out by many nations in 1979 under the leadership of the World Meteorological Organization to demonstrate what high-quality global observations could do to improve forecasting by numerical prediction models. The results of that effort continue to effect further improvement. A relatively recent development has been the construction of mesoscale numerical prediction models. The prefix Meso- means 'Middle' and here refers to middle-sized features in the atmosphere, between large cyclonic storms and individual clouds. Fronts, clusters of thunderstorms,

hurricane bands, and jet streams are mesoscale structures, and their evolution and behaviour are crucial forecasting problems that only recently have been dealt with in numerical prediction. Richard A. Anthes developed a widely used American research version, the NCAR/Penn State Mesoscale Model, which shows the potential for detailed predictions of the location and evolution of structures such as fronts, rainbands, and ice storms. By the late 1980s the national weather services of several countries were producing numerical forecasts of considerable detail by means of limited-area mesoscale models. Principles And Methodology Of Weather Forecasting:- Short-Range Forecasting:- Objective Predictions:- when people wait under a shelter for a downpour to end, they are making a very-short-range weather forecast. They are assuming, based on past experience, that such hard rain usually does not last very long. In short-term predictions the challenge for the forecaster is to improve on what the layperson can do. For years the type of situation represented in the above example proved particularly vexing for forecasters, but since the mid-1980s they have been developing a method called nowcasting to meet precisely this sort of challenge. In this method, radar and satellite observations of local atmospheric conditions are processed and displayed rapidly by computers to project weather several hours in advance. The US National Oceanic and Atmospheric Administration operates a facility known as PROFS (Program for Regional Observing and Forecasting Services) in Boulder, State of Colorado, the United States, specially equipped for nowcasting. Meteorologists can make somewhat longer-term forecasts (those for six, 12, 24, or even 48 hours) with considerable skill because they are able to measure and predict atmospheric conditions for large areas by computer. Using models that apply their accumulated expert knowledge quickly, accurately, and in a statistically valid form, meteorologists are now capable of making forecasts objectively (see above). As a consequence, the same results are produced time after time from the same data inputs, with all analysis accomplished mathematically. Unlike the prognostications of the past made with subjective methods, objective forecasts are consistent and can be studied, reevaluated, and improved. Another technique for objective short-range forecasting is called MOS (for Model Output Statistics). Conceived by Harry R. Glahn and D.A. Lowry of the US National Weather Service, this method involves the use of data relating to past weather phenomena and developments to extrapolate the values of certain weather elements, usually for a specific location and time period. It overcomes the weaknesses of numerical models by developing statistical relations between model forecasts and observed weather. These relations are then used to translate the model forecasts directly to specific weather forecasts. For example, a numerical model might not predict the occurrence of surface winds at all, and whatever winds it did predict might always be too strong. MOS relations can automatically correct for errors in wind speed and produce quite accurate forecasts of wind occurrence at a specific point, such as Heathrow Airport near London. As long as numerical weather prediction models are imperfect, there may be many uses for the MOS technique. Predictive Skills And Procedures:- short-range weather forecasts generally tend to lose accuracy as forecasters attempt to look farther ahead in time. Predictive skill is greatest for periods of about 12 hours and is still quite substantial for 48-hour predictions. An increasingly important group of short-range forecasts are economically motivated. Their reliability is determined in the marketplace by the economic gains they produce (or the losses they avert). Weather warnings are a special kind of short-range forecast; the protection of human life is the forecaster's greatest challenge and source of pride. The first national weather forecasting service in the United States (the predecessor of the Weather Bureau) was in fact formed, in 1870, in response to the need for storm warnings on the Great Lakes. Increase Lapham of Milwaukee urged Congress to take action to reduce the loss of hundreds of lives incurred each year by Great Lakes shipping during the 1860s. The effectiveness of the warnings and other forecasts assured the future of the American public weather service. Weather warnings are issued by government and military organizations throughout the world for all kinds of threatening weather events:- tropical storms variously called Hurricanes, Typhoons, or Tropical Cyclones, depending on location (see above Major forms of weather disturbances); great oceanic gales outside the tropics spanning hundreds of kilometers and at times packing winds comparable to those of tropical storms; and, on land, flash floods, high winds, fog, blizzards, ice, and snowstorms. A particular effort is made to warn of hail, lightning, and wind gusts associated with severe thunderstorms, sometimes called Severe Local Storms (SELS) or simply Severe Weather. Forecasts and warnings also are made for tornadoes, those intense, rotating windstorms that represent the most violent end of the weather scale (see above). Destruction of property and the risk of injury and death are extremely high in the path of a tornado, especially in the case of the largest systems (sometimes called Maxi-Tornadoes). Because tornadoes are so uniquely life-threatening and because they are so common in various regions of the United States, the National Weather Service operates a National Severe Storms Forecasting Center (NSSFC) in Kansas City, State of Missouri, the United States, where SELS forecasters survey the atmosphere for the conditions that can spawn tornadoes or severe thunderstorms. This group of SELS forecasters, assembled in 1952, monitors temperature and water vapor in an effort to identify the warm, moist regions where thunderstorms may form and studies maps of pressure and winds to find regions where the storms may organize into mesoscale structures. The group also monitors jet streams and dry air aloft that can combine to distort ordinary thunderstorms into rare rotating ones with tilted chimneys of upward rushing air that, because of the tilt, are unimpeded by heavy falling rain. These high-speed updrafts can quickly transport vast quantities of moisture to the cold upper regions of the storms, thereby promoting the formation of large hailstones. The hail and rain drag down air from aloft to complete a circuit of violent, cooperating updrafts and downdrafts. By correctly anticipating such conditions, SELS forecasters are able to provide time for the mobilization of special observing networks and personnel. If the storms actually develop, specific warnings are issued based on direct observations. This two-step process consists of the tornado or severe thunderstorm watch, which is the forecast prepared by the SELS forecaster, and the warning, which is usually released by a local observing facility. The watch may be issued when the skies are clear, and it usually covers a number of counties. It alerts the affected area to the threat but does not attempt to pinpoint which communities will be affected. By contrast, the warning is very specific to a locality and calls for immediate action. Radar of various types can be used to detect the large hailstones, the heavy load of raindrops, the relatively clear region of rapid updraft, and even the rotation in a tornado. These indicators, or an actual sighting, often trigger the tornado warning. In effect, a warning is a specific statement that danger is imminent, whereas a watch is a forecast that warnings may be necessary later in a given region. Long-Range Forecasting:- Techniques:- extended-range, or long-range, weather forecasting has had a different history and a different approach from short- or medium-range forecasting. In most cases, it has not applied the synoptic method of going forward in time from a specific initial map. Instead, long-range forecasters have tended to use the climatological approach, often concerning themselves with the broad weather picture over a period of time rather than attempting to forecast day-to-day details. There is good reason to believe that the limit of day-to-day forecasts based on the 'initial map' approach is about two weeks. Most long-range forecasts thus attempt to predict the departures from normal conditions for a given month or season. Such departures are called Anomalies. A forecast might state that 'spring temperatures in Minneapolis have a 65 percent probability of being above normal'. It would likely be based on a forecast anomaly map, which shows temperature anomaly patterns. The maps do not attempt to predict the weather for a particular day, but rather forecast trends (i.e. warmer than normal) for an extended amount of time, such as a season (i.e. spring). The US Weather Bureau began making experimental long-range forecasts just before the beginning of World War II, and its successor, the National Weather Service, continues to express such predictions in probabilistic terms, making it clear that they are subject to uncertainty. Verification shows that forecasts of temperature anomalies are more reliable than those of precipitation, that monthly forecasts are better than seasonal ones, and that winter months are predicted somewhat more accurately than other seasons. Prior to the 1980s the technique commonly used in long-range forecasting relied heavily on the analog method, in which groups of weather situations (maps) from previous years were compared to those of the current year to determine similarities with the atmosphere's present patterns (or 'habits'). An association was then made between what had happened

subsequently in those ‘similar’ years and what was going to happen in the current year. Most of the techniques were quite subjective, and there were often disagreements of interpretation and consequently uneven quality and marginal reliability. Persistence (warm summers follow warm springs) or anti-persistence (cold springs follow warm winters) also were used, even though, strictly speaking, most forecasters consider persistence forecasts ‘no-skill’ forecasts. Yet, they too have had limited success. Prospects For New Procedures:- in the last quarter of the XX century the approach of and prospects for long-range weather forecasting have changed significantly. Stimulated by the work of Jerome Namias, who headed the US Weather Bureau’s Long-Range Forecast Division for 30 years, scientists began to look at ocean-surface temperature anomalies as a potential cause for the temperature anomalies of the atmosphere in succeeding seasons and at distant locations. At the same time, other American meteorologists, most notably John M. Wallace, showed how certain repetitive patterns of atmospheric flow were related to each other in different parts of the world. With satellite-based observations available, investigators began to study the El Niño phenomenon (see Climate:- Climate And Life:- El Niño/Southern Oscillation). Atmospheric scientists also revived the work of Gilbert Walker, an early XX-century British climatologist who had studied the Southern Oscillation, the aforementioned up-and-down fluctuation of atmospheric pressure in the Southern Hemisphere. Walker had investigated related air circulations (later called the Walker Circulation) that resulted from abnormally high pressures in Australia and low pressures in Argentina or vice versa. All of this led to new knowledge about how the occurrence of abnormally warm or cold ocean waters and of abnormally high or low atmospheric pressures could be interrelated in vast global connections. Knowledge about these links – El Niño/Southern Oscillation (ENSO) – and about the behavior of parts of these vast systems enables forecasters to make better long-range predictions, at least in part, because the ENSO features change slowly and somewhat regularly. This approach of studying interconnections between the atmosphere and the ocean may represent the beginning of a revolutionary stage in long-range forecasting. Since the mid-1980s, interest has grown in applying numerical weather prediction models to long-range forecasting. In this case, the concern is not with the details of weather predicted 20 or 30 days in advance but rather with objectively predicted anomalies. The reliability of long-range forecasts, like that of short- and medium-range projections, has improved substantially in recent years. Yet, many significant problems remain unsolved, posing interesting challenges for all those engaged in the field. / Фрэнсис Дабл.Ю. Райкилдёфё (Francis W. Reichelderfer) был . Полковник Дьжей.Эм. Прогнозирование – разработка прогноза; в узком значении – специальное научное исследование конкретных перспектив развития какого-либо явления. Как одна из форм конкретизации научного предвидения в социальной сфере находится во взаимосвязи с планированием, программированием, проектированием, управлением. Прогноз Погоды – научно обоснованные предположения о будущем состоянии погоды; краткосрочные прогнозы погоды – на 1–3 суток и долгосрочные – от 5 суток до сезона. Прогноз погоды может быть выполнен на основе анализа синоптических карт погоды (Синоптический Прогноз Погоды) или с применением численных методов прогноза погоды. Прогноз Погоды – научно обоснованное предположение о предстоящих изменениях погоды, составленное на основе анализа развития крупномасштабных атмосферных процессов. Прогнозы погоды делятся на краткосрочные (от нескольких часов до 1–2 суток (сут)), долгосрочные малой заблаговременности (3–10 сут), долгосрочные большой заблаговременности (на месяц и более). Прогнозы погоды составляются для территорий (область, край, страна, акватории морей и тому подобное), а также отдельных населённых пунктов, аэропортов, авиатрасс, автомобильных и железнодорожных магистралей и тому подобного. Прогнозы погоды подразделяются на специализированные, предназначенные для различных отраслей народного хозяйства, и общего пользования – для населения. К первым относятся также предупреждения об опасных явлениях погоды (циклоны, грозы, туманы, метели, сильные ветры, пыльные бури, заморозки и другие), которые могут вызвать затруднения в работе отдельных отраслей народного хозяйства или причинить ущерб, а также угрожать безопасности населения. В краткосрочных прогнозах погоды и предупреждениях ожидаемые условия погоды указываются более детально, чем в долгосрочных. Так, например, в прогнозе погоды для авиации сообщаются ожидаемые условия погоды на высоте полёта самолёта (вид и количество облачности, направление и скорость ветра, температура воздуха, наличие таких опасных явлений, как болтанка, обледенение, грозовые разряды) и в аэропорту посадки (высота облачности и видимость, направление и скорость ветра, температура воздуха). В долгосрочных прогнозах погоды малой заблаговременности характер погоды на предстоящий период описывается в более общем виде:- преобладание ясной или облачной погоды, возможность выпадения осадков, пределы дневных и ночных температур, резкие изменения погоды, преобладающее направление и скорость ветра. Прогнозы погоды на месяц содержат знак и величину отклонения средней месячной температуры и осадков от нормы, а также указания периодов наиболее существенных изменений погоды:- похолоданий и потеплений, переходов от сухой к ненастной погоде и тому подобных. Кроме месячных прогнозов, в бывшем СССР существовали прогнозы погоды на так называемые естественные синоптические сезоны со средней продолжительностью каждого около 2 месяцев (мес), в которых даётся общая характеристика температуры и осадков. Прогнозы погоды составляются методами синоптической метеорологии. Для этой цели по данным наблюдений метеорологических и аэрологических станций готовят синоптические карты погоды для разных уровней атмосферы от земной поверхности до высоты 30 километров (км). Широко используется также информация, получаемая от метеорологических спутников. Анализ этого материала позволяет выявить на картах погоды крупные атмосферные образования:- воздушные массы, разделяющие их атмосферные фронты, циклоны и антициклоны и прочие, с движением и эволюцией которых связаны основные изменения погоды. Всё возрастающее применение находят численные методы, позволяющие решать на ЭВМ уравнения гидротермодинамики атмосферы и температуры на различных уровнях

атмосферы, а также рассчитывать количества осадков на несколько суток вперед. Все эти методы дают представление об общем фоне погоды, который детализируется прогнозистом для местных условий. В долгосрочных прогнозах погоды используются различного рода статистические связи между прошедшим и будущим развитием атмосферных процессов и состоянием погоды. Точность всех прогнозов погоды в пределах периода, на который они составляются, убывает со временем. Основой для оценки практической пригодности какого-либо метода составления прогнозов погоды служит сравнение их удачности с удачностью инерционных прогнозов, предполагающих сохранение существующего характера погоды на период прогноза. В среднем из 100 краткосрочных прогнозов погоды или долгосрочных прогнозов малой заблаговременности оправдываются более 80 прогнозов. Основная причина наиболее крупных ошибок – неточности в расчётах барического поля, направления и скорости перемещения циклонов и атмосферных фронтов, а также их эволюции; эти ошибки обусловлены несовершенством применяемых методов, отсутствием достаточной информации с океанов и малонаселённых территорий, в особенности же из высоких слоёв атмосферы. Применение численных методов прогноза погоды ограничено тем, что для их осуществления необходимы быстродействующие ЭВМ, способные хранить сотни миллионов слов информации и обрабатывать её со скоростью в несколько сотен миллионов операций в секунду (сек). Методы долгосрочных прогнозов погоды большой заблаговременности находятся ещё в состоянии разработки, а сами прогнозы не обладают нужным качеством. Достаточно точный долговременный прогноз погоды – одна из труднейших задач современной науки.

WEATHERING = ВЫДЕРЖИВАНИЕ – Weathering is the mechanical or chemical disintegration and discoloration of the surface of wood caused by exposure to light, the action of dust and sand carried by winds, and the alternate shrinking and swelling of the surface fibers with the continual variation in moisture content, brought by changes in the weather. / Выдерживание Древесины. WEATHERING = ЭРОЗИЯ (или ВЫВЕТРИВАНИЕ) – Weathering is the physical and chemical breakdown of bedrock and regolith. Water reacts with minerals in soils and rocks, releasing nutrient elements. When nutrients are released, they can be adsorbed by soil, used by plants, or removed in runoff. Weathering is the disintegration of rocks into small soil particles through the physical and chemical action of atmospheric agents, for example, rain, water, frost, wind, temperature changes, plant and animals. Weathering is the disintegration or alteration of rock in its natural or original position at or near the Earth's surface through physical, chemical, and biological processes induced or modified by wind, water, and climate. During the weathering process the translocation of disintegrated or altered material occurs within the immediate vicinity of the rock exposure, but the rock mass remains in situ. Weathering is distinguished from erosion by the fact that the latter usually includes the transportation of the disintegrated rock and soil away from the site of the degradation. A broader application of erosion, however, includes weathering as a component of the general denudation of all landforms along with wind action and fluvial, marine and glacial processes. The occurrence of weathering at or near the Earth's surface also distinguishes it from the physical and chemical alteration of rock through metamorphism, which usually takes place deep in the crust at much higher temperatures. Weathering involves physical, chemical, and biological processes acting separately or, more often, together to achieve the disintegration and decay of rock material. Physical weathering causes the disintegration of rock by mechanical processes and therefore depends on the application of force. Disintegration involves the breakdown of rock into its constituent minerals or particles with no decay of any rock-forming minerals. The principal sources of physical weathering are thermal expansion and contraction of rock, pressure release upon rock by erosion of overlaying materials, the alternate freezing and thawing of water between cracks and fissures within rock, crystal growth within rock, and the growth of plants and living organisms in rock. Rock alteration usually involves chemical weathering in which the mineral composition of the rock is changed, reorganized, or redistributed. The rock minerals are exposed to solution, carbonation, hydration, and oxidation by circulating waters. These effects on the mineral decomposition are added to the effects of living organisms and plants as nutrient extraction to alter rock. Several factors control the type of weathering and the rate at which rock weathers. The mineralogical composition of a rock will determine the rate of alteration or disintegration. The texture of the rock will affect the type of weathering that is most likely to occur. Fine-grain rock will usually be more susceptible to chemical alteration but less susceptible to physical disintegration. The pattern of joints, fractures, and fissures within rock may provide an avenue for water to penetrate. Thus, shattered and fractured rock masses are more likely to undergo weathering than are monolithic structures. Climate will also control the type and rate of weathering by affecting the likelihood of freeze–thaw cycles and chemical reactions. Chemical weathering is more likely to occur and to be more effective in humid tropical climates, and disintegration of rock from freeze–thaw cycles is more likely to take place and to be more effective in sub-Arctic climates. / Выветривание. WEATHER INSURANCE = СТРАХОВАНИЕ ОТ ПОГОДЫ (или ПОГОДНОЕ СТРАХОВАНИЕ) – Weather Insurance is a type of protection against a financial loss that may be incurred because of rain, snow, storms, wind, fog, undesirable temperatures or other adverse, measurable weather conditions. Weather insurance is used to insure an expensive event that could be ruined by bad weather, like an outdoor wedding or an outdoor film production. The premium for weather insurance is determined based on location and time of year, in other words, based on the likelihood of the insured weather event occurring and the amount of potential loss. Weather insurance is highly customizable, the insured can choose, for example, the number of days, weather events and severity of weather that will be covered by the policy. See also Pluvial Insurance. Weather Insurance is a type of business interruption insurance that compensates for financial losses caused by adverse weather conditions, such as constant rain on the day scheduled for a major outdoor concert. Weather Insurance is an insurance policy protecting one from loss of income due to adverse weather conditions. For example, are creational horseback riding facility is unlikely to have many customers during heavy rain, which could cause significant drops in profit. Weather insurance can replace at least some of what the profits would have been. It is a type of business interruption insurance. / Страхование от потерь вследствие плохих погодных условий. WEATHER–LINKED BONDS = ОБЛИГАЦИИ, СВЯЗАННЫЕ С ПОГОДОЙ – Weather-Linked Bonds:- the payout of weather-linked bonds, commonly known as nature-linked bonds, is linked to weather conditions. The return on the nature-linked bond is pegged to a suitable meteorological index. A trigger level is defined, which remains active during the exposure period. If this trigger is hit by the index, the issuer of the bond is allowed to default. Suitable indexes might include rainfall or temperature. Insurance companies commonly issue these bonds to hedge against high weather damage claims.

WEATHER–OMETER = ПОГОДОМЕТР (или ПОГОДНИК) – Weather-Ometer is an instrument used in measuring the weather resistance of textiles. It can simulate various weather conditions such as sunlight, rain, dew, and thermal shock. Weathering is accelerated to the degree that the effects of years of normal use are attained in only a few days.

WEATHER PERMITTING = ПРИ БЛАГОПРИЯТНОЙ ПОГОДЕ – Weather Permitting (WP):- re laytime, the time during which weather prevents work will not count. Weather Permitting (WP):- that time during which weather prevents working shall not count as laytime.

WEATHER RADAR = ПОГОДНЫЙ РАДАР – Weather Radar provides the flight crew with visual display of weather that could contain turbulence. The system's primary function is to assist in turbulence avoidance, although most airborne radar systems are also capable of terrain mapping.

WEATHER RISK MANAGEMENT ASSOCIATION = АССОЦИАЦИЯ ПО УПРАВЛЕНИЮ ПОГОДНЫМ РИСКОМ – Weather Risk Management Association (WRMA) is a Washington, DC-based trade association representing the interests of the global weather derivatives market.

WEATHER SIDE = ПОГОДНАЯ СТОРОНА (или НАВЕТРЕННАЯ СТОРОНА) – Weather Side:- like lee, the term Weather refers to a side of the ship in reference to wind. The weather side is the side toward the wind, or windward. Weather Side is the windward side (from where the wind is blowing). / Наветренная Сторона:- сторона судна, откуда дует ветер; или сторона судна, подверженная действию ветра; например, если судно идёт правым галсом, то правая сторона и будет в этом случае наветренной.

WEATHERSTRIPPING = ИЗОЛЯЦИЯ (или ГЕРМЕТИЗАЦИЯ) – Weatherstripping:- specially designed strips, seals and gaskets installed around doors and windows to limit air leakage. / :- специально разработанные накладки, уплотнения и набивки, установленные вокруг дверей и окон с целью ограничения утечки воздуха.

WEATHER STRIPPING OR CAULKING = ИЗОЛЯЦИЯ (или ГЕРМЕТИЧЕСКАЯ ПРОКЛАДКА) ИЛИ НАБИВКА (или КОНОПАТЕНИЕ) – Weather Stripping Or Caulking:- any of several kinds of crack-filling material around any windows or doors to the outside used to reduce the passage of air and moisture around moveable parts of a door or window. Weather stripping is available in strips or rolls of metal, vinyl, or foam rubber and can be applied on the inside or outside of a building.

WEATHER WORKING DAY = РАБОЧИЙ ПОГОЖИЙ ДЕНЬ – The term 'Weather Working Days' (WWDs) often forms part of the definition of laytime. Although the meaning should, at first glance, be straightforward, it continues to be a source for dispute:- The intention is that where weather conditions make it impossible to load or discharge, then that day (or period of a day) should not count as laytime. This carries with it a fairly broad scope for disagreement on whether the weather in fact does make loading or discharging really impossible. Weather working days have been be considered on several occasions:- one of them was in London arbitration 10/04 (LMLN 0639) where the vessel was chartered under a charter party (C/P) on the Gencon form (short for the General Charter Conditions form). This particular vessel was loading not one but various and different cargoes (amongst others both timber and steel cargo). Loading was disturbed by the weather including snow and rain. The particular problem was that some of these cargoes were more sensitive to the weather than other cargoes, the different cargoes were loaded by different shippers and whatever the weather, some cargoes could be loaded where others could not. The C/P provided only for a single laytime allowance which measured laytime in weather working days. The arbitrators held that a weather working day (or part of a day) was a day where cargo could be loaded (or discharged) without interference from the weather. Laytime would run if any of the cargoes could be loaded even if others could not. This would change if there was only one type of cargo left which was in fact sensitive to the weather and if only this type of cargo was left and the weather was bad (affecting loading of this particular cargo), then laytime would not run. This particular decision illustrates the difficulties which can arise (in this case where several types of cargoes of different sensitivity are involved), but also demonstrates the fact that safeguarding appropriate evidence during cargo operations can be crucial. The dispute might have to be resolved some time later and any discussion as to the influence of the weather, and on any particular type of cargo, would very much depend on what evidence is available. The use of term 'weather working day' can also be source for dispute where the vessel is not only disturbed in her cargo operation but simply has to leave her berth because of the weather (for safety reasons). It would perhaps be easy to assume that if the vessel has to leave her berth for safety reasons, then this cannot be a weather working day, but this is not necessarily the case. In The MARIA G (offshore supply ship or supply vessel), the vessel had to leave her berth (she was ordered to do so by the harbour master) because a so-called 'Bore Tide' was expected, and the harbour master wished to avoid damage not only to the vessel, but also to the jetty. The court decided that the term 'weather working day' could not be construed so widely so as to cover the circumstances of this particular situation. If the effect of weather was not to interfere with the cargo operations, but to make the berth unsafe, then the time which was lost was not what the parties contemplated when the referred to 'weather working day' in the C/P. In other words, weather working days are aimed specifically at cargo operation only and not necessarily the safety of the vessel. These two aspects, cargo operations and vessel safety, are distinct and separate. If the weather affects (and stops) cargo operations and thereafter compels the vessel to leave her berth, then time will not count against laytime measured in weather working days from the time the weather stopped cargo operations and until the weather again allows cargo operations to be carried out. It is of no importance for the laytime running or not running whether the weather stops the vessel from returning to her berth. Instead, the correct way to approach the laytime aspect is simply to ask whether or not cargo operations would be possible if the vessel was back in her berth. This was the subject of a fairly recent London Arbitration 11/10 ((2010) 802 LMLN 3(2)). Again, the vessel was chartered on a C/P on the Gencon form and again there was a dispute as to whether laytime was to count during a period whether the vessel left and waited off her discharging berth because of heavy swell in the port. During the time the vessel was outside her discharging berth, the harbour master had also issued orders to suspend pilotage and related services and closed the only available berth in the port for all operations and ordered, for safety reasons, vessels to leave this berth. The arbitrators referred to the MARIA G (and a number of London arbitrations which, over the years, had adopted the same approach as The MARIA G). The arbitrators then went on to consider the actual dispute which was whether the charterers could show, on the balance of probabilities, that discharging would have been prevented if the ship had been able to remain at the berth. The arbitrators inferred from the available information that the vessel would have been so prevented. They thought it was clear that the conditions that prevailed at the time when the vessel left the berth were such that even if cranes at the berth could have 'worked', they could not have done so safely – and the vessel could not safely have remained alongside. The fact that the vessel could not remain alongside, the arbitrators mentioned as a fact which alone, on itself, would have prevented discharging from continuing. In this particular case, there was no particular evidence to that effect, but this was not in itself surprising since the port was closed, and it was therefore impossible to know with any certainty what would have happened. The only option open to the arbitrators was to draw an inference from the information they had available to them to decide what would have happened, i.e. would cargo operations have been possible or not? With the inference made by the arbitrators that cargo operations could not have continued (safely), it follows that this was not a weather working day (or days), and the owners' claim for demurrage failed. (There was a separate issue about shifting expenses – the harbour master (and not the charterers) ordered the ship to leave the berth, and presumably ordered the vessel to return to a different berth – such a loss should (where no breach of contract had occurred) lie where it fell, and that meant with the owners). In this particular case it was necessary for the arbitrator to infer from whatever information was available, what had been (or could have been) the case. To some extent this would be necessary to do no matter what, but the case illustrates the need always to ensure that as much evidence as possible is collected and safeguarded at the

time – it may well become useful later. See also Lay Days. Weather Working Day is a day of 24 hours on which work is not prevented by bad weather. / хозяин (или капитан). Мариа Дьжи. (MARIA G). День, в который в течение всех 24 часов не прекращается работа вследствие возможной непогоды. Под Рабочими Погожими Днями понимаются рабочие дни, в течение которых погода позволяет проводить работу. WEAVE = ПЕРЕПЛЕТЕНИЕ – Weave is the particular manner in which a fabric is formed by interlacing yarns. The basic weaves include plain (or tabby), twills, and satins. Weave is a system or pattern of intersecting warp and filling yarns. There are three basic two dimensional weaves:- plain, twill, and sateen or satin. All other weaves are derived from one or more of these types. There are three basic Weaves that are used:- (i) the plain weave, the most common, is produced by passing the weft yarn over and under each warp yarn, alternating each row. This is used for cotton print cloth, sheeting, muslin and more. (ii) The twill weave is produced by interlacing yarns in an angle to form straight, diagonal ridges across the fabric. This is used for sturdy products such as denim, gabardine and ticking. (iii) The satin weave, has a surface that consists mostly of warp yarn which is passed over and under all but one weft yarn that intersects in a regular or irregular formation, not a straight line. This weave produces a fabric with a smooth surface. It is used for upholstery, home decorating and fashionable apparel. See also Plain Weave, Sateen Weave, Satin Weave, and Twill Weave. / основных и уточных пряж. Ткань с гладкой поверхностью. Переплетение:- Каждая ткань состоит из двух взаимно переплетающихся систем нитей:- основных и уточных. Основные нити располагаются вдоль ткани, уточные – поперёк. Чтобы из основных и уточных нитей получить ткань, их нужно переплести. Для этого на ткацком станке часть нитей основы поднимается, а оставшиеся нити – опускаются, и в образовавшийся таким образом зев прокладывается уточная нить. Перед следующей прокидкой уточины поднимаются другие нити. Основа и уток переплетаются, образуя ткань. Построение Заправочного Рисунка:- для того чтобы воспроизвести какой-либо вид переплетения ткани, получить на её поверхности определённый рисунок, создаётся заправочный рисунок. Заправочный рисунок – это условная технологическая графическая схема, в соответствии с которой производится заправка ткацкого станка. Заправочный рисунок состоит из четырех элементов:- (i) рисунок переплетения ткани; (ii) схема проборки нитей основы в бёрдо; (iii) порядок проборки нитей основы в ремиз; и (iv) рисунок картона (порядок подъёма ремизок). Нити основы на заправочном рисунке располагаются вертикально, а нити утка – горизонтально (показываются только на рисунке переплетения). Раппорт переплетения основных нитей R_o считается слева направо, уточных R_y – снизу вверх, соответственно очередности их прохождения в ткани. Счёт ремизок основан на практике Ивановских текстильных предприятий:- снизу вверх (первая ремизка самая близкая к бёрду). Законченная часть рисунка переплетения нитей основы с нитями утка (после чего идёт повторение) называется Раппортом Переплетения, или Раппортом Ткани, и состоит из раппорта по основе R_o и раппорта по утку R_y. Существует три способа изображения заправочного рисунка:- канвовый, линейный и комбинированный. Наибольшее распространение получил канвовый способ изображения заправочного рисунка. Главными (фундаментальными) называются такие переплетения, в которых каждая нить основы и утка в пределах раппорта перекрывает или перекрывается только одной нитью противоположенной системы. Класс главных переплетений является основополагающим при изучении теории переплетений, служит базой (фундаментом) для построения переплетений всех других классов. Входят в него три вида переплетений:- (i) полотняное (plain weave); (ii) саржевое (twill weave); и (iii) сатиновое (sateen weave) или атласное (satin weave). Все эти переплетения, резко отличаясь по внешнему виду, имеют ряд общих признаков, исходя из которых Профессором С.А. Ганешиным дано приведённое выше определение переплетений главного класса переплетений:- (i) наличие только одного основного или уточного перекрытия на каждой нити; (ii) одиночные перекрытия располагаются с постоянным сдвигом; и (iii) равное число основных и уточных нитей в раппорте. Для класса главных переплетений характерно так же постоянство сдвига перекрытий. Под Ткачеством понимается выработка ткани на ткацком станке. В широком смысле слова – то же, что ткацкое производство. Под Ткацким Производством понимается совокупность технологических процессов, необходимых для выработки текстильных тканей из пряжи. Ткацкое производство включает:- подготовительные операции, служащие для создания паковок нитей основы и утка, пригодных для работы на ткацких станках; изготовление ткани на ткацких станках; и заключительные операции, к которым относятся чистка, стрижка, складывание тканей и так далее. В ткачестве в качестве базовых используются три типа Переплетений:- (i) полотняное переплетение (plain weave); (ii) саржевое переплетение (twill weave); и (iii) сатиновое или атласное переплетение (sateen or satin weave). Нити основы и утка при формировании ткани на ткацком станке переплетаются между собой в определённом порядке в соответствии с программой, определяющей порядок подъёма ремизок. Ткацкие переплетения условно изображаются на клетчатой бумаге; основные нити вертикальными полосами, уточные – горизонтальными. Счёт основных нитей ведётся слева направо, уточных – снизу вверх. Места пересечения основных и уточных нитей образуют перекрытия. Место, где основная нить располагается над уточной, называется основным перекрытием; место, где уточная нить располагается над основной, – уточным перекрытием. Основные перекрытия принято заштриховывать или отмечать знаками, уточные перекрытия оставляют свободными. Наименьшее число нитей основы и утка, формирующих законченный рисунок переплетения, после которого рисунок на ткани повторяется, называется раппортом переплетения R. Иными словами, раппортом переплетения называется наименьшее число нитей, после которого последовательность расположения основных и уточных перекрытий повторяется, то есть раппорт – это элементарный законченный рисунок ткани. В раппорте переплетения различают:- (i) раппорт по основе R_O – число основных нитей в раппорте переплетения, после которого порядок расположения перекрытий в направлении утка повторяется; и (ii) раппорт по утку R_y – число уточных нитей в раппорте переплетения, после которого порядок расположения перекрытий вдоль основы повторяется. Для построения сдвига рисунка переплетения необходимо знать величину сдвига S. Сдвиг – это число, показывающее, на сколько нитей смещено перекрытие рассматриваемой нити от аналогичного перекрытия предыдущей нити. Различают:- (i) горизонтальный сдвиг S_y – это сдвиг между перекрытиями двух рядом расположенных уточных нитей; и (ii) вертикальный сдвиг S_O – это сдвиг между перекрытиями двух рядом расположенных основных нитей. Сдвиг может быть как положительным, так и отрицательным. В России используется следующая классификация ткацких переплетений:- главные и простые; мелкоузорчатые, включающие производные от полотняного переплетения (основный и уточный репс, основный и уточный полурепс, рогожка), от саржевого переплетения (зигзагообразная, ломаная, обратносдвинутая, ромбовидная, сложная, теневая и усиленная саржи), от сатинового и атласного переплетения (теневые и усиленные сатины и атласы) и комбинированные, получаемые путём различных комбинаций главных и производных переплетений (вафельные, креповые, рубчиковые, с продольными и поперечными полосами, квадратами и клетками, просвечивающиеся и другие); сложные, для построения которых требуется две и более систем основных или уточных нитей или несколько систем основных и уточных нитей (ажурные, ворсовые (уточные и основные), двойной и многократной ширины, двухслойные, многослойные, петельные, пике, полутораслойные, полые (мешковые)); крупноузорчатые или жаккардовые, содержащие в раппорте по основе более 32 разнопереплетающихся нитей (ажурные, ворсовые, двухслойные, махровые, многослойные, полутораслойные (двухосновные и двухуточные)). К главным (простым) переплетениям относятся полотняное, саржевое и сатиновое или атласное. В главных переплетениях каждая нить основы и утка в пределах раппорта имеет только одно перекрытие, отличающееся от других (одно основное среди уточных или одно уточное среди основных). Для главных переплетений $R_O = R_y = R$. Число основных перекрытий вдоль

уточной нити в пределах раппорта $m_O = 1$, или $m_O = R - 1$. Соответственно число уточных перекрытий вдоль основной нити в пределах раппорта $m_y = R - 1$, или $m_y = 1$. Саржевое переплетение условно обозначается дробью m_O/m_y. Числитель показывает число основных перекрытий, знаменатель – число уточных перекрытий. Раппорт саржевого переплетения равен сумме числителя и знаменателя. Сатиновые и атласные переплетения обозначают дробью, числителем которой является раппорт переплетения, а знаменателем – сдвиг (R / S). Для сатиновых переплетений это горизонтальный сдвиг S_y, для атласных – вертикальный S_O. Для правильных сатинов и атласов величины R и S должны быть целыми числами и не должны иметь общего делителя. Так, если R = 5, то S = 2, 3; если R = 7, то S = 2, 3, 4, 5; если R = 8, то S = 3, 5 и так далее. Переплетение Нитей – порядок взаимного расположения нитей в ткани, трикотаже, гардинно-тюлевых изделиях, определяющий их структуру, свойства и внешний вид. Все виды переплетения нитей ткани делят на простые, или главные (атласное, полотняное, саржевое, сатиновое), мелкоузорчатые (производные от главных и комбинированные), сложные (2-основные, 2-ниточные, 2-слойные и так далее) и жаккардовые (крупно-узорчатые). Переплетение нитей в трикотаже характеризуются формой и взаимным расположением петель. Их делят на поперечно- и продольновязаные (в первых ряды петель образованы одной нитью, во вторых – большим числом нитей основы), одинарные и двойные. Под Переплетением Нитей понимается порядок взаимного расположения нитей в тканях, трикотаже, гардинно-тюлевых изделиях, определяющий их структуру, внешний вид и свойства. В тканях переплетение нитей характеризуется обязательным наличием перпендикулярных друг другу систем нитей – основы и утка (в ажурных переплетениях имеется дополнительная система основных нитей, называемых перевивочными). Выбор переплетения нитей определяется назначением ткани, а также видом пряжи, из которой она изготовляется. Для графического изображения переплетения нитей ткани на бумаге существуют условные способы:- рисунок переплетения нитей изображают системой клеток (чёрными – основные перекрытия, белыми – уточные). Каждый вертикальный ряд клеток – нить основы, горизонтальный – нить утка. Любое переплетение нитей строится из определённого числа нитей основы и утка. Наименьшее число нитей, после которого повторяется порядок их взаимного перекрытия, называется Раппортом переплетения нитей. Порядок взаимного расположения перекрытий основы и утка для каждого ряда может быть выражен дробью, числитель которой показывает число подряд расположенных основных перекрытий, а знаменатель – уточных; ряды могут отличаться друг от друга. Они могут быть сдвинуты друг относительно друга, образуя определённый угол сдвига, количественное выражение которого входит в характеристику переплетения нитей. Сложные переплетения нитей характеризуются расположением нитей основы и утка не только в одном слое, но и в нескольких слоях. Количество видов переплетения нитей очень велико. В зависимости от сложности переплетения нитей подразделяются на простые или главные (полотняное, саржевое, атласное), мелкоузорчатые, сложные, крупноузорчатые. Наиболее распространены простые переплетения нитей. Число возможных переплетений нитей теоретически беспредельно, а практически ограничивается технологическими возможностями, эстетическими соображениями и целесообразностью. Переплетения нитей воспроизводятся с помощью зевообразовательного механизма ткацкого станка:- более простые – при помощи эксцентриковых зевообразовательных механизмов, более сложные – кареток или машин Жаккарда. Переплетения нитей в трикотаже характеризуются формой петель и их взаимным расположением. Они делятся на поперечновязаные (кулирные) и основовязаные. В первых горизонтальные ряды петель образованы одной нитью, во вторых – большим числом нитей основы. В зависимости от структуры в трикотаже различают группы переплетения нитей:- главные, производные, комбинированные и сложные. Переплетение – порядок пересечения в ткани нитей утка и основы, определяющий в результате внешний вид лицевой и изнаночной сторон ткани. Существует три основных типа перплетения:- (i) Полотняное, или Тафтяное, при котором чередуются при выходе на поверхность ткани одна нить основы и одна нить утка по всей ширине и длине. Ткань имеет одинаковые лицевую и изнаночную стороны. (ii) Саржевое, или Киперное, или Диагональное, при котором нить утка по отношению к нити основы в каждом последующем ряду сдвигается на один ход налево или направо. Места пересечения нитей утка и основы образуют на поверхности ткани диагональные полоски под углом 45 градусов. Если уток сдвигается вправо, получается лицевая саржа, если влево – изнаночная. (iii) Атласное, при котором не менее пяти нитей основы закрывают уток, выходящий на поверхность только над одной нитью основы (основной атлас), или не менее пяти нитей утка закрывают нити основы, и на поверхность выходит только одна её нить (уточный атлас).

WEAVERS = ВПЛЕТЕНИЯ (или ТКАЧИ) – Weavers are the yarns which run in the warp-thickness plane of a three dimensional fabric. These are the yarns which hold the longitudinal and filling yarns together. / и уточных пряж .

WEAVER'S BEAM = ТКАЦКИЙ НАВОЙ – Weaver's Beam is a beam carrying the warp which has a defined number of ends of identical length inserted in the loom and used for weaving the fabric.

WEAVING = ТКАЧЕСТВО (или ТКАНЬЁ) – Weaving is the process of forming a fabric on a loom by interlacing the warp (lengthwise yarns) and the filling (crosswise yarns) perpendicular to each other. Filling is fed into the goods from cones, filling bobbins or quills, which carry the filling yarns through the shed of the loom. Filling may also be inserted into the material without the use of a shuttle, as in the case of a shuttleless loom. The three basic weaves are Plain, Twill, and Sateen or Satin. All other weaves, no matter how intricate, employ one or more of these basic weaves in their composition. Variations on the basic weaves make a variety of different fabric surfaces and fabric strengths. The Weaving Process:- in weaving, the warp thread and weft yarn are crossed over one another in a set method in order to weave the required type of fabric. A machine designed to accomplish this task is called a loom. First, the warp thread and weft yarn are prepared so that they can be set into the loom. (i) Warping:- cheese or cones with yarns are set on a warping machine to wind the predetermined length and number of yarns onto the predetermined number of warping beams under constant tension. (ii) Sizing:- the warping beams of the required number of warps of the final textile are piled up for rewinding on beams after sizing and drying. (iii) Drawing-In:- to prepare for setting beams on a loom, warps are routed in the order of droppers, healds and guide bars. (iv) Weaving:- prepared beams are set on a looming frame to weave a textile in the following five motions:- (a) Shedding:- two groups of warps are opened to let the weft pass through; (b) Picking:- the weft is inserted between two groups of warps; (c) Beat-Up:- pushing the newly inserted yarn back into the fell using reed; (d) Let-Off:- the warp yarns are unwound from the warp beam; and (e) Take-Up:- the woven fabric is wound on the cloth beam. (v) Inspection/Folding:- the fabric is inspected and folded. Imperfections are corrected as required. The fabric is then graded. (vi) Packing:- the fabric is packed in a manner appropriate to the shipping conditions. (vii) Product:- the finished product (in pressed bales) is sold. Weaving is the process of forming a fabric on a loom by interlacing the warp and filling threads with each other. The fundamental weaves are Plain, Satin, and Twill. All other weaves, no matter how intricate, employ one of these basic weaves in their composition. There are many variations on the basic principles which make different types of fabric surfaces and fabric strengths. The effect formed by the interlacing of the warp, weft and ornamental threads in the fabric. In the strict technical sense of the word only fabrics produced on a loom are called Woven, and crocheted or knit goods, laces, nets, felts, etc, cannot be included in this class. The immense subvarieties of weaves are classed by some into three groups, viz., plain weave, twill weave and satin weave, while others place pile, leno, lappet and swivel weaves in different classes. That the principle of weaving was known for a very long time is shown by the fact that traces of it are to be found among the earliest remains of human art and industry. Since the inception of the primitive handloom the following inventions were among the most important ones in perfecting the loom as it appears today:- John Kay (1704–64) invents the flying shuttle in 1733 (it allowed the shuttle, containing the thread, to be shot

backwards and forwards across a much wider bed; it also allowed the thread to be woven at a faster rate, thus accelerating the weaving process); Vaucanson constructs in 1745 a self-acting loom, the forerunner of the Jacquard; John Kay and J Snell in 1745 and Snell in 1760 patent ribbon loom; James Hargreaves (1720–78) invents the Spinning Jenny (capable of spinning eight threads of cotton yarn, instead of the spinning wheel's one; it also improved the quality of the thread); Sir Richard Arkwright (1732–92) in 1769 invents water frame and in 1775 his spinning frame (a larger version of the Spinning Jenny powered by a watermill; it took spinning away from home bases to specific areas where fast-flowing streams could provide water power); James Hargreaves patents the Spinning Jenny in 1770; James Watt (1736–1819) invents steam engine in 1769 (introduced into the Cotton industry in 1785; in 1790 Richard Arkwright adopted the steam engine in his own factory and by 1800 it was established as the main source of power throughout the industry); Samuel Crompton (1753–1827) invents spinning mule in 1779 (an improved version of Arkwright's water frame, capable of producing stronger and finer thread); Edmund Cartwright (1743–1823) patents first power loom (improved the weaving process, initially powered by a bull and later by the steam engine) in 1785 and by the time he took out his final patent in 1792 he invented the positive let-off motion, warp and weft stop motions, the differential batten motion, shuttle stop motions, automatic temples and (in 1792) invented the multiple shuttle box; Eli Whitney (1765–1825) invents cotton gin in 1793 (mechanical separation of seed and lint which considerably reduced the costs of producing cotton lint); Robert Miller invents fast reed-stop motion in 1795; William Radcliffe patents in 1803 the beam warper and the warp sizing machine. Between 1801 and 1808 Jacquard perfected his invention of the loom named after him; in 1834 Hornby & Kenworthy invent loose reed stop-motion; in 1843 Luke Smith invents the revolving shuttle box; in 1845 Squire Diggle invents the automatic drop box; in 1894 James H. Northrop (Keighley, Yorkshire, England) invents the automatic cop changer. (1924). The manufacturing of cloth by the interlacing of yarns. Weaving is a widely used constructional method because it is cheap, basically simple, and adaptable. Woven fabrics have valuable characteristics resulting partly from the geometrical conformation of their components and partly from the fact that the components are held in position not by rigid bonding but by friction set up at the areas where they make contact. Woven fabrics are used in household, apparel, and industrial textiles. Textile designers can produce a very large variety of cloths by their selection of yarns, finishing processes, and binding systems. Yarns vary in thickness, smoothness, fibre content, twist, and color, all of which have a profound influence on the finished cloth. Finishing processes range from such simple treatment as brushing up the nap on a woven fabric to such a complicated chemical process as that employed to change opaque cotton fabric to transparent, permanently stiffened organdy. The binding system, or weave, however, is the basic factor in determining the character of a woven fabric. The three basic systems are plain or tabby, twill, and satin. In complex binding systems, the basic weaves are combined or enriched by hand manipulation or mechanical loom attachments; these include multiple-plane, pile, inlaid, and gauze weaves. Regardless of the binding system, other devices – manipulation of warp spacing, beating in, or tension – can be used to alter the appearance of any weave, to make it looser or more compact, to make it more or less regular. As musical notation conveys a composer's ideas, so weave drafts or point paper plans communicate a textile designer's directions for constructing woven fabrics. The draft is a plan on graph paper showing at least one repeat or weave unit of the fabric to be woven. This information enables the weaver or mill specialist to plot the drawing in of the warp, tie up of harnesses to shedding mechanism, and shedding order. The Weaving Process:- woven cloth is normally much longer in one direction than the other. The lengthwise threads are called the Warp; the other threads, which are combined with the warp and lie widthwise, are called the Weft (synonyms are 'Filling', 'Woof', and 'Shoot', or 'Shute'). An individual thread from the warp, of indefinite length, is called an End; each individual length of weft, extending from one edge of the cloth to the other, is called a Pick, or Shot. Consecutive picks are usually consecutive lengths of one piece of weft yarn that is repeatedly folded back on itself. In all methods of weaving cloth (except the rudimentary form of darning), before a length of weft is inserted in the warp, the warp is separated, over a short length extending from the cloth already formed, into two sheets. The process is called Shedding and the space between the sheets the shed. A pick of weft is then laid between the two sheets of warp, in the operation known as Picking. A new shed is then formed in accordance with the desired weave structure, with some or all of the ends in each sheet moving over to the position previously occupied by the other sheet. In this way the weft is clasped between two layers of warp. Since it is not possible to lay the weft close to the junction of the warp and the cloth already woven, a further operation called Beating In, or Beating Up, is necessary to push the pick to the desired distance away from the last one inserted previously. Although beating in usually takes place while the shed is changing, it is normally completed before the new shed is fully formed. The sequence of primary operations in one weaving cycle is thus shedding, picking, and beating in. At the end of the cycle the geometrical relation of the pick to the warp is the same as it would have been if the pick had been threaded through the spaces between alternate ends, first from one side of the cloth and then from the other, as in darning. This is the reason the weaving process is considered an interlacing method. Early Development of the Loom:- the word Loom (from Middle English lome, 'tool') is applied to any set of devices permitting a warp to be tensioned and a shed to be formed. Looms exist in great variety, from the bundles of cords and rods of primitive peoples to enormous machines of steel and cast iron. Except on certain experimental looms, the warp shed is formed with the aid of heddles (or healds). Usually one heddle is provided for each end, or multiple end, of warp thread, but on some primitive looms simple cloths are produced with heddles provided only for each alternate end. A heddle consists of a short length of cord, wire, or flat steel strip, supported (in its operative position) roughly perpendicular to the unseparated sheet of warp threads and provided, in modern looms, with an eyelet at its midpoint, through which the warp end is threaded. By pulling one end of the heddle or the other, the warp end can be deflected to one side or the other of the main sheet of ends. The frame holding the heddles is called a Harness. In most looms, the weft is supplied from a shuttle, a hollow projectile inside which a weft package is mounted in such a way that the weft can be freely unwound through an eyelet leading from the inside to the outside. The shuttle enters the shed and traverses the warp, leaving a trail of weft behind. Beating in is generally effected by means of a grating of uniformly spaced fine parallel wires, originally made of natural reeds and thus called a Reed, which, mounted at right angles to the warp, oscillates between the heddles and the junction of the warp and the cloth. The ends pass, one or more at a time, through the spaces between consecutive reed wires, so that the reed, in addition to beating in, controls the spacing of the ends in the cloth. Two-Bar:- The earliest evidence of the use of the loom (4400 BC) is a representation of a horizontal two-bar (or two-beamed, i.e. warp beam and cloth beam) loom pictured on a pottery dish found at al-Badārī, Egypt. The warp is stretched between two bars or beams, pegged to the ground at each of the four corners. Lease (or laze) rods are used to separate the warp yarns, forming a shed and aiding the hands in keeping the yarns separated and in order. Lease rods were found in some form on every later type of improved loom, and their use at this very early date indicates that the loom already had been in use long enough to have reached a stage of improvement by addition of devices to aid the hands. Before lease rods were added, it would have been necessary for the fingers to separate each odd from each even warp thread to create the shed through which the weft yarn was passed. A third rod also seen in this early drawing may be a heddle rod. If so, this loom represents a still more advanced stage of development. The heddle rod rests on top of the warps. To produce a plain weave, alternate warp yarns are tied to the rod, and, when it is raised, the shed is formed quickly and accurately. Some authorities consider the heddle to be the most important step in the evolution of the loom. A shed stick is ordinarily used with the heddle, forming the second, or countershed, opening for the return of the weft. In addition to the horizontal two-bar loom, there are two other primitive varieties, the warp-weighted and the vertical two-bar loom. The warp-weighted loom consists of a crossbar supported by two vertical posts. The warp threads hang from the crossbar and are held taut by weights of clay, ceramic, or chalk tied to their free ends. Loom weights have been found at archaeological sites dating from 3000 BC, but this type of loom may have originated even earlier. The earliest picture of a vertical two-

bar loom is from the Egyptian 18th dynasty (1567–1320 BC). It coincides with the appearance of more intricate textile patterns, the earliest known tapestries (datable between 1483 and 1411 BC) having been found in the tomb of Thutmose IV at Thebes. (Even today the vertical loom is preferred for tapestry weaving.) In the vertical two-bar loom the ends of the warp yarns are attached to a second crossbar, thus combining features of both the horizontal two-bar and the warp-weighted looms. The heddle rods and shed sticks are used in a similar way on all three types. Counterparts of these very early looms have been used through the ages in many cultures. The Navajo Indians, probably the best known of the American Indian weavers, have used the simple two-bar vertical loom for several centuries to produce their beautiful rugs and blankets. A form of the horizontal two-bar loom was the back-strap loom, in which one bar was tied to a tree or other stationary device, the second being attached to the weaver's waist by a strap. The weaver could control the tension of the warp yarns by applying pressure as necessary. The back-strap loom was used in pre-Columbian Peru, in other cultures of Central and South America, in Asia, and elsewhere. Horizontal Frame Looms:- by about 2500 BC a more advanced loom was apparently evolving in East Asia. Fragments of silk fabrics found adhering to bronzes of the Shang (or Yin) period (XVIII–XII centuries) in China show traces of a twill damask pattern, suggesting an advanced weaving knowledge, since such fabrics could not practicably be woven on the looms described above. These fabrics were probably produced on a horizontal frame loom with treadles. The logical connecting link between the horizontal two-bar and the horizontal frame loom with treadles would have been a loom with a heddle rod that was controlled by one foot, for which no early illustrations have been found. The earliest European pictorial record of the horizontal frame loom with a treadle dates from the XIII century, when it appears in a highly developed form, almost certainly introduced from the East. This two-bar loom was mounted in a frame; to this was connected a treadle operated by the feet, moving the heddles, an improvement of the heddle rod or cord controls now mounted between bars and called a Shaft. The advantages of this type of loom were many. First, in the two-bar loom, though more than two heddle rods could be used, the number of groupings of warp threads was limited. Although highly complex patterns could be woven, it was not practical to do so in producing any but very small quantities of cloth. The shaft loom allowed as many as 24 shafts to be set up easily, enabling the weaver to produce comparatively intricate patterns. Second, the weaver's sword or comb formerly used to beat the weft into place was replaced by the batten, supported in a heavy wooden frame from the main frame of the loom; its weight and free-swinging motion improved the beating-in action and made it easier. Third, use of the foot treadle freed both hands to throw the shuttle and swing the batten. The loom remained virtually unchanged for many centuries thereafter. Drawlooms:- the shaft loom was adequate for plain and for simply patterned fabrics, but a more complex loom was needed for the weaving of intricately figured fabrics, which might require 100 or more shafts. This kind of weaving was accomplished on the drawloom. Its origin is unknown, but it probably was first used in East Asia for silk weaving and was introduced into the silk-working centres of Italy during the Middle Ages. The drawloom had two devices for shedding: in addition to the shafts, which the weaver operated by treadles, cords were also used to raise the warp threads, gathered into groups as required by the pattern. The cords were worked by an operator (called a Drawboy) seated on top of the loom. The drawloom was improved in Italy and France in the early XVII century by the addition of a type of mechanical drawboy, allowing the assistant to stand on the floor at the side of the loom and increasing the control of the cords. The continued inconvenience of employing an assistant, however, who might also make errors, led to a search for an automatic mechanism that would perform all the work of the drawboy. Most of the later developments in automatic mechanisms to control the shedding operation originated in France, which had become one of the leading countries in the weaving of figured silks. In 1725 Basile Bouchon added to the mechanical drawboy a mechanism that selected the cords to be drawn to form the pattern. Selection was controlled by a roll of paper, perforated according to the pattern, which passed around a cylinder. The cylinder was pushed toward the selecting box and met with needles carrying the warp-controlling cords; the needles that met unperforated paper slid along, and the others passed through the holes and remained stationary. The selected cords were drawn down by a foot-operated treadle. The mechanical drawboy made the proper selection of warp threads, eliminating errors, but still required an operator. The mechanism was improved in 1728 by increasing the number of needles and using a rectangular perforated card for each individual shedding motion, the cards being strung together in an endless chain. In 1745 Jacques de Vaucanson constructed a loom incorporating a number of improvements. He mounted the selecting box above the loom, where it acted directly on hooks fastened to the cords that controlled the warp yarns. The hooks passed through needles and were raised by a strong metal bar. The needles were selected by perforated cards passing around a sliding cylinder, without the aid of a second operator or assistant. The cylinder was very complex, and the mechanism is not known to have been adopted, but it served as the foundation for the successful Jacquard attachment. The Jacquard Attachment:- The French inventor Joseph-Marie Jacquard, commissioned to overhaul Vaucanson's loom, did so without the directions, which were missing. In 1801, at the Paris Industrial Exhibition, he demonstrated an improved drawloom. In 1804–05 he introduced the invention that ever since has caused the loom to which it is attached to be called the Jacquard Loom. The Jacquard attachment is an automatic, selective shedding device, mounted on top of the loom and operated by a treadle controlled by the weaver. As in the drawloom, every warp yarn runs through a loop in a controlling cord, held taut by a weight. Each cord is suspended from a wire ('hook') that is bent at the bottom to hold the cord and bent at the top in order to hook around the blades or bars of the griff, the lifting mechanism. To allow only those warp threads that are needed to form the pattern to be raised, some hooks must be dislodged from the rising griff. This is accomplished by horizontally placed needles connected to the hooks. As the perforated pattern card moves into place on the cylinder (which is, in fact, a quadrangular block), the needles pass through the holes in the card, and the warps are raised; where there are no holes, the needles are pushed back (by a spring action on the opposite end of each), pulling the hooks away from the rising griff bar, and the warps are not raised. Each card represents one throw of the shuttle, and the pattern is transferred to the cards from the designer's weave draft. Although each Jacquard attachment is limited in the number of hooks it can control and, therefore, in the size of the repeat pattern, by adding several Jacquard attachments to one loom, the weaver not only can produce intricately figured fabrics but also can weave pictures of considerable size. The Flying Shuttle:- the first decisive step toward automation of the loom was the invention of the flying shuttle patented in 1733 by the Englishman John Kay. Kay was a weaver of broadloom fabrics, which because of their width required two weavers to sit side by side, one throwing the shuttle from the right to the centre, the other reaching between the warps and sending it on its way to the left and then returning it to the centre. The stopping of the shuttle and the reaching between the warps caused imperfections in the cloth. Kay devised a mechanical attachment controlled by a cord jerked by the weaver that sent the shuttle flying through the shed. Jerking the cord in the opposite direction sent the shuttle on its return trip. Using the flying shuttle, one weaver could weave fabrics of any width more quickly than two could before. A more important virtue of Kay's invention, however, lay in its adaptability to automatic weaving. Power-Driven Looms:- the first power-driven machine for weaving fabric-width goods, patented in 1785 by Edmund Cartwright, an English clergyman, was inadequate because it considered only three motions:- shedding, picking, and winding the woven cloth onto the cloth beam. Cartwright's second patent (1786) proved too ambitious, but his concept of a weaving machine became the basis for the successful power loom. One of the great obstacles to the success of the power loom was the necessity to stop the loom frequently in order to dress (i.e. apply sizing to) the warp, an operation that, like many others, had been done in proportionately reasonable time when the weaving was done by hand. With the power loom a second man had to be employed continuously to do this work, so there was no saving of expense or time. In the early XIX century a dressing machine was developed that prepared the warp after it had been wound onto the warp beam and as it was passed to the cloth beam. Although later superseded by an improved sizing apparatus, this device made the power loom a practical tool. Advances made by William Horrocks of Scotland

between 1803 and 1813 included an improvement in the method of taking up the cloth (i.e. winding the woven fabric onto the cloth beam) and making a more compact machine of iron, requiring little space as compared with wooden handlooms. Francis Cabot Lowell, of Boston, experimented with the power loom, adding improvements to increase the weaving speed, and also improved the dressing machine. A valuable improvement was that of the let-off and take-up motions, to maintain uniform warp tension automatically. The principle of holding at the beat (i.e. not permitting the warp to be let off until the pick was beaten into place) first applied by Erastus Brigham Bigelow in the carpet loom, was successfully applied to all kinds of weaving. Another Bigelow invention, applicable to power looms in general, although first used on a carpet loom, was the friction-brake stop mechanism, allowing the loom to be stopped without a shock. These developments were primarily concerned with the power loom used for weaving plain goods. William Crompton, an English machinist working in the machine shop attached to a cotton factory in Massachusetts, undertook the development of a loom that could weave fancy goods, patented in both the United States and England in 1837. The loom was later much improved by his son George Crompton. Such XIX-century inventions made possible the production of textile goods for every use in great volume and variety, and at low cost. Modern Looms:- modern looms still weave by repeating in sequence the operations of shedding, picking, and beating in, but within that framework there has been considerable development during the XX century. Several new types of loom have come into industrial use, whereas older types have been refined and their scope extended. Two main influences have been the rising cost of labour and the increasing use of man-made, continuous-filament yarns. The first has led to an increase in automatic control, in automatic handling of yarn packages, and in the use of larger packages; the second, to greater precision and finish in loom construction, because deficiency in these qualities is readily reflected in the quality of the cloth made from these yarns. Modern looms can be grouped into two classes according to whether they produce cloth in plane or tubular form. Looms of the first kind, comprising all but a few, are called Flat Looms; the others are described as circular. Since the majority are flat looms, the adjective is used only when a distinction has to be drawn. Flat looms fall into two categories: those that employ a shuttle and those that draw the weft from a stationary supply, usually called Shuttleless Looms. (This term is not entirely satisfactory, as some primitive looms make no use of a shuttle, merely passing through the shed a stick with weft wound on it.) Shuttle looms fall into two groups according to whether the shuttle is replenished by hand or automatically. The second kind is often described as an automatic loom, but, except for shuttle replenishment, it is no more automatic in its operation than the hand-replenished or so-called Nonautomatic Loom, which, like all modern looms, is power-operated by electric motor. With both types of loom the actual weaving operation is entirely automatic and is performed in exactly the same manner. Hand-replenished, or nonautomatic, looms are used only where particular circumstances – of yarns, fabrics, or use – make automatically replenished looms either technically unsuitable or uneconomic. Basically they differ little from the power looms of the latter half of the XIX century. They do not run appreciably faster but are better engineered, making use, for example, of machine-cut instead of cast gear wheels. Often there is no superstructure, which makes for cleanliness and improved illumination; frequently rigid heddle connectors are employed, leading to precise and stable setting of the shed; and usually the overpick mechanism has been replaced by the cleaner and safer underpick. Automatically replenished flat, or automatic, looms are the most important class of modern loom, available for a very wide range of fabrics. In virtually all such looms, the shuttle is replenished by automatically replacing the exhausted bobbin with a full one. In principle they are thus the same as the automatic looms introduced at the end of the XIX century. Since that time, automatic shuttle-changing looms have also been introduced but have largely become obsolete, because bobbin-changing looms have been developed to a point where they can deal with most of the yarns for which it was once thought necessary to use shuttle-changing looms. Apart from the general engineering refinements, automatic looms have advanced mainly in respect of the weft supply. Alternatives to the hand-replenished bobbin now exist in the form of the automatic bobbin loader, the loom being supplied with boxes of pirned (reeled) weft; and the automatic loom winder, the loom being fed with large cones of yarn, which is wound onto pirns at the loom. These alternatives are technically feasible and economic only with certain yarns. Therefore, all three types of weft supply continue to be used. An alternative to the rotary battery, when weft of more than one color is used, is a series of vertical stacks. The principle of shuttle replenishment is the same for all three systems. When the shuttle is stationary in the shuttle box, and the bar carrying the reed is farthest forward, a feeler enters the shuttle and senses whether the weft is on the point of exhaustion. Feelers may be mechanical or electrical, relying respectively on the change in friction or the change in electrical resistance brought about by the absence of weft. Alternatively, with delicate wefts, an optical feeler may be used that depends for its action on the change in the amount of light reflected when the bare pirn is revealed. When the feeler has sensed that the bobbin is nearly empty, mechanical or electrical signals are transmitted to the transfer mechanism that, when the shuttle is appropriately positioned and momentarily at rest, both as regards warp-way and weft-way motion, hammers a new bobbin into position, simultaneously ejecting the empty one through the open base of the shuttle. The loom continues to run at its normal speed throughout. In the course of this operation, there are created unwanted lengths of weft extending from the nearer selvage. These, if not controlled and disposed of, may find their way into the cloth and appear as defects. Modern looms supplement the earlier mechanical methods by pneumatic suction, with the result that the most delicate fabrics can be woven on automatic bobbin-changing looms without any loss of quality. To make certain of removal of the remnant of weft on the old bobbin, extending to the eye of the shuttle, a cutter moves forward into the shuttle box and cuts the weft close to the eye just before the bobbin is ejected. High speed, often combined with the use of large and heavy shuttles, means that these modern looms are noisier than ever. The noise level in a typical textile mill is above the level at which deafness occurs following prolonged exposure. Shuttleless looms are of three kinds, of which the first predominates:- dummy shuttle, rapier, and fluid jet. The dummy-shuttle type, the most successful of the shuttleless looms, makes use of a dummy shuttle, a projectile that contains no weft but that passes through the shed in the manner of a shuttle and leaves a trail of yarn behind it. The rapier type conveys a pick of weft from a stationary package through the shed by means of either a single rapier or a pair of rapiers. Rapiers are either rigid rods or flexible steel tapes, which are straight when in the shed but on withdrawal are wound onto a wheel, in order to save floor space. Rapier looms are, on the whole, simpler and more versatile than dummy-shuttle looms, but they have failed to achieve such high rates of weft insertion, the maximum being not more than 400 yards (365 meters) per minute. They differ in respect of the number of rapiers employed and the type of selvage provided; some of them operate by gripping the free end of the weft and conveying that through the shed rather than by starting with a loop. Fluid-jet looms, most recently developed of the shuttleless types, are produced and used on a much smaller scale than the two other types described above. They are of two kinds, one employing a jet of air, the other a water jet, to propel a measured length of weft through the shed. The significance of this development is that for the first time nothing solid is passed into the shed other than the weft, which eliminates the difficulties normally associated with checking and warp protection, and reduces the noise to an acceptable level. In addition to those looms that have established themselves industrially, there are looms still in the experimental stage. Loom development is always slow:- some of the looms just gaining favour had their origins in inventions made 50 or even 100 years earlier. The most intense activity is in the field of shuttleless looms, because these offer the greatest prospect of achieving increased rates of weft insertion and of avoiding the drawbacks of noise, danger, vibration, high power consumption, and wear attendant on the use of a shuttle. The ultimate in direct projection is a method, still experimental, in which the weft is projected longitudinally at high speed and traverses the warp under its own momentum, nothing entering the shed but the pick of weft. The name inertial has been given to this method. Another experimental loom employs multiple rapiers for weft insertion and, in addition, eliminates the heddles and the reed. Weaving is the process of interlacing two yarns of similar materials so that they cross each other at right angles to produce a woven fabric. Weaving production of

fabric by interlacing two sets of yarns so that they cross each other, normally at right angles, usually accomplished with a hand- or power-operated loom. In weaving, lengthwise yarns are called Warp; crosswise yarns are called Weft or Filling. Most woven fabrics are made with their outer edges finished in a manner that avoids raveling; these are called Selvages. They run lengthwise, parallel to the warp yarns. The three basic weaves are plain, twill, and satin. Fancy weaves – such as pile, Jacquard, dobby, and leno – require more complicated looms or special loom attachments for their construction. The manner in which the yarns are interlaced determines the type of weave. The yarn count and number of warp and filling yarns to the square inch determine the closeness or looseness of a weave. Woven fabrics may also be varied by the proportion of warp yarns to filling yarns. Some effects are achieved by the selection of yarns or of combinations of yarns. In the plain weave each filling yarn passes over and under the warp yarns, with the order reversed in alternating rows. Fabrics made in the plain weave include percale, muslin, and taffeta. Ribbed effects in such fabrics as faille and bengaline are produced by employing heavier yarns for either the warp or the filling. In the basket weave one or more filling yarns are passed alternately over and under two or more warp yarns, as seen in monk's cloth. Twill weaves are made by interlacing the yarns in a manner producing diagonal ribs, ridges, or wales across the fabric. Wales may run from the upper right to the lower left of the fabric, or the reverse. The herringbone weave has wales running both ways. Twill fabrics include denim, gabardine, and flannel. Satin weaves have a sheen produced by exposing more warps than fillings on the right side of the fabric. The exposed warps are called Floats. In the sateen weave the process is reversed, and the exposed fillings form the floats. The amount of twist in the yarns and the length of the floats produce variations. Fabrics made in these weaves include slipper satin, satin crêpe, and various sateen types. Pile weaves produce fabrics with raised, dense surfaces. They can be made by weaving extra warp yarns over wires, producing loops that are cut as the wires are withdrawn; by adjusting loom tension to produce loops that are frequently left uncut; by using extra filling yarns to produce floats that are cut after weaving; or by weaving two cloths face to face, binding them together with an extra set of warps that form the pile when the fabrics are cut apart. Examples of woven pile fabrics include velvet, plush, terry cloth, and many of the synthetic furs. Jacquard weaves, produced on a special loom, are characterized by complex woven-in designs, often with large design repeats or tapestry effects. Fabrics made by this method include brocade, damask, and brocatelle. Dobby weaves, requiring a special loom attachment, have small, geometric, textured, frequently repeated woven-in designs, as seen in bird's-eye piqué. Leno weaves, also made with a special attachment, are usually lightweight and open, giving a lacelike appearance, and are made by twisting adjacent warp yarns around each other, then passing the filling yarn through the twisted warps. Marquisette, casement cloth, and mosquito netting are produced by this method. Weaving is the method or process of interlacing two yarns of similar materials so that they cross each other at right angles to produce woven fabric. The warp yarns, or ends, run lengthwise in the fabric, and the filling threads (weft), or picks, run from side to side. Weaving can be done on a power or handloom or by several hand methods. See also Loom, and Woven Fabric. Weaving is the most basic process in which two different sets of yarns or threads are interlaced with each other to form a fabric or cloth. One of these sets is called Warp which is the lengthwise yarn running from the back to the front of the loom. The other set of crosswise yarns are the filling which are called the Weft or the Woof. Preparing Warps and Wefts for Weaving:- the warps form the basic structure of fabrics. As such, they are made to pass through many operations before actual weaving is done. These operations include spooling, warping and slashing. In spooling, the yarn is wound on larger spools, or cones, that are placed on a rack known as Creel. From the creel, the yarns are wound on a warp beam, which looks like a huge spool. These lengths of hundreds of warped yarns lie parallel to one another. These yarns are unwound for slashing, or sizing. The yarn is coated with sizing with the help of slasher machine. Slashing prevents chafing or breaking of yarns during weaving process. Sizing is either starch based or a synthetic like polyvinyl alcohol or a water soluble acrylic polymers. The sized yarns are then wound on a final warp beam and are ready for the loom. The filling yarns experience less strain during the weaving process. Their preparation includes spinning them to the required size and giving them just the right amount of twist desired for the kind of fabric they will be used. Basic Weaving Operations:- no matter what type of weaving is being done, four major operations are performed in sequence and are continuously repeated. (1) Shedding:- in shedding, alternate warp yarns are raised to insert the filling yarn into the warp to form a shed. Shedding is automatically performed by the harness on the modern weaving looms. Harness is a rectangular frame to which a series of wires, called Heddles, are attached. As each warp yarn comes from the warp beam, it passes through an opening in the heddle. The operation of drawing each warp yarn through its appropriate heddle eye is known as Drawing In. (2) Picking:- as the warp yarns are raised through shedding, the weft yarn is inserted through the shed by a carrier device. A single crossing of the filling from one side of the loom to the other is called a Pick. Different methods are used for carrying the filling yarn through the shed in different kinds of looms. There are many types of looms including shuttle loom, shuttle less loom, and circular loom. (i) Shuttle Loom:- the shuttle loom is the oldest type of weaving loom which uses a shuttle which contains a bobbin of filling yarn that appears through a hole situated in the side. The shuttle is batted across the loom and during this process, it leaves a trail of the filling at the rate of about 110 to 225 picks per minute (ppm). Although very effective and versatile, the shuttle looms are slow and noisy. Also the shuttle sometimes leads to abrasion on the warp yarns and at other times causes thread breaks. As a result the machine has to be stopped for tying the broken yarns. (ii) Shuttle Less Loom:- many kinds of shuttle less looms are used for weaving such as Projectile Looms; Rapier Looms; Water Jet Looms; and Air Jet Looms. (a) Projectile Loom:- it is sometimes called Missile Loom as the picking action is done by a series of small bullet like projectiles which hold the weft yarn and carry it through the shed and then return empty. All the filling yarns are inserted from the same side of the loom. A special tucking device holds the ends of the wefts in place at the edge of the cloth to form the selvage. This loom needs smooth, uniform yarn which is properly sized in order to reduce friction. Projectile loom can produce up to 300 ppm and is less noisier then the shuttle loom. (b) Rapier Loom:- rapier loom comes in many types. Early models of it use one long rapier device that travels along the width of the loom to carry the weft from one side to the other. Another type of rapier loom has two rapiers, one on each side of the loom. They may be rigid, flexible or telescopic. One rapier feeds the weft halfway through the sheds of warp yarns to the arm on the other side, which reaches in and carries it across the rest of the way. Rapier looms are very efficient and their speed ranges from 200 to 260 ppm. These looms can manufacture a variety of fabrics ranging from muslin fabric to drapery fabrics and even upholstery fabrics. (c) Water Jet Loom:- in it, a pre measured length of weft yarn is carried across the loom by a jet of water. These looms are very fast with speeds up to 600 ppm and very low noise. Also they don't place much tension on the filling yarn. As the pick is tension less, very high quality of warp yarns are needed for efficient operation. Also, only yarns that are not readily absorbent can be used to make fabrics on water jet looms such as filament yarn of acetate, nylon, polyester, and glass. However, it can produce very high quality fabrics having great appearance and feel. (d) Air Jet Looms:- in the air jet weaving looms, a jet of air is used to propel the weft yarn through the shed at speeds of up to 600 ppm. Uniform weft yarns are needed to make fabrics on this loom. Also heavier yarns are suitable for air jet looms as the lighter fabrics are very difficult to control through shed. However, too heavy yarns also can't be carried across the loom by air jet. In spite of these limitations, air jet loom can produce a wide variety of fabrics. (iii) Circular Looms:- these looms are particularly used for making tubular fabrics rather than flat fabrics. A shuttle device in it circulates the weft in a shed formed around the machine. A circular loom is primarily used for bagging material. (3) Beating Up:- this weaving operation is also called Battening. In it, all warp yarns pass through the heddle eyelets and through openings in another frame that looks like a comb and is known as Reed. With each picking operation, the reed pushes or beats each weft yarn against the portion of the fabric that has already been formed. It results in a firm and compact fabric construction. (4) Taking Up and Letting Off:- as the shedding, picking and battening processes are being operated, the new fabric is wound on the cloth beam. This is known as 'Taking Up'. At the same time, the warp

yarns are released from the warp beam which is known as ‘Letting Off’. The pattern of the weave depends on the manner in which groups of warped yarns are raised by the harnesses to allow the insertion of the weft yarn. These differences are responsible for producing different types of fabric weaves. Weave patterns can create various degrees of durability in fabrics apart from their utility and looks. Weaving consists of interlacing a series of filling yarns with a series of warp yarns at right angles. The filling yarns are inserted by an air jet, rapier or shuttle that traverses the yarns from one side of the warp to the other, interlacing the two systems of threads, ‘warp’ and ‘filling’, in a prearranged weave plan. Weaving is an ancient art of making fabric, with no new types of weaves having been developed since 1747. The warp yarns and weft yarns are interlaced (woven) with each other to make a fabric (vs. a knit where the yarns are looped together). There are three basic weaving constructions:- (i) Plain Weave:- a weave is made by weaving one weft yarn over and under each warp yarn, alternating each row. It is the most common type of weave; (ii) Twill Weave:- al weave is similar to a satin weave in the sense that the loom is floating the warp or weft yarns over yarns of the opposite direction, but with a twill the yarn is only passing over two of the opposite yarns. A twill is distinctive by the diagonal lines that appear in the fabric. A twill weave, like a satin weave, usually results in a softer fabric than a plain weave. It is excellent for brushed or napped cotton, and is superior for a feather pillow ticking because of its strength. (iii) Satin Weave:- a weave is made by ‘floating’ the warp or weft yarns across several yarns to bring them to the surface. Bringing the yarns to the surface gives the fabric sheen because light is reflected off the yarn surface, not absorbed by the intersections of yarns such as in a plain weave. / Уточина (Filling). Под Ткачеством понимается выработка ткани на ткацком станке. В широком смысле – то же, что ткацкое производство, которое предполагает под собой совокупность технологических процессов, выполняемых при выработке текстильных тканей из пряжи. Эти процессы обеспечивают формирование ткани из однониточной или кручёной пряжи, шёлковых и химических нитей. Различают хлопко-, шерсто-, льно- и шёлкоткацкие производства. Ткацкое производство складывается из приготовления пряжи, изготовления ткани на ткацких станках, заключительной обработки суровой ткани перед отделкой или выпуском (разбраковка, промеривание, взвешивание, а иногда складывание и тому подобное). Приготовление основы заключается в перематывании (в современном хлопчатобумажном ткацком производстве не требуется), сновании, шлихтовании (эмульсировании) и пробирании или привязывании. Для утка выполняются перематывание, увлажнение, запаривание или эмульсирование. В ткачестве наряду с бесчелночными используются многозевные ткацкие станки. Под Тканью понимается текстильное изделие, образуемое на ткацком станке переплетением двух взаимно перпендикулярных систем нитей:- (i) основных, идущих вдоль ткани, и (ii) уточных, идущих поперёк неё. Сущность ткачества заключается во взаимном переплетении основных и уточных нитей с заданной последовательностью их расположения, при этом направление нитей чаще всего взаимно перпендикулярное. Цель ткачества – формирование ткани определённой структуры, которая обеспечивает заданные механические и другие свойства ткани и её внешний вид. Ткачество – циклический процесс, включающий пять операций:- зевообразование, прокладывание и прибивание утка, продольное смещение основы и ткани. Ткань образуется на ткацком станке. Нити основы, сматываясь с навоя, огибают скало, проходят через отверстия ламелей и направляются к ремизкам. Каждая нить основы проходит через соответствующий ей глазок галева одной из ремизок, а затем между двумя зубьями бёрда. Часть основных нитей, которые проходят через глазки одной ремизки, периодически поднимается или остаётся на месте, а другая часть их, проходящая через глазки другой ремизки, в это время опускается. В образовавшееся между нитями основы пространство, называемое зевом, прокладывается уточная нить, например, с помощью нитепрокладчика, который движется по направляющему каналу, состоящему из отдельных пластин. С помощью бёрда, закреплённого в брусе батана, уточная нить прибивается к опушке ткани. Батан качается вперёд и назад. Наработанная ткань огибает опору для ткани, направляющий угольник-грудницу, вальян, направляющий валик и наматывается на товарный валик. Все эти операции повторяются при формировании каждого элемента ткани. Новый элемент ткани нарабатывается за каждый удар батана. По мере наработки ткани и отвода её из зоны формирования ткацкий навой поворачивается и тем самым обеспечивается продольное смещение основных нитей. Число ремизок на станке может быть различным. В зависимости от числа ремизок и порядка их подъёма и опускания на ткацком станке можно вырабатывать ткани различных переплетений. Для образования ткани необходимо, чтобы нити основы имели на станке некоторое натяжение. Оно создаётся специальными механизмами станка и непрерывно изменяется при каждом цикле образования ткани. Кроме того, нити основы в процессе ткачества подвергаются деформации изгиба и воздействию сил трения. Основа перемещается в продольном направлении на ткацком станке с небольшой скоростью, поэтому большинство перечисленных выше сил воздействует на пряжу многократно. Как показывают исследования, наибольшее натяжение соответствует моменту прибоя уточины к опушке ткани, а наименьшее – моменту полного закрытия зева. Основные нити должны обладать значительной прочностью, упругостью, должны быть стойкими к истирающим воздействиям и многократному изгибу. Кроме того, пряжа должна быть достаточно гладкой и ровной, не иметь больших утолщений. Уточная пряжа в процессе переработки на ткацком станке меньше подвержена воздействиям, чем основная. Действие этих сил немногократно, они не оказывают заметного влияния на пряжу, поэтому нити утка могут быть менее прочными, чем основные, но они должны быть достаточно эластичными. Пряжа, поступающая на ткацкую фабрику, должна иметь определённую влажность, так как в зависимости от влажности изменяются её масса, линейная плотность и некоторые физические свойства. Форма и размер паковок, применяемых на ткацком станке, влияют на его производительность. Паковки должны иметь такую форму, при которой обеспечивается свободное сматывание нитей в процессе ткачества. Размер паковки определяет массу и длину нити в ней, а следовательно, продолжительность работы с одной паковкой. Нити основы и утка, взаимодействуя в процессе ткачества при формировании ткани, изгибаются. Уработкой основных нитей в % называют разность между длиной основных нитей и длиной ткани, выработанной из них. Уработка уточных нитей в % есть разница между длиной уточных нитей, проложенных в зев, и шириной изготовленной ткани. Величина уработки зависит от ряда факторов, основными из которых являются натяжение нитей в процессе ткачества, параметры

заправки и выработки ткани на ткацком станке, переплетение, линейная плотность пряжи, род сырья, строение ткани и другие. Под усадкой (уменьшение) и присадкой (увеличение) суровой ткани понимается изменение её размеров в процессе отделки. Усадка и присадка ткани различается по длине и ширине готовой ткани. В ткацком производстве Снование – перематывание большого числа нитей (до 1 000) с бобин на одну общую паковку – сновальный валик. Выполняется на сновальных машинах. Впоследствии требуемое по ширине ткани число нитей с валиком наматывается на ткацкий навой. Прибой – продвижение (‘прибивание’) уточной нити к опушке ткани после введения её в зев (пространство между нитями основы). Прибой выполняется пластинками (‘зубьями’) бёрда ткацкого станка. На многозевных ткацких машинах прибой осуществляется специальными дисками сложного профиля. Скало – деталь ткацкого станка в виде пустотелого цилиндра, поверх которого проходят нити основы при их сматывании с ткацкого навоя. От положения скало зависит натяжение нитей основы. Прокладчик Утка – устройство бесчелночного станка для прокладывания уточной нити между нитями основы. Ткацкое Производство – совокупность технологических процессов, необходимых для изготовления суровых (неотделанных) текстильных тканей. Иногда ткацкое производство называют Ткачеством. В зависимости от вида перерабатываемого сырья (волокон, нитей) различают хлопко-, шерсто-, шёлко-, льноткачество и тому подобное. Историческая Справка:- ткачество, как и прядение, возникло в эпоху неолита и широко распространилось при первобытнообщинном строе. Ручной ткацкий станок с вертикальным расположением основы появился примерно за 5–6 тысяч лет до Нашей Эры. Изобретение ткацкого станка Фридрих Энгельс считал одним из важнейших достижений человека на первой ступени его развития. В феодальный период совершенствуется конструкция ткацкого станка, создаются приспособления для подготовки пряжи к ткачеству. Первые попытки механизации процесса ткачества относятся к XVI–XVIII векам. Среди них наибольшее значение имело изобретение Дьжоном Кэем (John Kay) в 1733 так называемого Летающего Челнока (flying shuttle). В конце XVIII века в Великобритании Эдмэндом Катрайтом (Edmund Cartwrite) был изобретён первый механически приводный ткацкий станок (first power loom), в конструкцию которого в дальнейшем вносились различные усовершенствования (главным образом в Великобритании):- приёмный товарный механизм (Шотландец Робёт Милёр (Robert Miller), 1796), ремизо-подъёмные устройства (lathe; heald roller, placing it on the top of the loom; Дьжон Тодд (John Todd), 1803), механизм координации движения основного навоя и товарного валика (Ричад Робётс (Richard Roberts), 1822) и другие. В 1833 в Северной Америке была изобретена самодействующая Шпарутка – устройство для растяжения ткани у опушки. Существенный вклад в совершенствование конструкции ткацкого станка внесли и Русские изобретатели:- Д.С. Лепёшкин, запатентовавший в 1844 механический самоостанов при обрыве уточной нити; С. Петров, предложивший в 1853 наиболее совершенную систему боевого механизма для прокладки челнока, и другие. В конце XIX и начале XX веков были созданы станки с автоматической сменой челноков. Наиболее удачное решение проблемы автоматической смены уточной шпули в челноке принадлежит Англичанину Дьжеймзу Хэнри Носропу (James Henry Northrop; 1890). Однако челночные ткацкие станки имеют существенные недостатки:- малый размер уточной паковки; свободный, с большими ускорениями полёт челнока через зев; одновременная прокладка лишь одной уточной нити и другие. В начале XX века появилось несколько конструкций бесчелночных станков, в которых уточная нить сматывалась с больших неподвижных паковок и особыми механическими устройствами прокладывалась в зеве. Станки этого типа создали в 1926 Ёхан Габля (Johann Gabler; Германия), Советский инженер В.Е. Леонтьев в 1936 и другие. В 1927 С.А. Дынник (СССР) предложил конструкцию многозевного круглого ткацкого станка; в 1949 В.А. Прозоровым (СССР) был создан плоский многозевный станок. Технология Ткацкого Производства:- в соответствии с технологическим процессом изготовления тканей ткацкое производство состоит из:- (i) подготовительных операций, собственно ткачества и (ii) заключительных операций. К подготовительным операциям относятся Перематывание Нитей Основы и Утка, Снование, Шлихтование, Пробирание Основы и Связывание Концов Нитей. Цель подготовительных операций – создание паковок нитей основы и утка, пригодных для работы на ткацком станке. Перематывание нитей основы обычно производится с прядильных початков на конические бобины крестовой намотки (реже на катушки), необходимые для следующей операции – снования. Перематывание осуществляется на мотальных машинах и мотальных автоматах. Если прядильные паковки удовлетворяют требованиям процесса снования, то перематывание исключают. При сновании нити с большого числа бобин или катушек (до 1 000 нитей) навивают на сновальный валик. Процесс осуществляется на сновальных машинах. Шлихтование основы (пропитка клейким коллоидным раствором – шлихтой) повышает выносливость нитей и сопротивляемость истиранию и многократному растяжению их при ткачестве. Пробирание нитей основы в ламели необходимо для автоматического останова станка при обрыве нити; в глазки галев ремизок нити продеваются для образования зева на станке (пространство для движения челнока) и получения ткани заданного переплетения. Пробирание нитей в зубья бёрда обеспечивает прибой уточной нити к опушке ткани и получение необходимой плотности ткани по основе. Перематывание утка на шпули для челночных станков производится на уточно-перемоточных автоматах. Для бесчелночных ткацких станков используется бобина с мотальных или непосредственно с прядильных машин. Уточная пряжа часто подвергается дополнительной операции – увлажнению (либо эмульсированию, запариванию) для сматывания её без так называемых слётов (спадение с паковки нескольких витков). Для ткачества основа и уток из приготовительного цеха поступают в ткацкий цех для выработки из них ткани. Нити основы в процессе ткачества испытывают большие воздействия рабочих органов станка, чем уточные, поэтому к ним предъявляются повышенные требования по прочности, выносливости и износостойкости. Основа, как правило, изготавливается из лучшего, чем уток, сырья, с более высокой круткой и дополнительно усиливается шлихтованием. Обрывность нитей, особенно основных, – главная причина останова ткацких станков, она ухудшает качество тканей и создаёт отходы пряжи. Заключительные операции ткацкого производства – измерение длины ткани на мерильных машинах, чистка и стрижка её, контроль качества на браковочных машинах и укладка на складальных машинах. Все заключительные операции осуществляются на поточных линиях, на которых суровая ткань движется непрерывным полотном, сшитым из отдельных кусков ткани. Пороки суровой ткани оцениваются по баллам (порочным единицам), число которых определяет сорт ткани. Ткацким производством называют также совокупность ткацкого цеха (цехов), приготовительного цеха и браковочного отдела. Ткацкое производство может быть самостоятельным (обычно называют фабрикой) или входить в состав текстильного комбината, состоящего из прядильного, крутильного, ткацкого и отделочного производств. Оптимальная мощность ткацких фабрик зависит от отрасли промышленности, например хлопчатобумажная фабрика обычно имеет 2 000–4 000 челночных станков или до 2 000 бесчелночных, шёлкоткацкая – до 3 000 пневматических, камвольно-суконная – до 800 бесчелночных. Дальнейшее совершенствование ткацкого производства направлено на механизацию трудоёмких операций и автоматизацию производственных процессов; внедрение бесчелночных и многозевных ткацких станков, разработку на их основе и освоение новых форм организации труда; агрегирование процессов и машин с целью сокращения переходов в подготовке пряжи к ткачеству. Пробирание Основы или Проборка Основы – последняя операция в подготовке нитей основы к ткачеству; нити последовательно пробираются (продеваются) в отверстия ламелей, глазки галев ремизок и просветы между зубьями берда. Осуществляется при заправке новых видов тканей и при замене изношенных берд и ремизок; в остальных случаях заменено механической привязкой основы. Пробирание основы выполняется ручным, полумеханическим и автоматическим способами. Автоматическое пробирание основы выполняется на проборных машинах; производительность пробирания повышается примерно в 4–5 раз (по сравнению с ручным). Управление работой проборной машины осуществляется с помощью

программного устройства. Привязка Основы – соединение узлами концов нитей доработанной основы с концами нитей вновь подготовленной основы. Осуществляется узловязальными машинами. Для привязки основы применяются узлы различных типов:- однопетельные (ткацкие), двухпетельные (портновские), самозатягивающиеся и другие. Ткачество – получение ткани на ткацком станке. Органы и механизмы ткацких станков, их классификация. Сущность процесса получения ткани на ткацком станке, посредством взаимного переплетения продольных (основных) и поперечных (уточных) нитей. Способы прокладки уточной нити в зев, образуемый нитями основы. Ткачество – получение ткани на ткацком станке – Ткачество – изготовление ткани на ткацких станках. Для ткачества основа и уток из приготовительного цеха поступают в ткацкий цех для выработки из них ткани. Основа в ткачестве нити, расположенные параллельно друг другу и идущие вдоль ткани. Ткань на ткацком станке образуется в результате последовательного переплетения двух систем нитей – основы и утка, расположенных перпендикулярно нити основы в процессе ткачества испытывают большие воздействия рабочих органов станка, чем уточные, поэтому к ним предъявляются повышенные требования прочности, выносливости и износостойкости. Соответственно, для выработки ткани используются ткацкие станки различных конструктивных особенностей. Однако, общий принцип образования ткани на ткацком станке остаётся незыблем. Ткачество – изготовление ткани на ткацком станке. В широком смысле слова под ткачеством понимают совокупность технологических процессов, составляющих ткацкое производство. Ткачество – технологический процесс изготовление тканей и тканых изделий. Ткачество возникло в древности за 2 500 лет до Нашей Эры. В начале это было ручное плетение, затем появились ручные ткацкие станки. В конце XIV века появились ручные ткацкие станки с батаном и ремизоподъёмным механизмом. В 1733 был изобретён челнок-самолёт, благодаря чему значительно повысилась производительность ручного ткацкого производства. В конце XVIII века в России появляются механические ткацкие станки. В 1798 была создана в Петербурге Александровская Мануфактура – первая механическая текстильная фабрика в России, на которой также было организовано производство и механических ткацких станков. В 1894 был выпущен автоматический станок оснащённый прибором для автоматической смены уточной шпули внутри челнока. В настоящее время производительность челночных станков считается недостаточной и ведущими фирмами зарубежных стран и России разработаны новые типы ткацких станков отличающихся способом введения утка и зевообразованием. Это так называемые станки новых принципов действия. К ним относятся:- (i) станки с микро-прокладчиками; (ii) пневматические станки (уточная нить прокладывается сильной струёй воздуха); (iii) пневморапирные станки; (iv) рапирные станки; (v) гидравлические станки (уточная нить пробрасывается через зев тонкой струёй воды (капли)); (vi) станки с волновым зевом; и (vii) станки челночные (классический тип станка). Технологическая схема Ткацкого Производства:- пришедшая из прядильного в ткацкое производство пряжа проходит через определённые технологические переходы, перед тем как ей суждено превратиться в готовое текстильное изделие. (1) Основная пряжа:- (i) Перематывание – осуществляется для того, чтобы получить паковку с большой длиной пряжи, удобную для последующей переработки. Перемотка осуществляется на мотальных машинах, либо на мотальных автоматах. В результате процесса перематывания получаются выходные паковки в виде конических бобин; (ii) Снование – из ставки бобин получают партию сновальных валиков. Снование бывает партионное (из ставки конических бобин получают на выходе партию сновальных валиков), ленточное (из ставки конических бобин получают на выходе ткацкий навой) и секционное (из ставки конических бобин, получают партию секций); (iii) Шлихтование – из партии сновальных валиков (сумма нитей на которых равна числу нитей на навое) получают ткацкий навой. Кроме того в процессе шлихтования пряжа пропитывается специальным составом – шлихтой, в результате чего приобретает тонкую наружную оболочку и становится стойкой к истиранию и более прочной на разрыв. Для шлихтования применяются машины:- многобарабанные, камерные и специальной сушки. Входная паковка – партия сновальных валиков, выходная паковка – ткацкий навой; (iv) Проборка – нити основы пробирают в съёмные рабочие органы ткацкого станка и заменяют сработанный навой на ткацком станке. Проборка осуществляется на проборных станках (ручных или механизированных) или на проборных автоматах; и (v) Привязка – замена ткацкого навоя вместо проработанного на ткацком станке. Осуществляется с помощью передвижных узловязальных машин. При этой операции нити основы отрезаются от старого навоя и их концы связываются с концами нитей от нового навоя. Затем эти узлы протаскиваются через съёмные рабочие органы ткацкого станка, после чего процесс ткачества продолжается. (2) Уточная пряжа:- (i) Перематывание – переработка пряжи с прядильных початков на конические бобины (способную вместить большую длину пряжи, которая в процессе перематываний проходит ещё и качественную проверку). Конические бобины используются в качестве уточных паковок на бесчелночных ткацких станках. Для челночных ткацких станков осуществляется вторая операция перематывания с конических бобин в уточные шпули, которые вставляются в челнок; и (ii) Увлажнение и эммульсирование – проводится с целью снять внутреннее напряжение в уточной пряже (чтобы она не образовывала сукрутин в моменты, когда челнок выстаивает, а уток провисает). Для этого применяются запарные камеры, эммульсирующие, увлажняющие установки, либо длительная выдержка в помещениях с повышенной влажностью.

WEAVING DEFECTS = ТКАЦКИЕ ПОРОКИ (или ДЕФЕКТЫ ТКАЧЕСТВА) – Weaving Defects:- fabric imperfections at the mill. Interlining defects. Weaving Defects are the defects which originate during the process of weaving. The different types of weaving defects are as follows:- Broken Ends, Broken Pattern, Double End, Float, Gout, Hole or Cut or Tear, Lashing-In, Local Distortion, Missing Ends, Oil or Other Stain, Oily Ends or Soiled Ends, Oily Weft, Reed Marks, Selvedge Defect, Slough Off, Smash, Snarls, Stitches, and Untrimmed Loose Threads. / развод (или потёк (stain)). Порок или дефект ткачества. Пороки суровой ткани оцениваются по баллам (порочным единицам), число которых определяет сорт ткани. Ткацкая Дыра (пробоины, просечки) – отверстия различных размеров, возникающие при повреждении ткани частями ткацкого станка.

WEB = ХОЛСТ (или ВАТКА, или ПРОЧЁС) – (1) Web is the wide film of fibers that is delivered from the card. / Текстильный Холст (Card Web) – тонкий слой частично ориентированных штапельных волокон, удерживаемых вместе силами трения, имеющий заданную ширину, линейную плотность и длину.

(2) Web is a similar product of other web-forming equipment, such as that formed by air deposition and used to make nonwoven fabrics. See also Webbing.

(3) Web is a term loosely used for lightweight nonwoven fabrics.

WEB–BASED TRAINING = ТРЕНЕРОВКА НА ОСНОВЕ СЕТИ – Web-Based Training (WBT) is the training sessions in which the trainer provides short periods of instruction, then the students perform activities using web-based training tools and examples. This approach provides mechanisms for tracking a student's progress and testing their learning, while still providing live interaction with the trainer and coach.

WEB BEAM = ТКАНЫЙ НАВОЙ (или ТКАЦКИЙ НАВОЙ) – Web Beam is another term for the Cloth Beam.

WEBBING = ХХ (или ТКАНАЯ ЛЕНТА) – Webbing is the strong, narrow fabric, closely woven in a variety of weaves and principally used for belts and straps that have to withstand strain, e.g., automobile seat belts, reinforcement of upholstery, suspenders, etc. Elastic webbing is made with spandex or rubber yarns in part of the warp or filling, or both. See also Web (2). Webbing is a strong, narrow

fabric made from jute or man-made fibers. It is used for belts and straps that must resist strain. Webbing is usually woven and is used on the underside of upholstered chairs and sofas. / основа или уточина, .

WEBB–POMERENE ACT OF 1918 = АКТ ВЭБА–ПОМЭРИНА ОТ 1918 – Webb-Pomerene Act Of 1918:- legislation in the United States that exempts associations of exporters from the provisions of the Sherman Antitrust Act. That is, it allows exporters to engage in acts that otherwise might be considered collusion in order to promote American trade abroad. However, they may not engage in importation or sales within the United States. These exporters may not combine services; that is, they may only collude to export similar products. Webb-Pomerene Act Of 1918 – US Federal legislation exempting certain exporters' associations from certain antitrust regulations. The Webb–Pomerene Act was a law passed in 1918 that exempted certain exporters' associations from certain antitrust regulations. Sponsored by the US Representative Edwin Yates Webb (May 23, 1872 – February 07, 1955; was a Democratic US Congressman from North Carolina from 1903 to 1919 and a federal judge from 1919 to 1948) of North Carolina and Senator Atlee Pomerene (December 06, 1863 – November 12, 1937; was a Democratic Party politician from Ohio; he represented Ohio in the United States Senate from 1911 until 1923) of Ohio, the act granted immunity from antitrust regulation to companies that combined to operate the export trade that was essential to the war effort. The act was important because it granted exemptions from the Clayton Antitrust Act of 1914. Many large conglomerates that had previously been subject to Federal anti-trust investigations were now free to continue 'business as usual' because they 'aided' the war effort. Webb-Pomerene exemptions lasted well into the 1920s as the Federal Trade Commission granted stays of investigation for those companies that initially qualified for exemption under the 1918 act. Webb-Pomerene Act of 1918 gives immunity to companies against antitrust laws. This Act granted exemption to the Clayton Anti-Trust Act of 1914, which is an act enacted in the United States to add further substance to the US antitrust law regime by seeking to prevent anticompetitive practices in their incipiency. The exemptions of Webb-Pomerene lasted until 1920, as the federal trade commission granted stays of investigation for those companies that initially qualified for exemption under the 1918 act. / привоз (importation). Шёмэн (Sherman). Эдвин Йэйтс Вэб (Edwin Yates Webb). Этли Помэрин (Atlee Pomerene). Клэйтэн (Clayton). Акт Вэба-Помэрина От 1918 – закон, предусматривающий изъятие из антитрестовских законов США ассоциаций из числа предприятий-конкурентов, занятых вывозной (или экспортной) торговлей. Они не должны ограничивать торговлю внутри США или торговлю любого другого Американского конкурента.

WEBBY WOOL = ПАУТИНЧАТАЯ ШЕРСТЬ – Webby Wool:- a thin fleece with poor staple formation and a large number of cross fibers.

WEB FORMS = ВЭБ ФОРМЫ – Web Forms:- a form on a website that enables visitors to communicate with the host by filling in the fields and submitting the information. Information received via a form can be received by email and processed by other specific software.

WEB LINK AGREEMENT = СОГЛАШЕНИЕ О ВЭБ ССЫЛКАХ – Web Link Agreement:- designed for use by the operator of an highly trafficked Web site and another party who wishes to take advantage of that traffic to attract visitors to its Web site. The owner of the highly trafficked site agrees to include an image incorporating the Uniform Resource Locator (URL) for the less trafficked site.

WEB RETURN ON INVESTMENT = ОТДАЧА НА ВЛОЖЕНИЕ В СЕТЬ – Web Return On Investment is the percent of profit over expenditures, or return on investment (ROI) for a website. The general formula is as follows:- (Net Website Revenues – Total Website Costs) / Total Website Costs. Net website revenues are determined by deducting any affiliate fees, cost of goods sold, marketing expenditures, shipping costs and all other expenses which directly impact the revenues. Website costs should include website design, maintenance and hosting fees, software licenses, and other website specific expenditures. / Сетевой Сайт или Вэбсайт.

WEBS = WORLD EQUITY BENCHMARK SERIES

WEBS = РАСКОСЫ (или ШЕЙКИ, или ПЕРЕМЫЧКИ, или ПЕРЕБОРКИ, или ПРОСТЕНКИ, или РЕШЁТКИ, или СТВОРКИ) – Webs are the members that join the top and bottom chords to form the triangular patterns that give truss action. They usually carrying tension or compression stresses. Web is any web-shaped part of a casting used for reinforcement. Web is the central section of an I-beam or H-beam that joins the two flanges of the beam. Web is the radial portion of a crank that connects the crankpin to the crankshaft. Webs are wood members that join the top and bottom chords that form the triangular patterns that give truss action, usually carrying tension or compression stresses. The term often given to the shorter members that join the top and bottom chords of a roof or floor truss, which form triangular patterns in that truss, usually carrying. transmitting tension or compression stresses, and are designed to prevent bending and/or flexing. / Web = Строительная решётка сквозной фермы. Элементы, соединяющие верхний и нижний пояса при формировании треугольных очертаний для придания связующего действия (восприятия нагрузки). это стенка (центральная секция) двутавровой балки (в Англоязычном мире она известна под сокращениями I-beam или H-beam; прописные буквы Английского алфавита I и H напоминают форму двутавра), соединяющая полки двутавра. В строительных конструкциях под Соединениями понимаются скрепление между собой элементов строительной конструкции с целью образования узлов, увеличения размеров конструкции или изменения условий её работы. Основными соединениями в стальных конструкциях – сварные (наиболее распространены), заклёпочные и болтовые. В деревянных конструкциях соединения бывают на врубках, шпонках, нагелях, болтах, хомутах, на клеях. В сборных железобетонных конструкциях соединения (стыки) образуются, как правило, путём сварки выпусков арматуры или стальных закладных деталей с последующим замоноличиванием бетоном стыка. Реже используются болтовые соединения.

WEBSITE = ВЭБСАЙТ – A Website, also written as Web Site, is a collection of related web pages, including multimedia content, typically identified with a common domain name, and published on at least one web server. A web site may be accessible via a public Internet Protocol (IP) network, such as the Internet, or a private local area network (LAN), by referencing a uniform resource locator (URL) that identifies the site. Websites have many functions and can be used in various fashions; a website can be a personal website, a commercial website for a company, a government website or a non-profit organization website. Websites can be the work of an individual, a business or other organization, and are typically dedicated to a particular topic or purpose, ranging from entertainment and social networking to providing news and education. All publicly accessible websites collectively constitute the World Wide Web, while private websites, such as a company's website for its employees, are typically a part of an intranet. Web pages, which are the building blocks of websites, are documents, typically composed in plain text interspersed with formatting instructions of Hypertext Markup Language (HTML, XHTML). They may incorporate elements from other websites with suitable markup anchors. Web pages are accessed and transported with the Hypertext Transfer Protocol (HTTP), which may optionally employ encryption (HTTP Secure, HTTPS) to provide security and privacy for the user. The user's application, often a web browser, renders the page content according to its HTML markup instructions onto a display terminal. Hyperlinking between web pages conveys to the reader the site structure and guides the navigation of the site, which often starts with a home page containing a directory of the site web content. Some websites require user registration or subscription to access content. Examples of subscription websites include many business sites, parts of news websites, academic journal websites, gaming websites, file-sharing websites, message boards, web-based email, social networking websites, websites providing real-time stock market data, as well as sites providing various other services. As of 2016, end

users can access websites on a range of devices, including desktop and laptop computers, tablet computers, smartphones and smart TVs. History:- The World Wide Web (WWW) was created in 1990 by the British CERN (short for the Conseil Européen pour la Recherche Nucléaire) physicist Tim Berners-Lee. On 30 April 1993, CERN announced that the World Wide Web would be free to use for anyone. Before the introduction of HTML and HTTP, other protocols such as File Transfer Protocol and the gopher protocol were used to retrieve individual files from a server. These protocols offer a simple directory structure which the user navigates and chooses files to download. Documents were most often presented as plain text files without formatting, or were encoded in word processor formats. Websites have many functions and can be used in various fashions; a website can be a personal website, a commercial website, a government website or a non-profit organization website. Websites can be the work of an individual, a business or other organization, and are typically dedicated to a particular topic or purpose. Any website can contain a hyperlink to any other website, so the distinction between individual sites, as perceived by the user, can be blurred. Websites are written in, or converted to, HTML (Hyper Text Markup Language) and are accessed using a software interface classified as a user agent. Web pages can be viewed or otherwise accessed from a range of computer-based and Internet-enabled devices of various sizes, including desktop computers, laptops, PDAs and cell phones. A website is hosted on a computer system known as a Web Server, also called an HTTP Server. These terms can also refer to the software that runs on these systems which retrieves and delivers the web pages in response to requests from the website's users. Apache is the most commonly used web server software (according to Netcraft statistics) and Microsoft's IIS (short for the Internet Information Services (IIS, formerly Internet Information Server)) is also commonly used. Some alternatives, such as Nginx, Lighttpd, Hiawatha or Cherokee, are fully functional and lightweight. (1) A Static Website is one that has web pages stored on the server in the format that is sent to a client web browser. It is primarily coded in Hypertext Markup Language (HTML); Cascading Style Sheets (CSS) are used to control appearance beyond basic HTML. Images are commonly used to effect the desired appearance and as part of the main content. Audio or video might also be considered 'static' content if it plays automatically or is generally non-interactive. This type of website usually displays the same information to all visitors. Similar to handing out a printed brochure to customers or clients, a static website will generally provide consistent, standard information for an extended period of time. Although the website owner may make updates periodically, it is a manual process to edit the text, photos and other content and may require basic website design skills and software. Simple forms or marketing examples of websites, such as classic website, a five-page website or a brochure website are often static websites, because they present pre-defined, static information to the user. This may include information about a company and its products and services through text, photos, animations, audio/video, and navigation menus. Static web sites can be edited using four broad categories of software:- (i) Text Editors, such as Notepad or TextEdit, where content and HTML markup are manipulated directly within the editor program; (ii) WYSIWYG (short for the What You See Is What You Get) Offline Editors, such as Microsoft FrontPage and Adobe Dreamweaver (previously Macromedia Dreamweaver), with which the site is edited using a GUI (short for the graphical user interface) and the final HTML markup is generated automatically by the editor software; (iii) WYSIWYG Online Editors which create media rich online presentation like web pages, widgets, intro, blogs, and other documents; and (iv) Template-Based Editors such as iWeb allow users to create and upload web pages to a web server without detailed HTML knowledge, as they pick a suitable template from a palette and add pictures and text to it in a desktop publishing fashion without direct manipulation of HTML code. Static websites may still use server side includes (SSI) as an editing convenience, such as sharing a common menu bar across many pages. As the site's behavior to the reader is still static, this is not considered a dynamic site. (2) A Dynamic Website is one that changes or customizes itself frequently and automatically. Server-side dynamic pages are generated 'on the fly' by computer code that produces the HTML (CSS are responsible for appearance and thus, are static files). There are a wide range of software systems, such as CGI (short for the Common Gateway Interface), Java Servlets and Java Server Pages (JSP), Active Server Pages and ColdFusion (CFML) that are available to generate dynamic web systems and dynamic sites. Various web application frameworks and web template systems are available for general-use programming languages like Perl, PHP, Python and Ruby to make it faster and easier to create complex dynamic web sites. A site can display the current state of a dialogue between users, monitor a changing situation, or provide information in some way personalized to the requirements of the individual user. For example, when the front page of a news site is requested, the code running on the web server might combine stored HTML fragments with news stories retrieved from a database or another web site via RSS (short for the Rich Site Summary; originally RDF Site Summary; often called Really Simple Syndication) to produce a page that includes the latest information. Dynamic sites can be interactive by using HTML forms, storing and reading back browser cookies, or by creating a series of pages that reflect the previous history of clicks. Another example of dynamic content is when a retail website with a database of media products allows a user to input a search request, e.g., for the keyword Beatles. In response, the content of the web page will spontaneously change the way it looked before, and will then display a list of Beatles products like CDs, DVDs and books. Dynamic HTML uses JavaScript code to instruct the web browser how to interactively modify the page contents. One way to simulate a certain type of dynamic web site while avoiding the performance loss of initiating the dynamic engine on a per-user or per-connection basis, is to periodically automatically regenerate a large series of static pages. Multimedia And Interactive Content:- Early web sites had only text, and soon after, images. Web browser plug ins were then used to add audio, video, and interactivity (such as for a rich Internet application that mirrors the complexity of a desktop application like a word processor). Examples of such plug-ins are Microsoft Silverlight, Adobe Flash, Adobe Shockwave, and applets written in Java. HTML 5 includes provisions for audio and video without plugins. JavaScript is also built into most modern web browsers, and allows for web site creators to send code to the web browser that instructs it how to interactively modify page content and communicate with the web server if needed. The browser's internal representation of the content is known as the Document Object Model (DOM) and the technique is known as Dynamic HTML. A 2010-era trend in websites called Responsive Design has given the best of viewing experience as it provides with a device based layout for users. These websites change their layout according to the device or mobile platform thus giving a rich user experience. Spelling:- the form Website has become the most common spelling, but Web Site (capitalised) and Web Site are also widely used, though declining. Some in academia, some large book publishers, and some dictionaries still use Web Site, reflecting the origin of the term in the proper name World Wide Web. There has also been similar debate regarding related terms such as web page, web server, and webcam. Among leading style guides, the Reuters style guide, The Chicago Manual of Style, and the AP Stylebook (since April 2010) all recommend Website. Among leading dictionaries and encyclopedias, the Canadian Oxford Dictionary prefers Website, and the Oxford English Dictionary changed to Website in 2004. Wikipedia also uses Website, but Encyclopædia Britannica uses both Web Site and Website. Britannica's Merriam-Webster subsidiary uses 'Web Site', recognising Website as a variant. Among leading language-usage commentators, Garner's Modern American Usage says that Website is the standard form, but Bill Walsh, of The Washington Post, argues for using Web Site in his books and on his website (however, The Washington Post itself uses Website). Among major Internet technology companies and corporations, Google uses Website, as does Apple, though Microsoft uses both Website and Web Site. Types:- Websites can be divided into two broad categories – static and interactive. Interactive sites are part of the Web 2.0 community of sites, and allow for interactivity between the site owner and site visitors or users. Static sites serve or capture information but do not allow engagement with the audience or users directly. Some web sites are informational or produced by enthusiasts or for personal use or entertainment. Many web sites do aim to make money, using one or more business models, including:- (i) Posting interesting content and selling contextual advertising either through direct sales or through an advertising network; (ii) E-commerce:- products or services

are purchased directly through the web site; (iii) Advertising products or services available at a brick and mortar business; and (iv) Freemium:- basic content is available for free but premium content requires a payment, e.g., WordPress website. There are many varieties of websites, each specializing in a particular type of content or use, and they may be arbitrarily classified in any number of ways. Some websites may be included in one or more of these categories. For example, a business website may promote the business's products, but may also host informative documents, such as white papers. There are also numerous sub-categories to the ones listed above. For example, a porn site is a specific type of e-commerce site or business site (that is, it is trying to sell memberships for access to its site) or have social networking capabilities. A fansite may be a dedication from the owner to a particular celebrity. Websites are constrained by architectural limits, e.g., the computing power dedicated to the website. Very large websites, such as Facebook, Yahoo!, Microsoft, and Google employ many servers and load balancing equipment such as Cisco Content Services Switches to distribute visitor loads over multiple computers at multiple locations. As of early 2011, Facebook utilized 9 data centers with approximately 63 000 servers. In February 2009, Netcraft, an Internet monitoring company that has tracked Web growth since 1995, reported that there were 215 675 903 websites with domain names and content on them in 2009, compared to just 19 732 websites in August 1995. After reaching 1 billion websites in September 2014, a milestone confirmed by NetCraft in its October 2014 Web Server Survey and that Internet Live Stats was the first to announce – as attested by this tweet from the inventor of the World Wide Web himself, Tim Berners-Lee – the number of websites in the world has subsequently declined, reverting to a level below 1 billion. This is due to the monthly fluctuations in the count of inactive websites. We do expect, however, to exceed 1 billion websites again sometime in 2015 and to stabilize the count above this historic milestone in 2016. Вэбсайт (или просто Сайт для краткости) в сети (как правило, Интернет) – это ресурс, который состоит из одной или нескольких вэб-страниц с гипер-текстовым, текстовым, медийным (картинки, видео, аудио) и другими типами содержания, доступного по одному из протоколов вэб-семейства. Вэб страницы и другие вэб-файлы обслуживаются вэб-серверами – специальным программным обеспечением, которое доставляет вэб-контент клиентам по вэб-протоколам. На сегодняшний день наиболее распространены такие вэб-протоколы:- (i) HTTP – самый старый, наиболее известный и используемый; (ii) HTTPS – такой же, как и HTTP, но с использованием безопасного слоя передачи данных; (iii) SPDY – новый безопасный, совместимый с HTTP протокол, разработанный компанией Гугл (Google) и поддерживаемый некоторыми современными браузерами); и (iv) WebSocket – новый протокол двустороннего взаимодействия, который пока что поддерживается только несколькими современными браузерами. В качестве клиента, которому вэб-сервер обычно доставляет содержимое вэбсайта, является, как правило, вэб-браузер – специальное программное обеспечение, которое способно отображать вэб-страницы и умеет взаимодействовать с другими типами вэб-содержимого. Обычно под понятием Вэбсайт принято понимать всё вэб-содержимое обслуживаемое вэб-серверами на уникальном доменном имени. Вэб-контент как и вэб-сайты могут быть статическими и динамическими. Статический вэб-сайт или веэб-страница хранятся на сервере в виде отдельных файлов, и доставляются вэб-сервером без каких либо изменений в том виде, в котором они были созданы автором. Как правило, такие типы вэб-страниц не обладают способностью интерактивного взаимодействия с пользователем и предназначены исключительно для просмотра размещённой на них информации. Динамические вэб-страницы генерируются специальной программой, которая работает на вэб-сервере, и могут собираться из различных компонентов вэб-сервером 'на лету'. Как правило, такие страницы также позволяют осуществлять интерактивное взаимодействие с пользователем, предоставляя расширенные возможности не только для просмотра, но и для сохранения или изменения информации. Содержание динамических страниц по одному и тому же адресу может различаться с течением времени, или быть различным для разных посетителей в одно и то же время.

WEB SITE NOTICES AND DISCLAIMERS = УВЕДОМЛЕНИЯ И ОТКАЗЫ ОТ ОТВЕТСТВЕННОСТИ ВЭБ САЙТА – Web Site Notices And Disclaimers:- an operator has virtually no control over who views its Web Site. This often raises a number of legal concerns for Web site operators. They can post notices and disclaimers in an attempt to protect themselves.

WEB WRAP AGREEMENT = СОГЛАШЕНИЕ О ВЭБ ОБЁРТКЕ – A Web-Wrap Agreement is an agreement to abide by the terms of a license agreement signified by downloading the software, data or content to which the license agreement applies. Such agreements generally do not provide for any means by which the user can acknowledge acceptance of the terms of the agreement, separate from the act of downloading itself. Web Wrap Agreement is also known as Browse Wrap Agreement. Web Wrap Agreement is an agreement requiring a party to manifest its assent by hitting a key or clicking an on-screen button. It is especially designed for use in the context of the on-line sale of goods.

WED = WATER ENFORCEMENT DIVISION

WED = WOMEN'S EQUALITY DAY

WEDGE = КЛИН – (1) Wedge:- in mechanics, device that tapers to a thin edge, usually made of metal or wood, and used for splitting, lifting, or tightening, as to secure a hammer head onto its handle. Along with the lever, wheel and axle, pulley, and screw, the wedge is considered one of the five simple machines. The wedge was used in prehistoric times to split logs and rocks; for rocks, wooden wedges, caused to swell by wetting, were employed. In terms of its mechanical function, the screw may be thought of as a wedge wrapped around a cylinder. / Под Клином понимается простейшее орудие с рабочими гранями в виде наклонных плоскостей. Клин используют в качестве режущего инструмента (например, зубило), как деталь клинового соединения или как установочную (регулирующую) деталь (в основном при монтаже машин).

(2) Wedge is a chart pattern composed of two converging lines connecting peaks and troughs. In the case of falling wedges, the pattern indicates temporary interruptions of upward price rallies. In the case of rising wedges, indicates interruptions of a falling price trend. In visual analysis, Wedge is a reversal chart pattern characterized by two converging trendlines that connect at an apex. The wedge is slanted either downwards (Falling Wedge) or upwards (Rising Wedge) demonstrating bullish or bearish behavior respectively. The Wedge chart pattern can be either a continuation or reversal pattern. It is similar to a symmetrical triangle except that the wedge pattern slants in an upward or downward direction, while the symmetrical triangle generally shows a sideways movement. The other

difference is that wedges tend to form over longer periods, usually between three and six months. The fact that wedges are classified as both continuation and reversal patterns can make reading signals confusing. However, at the most basic level, a falling wedge is bullish and a rising wedge is bearish. In Figure 6, we have a falling wedge in which two trendlines are converging in a downward direction. If the price was to rise above the upper trendline, it would form a continuation pattern, while a move below the lower trendline would signal a reversal pattern. / В техническом анализе биржевых рынков . Клин – графическая модель в техническом анализе движения цены, в которой две сходящиеся линии соединяются в серию вершин и впадин, образуя клин. Понижающиеся клины являются временными перерывами в повышении цен. Повышающиеся клины являются выражением перерывов в тенденции падения цен. Клин – модель графика технического анализа, похожая на треугольник (triangle), хотя и отличающаяся от него. Две сближающиеся линии соединяют последовательность пиков и локальных минимумов, образуя клин. Эти сближающиеся линии движутся в одном и том же направлении, но в отличие от треугольника, в котором одна линия идёт вверх, а другая – вниз или одна идёт вверх или вниз, а другая остаётся горизонтальной. Получающийся из них клин обычно отражает временное прерывание тенденции повышения цен, в то время как направленный вверх клин возникает в результате прерывания тенденции к понижению цен. WEDGE = ТАНКЕТКА (или КЛИН) – Wedge is a shoe having a heel extending from the back of the shoe to the front of the shank and a tread formed by an extension of the sole. / heel = каблук или пятка.

WEDGIE = ТАНКЕТКИ (или ВЭДЬЖИ) – Wedgie is a shoe having a wedge-shaped piece serving as the heel and joining the half-sole to form a continuous flat undersurface. / heel = каблук или пятка. Обувь с клиновидным каблуком.

WEED = СОРНЯК (или СОРНОЕ РАСТЕНИЕ) – Weed is a Plant growing in a place where it is not desired. Weed is a plant out of place. Weeds are unwanted and undesirable Plants which interfere with the utilization of land and resources (nutrient, light and water) and thus adversely affect human welfare. Weed is a Plant growing in the wrong place. Weed is any Plant that is unwanted and grows or spreads aggressively. See also Exotic Weed, Invasive Weed, Noxious Weed, and Weeding. Weed is any unwanted Plant that is injurious to the crop. Weed is any Plant growing where it is not wanted. Ever since human beings first attempted the cultivation of plants, they have had to fight the invasion by weeds into areas chosen for crops. Some unwanted plants later were found to have virtues not originally suspected and so were removed from the category of weeds and taken under cultivation. Other cultivated plants, when transplanted to new climates, escaped cultivation and became Weeds. The category of Weeds thus is ever changing, and the term is a relative one. Because, for various reasons, Weeds interfere with man's activities, many ways have been developed for suppressing or eliminating them. These methods vary with the nature of the Weed itself, the means at hand for disposal, and the relation of the method to the environment. For financial reasons, methods used on a golf course or a public park cannot be applied on range land or in the forest. Chemicals sprayed on a roadside to eliminate unsightly Weeds that constitute a fire or traffic hazard are not proper for use on cropland. And mulching, used to keep down Weeds in a home garden, is not feasible on large farms. Weed control, in any event, has become a highly specialized activity employing thousands of trained persons. Universities and agricultural colleges teach courses in Weed control, and industry provides the necessary technology. Governmental workers and private individuals are engaged daily in the practice of Weed control because the growing of food and fiber crops depends on it for current levels of production. The many reasons for controlling Weeds become more complex with the increasing development of technology. Plants become Weeds as a function of time and place. Tall Weeds on roadsides were no problem in the horse-and-buggy days, but today they obscure vision on roads built for speed and make death traps of intersections. Sharp-edged grasses are nominal nuisances in a cow pasture; when the area is converted to a golf course or a public park, they become insufferable. Poison Oak is rather a pleasant shrub on a sunny hillside in the open country; in a Boy Scout camp ground it is a definite health hazard. And nothing is more pleasant than the waving heads of grass on the hillside in spring. But when the hillside becomes a tank farm for storage of oil the fire hazard becomes serious in summer. Such examples could be given ad infinitum to cover every aspect of agriculture, forestry, highway, waterway and public land management, arboretum, park and golf-course care, and finally home landscape maintenance. Weeds compete with crop plants for water, light, and nutrients. Weeds of range lands and pastures may be unpalatable to animals, or even poisonous; they may cause injuries, as with lodging of foxtails (Alopecurus species) in horses' mouths; they may lower values of animal products, as in the cases of cockleburs (Xanthium species) in wool; they may add to the burden of animal care, as when horses graze in tarweeds (Madia species) and become covered with a black, sticky mess. Many Weeds are hosts of plant disease organisms. Examples are Prickly Lettuce (Lactuca scariola) and Sowthistle (Sonchus species) that serve as hosts for downy mildew; Wild Mustards (Brassica species) that host clubroot of cabbage; and Saltbrush (Atriplex species) and Russian Thistle, in which curly top virus overwinters, to be carried to sugar beets by leafhoppers. Many Weeds are hosts of insect pests. Modern Weed control can be classified as mechanical, chemical, or biological. Mechanical Control:- mechanical Weed control began when man first pulled Weeds from his cereal crop and attempted to grow a single plant species, free from all plant competition. This was the start of monoculture, a method that since has come to dominate agriculture, but a process that opposes nature's way of growing plants. Contrary to the principles of ecology, farmers throughout the world grow the major food, fiber, and forage crops in a monoculture because experience has shown that the highly improved modern crop species give their highest yield under this system. From hand pulling, man devised simple tools such as the spud, the knife, and the hoe to eliminate weeds. For thousands of years, from the Egyptian culture to the Renaissance, these simple methods were used. The first efforts to turn away from simple hand methods and mechanize the arduous task of weed control began in XVII-century England. Since then there has been continuous improvement of agricultural tools used to destroy weeds and of cultural methods employed to minimize weed growth. The principal virtue of cultivation of row crops is the control of weeds. And any method of weed control that minimizes tillage tends to conserve soil structure and maintain fertility. In addition to tillage, other mechanical methods of weed control involve burning, grazing, the use of ducks or geese in certain crops (in cotton and mint especially), and electrovating, applying a strong electrical current. All of these methods have drawbacks:- there is the arduous, painful nature of hand weeding; the repetitious and often harmful nature of clean tillage with machinery; the slow, fuel-consuming nature of burning; and the costly requirement of livestock or fowl for the biological grazing methods. Tillage, still the most widely used method of row-crop weed control, has been greatly improved by development of precision seeding and close preadjustment of tiller tools, allowing the passage of weed knives within an inch or less of the young crop plants. Despite these improvements it is known that weed knives injure crop roots, especially late in the tillage season. And where perennial weeds occur, tillage tools spread these rapidly, bringing about rapid infestation of whole fields. Such methods as crop rotation, use of smother crops, use of weedfree seed, mulching and covering, and cleaning of machinery to prevent spread of weed seeds are also classified as mechanical. Chemical Control:- chemical weed control (see Herbicide) has been used for a very long time:- sea salt, industrial by-products, and oils were first employed. Selective control of broad-leaved weeds in fields of cereal crops was discovered in France in the late 1800s, and this practice soon spread throughout Europe. Sulfates and nitrates of copper and iron were used; sulfuric acid proved even more effective. Application was by spraying. Soon sodium arsenite became popular both as a spray and as a soil sterilant. On thousands of miles of railroad right-of-way, and in sugar and rubber plantations in the tropics, this hazardous material was used in tremendous quantities, often resulting in the poisoning of animals and occasionally humans. Diesel oil, as a general herbicide, and sodium dinitrocresylate (Sinox), as a selective plant killer, were introduced during the first three decades of the XX century. Sinox, the first major organic

chemical herbicide, was developed in France in 1896. In the late 1940s new herbicides were developed out of the research during World War II, and the era of the miracle weed killers began. Within 20 years over 100 new chemicals were synthesized, developed, and put into use. Chemical weed control superseded both plant-disease and insect-pest control in economic impact. The year 1945 marked the beginning of a new era in chemical weed control. Introduced then were 2,4-D, 2,4,5,-T and IPC, the first two selective as foliar sprays against broad-leaved weeds, the third selective against grass species when applied through the soil. These new organic herbicides were revolutionary in that their high toxicity allowed for effective weed control at dosage rates as low as one to two pounds per acre. This contrasts with carbon bisulfide, borax, and arsenic trioxide, which were required at rates of up to one ton per acre, and with sodium chlorate, required at rates of around 100 pounds per acre. Herbicides may be grouped into two categories: selective and nonselective. Each category may be subdivided into foliage-applied and soil-applied materials and, in cases where field crops are treated, the application may be made before sowing the crop (preplanting), after sowing but before emergence of seedlings (pre-emergence), or after seedlings have emerged (postemergence). A great advantage of chemical over mechanical weed control is the ease of application. This is particularly true in cereal croplands, pastures, rangelands, forests, and other situations where the airplane can be used. Many millions of acres are treated from the air each year, many under conditions that would not submit to any other method. And modern equipment for treating row-crop land with herbicides is making weed control increasingly convenient. Sprayers, soil incorporation equipment, and spreaders for pelleted herbicides are all adding to the convenience of, and removing uncertainty from, herbicide application. Machinery is available that simultaneously builds up beds, plants the seed, sprays with insecticide, and incorporates fertilizer and pre-emergence herbicide all in one operation. This is extremely popular on the modern mechanized farm. A balanced view of recent developments in agriculture, however, includes some of the changes that affect human ecology. Pesticides in general have created problems through their persistence in soils and food chains. While most of these problems revolve around DDT and other chlorinated hydrocarbons, there has been interest in the possible injurious effects of 2,4,5-T, a herbicide of major importance in forest and range management. Biological Control:- efforts by man to control weeds biologically are a recent development. An early report from 1902 described the importation of insects from Mexico to Hawaii in an effort to control Lantana, an imported shrubby climbing weed that had spread over thousands of acres of pastureland, rendering them useless for grazing. Work has continued since this early attempt; additional insect species have been introduced, and this plant is slowly yielding to attacks by a number of introduced insects. Prickly pear cacti have been very effectively controlled in Australia; some 60 million acres (24 million hectares) have been converted from cactus thicket to plowland and pasture by an insect, Cactoblastis cactorum, introduced from Argentina in 1925. By 1933 the major cactus areas were under control. The next most successful use of biological weed control was in California, where St. Johnswort, locally called Klamath Weed, was subjected to depredation by three insect species in 1945. Release of insects continued for a number of years, the effort being carried to Oregon, Washington, and Idaho by 1950. The insects spread rapidly after introduction, and recent reports indicate that some 2.5 million acres (1 million hectares) of rangeland have been reclaimed. Two insects of the genus Chrysolina and one of the Genus Agrilus have become established, and St. Johnswort is considered to be in a satisfactory state of suppression. Many weed–insect relationships are now under study, and more instances of successful control are being recorded. A number of vertebrate animals have been used to control certain specific weeds. Sheep and goats have been employed to control brushy plants on rangelands in many countries. Their effectiveness is evident in parts of the Middle East and Africa where dry range and desert lands have been almost completely denuded by grazing goats. In these cases, however, the destructiveness of the goats far outweighs their usefulness in plant pest control, which indicates the need for rational management in all efforts at weed control. Geese have been used to control weeds in cotton fields in California and in mint plantations in Oregon. Certain fishes are useful in keeping aquatic plants under control; examples are the Congo tilapia, the Israeli carp, and the grass carp. The Florida manatee is known to consume many aquatic plants, and the snail Marisa Cornuarietis feeds on alligator weed, pondweed, and water hyacinth. Although much more desirable than chemical weed control from the standpoint of time-ecological effects, biological weed control has definite limitations. It is ideal for situations such as the cactus infestation in Australia, where a weedy plant was introduced free of its natural predators. There are places where it offers the only hope for coping with serious weed situations, for example, the control of Halogeton, a poisonous plant covering millions of acres of low-value land, and Canada thistle control in the north-central and northwestern United States, where millions of acres of forest, parkland, and agricultural lands are infested. On the other hand, the control by biological methods of many of the common annual weeds that occur in crops is out of the question, because the number and variety of species involved will not submit to safe introduction of suitable predators. There are many disadvantages to biological control. Control using insects is limited almost entirely to perennial plants. Few insects can overwinter during the part of the annual cycle of an annual weed when the plant is dead and only seed carry over. Biological control is restricted mainly to weeds of uncultivated areas. The broad spectrum of weed species, the great number of seeds in the soil, and the fact that many weed seeds will live for decades in the soil all militate against success by biological agents in principal annual crops. In these cases cheap and effective herbicides have proved most useful. The introduction of alien organisms is hazardous in that these same organisms may become pests in the new habitat. Kikuyu grass, which was introduced into California to prevent soil erosion on hillsides and roadways, soon spread into orchards, turf, and crop areas, where it became a serious weed. Biological weed control tends to be only periodically effective. Experience has proved that the weed species, when subjected to control by insects, may be reduced initially to a very low level. The insects then die off for lack of food. Soon the weed recovers or becomes reestablished from seed. The predators then flourish; the weed is reduced and so on, through reciprocal cycles. / виды (species). привоз (importation). Под Сорными Растениями или Сорняками понимаются растения, произрастающее в посевах сельскохозяйственных культур (сегетальное растение – Осот, Пырей и многие другие), а также по обочинам дорог, вдоль оград, в мусорных местах (рудеральное растение – Белена, Дурман, Крапива и другие). Под Сорными Растениями или Сорняками понимаются растения, произрастание которых на определённых участках нежелательно. Несколько тысяч Видов, на территории бывшего Союза Советских Социалистических Республик (СССР) – около 1 500. Понятие Сорное Растение относительно (например, Подсолнечник при прорастании его падалицы в посевах озимой Пшеницы становится засорителем этой культуры). Сорные растения засоряют посевы сельскохозяйственных культур, сады, виноградники, лесные полосы, лесные культуры, зелёные насаждения и цветники, осушительные и оросительные каналы, реки и водоёмы, стадионы и так далее. Сорняки затеняют и заглушают культурные растения, лишая их света и поглощая из почвы влагу и питательные вещества; вьющиеся сорные растения (например, Вьюнок полевой, Горец вьюнковый) вызывают полегание растений, они забивают рабочие органы машин, что затрудняет уборку урожая. Всё это снижает урожайность и нередко приводит посевы к гибели. Зерно с примесью семян ядовитых сорняков (Гелиотропа опушённоплодного, Плевела опьяняющего) может быть причиной отравления людей и животных. Вытесняя кормовые травы на сенокосах и пастбищах, сорные растения снижают урожайность кормовых угодий и питательную ценность кормов; засоряя каналы, они уменьшают их пропускную способность и увеличивают заиление. Являются очагами размножения многих вредителей и болезней сельскохозяйственных культур. В зависимости от места произрастания и специализации сорные растения подразделяют на:- (i) Сегетальные – сорнополевые и пашенные (большинство сорняков); (ii) Естественных Угодий – сенокосные и пастбищные (ядовитые, вредные, малопродуктивные, плохопоедаемые, несъедобные), лесные, сорняки водоёмов, рек, каналов и их берегов и тому подобные; (iii) Рудеральные – мусорные, бурьянистые и другие; (iv) Специальных Площадей – труднообнаруживаемые в посевах (например, Овсюг в посевах Овса) и трудновыделяемые из

семенного материала, так как их семена сходны с семенами засоряемых культур. Выделяют также Карантинные Сорные Растения. По особенностям размножения, распространения и возобновления различают:- (i) Семенные Малолетники (однолетние ранние и поздние яровые, озимые и двулетние) – размножаются и распространяются семенами, обладают высокой семенной продуктивностью, плодоносят 1 раз в жизни и отмирают (Лебеда, Марь, Овсюг, Плевел, Щетинник, Щирица и другие); (ii) Вегетативные Малолетники – размножаются семенами, а также клубнями и луковицами (Гулявник изменчивый, Чистец болотный и другие); (iii) Многолетники (стержнекорневые, дерновые, корнеопрысковые и корневищные) – подземные органы их живут долго, ежегодно образуя плодоносящие побеги, размножаются семенами, корневыми отпрысками, отрезками корней и корневищ, возобновляются от узла кущения из стеблевых почек, от корня (горькая Полынь, полевой Бодяк, полевой Осот, ползучий Горчак, ползучий Пырей, Ценхрус и другие). Тип засорённости земель (корнеотпрысковый, корневищный, малолетний и сложный) определяется произрастанием характерных, наиболее вредоносных сорных растений; степень засорённости – количеством Сорняков в посевах (слабая – единичные Сорняки, средняя – до 1/4 травостоя, сильная – Сорняков примерно столько, сколько культурных растений, очень сильная – Сорняки преобладают). Для каждого поля разрабатывают систему профилактических и истребительных мер борьбы с Сорняками, учитывая тип и степень засорённости. Сюда входят агротехнические меры – севооборот, своевременные обработка почвы, посев и уборка урожая; химическая прополка (применение гербицидов), карантинные мероприятия против карантинных Сорняков, контроль за чистотой семенного материала и его очистка.

WEED CONTROL = БОРЬБА С СОРНЯКАМИ – Weed Control is a prevention or eradication of Weeds by physical removal (hand weeding) or limiting their growth by mechanical or chemical means.

WEED ESCAPES = УСТОЯВШИЕ СОРНЯКИ – Weed Escapes:- Weeds that have survived a Weed management method.

WEEDICIDE = ВИДИЦИД – Weedicide is a term used for chemicals that control Weeds.

WEEDING = ПРОПОЛКА (или УНИЧТОЖЕНИЕ СОРНЯКОВ) – Weeding is a removing unwanted plants by hand from a crop, or tillage action which lightly cultivates the soil for the purpose of destroying the Weeds. Weeding is the process by which unexpected plants are removed from the desired crop is known as weeding. Methods Of Weeding:- (a) mechanical methods; (b) physical approaches; (c) cultural methods; (d) biological methods; and (e) chemical or herbicidal methods. (1) Mechanical Control:- (A) Mechanical Method:- this method involves the use of physical energy directly or through implements, either manual, bullock drawn or power operator. (i) Hand Weeding:- hand weeding involves the physical removal or pulling out of weeds by hand or removal by implements (khurpi). (ii) Hoeing:- it involves the removal of weeds by using hand hoe. (iii) Tilling:- in this process ploughing, harrowing, levelling etc pre-planting tillage operations injured or destroy both top and underground parts of the perennial weeds. (iv) Mowing:- this method is consisted with the removal of above ground portion of weeds by using different types of mows. (v) Flooding:- Flooding is successful against weed species sensitive to longer period of submergence under water. In this process 15–30 cm depth water level maintained 3 to 8 weeks. Due to shortage of oxygen supply underground part of the flood sensitive weed species reduced or destroyed, e.g., Mutha (Cyperus Totundus). (vi) Smoothing/Shading:- smoothing is the completely exclusive of light by artificial mulch or by using crop plants to prevent all top growth or underground part (rhizome, tuber of Mutha) of perennial weeds. Advantages Of Mechanical Control:- (i) it is the widely practiced methods and more effective; (ii) it can control all kinds of weed; (iii) soil loosening and thinning are also performed as well; (iv) no technical know-how is needed; and (v) it facilitates aeration of soil. Limitations Of Mechanical Control:- (i) it is more costly; (ii) it needed more time and labor; (iii) crop plant (especially root) may be injured; (iv) various implements are needed; (v) it causes soil erosion (especially in high topographic areas); and (vi) risky at the places adjacent to crop roots. (2) Biological Control:- biological weed control is the use of natural enemies (animal, insect, mite, pathogen etc) to reduce weed population to an economically acceptable limit. The organisms which are used as natural enemies to control the weeds are called Bio Agent. The important bio agents which are engages in controlling weeds are as follows:- Insects; Mites; Pathogens; Animals:- Grazing Animals, Fishes, Tadpole Shrimp, and Snail. Advantages Of Biological Weed Control:- (i) non toxic; (ii) non laborious; (iii) does not hamper the soil properties, environment and soil micro-organism; (iv) no mechanical injury to plant; (v) economic; and (vi) no pollution or degradation to the environment. Limitations Of Biological Weed Control:- (i) slow process (even years after years); (ii) host specificity; (iii) biological control agent (BCA) is sensitive to environment and weather conditions; (iv) not suitable for diverse and complex weed problem; and (v) total control is not possible. (3) Chemical Control:- in this method chemical substance named weedicides or herbicides are applied to remove weeds. The chemicals which are used to control weeds are called Herbicide. Some common herbicides:- Ronstar®, Dalapon®, Propanil®, Diquat®, Balasta®, Sunrice®, Paraquat®, EPTC, Alachlor®, etc. Some common herbicides for Rice field:- Butachlor®, Amchlor®, Clear®, Rifir®, Ronstar®, Oxstar®, Corostar®, etc. Advantages Of Chemical Control :- (i) it needed less time and labor as well as money; (ii) no possibility of soil erosion; (iii) incorporation of weeds causes the addition of organic matter; (iv) can control selected weeds; (v) can also control weeds adjacent to crop roots; (vi) applicable both in wet and dry land; and (vii) crops are not injured. Limitations Of Chemical Control:- (i) technical knowledge is needed; (ii) if herbicide application is not appropriate, it can cause damage to the crop; (iii) causes adverse effect on physical, chemical and biological properties of soil as well as environment; (iv) improper selection of herbicide may cause serious effect; (v) it may cause resistance to weeds; (vi) herbicides may not be available in the market; (vii) special machineries are needed for herbicide application; and (viii) create unemployment problem. Calculation Of Weeding Efficiency (sample):- (a) Length of the land:- 15 m; (b) Breadth of the land:- 8 m; (c) Area of the land = 15 x 8 m = 120 m^2; (d) Time of ploughing:- 20 min. We know, Efficiency = Area / Time = (120 / 20 min) x (1 ha / 10 000 m^2) x (60 min / 1 h) x (8 h / 1 working day) = ((120 x 60 x 8) / (20 x 10 000)) (ha / working day) = 0.288 ha working day^{-1}. / Под Прополкой понимается уничтожение сорных растений в посевах и посадках сельскохозяйственных и лесных культур:- механически (боронами, культиваторами, лущильниками и тому подобным), химически (гербицидами) и вручную.

WEED MANAGEMENT ENTITY = ЛИЦО ПО УПРАВЛЕНИЮ СОРНЯКАМИ – Weed Management Entity is an entity established for the purpose of controlling or eradicating harmful, invasive weeds and increasing public knowledge and education concerning the need to control or eradicate harmful, invasive weeds.

WEED MAP = КАРТА СОРНЯКОВ – Weed Map is a simple diagram, typically developed in the fall, of a field or field portion showing the location of predominant, economically important weeds; used in planning weed management programs.

WEED MAPPING = КАРТИРОВАНИЕ СОРНЯКОВ – Weed Mapping is a weed management tool requiring the surveying of fields each fall and recording on a field map the weed species and the general population levels present. Species present in the fall will be the predominant problems during the following year, thus allowing producers to better plan herbicide application.

WEED SPECTRUM = СПЕКТР СОРНЯКОВ – Weed Spectrum:- the different species of weeds present within a community or given area.

WEED STAIN = ПРОТРАВА СОРНЯКАМИ – A Weed Stain is a type of natural stain. A Weed stain refers to:- (i) the blotched or stained appearance of kernels caused by contact with the sap from green foliage of such Weeds as Russian Thistle; and (ii) kernels

with adhered foliage of Weeds. / Протрава Сорняками является одной из разновидностей натуральных (или естественных) протрав. Протрава Сорняками относится к:- (i) появлению пятнистых или протравленных зерновок (ядер) вследствие их контакта с соком из зелёной листвы таких Сорняков как Российский Чертополох (Russian Thistle); и (ii) зерновок (ядер) с приклеившейся листвой сорняков.

WEEKDAY = БУДНИЙ ДЕНЬ – In the United States, Weekday:- from 06 am Monday to 05:59 pm Friday.

WEEKEND = КОНЕЦ НЕДЕЛИ (или ВЫХОДНЫЕ, или УИКЭНД) – In the United States, Weekend:- from 06 pm Friday to 05:59 am Monday.

WEEKEND EFFECT = ЭФФЕКТ КОНЦА НЕДЕЛИ (или ЭФФЕКТ ВЫХОДНЫХ, или ЭФФЕКТ УИКЭНДА) – Weekend Effect:- the common recurrent low or negative average return from Friday to Monday in the stock market.

WEEKLY CHARTS = ПОНЕДЕЛЬНЫЕ ГРАФИКИ – In visual analysis, Weekly Charts is a graphical representation of price where the time interval is one week for each bar or candle. A term weekly is used to describe those charts that are constructed of weekly bars or candles. Each weekly bar or candle contains the Open, High, Low, and Close that occurred during each week. Weekly Charts:- the term Weekly is used to describe those charts that are constructed of weekly bars. Each weekly bar contains the Open, High, Low, and Close that occurred during that week. / В техническом анализе биржевых рынков, Понедельные Графики представляют собой графическое отображение цены, где временным интервалом для каждого штриха или свечи служит одна неделя. Термин понедельные используется для описания таких графиков, которые строятся на основе понедельных штрихов или свечей. Каждый понедельный штрих или свеча содержит цены Открытия, Максимума, Минимума и Закрытия, имевшие место в течение каждой недели. Понедельные Графики:- термин Понедельные используется для описания графиков, которые используют понедельные штрихи. Каждый понедельный штрих содержит Открытие (Open), Максимум (High), Минимум (Low) и Закрытие (Close), которые были в течение той недели.

WEEKLY PRICES' DIFFERENTIALS TO DATED BRENT = ПОНЕДЕЛЬНЫЕ ЦЕНОВЫЕ ДИФФЕРЕНЦИАЛЫ К ДАТИРОВАННОМУ БРЭНТ – Weekly prices' differentials to Dated Brent are assessed once a week on Friday, and then move in line with Dated Brent Monday through Thursday. If Friday is a holiday then the new assessment will be made on the business day preceding the start of the holiday. For example, this represents the differential between a basket of Tengiz FOB, Saharan Blend FOB and Azeri Light FOB on the one hand and Urals FOB Novorossiisk on the other hand; or this represents the differential between the North Sea Basket and Urals FOB Ventspils. Es Sider and Zuetina priced on a monthly average of Dated Brent. Arab Lt and Hvy are priced FOB Ras Tanura off the IPE's Brent weighted average (BWAVE) and are for European destinations. Iran Lt OSP is for NWE, FOB Kharg Island. / Понедельные Ценовые Дифференциалы к Датированному Брэнт оцениваются один раз в неделю – в Пятницу, и затем меняются с изменением цен Датированного Брэнт с Понедельника по Четверг. Если Пятница – праздничный день, тогда новая оценка будет произведена в ближайший рабочий день. Например, оценка представляет собой разницу между ценой корзины Тэнгиз (Tengiz) ФОБ, Сахарской ФОБ и Азербайджанской лёгкой ФОБ, с одной стороны, и ценой на Юрэлз (Urals) ФОБ Новороссийск – с другой; или оценка представляет собой дифференциал между ценой Корзины Северного Моря и ценой на Юрэлз ФОБ Вентспилс. Эс Сидер (Es Sider) и Зуетина (Zuetina) оцениваются на основе ежемесячного среднего Датированного Брэнт. Арабская лёгкая и Арабская тяжёлая оцениваются на основе средневзвешенного Брэнт МБН на условиях поставки ФОБ Европа. Официальная цена продажи Иранской лёгкой предназначена для СЗЕ, ФОБ Остров Харг.

WEEKLY RESET FORWARD = ПОНЕДЕЛЬНО ПЕРЕУСТАНАВЛИВАЕМЫЙ ФОРВАРД – A Weekly Reset Forward is a synthetic forward where a portion of the contract is locked in each week, provided that the spot rate that week meets a predetermined fixing criterion. Hence the purchaser can deal at a rate better than the forward outright, but only in an amount corresponding to the frequency with which the criterion has been met. If the criterion is met in none of the weeks during the life of the contract, then the contract is not activated at all; if it is met every week, the overall rate is favorable compared to the initial prevailing market rate. The weekly reset forward is used for those with cash-flows spread over time or to hedge balance sheets.

WEEKLY REVERSAL = ПОНЕДЕЛЬНЫЙ РАЗВОРОТ – Weekly Reversal:- an upside weekly reversal is present when prices open lower on Monday and then on Friday close above the previous week's close. A downside weekly reversal opens the week higher but closes down by Friday. A specific pattern of one week in duration (one bar or candle on the weekly chart) that is expected to lead to a change in direction for the market. / В техническом анализе биржевых рынков, .

WEEK ORDER = НЕДЕЛЬНОЕ РАСПОРЯЖЕНИЕ – A Week Order is one which is valid for a week. / Недельное Распоряжение – на фондовой бирже распоряжение купить или продать, срок действия которого автоматически истекает, если он не сможет быть исполнен в течение текущей недели.

WEEL = WORKPLACE ENVIRONMENTAL EXPOSURE LEVEL

WEEP = ВЫПОТЕВАНИЕ (или ОТПОТЕВАНИЕ, или ЗАПОТЕВАНИЕ, или СИНЕРЕЗИС) – Weep is a term usually applied to a minute leak in a boiler joint which forms droplets (or tears) of water very slowly.

WEEVIL = ДОЛГОНОСИК – Weevils are small Beetles that possess conspicuous snouts. They are often lightbulb- or pear-shaped. When immature, the legless, grub-like larvae feed on Plants. After developing into adults, some Weevil Species are attracted to buildings. It appears they do this to seek shelter from unfavorable weather conditions, especially when it is hot and dry. These Weevils enter buildings by crawling through cracks or openings around foundations, doors, and windows. They do not harm people or pets, or damage buildings or property, or infest food products. They are just a temporary nuisance. Weevils:- a term that is utilized for a number of Insects that consume grains (i.e. grown and used by man). Many of the Weevils consume and proliferate in stored grains (e.g., the Indian Meal Moth Plodia Interpunctella), and stored grain products (e.g., flour, etc). One example of a Weevil is the Insect known as the Pea Weevil, which lay their eggs on pea pods or dried peas. When the larvae hatch, they burrow into the pod and eat the peas inside. Weevil:- also called Snout Beetle True Weevil of the Insect Family Curculionidae. This Family is not only the largest Family of the Order

Coleoptera (about 40 000 Species) but is also the largest Family in the animal Kingdom. Most weevils have long, elbowed antennae that may fold into special grooves on the prominent snout, which has mouthparts at its end. Many have no wings; others are excellent fliers. Most are less than 6 mm (0.25 inch) in length, although the largest exceed 80 mm (3 inches). Most are plainly colored and marked; however, a few (e.g., the diamond beetle Entimus of Brazil) are brightly colored. The majority of Weevils feed exclusively on plants. The fleshy, legless larvae of most Species feed only on a certain part of a plant – the flower head, seeds, fleshy fruits, stems, or roots. Many larvae feed either on a single Plant Species or on closely related ones. Adult Weevils tend to be less specialized in their feeding habits. Weevils have probably been successful because of the development of the snout, which is used not only for penetration and feeding but also for boring holes for eggs. This family includes some extremely destructive Pests, e.g., the Grain Weevil (Sitophilus Granaries), the Rice Weevil (Sitophilus Oryzae), and the Boll Weevil (Anthonomus Grandis). Weevil is the adult form of a certain Coleopterous Species. A Weevil is any bBeetle from the Curculionoidea Superfamily. They are usually small, less than 6 millimeters (0.24 in), and herbivorous. There are over 60 000 Species in several Families, mostly in the Family Curculionidae (the True Weevils). Some other Beetles, although not closely related, bear the name 'Weevil', such as the Biscuit Weevil (Stegobium Paniceum), which belongs to the Family Anobiidae. Many Weevils are damaging to crops. The grain or Wheat Weevil (Sitophilus Granarius) damages stored grain. The Boll Weevil (Anthonomus Grandis) attacks Cotton crops. It lays its eggs inside Cotton bolls, and the young Weevils eat their way out. Weevils are often found in dry foods including nuts and seeds, cereal and grain products, such as pancake mix. In the domestic setting, they are most likely to be observed when a bag of flour is opened. Their presence is often indicated by the granules of the infested item sticking together in strings, as if caught in a cobweb. Because there are so many species and such diversity, the higher classification of Weevils is in a state of flux. Weevils are generally divided into two major divisions, the Orthoceri or Primitive Weevils, and the Gonatoceri or True Weevils (Curculionidae). An American entomologist Elwood Curtin Zimmerman (born in Spokane, Washington on December 08, 1912; died in Tura Beach, New South Wales on June 18, 2004) proposed a third division, the Heteromorphi, for several intermediate forms. Primitive Weevils are distinguished by having straight antennae, while True Weevils have elbowed (geniculate) antennae. The elbow occurs at the end of the scape (first antennal segment) in True Weevils, and the scape is usually much longer than the other antennal segments. Some exceptions occur. Nanophyini are primitive Weevils (with very long trochanters) but have long scapes and geniculate antennae. From the True Weevils, Gonipterinae and Ramphus have short scapes and little or no elbow. The most recent phylogenetic classification system to Family level was provided by Kuschel (1995), with updates from Marvaldi et al. (2002), and was achieved using phylogenetic analyses. The accepted Families are the Primitive Weevils, Anthribidae, Attelabidae, Belidae, Brentidae, Caridae and Nemonychidae, and the True Weevils Curculionidae. Most other Weevil Families were demoted to Subfamilies or Tribes. Weevil Species radiation was shown to follow steps in plant evolution upon which the Weevils feed. Weevils can vary in color from black to light brown. / Американский энтомолог Элвод Кётин Зимёмэн (Elwood Curtin Zimmerman). Кушэль (Kuschel), (Marvaldi). Под Долгоносиками или Слониками (Curculionidae) понимается Семейство Жуков. До 45 000 Видов. В бывшем Союзе Советских Социалистических Республик (СССР) насчитывалось свыше 4 000 Видов. Распространены широко. Тело длиной до 5 сантиметров, часто с металлическим блеском; передняя часть головы вытянута в головотрубку (неправильно называют хоботком). Усики обычно коленчатые, булавовидные. Личинки, как правило, безногие. С-образной формы, белые или кремовые, с тёмной головой. Жуки и личинки растительноядны, большинство Долгоносиков питаются на Растениях определённых Семейств, Родов и Видов. К числу опасных вредителей сельскохозяйственных культур относятся Свёкловичные, Клеверные и Клубеньковые Долгоносики, Фитономус, Тихиусы, Большой Люцерновый Долгоносик, Скрытнохоботники, Бариды, Виноградные Скосари, Малинно-Земляничный и Почковый Долгоносики, Яблонный Цветоед. Зерно и зернопродукты повреждают Амбарный и Рисовый Долгоносики.

WEFT = УТОК – Weft is one of the principal sets of yarn, found in every woven fabric. It runs crosswise in the fabric, binding the warp ends together, the two forming the different weaves according to the manner of interlacing. While it usually reaches from selvedge to selvedge often it extends only a part of this distance, like in tapestries, etc, forming figures. The weft is often of lower count and slacker twist than the warp. It is also called Filling, Pick, Shoot, and Woof. (1924). Weft is the filling yarns that run crosswise in woven fabric or weft-knit fabric. Allied with the British term, Woof. In this country there is much discussion of these two terms and they seem to be considered as more or less interchangeable. Both of them here may mean threads that run in the filling direction. One may imply a warp series of ends, while the other would specify the opposite system of yarns or threads. The term are often resorted to in the advertising of textiles since they seem to give an English 'Quirk' which may attract the reader's attention. Other names for weft are Pick and 'Pick-And-Shot'. In the carpet trade and in hand weaving, in this country, the term weft is used instead of filling in most instances and is accepted in lieu of the American term. Threads which run at right angles to the warp. Weft is the set of threads which crosses the warp at right angles. Depending on the use, there may be more than one weft used:- ground weft, pattern weft, ... Weft, in woven fabric, the filling yarns that run perpendicular to the warp yarns. Weft is another name for Filling, the crosswise thread that interlaces with the warp threads on a woven fabric. Other names are Shoot, Shute, and Woof. See also Filling, and Woof. Weft:- the transverse threads or fibers in a woven fabric. Those fibers running perpendicular to the warp. Also called Fill or Filling Yarn. Weft or Filling:- the yarns that are woven across the loom, with Weft being the English term and Filling being the American term. The individual yarns are also known as Picks. / Уточина (Filling), Поперечная Нить (Pick) В ткачестве под Утком понимаются поперечные нити ткани, расположенные обычно перпендикулярно к продольным нитям основы и переплетающиеся с ними. Нить утка (уточина). Челнок, рабочий орган ткацкого станка, прокладывающий уточную (поперечную) нить (уток) между нитями основы при выработке ткани, и содержащий её в количестве, достаточном для длительной работы станка. Уточно-Мотальная или Уточно-Перемоточная Машина – машина для перематывания нитей утка на шпули или початки, которые помещают в челнок ткацкого станка. Уточно-мотальные машины, автоматически заменяюшие намотанную шпулю пустой, называются уточно-мотальным автоматом. Прокладчик Утка – устройство бесчелночного станка для прокладывания уточной нити между нитями основы.

WEFT BAR = ПОЛОСАТОСТЬ ПО УТКУ (или УТОЧНАЯ ПЛАНКА, или УТОЧНАЯ ЗАКЛАДКА, или УТОЧНАЯ ПОЛОСА) – Weft Bar is dark or light band across the width of the fabric which shows up prominently particularly in dyed fabrics. Medium to long term periodic irregularity in yarn will produce regular weft bars in the fabric. The remedial measures can be better process control such as:- (i) uniformity of count on groups of ring frames spinning the same count; (ii) prevention of periodic irregularity in the yarn; (iii) control of winding and pirning tension; (iv) proper maintenance of let off and take up motion; (v) control over blend proportion; and (vi) better housekeeping to prevent mixing up of yarn from frames. See also Bar. Weft Bar:- an unwanted bar, running across the full width of a piece which differs in appearance from the adjacent normal fabric. Causes:- (i) difference in count, twist, color and luster; and (ii) faulty let-off and take-up motion. Mending:- non mendable. Weft Bar:- it is an unwanted bar running for full width of the fabric that differs in appearance from the adjacent normal fabric. The bar formation may be due to mix up of finer and coarser weft yarn with normal one running in the fabric, long term periodic variation in the yarn during spinning or faulty take up motion on the looms. Remedy

could be to control the count of the yarn and attending to the mechanical condition of the loom. Minor Defect Classification:- Not Prominent. Major Defect Classification:- Prominent >= 5 cm. Weft Bar:- it is a band running weft-wise across the full width of the cloth. The normal reasons are the periodic medium to long term irregularity in the weft yarn, count difference in weft, excessive tension in the weft feed package, especially in filaments, variability in pick density and difference in twist, colour or shade of adjacent group of picks, difference in blend composition or in the cottons used. / Полосатость По Утку (bar, weft bar):- порок утка в виде полосы во всю ширину ткани из-за различной плотности ткани, линейной плотности пряжи, цвета утка, крутки. Примечание:- этот порок часто вызывается изменением в характеристике уточной пряжи, например, сырьевом составе, линейной плотности, натяжении, крутке и неисправностью механизма, регулирующего плотность нитей в ткани по утку.

WEFT BREAKS = УТОЧНЫЕ РАЗРЫВЫ (или ХХ ПО УТКУ) – Weft Breaks:- high weft tension, improper build of pirn, knots at the nose or chase of pirns, back stitches in cones fed as weft in shuttleless looms, rough and damaged surface of pirns, shuttle tongue not in level, rough places inside the shuttle, damaged nylon loops, sloughing off or loosely built weft package, shuttle eye chipped or broken, weft trapped in the box, selvedge ends cutting the weft, weft fork too far through the grate, rough box fronts or shuttle guides, improper alignment of cone in weft feeder, lower twist in weft resulting in weft opening out in air-jet looms, grippers missing the picks, improper knotting of tail ends, and rough handling of cones are the main reasons for higher weft breaks. / Найлан^{T3} (Nylon^{TM}).

WEFT CRACK = УТОЧНАЯ ПОЛОСКА (или УТОЧНАЯ НЕДОСЕКА, или ПОЛОСАТОСТЬ ПО УТКУ, или НЕРОВНЫЙ БОЙ) – Weft Crack:- it is a open place causing a streak of variable length or width. This defect is introduced on woven fabric when an open space is formed across the piece due to absence of weft yarn. A stripe in the fabric where the pick is lower than the normal is called weft crack or jerky. This defect is caused due to mechanical fault on the loom such as incorrect setting of anti-crack motion, loose crank arm and loose fitting of reed. Minor Defect Classification:- < two picks missing. Major Defect Classification:- two picks missing up to 0.5 cm. Weft Crack or Jerki (in India) is a strip in the fabric where the pick density is lower than normal. Weft Crack:- it is a thin place or missing weft across the body of the fabric. The main causes are improper setting of anti crack motion, loose fitting of reed, loose or worn out crank, worn out crank arm, worn out crank shaft bearings, loose belt, worn out duck bills and beaters, weft fork not functioning properly, faulty take up, brake motion not acting instantaneously, shuttle striking on the weft fork due to weak picking, swing rail worn out, weaver not adjusting the fell of cloth properly at the time of starting a loom, and gripper not holding the weft firmly. Crack is a blemish in cloth caused by a mispick; runs in filling direction. Weft Cracks is a thin place or missing weft across the body of the fabric. It is because of the, improper setting of anti-crack motion; loose fitting of reed; loose or worn-out crank, crank arm or crankshaft; loose belt; worn out duck bills and heaters; faulty take-up; brake motion not acting instantaneously; shuttle striking on the weft fork due to weak picking, swing rail worn-out, weaver not adjusting the fell of the cloth or cloth properly at the time of starting a loom. / поперечная нить (pick) . Недосека – местный порок ткани в виде полосы во всю ширину ткани из-за пониженной плотности ткани по утку. Недосека с разрежением плотности свыше двух до четырёх нитей в 1 см. Размер порока – за каждое место. Под Недосеками понимается дефект суровой ткани в виде поперечных полос с пониженным числом уточных нитей на 1 дм ткани, причина разладка основного регулятора или товарного механизма. Недосечка – поперечные полосы по всей ширине ткани, возникающие из-за пониженной плотности ткани по утку.

WEFT CRACKINESS = РАСЩЕПЛЕНИЕ ПО УТКУ – Weft Crackiness:- fine weftways cracks distributed randomly across the whole or part of the fabric. Note:- this defect is often caused by variations in warp let-off and fabric take-up when weaving an underset fabric, or irregularities of cohesion points in man-made intermingled continuous-filament yarns. / Недосека Утка (weft crackiness):- порок утка; пониженная плотность ткани по утку по всей ширине. Примечание:- этот порок часто вызывается поломками механизма подачи основы ткани на ткацком станке. Недосека с разрежением плотности свыше двух до четырёх нитей в 1 см. Размер порока – за каждое место. Под Недосеками понимается дефект суровой ткани в виде поперечных полос с пониженным числом уточных нитей на 1 дм ткани, причина разладка основного регулятора или товарного механизма. Недосечка – поперечные полосы по всей ширине ткани, возникающие из-за пониженной плотности ткани по утку.

WEFT CURLING = ЗАВИВКА УТКА (или ИЗВИВАНИЕ УТКА) – The Weft Curling is caused by inserting highly twisted, weft yarn or weft running too freely, causes twisted of weft yarn and appear on the surface of fabric. Fabrics defect.

WEFT–FACE FABRICS = УТОЧНОНАСТИЛОЧНЫЕ ТКАНИ – Weft-Face Fabrics:- any fabric in which the warp is completely covered with weft.

WEFT FLOAT = ГОЛЫЙ УТОК (или ПОВЕРХ ЛЕЖАЩИЙ УТОК, или УТОЧНЫЙ НАСТИЛ) – Weft Float:- weft yarns which haven't been overlapped for a particular region of the fabric and just lie above the fabric in the form lose yarns. Possible Cause:- series of warp yarns getting stuck in their bottom position resulting in the yarns not being lifted during weft insertion. Depending upon frequency and visibility, this could be major or minor. Here it seems like a minor defect. Weaving Defect.

WEFTING = ПРИБИВАНИЕ УТКА (или ПО УТКУ) – Wefting:- once the yarn is warped, the second part of weaving can be done. The weft yarn is moved from side to side throughout the warp yarn. Weft yarn moves over and under each warp end, wrapped around the last end, and laced back through the warp yarn repeatedly. Weft yarn is also sometimes referred to as Fill Yarn, because it is the material that fills the bare warp threads and creates the weaving effect. See also Warping.

WEFT INSERTION = ПРОКЛАДЫВАНИЕ УТКА – Weft Insertion is:- (1) any one of the various methods, shuttle, rapier, water jet, etc, for making a pick during weaving. (2) A marriage of warp knitting and weaving brought about by inserting a length of yarn across the width of the knitting elements and fastening the weft yarn between the needle loop and the underlap. See also Metap Weave-Knit Process.

WEFT–KNIT FABRIC = УТОЧНОВЯЗАЛЬНАЯ ТРИКОТАЖНАЯ ТКАНЬ (или УТОЧНОВЯЗАНАЯ ТКАНЬ, или ПОПЕРЕЧНОВЯЗАНАЯ ТРИКОТАЖНАЯ ТКАНЬ, или КУЛИРНАЯ ТКАНЬ) – Weft Knit is a type of knitted fabric in which yarns are formed into stitches in widthwise manner. Common examples of weft knits are circular knits and flat knits. See also Circular-Knit Fabric, and Flat-Knit Fabric. Weft Knit is a knit fabric produced in machine or hand knitting with the yarns running crosswise or in a circle.

WEFT KNITTING = УТОЧНОВЯЗАЛЬНЫЙ ТРИКОТАЖ – Weft Knitting is a common type of knitting, in which one continuous thread runs crosswise in the fabric making all of the loops in one course. Weft knitting types are circular and flat knitting. Circular Knitting is the fabric is produced on the knitting machine in the form of a tube, the threads running continuously around the fabric. Flat Knitting is the fabric is produced on the knitting machine in flat form, the threads alternating back and forth across the fabric. The fabric can be given shape in the knitting process by increasing or decreasing loops. Full-fashioned garments are made on a flatknitting machine. See also Flat-Knit Fabric. Weft Knitting is a common type of knitting, in which one continuous thread runs crosswise in the fabric making all of the loops in one course. Weft knitting types are circular knitting and flat knitting. Weft Knitting:- loops are formed by needles knitting the yarn across the width of the fabric. Each weft thread is fed at right angles to the direction of fabric formation. Weft Knitting is a process in which the thread runs back and forth crosswise in a fabric. See also Warp Knitting. / на вязальной машине в форме .

WEFT LOOPS = УТОЧНЫЕ ПЕТЛИ – Weft Loops project from the surface of cloth either on one or both sides of a cloth. The main causes are late shedding, low warp tension and use of bad temples. To overcome this defect, by reducing warp entanglements. The warp tension should be increased within some limits and the lease rods should be brought closer to the healds to promote, clear shed formation. By adjusting the shedding timing that about 15–20 degree early shedding is suggested for preventing this defect. Worn out temples should be replaced and the cloth is kept stretched widthwise at the temples. This will help to reduce the formation of loops near the selvages. Weft Loops are loops project from the surface of cloth either on one or both sides of a cloth because of a small portion of weft getting caught by the warp threads. The main reasons are late shedding, low warp tension and use of bad temples.

WEFT LOSE = ПОТЕРЯ УТКА (или ОТСУТСТВИЕ УТКА, или ПРОЛЁТ) – Weft Lose:- Xxxxx. / Picks Out – Пролёты или Прометки – нарушение переплетения, порок ткани. Пролёт – местный порок текстильного полотна, заключающийся в отсутствии одной или нескольких уточных нитей по всей ширине ткани или на ограниченном участке. Пролёты в одну уточную прокидку. Размер порока – за каждое место. Отсутствующая Нить – местный порок текстильного полотна в виде отсутствия одной или нескольких нитей.

WEFT SLOUGH = СЛЁТ УТКА (или УТОЧНЫЙ СПУСК, или УТОЧНЫЙ СЛЁТ) – Weft Slough of one or two coils. The main causes of slough are softly wound pirn, overfilled pirns, high density of coils, short chase length etc. / Уточный Слёт – порок ткани в виде заработанных в полотно уточных петель. Непропрядка – Слёт Утка – короткий утолщённый участок по утку, возникающий в том случае, если уточная нить слетает пакетиком с конца початка и в таком виде зарабатывается в ткань. Непропряды более пятикратной до восьмикратной толщины включительно. Размер порока – за каждое место. Непропряды более восьмикратной толщины.

WEFT SNARL = ПЕТЛЯНИЕ УТКА (или УТОЧНАЯ ПЕТЛЯ, или УТОЧНАЯ СУКРУТИНА, или УТОЧНЫЙ КЛУБОК) – Weft Snarl in a fabric is caused by a short length of three fold weft yarn of which two folds are intertwisted. The incidence of such snarls can be reduced by ensuring the process setting of twist and by minimizing the possibility of severe rubbing of yarn between the shuttle and the box front plate. Snarl is a technical term for small loops or curls formed by the yarn in the mule in case of spinning is not done under proper tension. Snarls are loops or curls seen when yarn is being mule-spun. They are caused by improper tension or poor atmospheric conditions. / протирание или притирка (rubbing). Под Петлёй понимается местный порок в виде нежелательных петель, выступающих на поверхности ткани из-за ненатянутой уточной нити. Петли и Сукрутины – образуются при намотке пряжи вследствие очень большой крутки или слабого натяжения.

WEFT STREAKS = ПОЛОСЫ ПО УТКУ (или ПОЛОСКИ ПО УТКУ, или УТОЧНЫЕ ПОЛОСЫ, или УТОЧНЫЕ ЧЕРТЫ, или УТОЧНЫЙ ЗАТАСК) – Weft Streaks are faint or sometimes prominent lines along the length of the fabric. Use of good quality reeds will largly reduce streaks due to uneven end spacing. Streaks can also be avoided through careful housekeeping and ensuring that different batches of yarns do not get mixed up. Streaks:- flaw in solid colored, yarn dyed goods, consisting of shaded streaks, caused by imperfect dyeing. / Под Полосой По Утку понимается местный порок ткани в виде полосы во всю ширину ткани из-за различной линейной плотности нитей и пряжи, цвета утка или от декатира. Уточный Затаск – порок печатного товара в виде параллельных цветных полос.

WEG = WICKED EVIL GRIN

WEIGH = СНИМАТЬСЯ – Weigh:- lift anchor off the bottom. / Сниматься с якоря – поднимать якорь со дна.

WEIGH FACILITY = ВЕСОВОЕ ПОМЕЩЕНИЕ (или ВЕСОВАЯ) – In the United States, Weigh Facility is an area having facilities for weighing of trucks by state highway authority.

WEIGHING = ВЗВЕШИВАНИЕ (или ПЕРЕВЕСКА) – (1) Weighing covers actual determination of the weight by the inspection company or witnessing by the inspection company of the weighing operations executed by other parties. It applies to weighing systems for determining, indicating or printing weight and include also calibration of scales against standard weights. Draught surveys of ships are included in this group of services. / или засвидетельствование (witnessing). Под Взвешиванием понимается определение веса (ранее массы) тел при помощи весов. При взвешивании на рычажных весах, не требующем высокой точности, вес тела принимается равным алгебраической сумме весов гирь, уравновешивающих тело, и показаний отсчётного устройства весов.

(2) Weighing:- xxxxx. / Взвешивание – определение относительной важности объединяемых объектов исследования. Например, ценные бумаги, включаемые в индекс, могут быть равно взвешены или взвешены в соответствии с их стоимостью.

WEIGH–IN–MOTION = ВЗВЕШИВАНИЕ В ДВИЖЕНИИ – Weigh-In-Motion (WIM) is a technology for determining a vehicle's weight without requiring it to come to a complete stop.

WEIGHT = ВЕС – (1) Weight is a deprecated term still commonly but improperly used for mass. Weight:- either Gross Weight, Net Weight, or Tare Weight. See also Mass. Weight:- gravitational force of attraction on an object, caused by the presence of a massive second object, such as the Earth or Moon. Weight is a consequence of the universal law of gravitation:- any two objects, because of their masses, attract each other with a force that is directly proportional to the product of their masses and inversely proportional to the square of the distance between them. Thus more massive objects, of course, weigh more in the same location; the farther an object is from the Earth, the smaller is its weight. The weight of an object at the Earth's South Pole is slightly more than its weight at the Equator because the polar radius of the Earth is slightly less than the equatorial radius. Though the mass of an object remains constant, its weight varies according to its location. The smaller mass and radius of the Moon compared with those of the Earth combine to make the same object on the Moon's surface weigh one-sixth the value of its weight on Earth. Because of all the mass in the universe, each point of space has a property called the gravitational field at that point, numerically equal to the acceleration of gravity at that point. Alternatively, weight is the product of an object's mass and either the gravitational field or the acceleration of gravity at the point where the object is located. Units of weight are those of force, not mass (see Force). / Под Весом Тела понимается сила, с которой тело действует вследствие тяготения к Земле на опору (или подвес), удерживающую его от свободного падения. Если тело и опора неподвижны относительно Земли, то вес тела равен его силе тяжести. Единица веса тела (в системе СИ) – Ньютон (Н). Под Весом понимается сила, с которой тело действует на опору (или подвес), препятствующую его свободному падению. Численно равен произведению массы тела на ускорение свободного падения. Из-за несферичности Земли и её суточного вращения вес данного тела несколько изменяется с широтой; на экваторе он приблизительно на 0.5% меньше, чем на полюсах.

(2) Weight (for sea transport):- the weight to be taken into consideration is the gross-gross weight of goods. This includes the total weight of the goods, all packaging, and the tare weight of the container, swap-body and pallets containing goods as well as road goods vehicles, wagons or barges carried by sea. When this tare-weight is excluded, the weight is the gross weight.

(3) Weight (for inland waterways transport):- the weight to be taken into consideration is the gross-gross weight of goods. The weight taken into consideration is equivalent to the total weight of the goods and packaging and the tare weight of equipment such as containers, swap bodies and pallets. When this tare-weight is excluded, the weight is gross weight.

(5) Weight (of goods carried by rail):- the weight to be taken into consideration is the gross-gross weight of goods. This includes the total weight of the goods, all packaging, and tare-weight of the container, swap-body and pallets containing goods as well as road goods vehicles carried by rail. When this tare-weight is excluded, the weight is the gross weight.

(5) Weight (for road transport):- the weight to be taken into consideration is the gross-gross weight of goods. This includes the total weight of the goods, all packaging, and tare-weight of the container, swap-body and pallets containing goods. When this tare-weight is excluded, the weight is gross weight.

WEIGHT AGREEMENT = ВЕСОВОЕ СОГЛАШЕНИЕ (или СОГЛАШЕНИЕ ПО ВЕСУ) – Weight Agreement is an arrangement between shippers and carriers that allows the use of estimated weight of shipment components in obtaining freight charges and total weight. / Соглашение Относительно Веса (Weight Agreement) – соглашение между грузоотправителем и перевозчиком, которое обычно следует за рядом проверок веса грузов; в соответствии с соглашением перевозчик принимает груз к перевозке по определённым согласованным весам.

WEIGHT AT BIRTH = ВЕС ПРИ РОЖДЕНИИ – The Weight At Birth is the weight determined immediately after a child is born, whether alive or dead (generally expressed in grams).

WEIGHT BIAS = ВЕСОВАЯ ПОГРЕШНОСТЬ – Weight Bias is a bias, usually in an index number, due to the use of incorrect or undesirable weights. Since the true value of the complete quantity which an index purports to measure is not in general capable of direct measurement, bias in this sense is to some extent an arbitrary quantity.

WEIGHT BREAK = НАРУШЕНИЕ ПО ВЕСУ – Weight Break:- the shipment volume at which the LTL (short for the Less Than Truckload) charges equal the TL (short for the Truckload) charges at the minimum weight. Truckload (TL) is defined as any shipment having a total weight of 20 000 lbs or more; or moving as Capacity Load or Exclusive Use or Sealed Trailer or Cubic Capacity. LTL shipments typically weigh between 151 and 20 000 lbs. LTL carriers will usually apply a discount on shipments as the freight moves up in weight, meaning there are various 'Weight Break' discounts an LTL carrier may give. Shipments larger than 5 pallets can still ship with an LTL carrier but these moves are normally considered volume moves and are spot quoted by the carrier's rate department. LTL freight rates can be very confusing. Unlike truckload which has rates usually based on a per-mile rate or a price per-hundred weight plus a fuel charge, many factors regulate LTL rates which will most definitely impact the cost of a shipment. Less-than-truckload (LTL) mode of shipping is used for smaller shipments that are too large to be sent as parcel but too small to fill an entire truckload. LTL carriers collect freight from various shippers and consolidate that freight onto trailers for line-haul to the delivering terminal or to a hub terminal where the freight will be further sorted and consolidated for additional line-hauls. In most cases, drivers start the day by loading up and heading out to make deliveries first, then begin making pickups once the trailer has been emptied for return to the terminal for sorting and delivery next day; thus, most pickups are made in the afternoon and most deliveries are performed in the morning. / Снижения Платы За Вес (Weight Breaks):- размеры снижения провозной платы в расчёте на 100 фунтов при увеличении веса груза.

WEIGHT BY VOLUME = ВЕС К ОБЪЁМУ – w/v is an abbreviation for Weight By Volume, a slightly confusing phrase used in chemistry and pharmacology to describe the concentration of a substance in a mixture or solution. The weight by volume is the mass (in grams) of the substance dissolved in or mixed with 100 milliliters of solution or mixture. For example, the concentration of fluoride in toothpaste is usually about 0.15% w/v, meaning that there is 0.15 gram of fluoride per 100 milliliters of toothpaste. Thus 1% w/v is equal to 1 gram per deciliter (g/dL) or 10 grams per liter (g/L). Weight/Volume (W/V):- solutions are sometimes specified as being made as some percentage weight/volume. This means that the substance dissolved is measured by weight, and the final solution is measured by volume. For example, 5% sodium chloride w/v would mean that 5 grams of salt would be dissolved in enough water to make a total solution volume of 100 milliliters (or, say, 150 g to make 3 liters, etc), and would be labeled 'Sodium chloride 5% w/v'. Solutions are most commonly made this way, and it can be assumed to be this way unless otherwise specified. See also Weight/Volume; and Weight/Weight.

WEIGHT CARGO = ВЕСОВОЙ ГРУЗ – Weight Cargo is a cargo on which the transportation charge is assessed on the basis of weight. / Весовой Груз – груз, транспортировка которого оплачивается в зависимости от веса.

WEIGHT CERTIFICATE = ВЕСОВОЙ СЕРТИФИКАТ (или СЕРТИФИКАТ ВЕСА) – Weight Certificate:- in the United States, the certified weight ticket shall be of a form approved by the director and shall contain the following information:- (1) the date of issuance; (2) the kind of commodity weighed, measured, or counted; (3) the name of owner, agent, or consignee of the commodity weighed; (4) the name of seller, agent or consignor; (5) the accurate weight, measure or count of the commodity weighed, measured or counted; including the entry of the gross, tare and/or net weight, where applicable; (6) the identifying numerals or symbols, if any, of each container separately weighed and the motor vehicle license number of each vehicle separately weighed; (7) the means by which the commodity was being transported at the time it was weighed, measured or counted; (8) the name of the city or town where such commodity was weighed; (9) the complete signature of weighmaster or weigher who weighed, measured or counted the commodity; and (10) such other available information as may be necessary to distinguish or identify the commodity. Such weight certificates when so made and properly signed and sealed shall be prima facie evidence of the accuracy of the weights, measures or count shown, as a certified weight, measure or count. Weight Certificate:- this is usually issued by an official weigher on the dock with the weight (as well as measurements) then being entered on the back of the second and third copies of the dock receipt by clerk on the dock. / сразу или на первый взгляд (prima facie). Обычно, Сертификат Веса или Весовой Сертификат выдается официальным весовщиком, работающем в доке. Он указывает в нём вес, впрочем как и иные количественные показатели, которые затем прописываются клерком, работающим в этом же доке, на оборотах второй и третей копий доковой расписки.

WEIGHT CHARGE = ВЕСОВОЙ СБОР – Weight Charge:- the charge for carriage of goods based on their weight (aircargo).

WEIGHT–DISTANCE TAX = НАЛОГ ВЕС–ДИСТАНЦИЯ – Weight-Distance Tax is a tax basing the fee per mile on the registered gross weight of the vehicle. Total tax liability is calculated by multiplying this rate times miles traveled.

WEIGHTED ARITHMETIC AVERAGE INDEX = ИНДЕКС ПО ВЗВЕШЕННЫМ АРИФМЕТИЧЕСКИМ СРЕДНИМ ВЕЛИЧИНАМ – Weighted Arithmetic Average Index is an index defined as a weighted arithmetic average of the price relatives.

WEIGHTED AVERAGE = ВЗВЕШЕННАЯ СРЕДНЯЯ ВЕЛИЧИНА (или ВЗВЕШЕННОЕ СРЕДНЕАРИФМЕТИЧЕСКОЕ) – A Weighted Average is more heavily influenced by some of the numbers it is calculated from than others. It is calculated by:- multiplying each number by a weight, adding the results together, and dividing the total by the sum of the weights. Stock market indices are based

on weighted averages of share prices. The weights are the market caps of the companies in the index. More complex variants on this are often used. A useful weighted average for time series data (common in finance and economics) is and exponential one:- $S_t = \alpha x_t + (1 - \alpha)S_{t-1}$, and $S_0 = x_0$; where S is the exponentially weighted average, or smoothed value, x is the series being averaged, subscripts denote time, with the first period being 0, and $0 < \alpha < 1$. This gives weightings to x_t, x_{t-1}, x_{t-2}, etc in proportions 1, $(1 - \alpha)$, $(1 - \alpha)^2$, etc. When this is used to produce a new time series (often to draw a graph), when it is called Exponential Smoothing. Weighted Average is a moving average that uses a selected time span, but gives greater weight to the more recent price data. Weighted Average is one in which different data in the data set are given different 'weights'. Varying subjective assumptions are derived for determining the level of importance for each data category. For example, many teachers will use a 'weighted average' when calculating a student's grade in a course. A teacher might determine the final grade for the course by calculating that the test average is 60% of the grade, quiz average is 30% of the grade, and a single project is 10% of the grade. Weighted Average:- an average which is obtained by combining different numbers (e.g., prices or index numbers) according to the relative importance of each. / Взвешенная Средняя Величина или Средневзвешенное – среднее арифметическое значение, в котором учтён вес каждого из слагаемых, для которых рассчитывается это среднее значение. Например, если кто-то покупает товар тремя партиями, одна из которых 100 тонн по 70 Долларов за тонну, вторая – 300 тонн по 80 Долларов за тонну и третья – 50 тонн по 95 Долларов за тонну, то в общей сложности он закупил 450 тонн товара. Обычная средняя цена закупки составляет (70 + 80 + 95) / 3 = 81.70 Долларов за тонну. Средневзвешенная цена с учётом объёмов каждой из закупленных партий равна ((100 x 70) + (300 x 80) + (50 x 95)) / 450 = 79.40 Долларов за тонну.

WEIGHTED AVERAGE CONTRIBUTION MARGIN RATIO = СООТНОШЕНИЕ СО ВЗВЕШЕННОЙ СРЕДНЕАРИФМЕТИЧЕСКОЙ МАРЖЁЙ КОНТРИБУЦИИ – Weighted Average Contribution Margin Ratio:- average contribution margin that is weighted to reflect the relative contribution of each operating department of a multi-department firm to its ability to pay fixed costs and to generate income. The Weighted Average Contribution Margin is the average amount that a group of products or services contribute to paying down the fixed costs of a business. The concept is a key element of breakeven analysis, which is used to project profit levels at varying sales levels. Its main weakness is that projections based on this average margin incorporate the assumption that the same mix of product sales and margins will apply in the future, which is not necessarily the case. The measurement is compiled by accumulating the revenue for all items being measured, subtracting from this aggregate revenue figure the total amount of all variable expenses related to the items in the measurement group, and dividing by the number of units sold. For the purposes of this calculation, variable expenses are those that vary directly with sales. Thus, an expense is only incurred if a sale is generated. Examples of these variable expenses are:- (i) direct materials; (ii) production supplies; (iii) commissions; (iv) piece rate wages; and (v) freight out. Thus, the calculation of the weighted average contribution margin is:- (Aggregate Sales – Aggregate Variable Expenses) / Number Of Units Sold. For example, ABC International has two product lines, each of which is responsible for 50% of sales. The contribution from Line A is USD100 000 and the contribution from Line B is USD50 000. In aggregate, ABC sold 15 000 units. This means that the weighted average contribution margin for the entire business is USD10/unit (calculated as USD150 000 total contribution / 15 000 units). The weighted average contribution margin is useful for calculating the number of units that a business must sell in order to cover its fixed expenses and at least break even, if not earn a profit. This analysis is known as Cost-Volume-Profit Analysis. To continue with the example, ABC International has calculated that it generates a contribution margin of USD10 per unit, based on current sales of 15 000 units. However, the business also has USD200 000 of fixed costs, so it is currently losing USD50 000 per period. ABC can use the weighted average contribution margin to calculate how many units it must sell in order to break even. Thus, fixed costs of USD200 000 divided by a contribution margin of USD10 per unit results in a requirement of 20 000 in unit sales in order to break even. Weighted Average Contribution Margin Ratio is the average contribution margin that is weighted to reflect the relative contribution of each operating department of a multi-department firm to its ability to pay fixed costs and to generate income. / Эй.Би.Си. Интёнэшэнэл (ABC International).

WEIGHTED AVERAGE COST = ВЗВЕШЕННАЯ СРЕДНЯЯ ВЕЛИЧИНА СТОИМОСТИ (или СРЕДНЕВЗВЕШЕННАЯ СТОИМОСТЬ) – Weighted Average Cost is the average price per unit of stock delivered in a period calculated either at the end of the period ('Periodic Weighted Average') or each time a new delivery is received ('Cumulative Weighted Average').

WEIGHTED AVERAGE COST METHOD = МЕТОД ВЗВЕШЕННОЙ СРЕДНЕЙ ВЕЛИЧИНЫ СТОИМОСТИ (или МЕТОД СРЕДНЕВЗВЕШЕННОЙ СТОИМОСТИ) – Weighted Average Cost Method is a method of calculating Ending Inventory cost. It is also known as WAVCOs. It takes Cost of Goods Available for Sale and divides it by the number of units available for sale (number of goods from Beginning Inventory + Purchases / production). This gives a Weighted Average Cost per Unit. A physical count is then performed on the ending inventory to determine the number of goods left. Finally, this quantity is multiplied by Weighted Average Cost per Unit to give an estimate of ending inventory cost. The cost of goods sold valuation is the amount of goods sold times the Weighted Average Cost per Unit. The sum of these two amounts (less a rounding error) equals the total actual cost of all purchases and beginning inventory. / Метод Средневзвешенной Стоимости:- согласно этому методу стоимость каждого изделия определяется по средневзвешенной стоимости аналогичных изделий, имеющихся в наличии на начало периода и приобретённых или произведённых в течение периода. Средневзвешенная стоимость может рассчитываться на периодической основе или, в зависимости от конкретных условий компании, по получении каждой дополнительной поставки.

WEIGHTED AVERAGE COST OF CAPITAL = ВЗВЕШЕННАЯ СРЕДНЯЯ ВЕЛИЧИНА СТОИМОСТИ КАПИТАЛА – Weighted Average Cost of Capital (WACC) is the return that the providers of a company's capital require. Calculating it requires knowing the rates of return required focr each source of capital. See also Cost Of Capital. The cost of capital will be different for each source of capital and class of securities a company has, reflecting the different risks. The WACC is the weighted average of the costs of each of the different types of capital. The weights are proportion of the company's capital that comes from each source. In a simple case:- $WACC = (D / (D + E)) \times i + (E / (D + E)) \times r$; where i is the interest rate, r is the required return on equity, D is the amount of debt capital, and E is the amount of equity capital. This is not complete. WACC unifies the costs of sources of capital that are subject to different tax treatments. This needs to be adjusted for. It is particularly important to adjust the cost of debt capital (usually tax deductible) to put it on the same basis as equity capital. To do this we need to adjust the tax deductible costs by correcting the cost of debt for the tax savings made. This means the calculation becomes:- $WACC = (D / (D + E)) \times (((1 / (1 - t)) \times i) + (E / (D + E)) \times r$; where t is the tax rate. This may need to be adjusted further where there is more than one type of debt or equity capital. To take a common example supposedly debt D is actually split into senior debt and subordinated debt, then:- $WACC = (D_1 / (D + E)) \times (((1 / (1 - t)) \times i_1) + (D_2 / (D + E)) \times (((1 / (1 - t)) \times i_2) + (E / (D + E)) \times r$; where D_1 is the amount of senior debt, D_2 is the amount of subordinated debt, $D = D_1 + D_2$, i_1 is the Yield to Maturity (YTM) of the senior debt, and i_2 is the YTM of the subordinated debt. More complex forms of capital such as convertible debt would require considerably more complex adjustments. Weighted Average Cost Of Capital is a cost of acquiring debt and/or equity capital, computed on the basis of interest rate, income tax rate, and return on equity goal. Expressed usually as a percentage, it is used as a discount rate to determine present value of specific investments. See also Composite Cost Of Capital. Weighted Average Cost Of Capital (WACC):- expected return on a portfolio of all a firm's securities. Used as a hurdle rate for

capital investment. Often the weighted average of the cost of equity and the cost of debt. The weights are determined by the relative proportions of equity and debt in a firm's capital structure. Weighted Average Cost of Capital (WACC) is the sum of the market returns of each component of a corporate capitalization, weighted by each component's share of the total capitalization. Weighted Average Cost of Capital (WACC):- a firms capital comes from debt and equity. WACC breaks down each type of capital cost and its weight against the other capital and then sums together all these values to calculate the weighted cost of capital. Equity is usually common stock but might also include preferred stock and options. Debt will be used lines of credit, bank loans, and bonds. A simple formula for WACC is:- WACC = (E / C) * Re + (D / C) * Rd * (1 – T); where, E – company's market capitalization value, D – company's debt at market value, Re – cost of equity, Rd – cost of debt, C = E + D, T – tax rate applicable for this corporation. The Net Present Value (NPV) of the cash flows from a project that a company takes on needs an 'inflation' rate plugged into the formula. Companies often use the value of WACC for this rate. Weighted Average Cost Of Capital (WACC) is an average representing the expected return on all of a company's securities. Each source of capital, such as stocks, bonds, and other debt, is weighted in the calculation according to its prominence in the company's capital structure.

WEIGHTED AVERAGE COST OF INVENTORY = ВЗВЕШЕННАЯ СРЕДНЯЯ ВЕЛИЧИНА СТОИМОСТИ ИНВЕНТАРЯ – Weighted Average Cost Of Inventory is the inventory valuation method used where different quantities of goods are purchased at different unit costs. Under this method, weights are assigned to the cost price on the basis of the quantity of each item at each price.

WEIGHTED AVERAGE COUPON = СРЕДНЕВЗВЕШЕННЫЙ КУПОН – Weighted Average Coupon (WAC):- the weighted average of the gross interest rates of mortgages underlying a pool as of the pool issue date; the balance of each mortgage is used as the weighting factor. Weighted Average Coupon (WAC):- most recently disclosed weighted average of the coupons of the mortgages contained in each PC pool. The Weighted Average Coupon (WAC) of any group of mortgages is calculated by:- (i) multiplying the purchased unpaid principal balance (UPB) of each mortgage by the note rate of such mortgage (resulting in a 'product' for each mortgage); (ii) adding the products so obtained for all of the mortgages; (iii) dividing the sum of the products by the purchased aggregate UPB of all the mortgages in the group; and (iv) Freddie Mac's determination of the WAC is conclusive. Weighted Average Coupon (WAC) is calculated by multiplying the coupon of each mortgage (Gross WAC) or mortgage security (Net WAC) by its remaining balance, summing the products, and dividing the result by the total remaining balance. Weighted Average Coupon (WAC):- the weighted average of the gross coupons for the mortgages underlying the pool as of the pool issue date, with the balance of each mortgage used as the weighting factor. The WAC is calculated by multiplying the gross coupon of each mortgage by the pool's remaining balance, summing the products, then dividing the result by the pool's total remaining balance. For a CMO, the WAC is the weighted average of the WACs of the pools used as collateral. / Средневзвешенный Купон (СВК) – усреднённая процентная ставка по пулу ипотечных кредитов или ценных бумаг, вычисленная как средневзвешенная величина по размерам непогашенного основного долга.

WEIGHTED AVERAGE FORECLOSURE FREQUENCY = СРЕДНЕВЗВЕШЕННАЯ ЧАСТОТА ОБРАЩЕНИЯ ВЗЫСКАНИЯ – Weighted Average Foreclosure Frequency (WAFF) represents the likelihood a borrower will default on a loan. From an analysis standpoint, the WAFF is a proxy for the quality of lending practices, and the overall state of the economy. An investor in the residential mortgage-backed security (RMBS) with a WAFF of 20% is comfortable with the expectation that no more than 20% of borrowers will be unable to meet their commitments. In the context of RMBS and in the real world, the Weighted Average Loss Severity (WALS) and WAFF are closely related. In the above examples an investor would need to be comfortable that not more than 20% of mortgagees would default and that residential prices will not drop by more than 30%. If house prices drop by 50% but no-one defaults, the principal will be repaid. There is however a correlation in the economy between defaults and house prices. In a weak economy you would expect to see defaults increase and residential prices decrease at the same time. WAFF is the weighted-average foreclosure frequency of the mortgage loans in the cover pool. The foreclosure frequency reflects the probability that a default on a mortgage loan would lead to foreclosure. The estimated foreclosure frequency is a function of borrower and loan characteristics, as well as the economic stress scenario commensurate with a certain rating level. This figure is comparable to the SDR for public-sector and other assets. / Средневзвешенная Частота Обращения Взыскания (СВЧОВ) – выраженная в процентах доля активов в пуле, по которым обращено или будет обращено взыскание в условиях предполагаемого экономического сценария.

WEIGHTED AVERAGE LIFE = СРЕДНЕВЗВЕШЕННАЯ ЖИЗНЬ – Weighted Average Life (WAL):- the average number of years for which each dollar of unpaid principal on a loan or mortgage remains outstanding. Once calculated, WAL tells how many years it will take to pay half of the outstanding principal. The time weightings are based on the principal paydowns – the higher the dollar amount, the more weight that corresponding time period will have. For example, if the majority of the repayment amount is in 10 years the WAL will be closer to 10 years. Let's say there's an outstanding bond with five years of USD1 000 annual payments. The weighted average life would be three years, assuming payment is made at the end of each year. This indicates that after three years over half of the payments will be made. See also Average Life. Weighted Average Life (WAL):- for a portfolio or mortgage pool, the Dollar-weighted time (in years) to repayment of principal. For a CMO tranche, the weighted average of the WALs of the pools used as collateral. Weighted Average Life (WAL):- the assumed weighted average amount of time that will elapse from the date of a security's issuance until each Dollar of principal is repaid to the investor. The WAL will change as the security ages and depending on the actual realized rate at which principal, scheduled and unscheduled, is paid to the loans underlying the Mortgage-Backed Security (MBS).

WEIGHTED AVERAGE LOAN AGE = СРЕДНЕВЗВЕШЕННЫЙ ВОЗРАСТ ССУДЫ – Weighted Average Loan Age (WALA):- for mortgage-backed securities, an estimate of the weighted average number of months since the mortgages backing the pool were issued. GNMA and FHLMC supply WALAs for their mortgage pools. Bridge calculates the loan ages for pools from all other agencies and issuers. Weighted Average Loan Age (WALA):- most recently disclosed, calendar-adjusted, weighted average of the number of months since note origination of the mortgages contained in each PC (short for the Participation Certificate) pool. / Средневзвешенный Возраст Ссуды (СВВС):- усреднённая продолжительность обращения (в месяцах) по пулу ипотечных кредитов, вычисленная как средневзвешенная величина по размерам непогашенного основного долга.

WEIGHTED AVERAGE LOSS SEVERITY = СРЕДНЕВЗВЕШЕННАЯ ТЯЖЕСТЬ ПОТЕРЬ – Weighted Average Loss Severity (WALS):- the loss severity quantifies the loss realized as a result of foreclosure. The expected loss is predicated on assumptions about the potential decline in the market value of collateral that may secure the asset, as well as the expenses incurred in foreclosing on and reselling the property, considering an economic stress scenario, commensurate typically with a certain rating level. / Средневзвешенная Величина Потерь (СВВП) – средняя величина потерь в случае дифолта одного актива в пуле, выражаемая в процентах от непогашенной суммы основного долга по такому активу на день дифолта.

WEIGHTED AVERAGE MATURITY = СРЕДНЕВЗВЕШЕННЫЙ СРОК ПОГАШЕНИЯ – Weighted Average Maturity (WAM):- the weighted average of the time until all maturities on mortgages in a mortgage-backed security (MBS). The higher the weighted average to maturity, the longer the mortgages in the security have until maturity. Also known as Average Effective Maturity. The measure is calculated by totaling each mortgage value represented by the MBS. The weights of each mortgage is found by dividing the value of

each into the total of all. To arrive at the WAM number the weight of each security is multiplied by the time until maturity of each mortgage, and then all the values are added together. For example say an MBS has three mortgages valued at USD1 000, USD2 000 and USD3 000 (a total of USD6 000) and mature in one, two and three years respectively. The weights of these are 1/6 (1 000 / 6 000), 1/3 (2 000 / 6 000) and 1/2 (3 000 / 6 000). The WAM is 2 1/3 years (1 / 6 x 1 year + 1 / 3 x 2 years + 1 / 2 x 3 years). Weighted Average Maturity is the average maturity of all mortgages held in a mortgage-backed security. It is calculated by taking the value of each mortgage, dividing it by the total value of all mortgages (which finds the weight), and then multiplying that value by the number of years left on the mortgage. For example, a mortgage-backed security comprised of a USD5 000 note due in 2 years and a USD2 000 note due in 3 years has a weighted average maturity of (USD5 000 / USD7 000) x 2 + (USD2 000 / USD7 000) x 3, or 2.28. A high WAM means that the mortgages comprising the security will not mature for a long time. The Weighted Average Maturity of an Mortgage-Backed Security (MBS) is the weighted average of the remaining terms to maturity of the mortgages underlying the collateral pool at the date issue, using as the weighting factor the balance of each of the mortgages as of the issue date. The average amount of time remaining before maturity in the mortgages underlying a mortgage-backed security, weighted by the percentage of the MBS that each mortgage constitutes. For example, suppose a mortgage-backed security contains two mortgages, one worth USD10 000 and one worth USD20 000, for a total of USD30 000. The USD10 000 mortgage matures in five years, and the USD20 000 mortgage in 10 years. The weighted average remaining maturity is calculated as:- WAM = (USD10 000 / USD30 000) x 5 years + (USD20 000 / USD30 000) x 10 years = 8 1/3 years. The weighted average maturity is also known as Weighted Average Remaining Maturity. Weighted Average Maturity:- the weighted average maturity of an mortgage-backed security (MBS) is the weighted average of the remaining terms to maturity of the mortgages underlying the collateral pool at the date issue, using as the weighting factor the balance of each of the mortgages as of the issue date. Weighted Average Maturity is the average time it takes for securities in a portfolio to mature, weighted in proportion to the Dollar amount that is invested in the portfolio. Weighted average maturity measures the sensitivity of fixed-income portfolios to interest rate changes. Portfolios with longer WAMs are more sensitive to changes in interest rates because the longer a bond is held, the greater the opportunity for interest rates to move up or down and affect the performance of the bonds in the portfolio. If interest rates move up, the value of a bond decreases because there are bonds in the market that now pay more interest and therefore are more attractive. Weighted Average Maturity (WAM) is calculated by multiplying the maturity of each mortgage in a given pool by its remaining balance, summing the products, and dividing the result by the total remaining balance. Weighted Average Maturity (WAM):- for mortgage pools, the weighted average of the remaining terms of the underlying mortgages, using the current balance of each mortgage as the weighting factor. The at-issue WAM is published for most mortgage pools. In addition, FNMA, FHLMC, and GNMA publish periodic updates. / Средневзвешенный Срок До Погашения (СВСДП) – усреднённый срок до погашения (в месяцах) по пулу ипотечных кредитов, вычисленный как средневзвешенная величина по размерам непогашенного основного долга. Средневзвешенный Срок Погашения:- показатель дюрации пула кредитов, определяемый как сумма выраженных в месяцах сроков погашения кредитов, умноженная на долю непогашенного основного долга по такому кредиту в совокупном непогашенном основном долге такого пула. Средневзвешенный Срок (облигаций), обеспеченных ипотеками.

WEIGHTED AVERAGE METHOD = МЕТОД ВЗВЕШЕННОЙ СРЕДНЕЙ ВЕЛИЧИНЫ – Weighted Average Method:- this amount represents how many products or services were created in relation to the amount of sales recorded on the company's general ledger.

WEIGHTED AVERAGE NUMBER OF ORDINARY SHARES OUTSTANDING DURING THE PERIOD = СРЕДНЕВЗВЕШЕННОЕ ЧИСЛО ОБЫКНОВЕННЫХ АКЦИЙ, НАХОДЯЩИХСЯ В ОБРАЩЕНИИ В ТЕЧЕНИЕ ДАННОГО ПЕРИОДА – Weighted Average Number Of Ordinary Shares Outstanding During The Period:- Use the weighted-average number of shares during the period in the denominator. You do this by adjusting the number of shares outstanding at the beginning of the reporting period for common shares repurchased or issued in the period. This adjustment is based on the proportion of the days in the reporting period that the shares are outstanding. Weighted Average Number Of Shares Outstanding is the number of shares of common stock at the beginning of a period, adjusted for shares canceled, bought back, or issued during the period, multiplied by a time-weighting factor. This number is used in the calculation of earnings per share. Weighted Average Of Outstanding Shares is a amount of shares outstanding in a company will often change due to a company issuing new shares, repurchasing and retiring existing shares, and other financial instruments such as employee options being converted into shares. The weighted average of outstanding shares is a calculation that incorporates any changes in the amount of outstanding shares over a reporting period. It is an important number, as it is used to calculate key financial measures such as earnings per share (EPS) for the time period. Let's look at an example:- Say a company has 100 000 shares outstanding at the start of the year. Halfway through the year, it issues an additional 100 000 shares, so the total amount of shares outstanding increases to 200 000. If at the end of the year the company reports earnings of USD200 000, which amount of shares should be used to calculate EPS:- 100 000 or 200 000? If the 200 000 shares were used, the EPS would be USD1, and if 100 000 shares were used, the EPS would be USD2 – this is quite a large range! This potentially large range is the reason why a weighted average is used, as it ensures that financial calculations will be as accurate as possible in the event the amount of a company's shares changes over time. The weighted average number of shares is calculated by taking the number of outstanding shares and multiplying the portion of the reporting period those shares covered, doing this for each portion and, finally, summing the total. The weighted average number of outstanding shares in our example would be 150 000 shares. The earnings per share calculation for the year would then be calculated as earnings divided by the weighted average number of shares (USD200 000/150 000), which is equal to USD1.33 per share. / Средневзвешенное Количество Циркулирующих Обыкновенных Акций За Период:- количество обыкновенных акций, выпущенных и обращающихся на начало периода, скорректированное на количество погашенных, выкупленных эмитентом или выпущенных за период акций, умноженное на временной весовой множитель.

WEIGHTED AVERAGE PORTFOLIO YIELD = СРЕДНЕВЗВЕШЕННАЯ ДОХОДНОСТЬ ПОРТФЕЛЯ – Weighted Average Portfolio Yield:- the weighted average of the yield of all the bonds in a portfolio. / Средневзвешенная Доходность Портфеля (Weighted Average Portfolio Yield):- средневзвешенная величина доходности всех облигаций, составляющих портфель.

WEIGHTED AVERAGE QUANTITY = КОЛИЧЕСТВО В ВИДЕ ВЗВЕШЕННОЙ СРЕДНЕЙ ВЕЛИЧИНЫ (или СРЕДНЕВЗВЕШЕННОЕ КОЛИЧЕСТВО) – Weighted Average Quantity (sugar) is the quantity of an allocation of the beet allotment made to a beet sugar processor for the crop year that allotments are in effect. Before adjustments, the processor's share equals 25 percent of beet sugar produced by the processor in 1998, plus 35 percent of the same in 1999, plus 40 percent of the same in 2000.

WEIGHTED AVERAGE RATING FACTOR = СРЕДНЕВЗВЕШЕННЫЙ ФАКТОР РЭЙТИНЬГА – A Weighted Average Rating Factor (WARF) is a method of calculating and communicating the overall risk of a portfolio of investments. It is most commonly associated with collateralized debt obligations. The weighted average rating factor takes into account each individual asset in the portfolio, but gives emphasis based on the relative proportion of the portfolio made up by each asset. The main use of a weighted average rating factor is with collateralized debt obligations. These are financial products where the rights to income from multiple loans and credit deals have been bought up and packaged together. Investors then buy bonds in the collateralized debt obligation (CDO), with the repayments and interest from the bonds ultimately coming from the income from the original loans. There are two main benefits to this

system:- tying multiple loans together limits the damage caused by a single borrower defaulting; and the bonds can be issued in a way such that investors can choose a particular balance between getting a higher rate of interest or having a priority claim in the event that defaults mean there isn't enough money to pay all bondholders. With so many loans packaged together, it can be difficult to assess the overall risk of default on a particular CDO and its range of bonds. The weighted average rating factor is a relatively simple way of achieving this. It involves first assigning a risk factor to each individual asset:- in effect, an attempt to predict the statistical likelihood of the relevant borrower defaulting. These risk factor figures are then averaged using weighting. This means adjusting the figures to match the proportions each asset contributes to the overall portfolio. As an extremely simplified example, if 60% of the portfolio is made up of income from mortgage A and 40% is made up of income from mortgage B, then the overall risk factor is simply the risk factor of mortgage A multiplied by 0.4, plus the risk factor of mortgage B multiplied by 0.6. Exactly what the final weighted average rating factor figure represents may vary depending on who produces the ratings. One system, operated by ratings agency Moody's, uses ratings by which a score of 100 represents a 1% chance of default during 10 years, a score of 150 represents a 1.5% chance, and so on. Investors should check carefully to see exactly what system is being used, particularly when comparing investment options from different providers. Weighted Average Rating Factor (WARF) is a measure of credit quality giving exponentially bigger weigths to companies with lower ratings. It's a number corresponding to an average rating for f.income portfolios. Usually it's used to assess credit quality of CDO underlying bond portfolios. Weighted Average Rating Factor (WARF) is a measure that is used by credit rating companies to determine the credit quality of a portfolio. This measure allows rating companies to look at a portfolio as a single security, and assign it a single rating. WARFs are most often calculated by rating companies for collateralized debt obligations (CDOs). To calculate the WARF on a CDO the rating agencies must first calculate the rating factor for each instrument (or trading asset) underlying the CDO. Once this is done, a weighted average of the factors is taken based on the size of the underlying instruments. When the WARF is combined with the amortization profile of the CDO portfolio you can determine the chance of default on the pool on investments. / рэйтиньговое агентство Мудиз Инвэстоз Сёвис Лимитид (Moody's Investor Service Ltd). Средневзвешенный Фактор Рэйтиньга (СВФР) – средневзвешенная величина факторов рэйтиньга по размерам непогашенного основного долга активов портфеля. Средневзвешенный Фактор Рэйтиньга позволяет рассмотреть портфель активов как единую ценную бумагу с определённым рэйтиньгом и широко используется в секьюритизации долговых обязательств. WEIGHTED AVERAGE REMAINING MATURITY = СРЕДНЕВЗВЕШЕННЫЙ ОСТАВШИЙСЯ СРОК ПОГАШЕНИЯ – Weighted Average Remaining Maturity (WARM):- the average remaining term of the mortgages underlying a mortgage-backed securities (MBS). Weighted Average Remaining Maturity (WARM):- most recently disclosed, calendar-adjusted, weighted average of the remaining terms to maturity (in months) of mortgages contained in each PC (short for the participation certificate) pool.

WEIGHTED AVERAGE REMAINING TERM = СРЕДНЕВЗВЕШЕННЫЙ ОСТАВШИЙСЯ СРОК – Weighted Average Remaining Term (WART) is the equivalent to the Weighted Average Maturity (WAM) expressed in months or years, and often used interchangeably.

WEIGHTED BALLOT = ПРОПОРЦИОНАЛЬНАЯ ЖЕРЕБЬЁВКА (или ВЗВЕШЕННАЯ ЖЕРЕБЬЁВКА) – Weighted Ballot:- after an oversubscription for a new issue, a ballot used to allot new shares in such a way that either those who have subscribed to larger or smaller portions of the issue receive a disproportionate amount. That is, the weighted ballot is used to allocate available shares in the new issue either to small investors or large investors. / Пропорциональная Жеребьёвка – жеребьёвка, которая проводится в тех случаях, когда имеет место избыточная подписка на новый выпуск акций. При такой жеребьёвке распределение акций происходит на основе количества заказанных акций, а преимущество получают либо мелкие инвесторы, либо крупные.

WEIGHTED CLOSE = ВЗВЕШЕННОЕ ЗАКРЫТИЕ – In technical analysis, Weighted Close is a weighted average of the high, low and close that places more weight on the closing value by counting it twice. Weighted Close = (High + Low + Close + Close) / 4. / В техническом анализе биржевых рынков взвешенное усреднение максимума, минимума и закрытия, последнему из которых уделяется больший вес в установлении стоимости по закрытии, в связи с чем он учитывается в расчёте дважды. Взвешенное Закрытие = (Максимум + Минимум + Закрытие + Закрытие) / 4.

WEIGHTED COST OF CAPITAL = ВЗВЕШЕННАЯ СТОИМОСТЬ КАПИТАЛА – Weighted Cost Of Capital is the cost of capital computed by weighing the percentage borrowed and the percentage from investment sources. See also Cost Of Capital.

WEIGHTED INDEX NUMBER = ВЗВЕШЕННОЕ ЧИСЛО ИНДЕКСА – Weighted Index Number is an index number in which the component items are weighted according to some system of weights reflecting their relative importance. In one sense nearly all index numbers are weighted by implication; for example, an index number of prices amalgamates prices per unit of quantity and the size of these units may vary from one commodity to another in such a way as to constitute weighting. It is, however, usual to describe an index as 'weighted' only when weighting coefficients enter explicitly into its definition and calculation.

WEIGHTED MINIMAL SET = ВЗВЕШЕННЫЙ МИНИМАЛЬНЫЙ НАБОР – A Weighted Minimal Set is a minimal set in which fields are weighted according to reliability in generating imputations. If fields (variables) are given weights, then it is the set of fields that give the minimum weight. There may be two of more sets that give the same minimum.

WEIGHTED MOVING AVERAGE = ВЗВЕШЕННАЯ СКОЛЬЗЯЩАЯ СРЕДНЯЯ ВЕЛИЧИНА (или ВЗВЕШЕННОЕ СКОЛЬЗЯЩЕЕ СРЕДНЕАРИФМЕТИЧЕСКОЕ) – Used in technical analysis, a Weighted Moving Average (WMA) gives a greater weighting to more recent price data, as opposed to a Simple Moving Average (SMA) that gives equal weighting to all prices. See also Moving Average, and Simple Moving Average. In technical analysis, a moving average that uses a selected time span, but gives greater weight to the more recent price data. A Weighted Moving Average (WMA) attaches greater weight to the most recent data. The weighting is calculated from the sum of days. Example:- For a 5-day weighted moving average the Sum of Days is 1 + 2 + 3 + 4 + 5 = 15. The weighting is shown below:- (i) Day 1, 2, 3, 4, 5; (ii) Price (USD) 16, 17, 17, 10, 17; (iii) Weighting 1/15, 2/15, 3/15, 4/15, 5/15; (iv) Weighted value 1.07, 2.27, 3.40, 2.67, 5.67; and (v) 5 Day WMA no, no, no, no, 15.07. Weighted values are calculated by multiplying today's price by 5/15, yesterday by 4/15, and so on. The weighted moving average is the sum of the 5 weighted values. Weighted Moving Average is the average of prices over a certain period, but weighted to give more importance to the latest price. So, if it were a 5-day MA, the latest price might be weighted by a factor of 5, yesterday's by a factor of 4, the day before by 3 times, the day before twice, and before that, the simple price. Different weighting systems can be used. A Weighted Moving Average is simply a moving average that is weighted so that more recent values are more heavily weighted than values further in the past. The commonest type of weighted moving average is exponential smoothing. The calculation is quite simple:- $P_0 + \alpha P_1 + \alpha^2 P_2 + \alpha^3 P_3 + \cdots + \alpha^n P_n + \cdots$; where α, the smoothing factor, is more than zero and less than one, P_0 is the latest value on which the moving average is being calculated, and P_i is the value i periods previously (usually i days ago). It is not necessary to sum the entire infinite series, just enough of it to give an accurate estimate. There is evidence that the use of weighted moving averages gives better volatility estimates than simple moving averages do. Weighted Moving Average (WMA) is calculated by like a Simple Moving Average (SMA) except that more weighting is

given to the more recent prices. The theory is that the older the price the less relevance (and hence weighting) it should have on the Moving Average (MA). / В техническом анализе биржевых рынков, под Взвешенной Скользящей Средней Величиной или Взвешенным Скользящим Среднеарифметическим понимается скользящая средняя величина или скользящее среднеарифметическое, взвешенное таким образом, что более недавние значения имеют большую весовую оценку, нежели более давние. интервал сглаживания (smoothing) или временной интервал; средняя арифметическая взвешенная; смещающиеся точки. Взвешенная Скользящая Средняя Величина или Взвешенное Скользящее Среднеарифметическое – среднее значение цен за определённый период, но утяжелённое с целью отражения большей значимости самой последней цены. Таким образом, при расчёте скользящей средней величины за 5 суток последней цене присваивается весовой коэффициент 5, вчерашней цене – весовой коэффициент 4, позавчерашней – 3, цене отмеченной три дня назад – 2, а в отношении цены, отмеченной раньше, весовой коэффициент не применяется. В расчётах могут использоваться разные системы взвешивания.

WEIGHTED SILK = ПРИВЕСНОЙ ШЁЛК (или УТЯЖЕЛЁННЫЙ ШЁЛК) – Weighted Silk is a fabric in which metallic salts have been added in the dyeing and finishing to increase its weight and to give a heavier hand. A ruling requires weighted silk to be marked and the amount of weighting indicated. Weighted Silk is a silk that has been treated with metallic salts during dyeing and finishing to increase the fabric's weight and improve its drape. Over-weighting can cause deterioration of the fabric. / Привесной Шёлк – шёлк, обработанный растворами металлических солей.

WEIGHTING = УТЯЖЕЛЕНИЕ (или УПЛОТНЕНИЕ) – Weighting is a process by which the weight of a fabric is increased by impregnating it with mineral salts, starch, or other materials. This process was often used on yardage that was sold by the pound, e.g., silk. Weighting:- finishing materials applied to a fabric to give increased weight. / Увеличение веса тканей отяжеляющими веществами (для фальсификации плотности и застила).

WEIGHTING BASE = ВЗВЕШИВАЮЩАЯ БАЗА – Weighting Base is the period to which the fixed weights relate.

WEIGHTING COEFFICIENT = ВЗВЕШИВАЮЩИЙ КОЭФФИЦИЕНТ – Weighting Coefficient is the coefficient attached to an observation as its weight in a procedure involving weighting.

WEIGHT LOAD FACTOR = ФАКТОР ЗАГРУЗКИ ПО ВЕСУ – Weight Load Factor:- payload achieved as against available, expressed as a percentage. Volume rather than weight frequently limit cargo; load factors of 100 percent are rarely achieved.

WEIGHT/MEASUREMENT = ВЕС/РАЗМЕР – Weight/Measurement (W/M):- basis of calculation of ocean freight charges, either on weight or on measurement, at ship's option.

WEIGHT/MEASUREMENT TON = ВЕСОВАЯ/МЕРНАЯ ТОННА – Weight/Measurement Ton:- in many cases, a rate is shown per weight/measurement ton, carrier's option. This means that the rate will be assessed on either a weight ton or measurement ton basis, whichever will yield the carrier the greater revenue. For example, the rate may be quoted on the basis of 2 240 pounds or 40 cubic feet or 1 metric ton or 1 cubic meter. / Соотношение Вес/Размерность – соотношение между весом и объёмом груза, учитываемое при расчёте транспортных расходов.

WEIGHT NOTE = ВЕСОВОЙ БИЛЕТ (или ВЕСОВАЯ НОТА) – Weight Note is a document issued by either the exporter or a third party declaring the weight of goods in a consignment. This must tally with the weight declared on the transport document and shown on the invoice. / Весовая Накладная – документ, выписываемый продавцом товаров, в котором перечисляется брутто вес упаковок товара. В весовой накладной также указывается маркировка, количество упаковок и средний вес тары. Весовой Сертификат или Отвес (Weight Note) – документ, подтверждающий массу поставленного товара и признающийся бесспорным доказательством массы. По согласованию заинтересованных сторон весовой сертификат составляется весовщиками в точках отгрузки, перевалки и выгрузки товара.

WEIGHT OF CLOTH = ВЕС ПОЛОТНА (или ВЕС ТКАНИ) – Weight Of Cloth:- this term describes the variety of ways that fabric is sold:- Ounces per linear yard, Yards per pound, and Ounces per square yard. Also known as Weight Of Fabric. / Известен также как Вес Ткани (Weight Of Fabric).

WEIGHT OF EVIDENCE = ВЕС ДОКАЗАТЕЛЬСТВА (или ВЕС ПОКАЗАНИЙ, или ХХ) – Weight Of Evidence:- an EPA classification system for characterizing the extent to which the available data indicate that an agent is a human carcinogen.

WEIGHT OF FABRIC = ВЕС ТКАНИ – Weight Of Fabric:- three methods are used to measure fabric weight:- (i) linear yards per pound; (ii) ounces per linear yard; and (iii) ounces per square yard. Also known as Weight Of Cloth. / В большинстве стран мира для определения веса ткани используются три метода:- (i) линейных ярдов на фунт или погонных ярдов на фунт (linear yards per pound); (ii) унций за линейный ярд или унций за погонный ярд (ounces per linear yard); и (iii) унций за квадратный ярд (ounces per square yard). В России для определения веса ткани используются граммы за квадратный метр. Кроме того, текстильщики в республиках (ныне самостоятельных странах) бывшего Союза Советских Социалистических Республик (СССР) вместо термина Вес Ткани использовали термин Поверхностная Плотность (Linear Density).

WEIGHT OR MEASUREMENT = ВЕС ИЛИ РАЗМЕРНОСТЬ – Weight or Measurement (W/M or WORM):- the basis for assessing freight charges. Also known as WORM. The rate charged under W/M will be whichever produces the highest revenue between the weight of the shipment and the measure of the shipment. The comparison is based on the number of metric tons the cargo weights compared to the number of cubic meters of space the cargo measures. The prior English method was one long ton compared to forty cubic feet. See also Freight.

WEIGHT REFERENCE PERIOD = СПРАВОЧНЫЙ ПЕРИОД ПО ВЕСУ – Weight Reference Period is the period whose value shares serve as weights for a set of price relatives or elementary price indices. It does not have to have the same duration as the periods for which the index is calculated and in the case of a Producer Price Index (PPI) is typically longer, a year or more, rather than a month or quarter. Nor does it have to be a single period as in the case of symmetric indices such as the Marshall Edgeworth, the Walsh and the Törnqvist price indices. / таких как индексы по ценам от Маршала Эдьжворса (Marshall Edgeworth), Волша (Walsh) и Тонкиста (Törnqvist).

WEIGHTS = ВЕСА – Weights:- the importance of an object in relation to a set of objects to which it belongs; a numerical coefficient attached to an observation, frequently by multiplication, in order that it shall assume a desired degree of importance in a function of all the observations of the set. Reweighting consists of raising the original weights for the respondent values when estimates are computed. Reweighting concerns mainly unit non-response. It may also be used to increase precision through the use of auxiliary information. Standard methods include post-stratification, calibration and response propensity modelling. Weights:- within the OECD's (short for the Organisation for Economic Co-operation and Development) list of Metadata Types refers to information on sources of weights, nature of weights, period of current index weights, frequency of weight updates, weights (other).

WEIGHTS AND MEASURES = ВЕСА И МЕРЫ – Weights and Measures:- in many cases, a rate is shown per weight/measurement ton, carrier's option. This means that the rate will be assessed on either a weight ton or measurement ton basis, whichever will yield the carrier the greater revenue. For example, the rate may be quoted based on 2 240 pounds, 40 cubic feet, one metric ton, or one cubic meter. (5) Weight Ton:- there are three types of weight ton:- the short ton, weighing 2 000 pounds; the long ton, weighing 2 240 pounds; and the metric ton weighing 2 204.68 pounds. The last is frequently quoted for cargo being exported from Europe. Measurement ton:- (i) 40 cubic ft or one cubic meter; (ii) Net ton/Short ton – 2 000 lbs; (iii) Gross ton/Long ton – 2 204.68 lbs; (iv) Metric ton/Kilo ton – 2 204.68 lbs; and (v) Cubic Meter – 35.314 cubic ft. Weights:- (i) Gross Ton/Long Ton:- 2 240 lbs. (1 016 kg); (ii) Net Ton/Short Ton:- 2 000 lbs (907.19 kg); (iii) Metric/Kilo Ton:- 2 204.68 lbs (1 000 kg); and (iv) Measurement Ton:- 40 cubic ft or one cubic meter. Weights And Measures:- the standard or agreed upon units for expressing the amount of some quantity, such as capacity, volume, length, area, number, and weight. See also Measurement System. / Веса И Меры – стандарты при измерениях, анализе и испытаниях.

WEIGHTS AND MEASURES/MEASUREMENT TON = ВЕСА И МЕРЫ/ОБМЕРНАЯ ТОННА – Weights and Measures/Measurement Ton:- (i) 40 cubic ft or one cubic meter; (ii) Net ton/short ton – 2 000 lbs; (iii) Gross ton/long ton – 2 240 lbs; (iv) Metric ton/kilo ton – 2 204.6 lbs; and (v) Cubic meter – 35.314 cubic ft. See also Measurement Ton. / Смотрите также Обмерная Тонна (Measurement Ton).

WEIGHT SEPARATOR = УСТАНОВКА ДЛЯ ОТДЕЛЕНИЯ ТЯЖЁЛЫХ ПРИМЕСЕЙ – In spinning process, Weight Separator is used for excluding most of trash and abnormal matter in fiber tuft. When cotton pass through bridge-magnet, iron-trash is removed at the same time. Weight separator, working in fiber current, is made up of adjustation grid bar. When cotton fiber contact grid bar, trash is separated from fiber tuft due to difference of centrifugal force then sucked away through dust pipe. / В прядильном производстве.

WEIGHT SHEET = ВЕСОВОЙ ЛИСТ – Weight Sheet:- xxxxx. / Весовая Спецификация (Weight Sheet) – попредметный список, представляемый грузоотправителем весовой конторе с указанием грузов в каждой отправке.

WEIGHTS, MEASURES, AND CONVERSION FACTORS = ВЕСА, МЕРЫ И ФАКТОРЫ ПЕРЕСЧЁТА – Weights, Measures, And Conversion Factors:- standard weights:- gallon of milk = 8.6 pounds bushel of Virginia Peanuts = 17 pounds bushel of Runners Peanuts = 21 pounds bushel of Spanish Peanuts = 25 pounds bushel of sunflowerseed = 28 pounds bushel of Oats and cottonseed = 32 pounds bushel of malt = 34 pounds bushel of safflowerseed = 40 pounds bushel of Rice = 45 pounds bushel of Barley (grain) = 48 pounds bushel of rapeseed and Canola = 50 pounds bushel of Mustard seed = 54 pounds bushel of Corn, grain Sorghum, flaxseed, or Rye = 56 pounds bushel of Wheat or Soybeans = 60 pounds bale of Cotton (net) = 480 pounds bale of Cotton (gross) = 500 pounds hogshead of Maryland Tobacco = 775 pounds hogshead of Flue-cured Tobacco = 950 pounds hogshead of Burley Tobacco = 975 pounds hogshead of Air-cured (dark) Tobacco = 1 150 pounds hogshead of Fire-cured Tobacco = 1 500 pounds. As an example, to convert bushels of Wheat to metric tons of 2 204 pounds each, divide 2 204 by the above bushel weights. For example, 2 204 / 60 = 36.7 bushels of Wheat in one metric ton. Given the number of bushels of Wheat, divide this figure by 36.7 to get the number of metric tons. For example, if the US Wheat crop is approximately 2.5 billion bushels, this is equivalent to approximately 68 million metric tons (2.5 billion bushels / 36.7 = 68.12 million metric tons). To convert metric tons to bushels, multiply tons by the number of bushels in each ton. For example, if the Wheat crop in India is reported to be 50 million metric tons, this is equivalent to approximately 1.835 billion bushels (50 million metric tons x 36.7 = 1.835 billion bushels).

WEIGHT TICKET = ВЕСОВАЯ КВИТАНЦИЯ (или ВЕСОВОЙ БИЛЕТ) – Weight Ticket:- you must base your freight bill charges upon the re-weigh weight. You must obtain weight tickets whenever we require you to weigh the shipment in accordance with this subpart. You must obtain a separate weight ticket for each weighing. The weigh master must sign each weight ticket. Each weight ticket must contain the following six items:- (i) the complete name and location of the scale; (ii) the date of each weighing; (iii) the identification of the weight entries as being the tare, gross, or net weights; (iv) the company or carrier identification of the vehicle; (v) the last name of the individual shipper as it appears on the bill of lading; and (vi) the carrier's shipment registration or bill of lading number. When both weighings are performed on the same scale, one weight ticket may be used to record both weighings. As part of the file on the shipment, you must retain the original weight ticket or tickets relating to the determination of the weight of a shipment. All freight bills you present to an individual shipper must include true copies of all weight tickets obtained in the determination of the shipment weight in order to collect any shipment charges dependent upon the weight transported. See also Scale Ticket, and Weight Certificate.

WEIGHT TON = ВЕСОВАЯ ТОННА (или ТОННА ВЕСА) – Weight Ton:- there are three types of weight tons:- (1) the short ton, weighing 2 000 pounds; (2) the long ton, weighing 2 240 pounds; and (3) the Metric ton, weighing 2 204.68 pounds. The last is frequently quoted for cargo being exported from Europe. Weight Ton is a ton of 1 000 kilos. Weight Ton:- in shipping industry, three types of tons are used:- (i) long ton (2 240 pounds); (ii) short ton (2 000 pounds); and (iii) Metric ton (1 000 kilograms or 2 204.68 pounds). / Тонна, насчитывающая 1 000 килограмм.

WEIGHT UNIT QUALIFIER = КВАЛИФИКАТОР ЕДИНИЦЫ ВЕСА (или XX) – Weight Unit Qualifier:- the unit of measure that the user wants to see for weight.

WEIGHT/VOLUME = ВЕС/ОБЪЁМ – Weight/Volume (W/V):- solutions are sometimes specified as being made as some percentage weight/volume. This means that the substance dissolved is measured by weight, and the final solution is measured by volume. For example, 5% sodium chloride w/v would mean that 5 grams of salt would be dissolved in enough water to make a total solution volume of 100 milliliters (or, say, 150 g to make 3 liters, etc), and would be labeled 'Sodium chloride 5% w/v'. Solutions are most commonly made this way, and it can be assumed to be this way unless otherwise specified. See also Weight By Volume; and Weight/Weight. w/v is an abbreviation for Weight By Volume, a slightly confusing phrase used in chemistry and pharmacology to describe the concentration of a substance in a mixture or solution. The weight by volume is the mass (in grams) of the substance dissolved in or mixed with 100 milliliters of solution or mixture. For example, the concentration of fluoride in toothpaste is usually about 0.15% w/v, meaning that there is 0.15 gram of fluoride per 100 milliliters of toothpaste. Thus 1% w/v is equal to 1 gram per deciliter (g/dL) or 10 grams per liter (g/L).

WEIGHT/WEIGHT = ВЕС/ВЕС – Weight/Weight (W/W):- solutions are sometimes specified as being made as some percentage weight/weight. Both the substance dissolved and the final solution are measured by weight. For example, a 10% solution of urea w/w would be made by dissolving one pound of urea in 9 pounds of water, and would be labeled 'Urea 10% w/w'. This method is sometimes preferred in industry since automatic mixing equipment is often designed to handle everything by weight rather than volume. See also Weight/Volume. See also By Weight. w/w is an abbreviation for By Weight, used in chemistry and pharmacology to describe the concentration of a substance in a mixture or solution. Properly speaking, 2% w/w means that the mass of the substance is 2% of the total mass of the solution or mixture. The metric symbol g/g has the same meaning as w/w.

WEIR = ПЛОТИНА – Weir is a dam in a waterway over which water flows and that serves to raise the water level or to direct or regulate flow. See also Low Water Dam. Weir:- any control or barrier placed in an open channel to permit measurement of water

discharge. The latter may be computed from a formula expressing the discharge in terms of crest length of the weir, depth of flow above the weir, weir geometry, and other factors. A variety of weirs have been used in streams, the so-called sharp-crested and trapezoidal forms being relatively common; but broad-crested, triangular, and contracted weirs are also favoured in certain circumstances. Spillways, controls, and embankments designed to permit discharge measurements are simply different kinds of broad-crested weirs.

WELCHER = КИДАЛЬЩИК – Welcher is a someone who refuses to pay his or her debts after a bet. For example, I bet him USD20 that the Dallas Cowboys would beat the Washington Redskins and when they did the welcher refused to pay. / непорядочный партнёр.

WELDED SHELL = ПРИВАРЕННАЯ ОБОЛОЧКА – Welded Shell is the outer layer of a bonded wor welded garment, such as a jacket.

WELDING = СВАРКА – Welding:- technique used for joining metallic parts usually through the application of heat. This technique was discovered during efforts to manipulate iron into useful shapes. Welded blades were developed in the first millennium AD, the most famous being those produced by Arab armourers at Damascus, Syria. The process of carburization of iron to produce hard steel was known at this time, but the resultant steel was very brittle. The welding technique – which involved interlayering relatively soft and tough iron with high-carbon material, followed by hammer forging – produced a strong, tough blade. In modern times the improvement in iron-making techniques, especially the introduction of cast iron, restricted welding to the blacksmith and the jeweler. Other joining techniques, such as fastening by bolts or rivets, were widely applied to new products, from bridges and railway engines to kitchen utensils. Modern fusion welding processes are an outgrowth of the need to obtain a continuous joint on large steel plates. Rivetting had been shown to have disadvantages, especially for an enclosed container such as a boiler. Gas welding, arc welding, and resistance welding all appeared at the end of the XIX century. The first real attempt to adopt welding processes on a wide scale was made during World War I. By 1916 the oxyacetylene process was well developed, and the welding techniques employed then are still used. The main improvements since then have been in equipment and safety. Arc welding, using a consumable electrode, was also introduced in this period, but the bare wires initially used produced brittle welds. A solution was found by wrapping the bare wire with asbestos and an entwined aluminum wire. The modern electrode, introduced in 1907, consists of a bare wire with a complex coating of minerals and metals. Arc welding was not universally used until World War II, when the urgent need for rapid means of construction for shipping, power plants, transportation, and structures spurred the necessary development work. Resistance welding, invented in 1877 by Elihu Thomson, was accepted long before arc welding for spot and seam joining of sheet. Butt welding for chain making and joining bars and rods was developed during the 1920s. In the 1940s the tungsten-inert gas process, using a nonconsumable tungsten electrode to perform fusion welds, was introduced. In 1948 a new gas-shielded process utilized a wire electrode that was consumed in the weld. More recently, electron-beam welding, laser welding, and several solid-phase processes such as diffusion bonding, friction welding, and ultrasonic joining have been developed. Basic Principles Of Welding:- a weld can be defined as a coalescence of metals produced by heating to a suitable temperature with or without the application of pressure, and with or without the use of a filler material. In fusion welding a heat source generates sufficient heat to create and maintain a molten pool of metal of the required size. The heat may be supplied by electricity or by a gas flame. Electric resistance welding can be considered fusion welding because some molten metal is formed. Solid-phase processes produce welds without melting the base material and without the addition of a filler metal. Pressure is always employed, and generally some heat is provided. Frictional heat is developed in ultrasonic and friction joining, and furnace heating is usually employed in diffusion bonding. The electric arc used in welding is a high-current, low-voltage discharge generally in the range 10–2 000 Amperes at 10–50 Volts. An arc column is complex but, broadly speaking, consists of a cathode that emits electrons, a gas plasma for current conduction, and an anode region that becomes comparatively hotter than the cathode due to electron bombardment. Therefore, the electrode, if consumable, is made positive and, if nonconsumable, is made negative. A direct current (dc) arc is usually used, but alternating current (ac) arcs can be employed. Total energy input in all welding processes exceeds that which is required to produce a joint, because not all the heat generated can be effectively utilized. Efficiencies vary from 60 to 90 percent, depending on the process; some special processes deviate widely from this figure. Heat is lost by conduction through the base metal and by radiation to the surroundings. Most metals, when heated, react with the atmosphere or other nearby metals. These reactions can be extremely detrimental to the properties of a welded joint. Most metals, for example, rapidly oxidize when molten. A layer of oxide can prevent proper bonding of the metal. Molten-metal droplets coated with oxide become entrapped in the weld and make the joint brittle. Some valuable materials added for specific properties react so quickly on exposure to the air that the metal deposited does not have the same composition as it had initially. These problems have led to the use of fluxes and inert atmospheres. In fusion welding the flux has a protective role in facilitating a controlled reaction of the metal and then preventing oxidation by forming a blanket over the molten material. Fluxes can be active and help in the process or inactive and simply protect the surfaces during joining. Inert atmospheres play a protective role similar to that of fluxes. In gas-shielded metal-arc and gas-shielded tungsten-arc welding an inert gas – usually argon – flows from an annulus surrounding the torch in a continuous stream, displacing the air from around the arc. The gas does not chemically react with the metal but simply protects it from contact with the oxygen in the air. The metallurgy of metal joining is important to the functional capabilities of the joint. The arc weld illustrates all the basic features of a joint. Three zones result from the passage of a welding arc:- (i) the weld metal, or fusion zone, (ii) the heat-affected zone, and (iii) the unaffected zone. The weld metal is that portion of the joint that has been melted during welding. The heat-affected zone is a region adjacent to the weld metal that has not been welded but has undergone a change in microstructure or mechanical properties due to the heat of welding. The unaffected material is that which was not heated sufficiently to alter its properties. Weld-metal composition and the conditions under which it freezes (solidifies) significantly affect the ability of the joint to meet service requirements. In arc welding, the weld metal comprises filler material plus the base metal that has melted. After the arc passes, rapid cooling of the weld metal occurs. A one-pass weld has a cast structure with columnar grains extending from the edge of the molten pool to the center of the weld. In a multipass weld, this cast structure may be modified, depending on the particular metal that is being welded. The base metal adjacent to the weld, or the heat-affected zone, is subjected to a range of temperature cycles, and its change in structure is directly related to the peak temperature at any given point, the time of exposure, and the cooling rates. The types of base metal are too numerous to discuss here, but they can be grouped in three classes:- (i) materials unaffected by welding heat, (ii) materials hardened by structural change, and (iii) materials hardened by precipitation processes. Welding produces stresses in materials. These forces are induced by contraction of the weld metal and by expansion and then contraction of the heat-affected zone. The unheated metal imposes a restraint on the above, and as contraction predominates, the weld metal cannot contract freely, and a stress is built up in the joint. This is generally known as Residual Stress, and for some critical applications must be removed by heat treatment of the whole fabrication. Residual stress is unavoidable in all welded structures, and if it is not controlled bowing or distortion of the weldment will take place. Control is exercised by welding technique, jigs and fixtures, fabrication procedures, and final heat treatment. There are a wide variety of welding processes. Several of the most important are discussed below. Forge Welding:- this original fusion technique dates from the earliest uses of iron. The process was first employed to make small pieces of iron into larger useful pieces by joining them. The parts to be joined were first shaped, then heated to welding temperature in a forge and finally hammered or pressed together. The Damascus

sword, for example, consisted of wrought-iron bars hammered until thin, doubled back on themselves, and then rehammered to produce a forged weld. The larger the number of times this process was repeated, the tougher the sword that was obtained. In the Middle Ages cannons were made by welding together several iron bands, and bolts tipped with steel fired from crossbows were fabricated by forge welding. Forge welding has mainly survived as a blacksmith's craft and is still used to some extent in chain making. Arc Welding:- shielded metal-arc welding accounts for the largest total volume of welding today. In this process an electric arc is struck between the metallic electrode and the workpiece. Tiny globules of molten metal are transferred from the metal electrode to the weld joint. Since arc welding can be done with either alternating or direct current, some welding units accommodate both for wider application. A holder or clamping device with an insulated handle is used to conduct the welding current to the electrode. A return circuit to the power source is made by means of a clamp to the workpiece. Gas-shielded arc welding, in which the arc is shielded from the air by an inert gas such as argon or helium, has become increasingly important because it can deposit more material at a higher efficiency and can be readily automated. The tungsten electrode version finds its major applications in highly alloyed sheet materials. Either direct or alternating current is used, and filler metal is added either hot or cold into the arc. Consumable electrode gas-metal arc welding with a carbon dioxide shielding gas is widely used for steel welding. Two processes known as Spray Arc and Short-Circuiting Arc are utilized. Metal transfer is rapid, and the gas protection ensures a tough weld deposit. Submerged arc welding is similar to the above except that the gas shield is replaced with a granulated mineral material as a flux, which is mounded around the electrode so that no arc is visible. Plasma welding is an arc process in which a hot plasma is the source of heat. It has some similarity to gas-shielded tungsten-arc welding, the main advantages being greater energy concentration, improved arc stability, and easier operator control. Better arc stability means less sensitivity to joint alignment and arc length variation. In most plasma welding equipment, a secondary arc must first be struck to create an ionized gas stream and permit the main arc to be started. This secondary arc may utilize either a high-frequency or a direct contact start. Water cooling is used because of the high energies forced through a small orifice. The process is amenable to mechanization, and rapid production rates are possible. Thermochemical Processes:- one such process is gas welding. It once ranked as equal in importance to the metal-arc welding processes but is now confined to a specialized area of sheet fabrication and is probably used as much by artists as in industry. Gas welding is a fusion process with heat supplied by burning acetylene in oxygen to provide an intense, closely controlled flame. Metal is added to the joint in the form of a cold filler wire. A neutral or reducing flame is generally desirable to prevent base-metal oxidation. By deft craftsmanship very good welds can be produced, but welding speeds are very low. Fluxes aid in preventing oxide contamination of the joint. Another thermochemical process is aluminothermic (thermite) joining. It has been successfully used for both ferrous and nonferrous metals but is more frequently used for the former. A mixture of finely divided aluminum and iron oxide is ignited to produce a superheated liquid metal at about 2 800 °C (5 000 °F). The reaction is completed in 30 seconds to 2 minutes regardless of the size of the charge. The process is suited to joining sections with large, compact cross sections, such as rectangles and rounds. A mold is used to contain the liquid metal. Resistance Welding:- spot, seam, and projection welding are resistance welding processes in which the required heat for joining is generated at the interface by the electrical resistance of the joint. Welds are made in a relatively short time (typically 0.2 seconds) using a low-voltage, high-current power source with force applied to the joint through two electrodes, one on each side. Spot welds are made at regular intervals on sheet metal that has an overlap. Joint strength depends on the number and size of the welds. Seam welding is a continuous process wherein the electric current is successively pulsed into the joint to form a series of overlapping spots or a continuous seam. This process is used to weld containers or structures where spot welding is insufficient. A projection weld is formed when one of the parts to be welded in the resistance machine has been dimpled or pressed to form a protuberance that is melted down during the weld cycle. The process allows a number of predetermined spots to be welded at one time. All of these processes are capable of very high rates of production with continuous quality control. The most modern equipment in resistance welding includes complete feedback control systems to self-correct any weld that does not meet the desired specifications. Flash welding is a resistance welding process where parts to be joined are clamped, the ends brought together slowly and then drawn apart to cause an arc or flash. Flashing or arcing is continued until the entire area of the joint is heated; the parts are then forced together and pressure maintained until the joint is formed and cooled. Low- and high-frequency resistance welding is used for the manufacture of tubing. The longitudinal joint in a tube is formed from metal squeezed into shape with edges abutted. Welding heat is governed by the current passing through the work and the speed at which the tube goes through the rolls. Welding speeds of 60 m (200 feet) per minute are possible in this process. Electron-Beam Welding:- in electron-beam welding, the workpiece is bombarded with a dense stream of high-velocity electrons. The energy of these electrons is converted to heat upon impact. A beam-focusing device is included, and the workpiece is usually placed in an evacuated chamber to allow uninterrupted electron travel. Heating is so intense that the beam almost instantaneously vaporizes a hole through the joint. Extremely narrow deep-penetration welds can be produced using very high voltages – up to 150 kiloVolts. Workpieces are positioned accurately by an automatic traverse device; for example, a weld in material 13 mm (0.5 inch) thick would only be 1 mm (0.04 inch) wide. Typical welding speeds are 125 to 250 cm (50 to 100 inches) per minute. Cold Welding:- cold welding, the joining of materials without the use of heat, can be accomplished simply by pressing them together. Surfaces have to be well prepared, and pressure sufficient to produce 35 to 90 percent deformation at the joint is necessary, depending on the material. Lapped joints in sheets and cold-butt welding of wires constitute the major applications of this technique. Pressure can be applied by punch presses, rolling stands, or pneumatic tooling. Pressures of 1 400 000 to 2 800 000 kiloPascals (200 000 to 400 000 pounds per square inch) are needed to produce a joint in aluminum; almost all other metals need higher pressures. Friction Welding:- in friction welding two workpieces are brought together under load with one part rapidly revolving. Frictional heat is developed at the interface until the material becomes plastic, at which time the rotation is stopped and the load is increased to consolidate the joint. A strong joint results with the plastic deformation, and in this sense the process may be considered a variation of pressure welding. The process is self-regulating, for, as the temperature at the joint rises, the friction coefficient is reduced and overheating cannot occur. The machines are almost like lathes in appearance. Speed, force, and time are the main variables. The process has been automated for the production of axle casings in the automotive industry. Laser Welding:- laser welding is accomplished when the light energy emitted from a laser source is focused upon a workpiece to fuse materials together. The limited availability of lasers of sufficient power for most welding purposes has so far restricted its use in this area. Another difficulty is that the speed and the thickness that can be welded are controlled not so much by power but by the thermal conductivity of the metals and by the avoidance of metal vaporization at the surface. Particular applications of the process with very thin materials up to 0.5 mm (0.02 inch) have, however, been very successful. The process is useful in the joining of miniaturized electrical circuitry. Diffusion Bonding:- this type of bonding relies on the effect of applied pressure at an elevated temperature for an appreciable period of time. Generally, the pressure applied must be less than that necessary to cause 5 percent deformation so that the process can be applied to finished machine parts. The process has been used most extensively in the aerospace industries for joining materials and shapes that otherwise could not be made, for example, multiple-finned channels and honeycomb construction. Steel can be diffusion bonded at above 1 000 °C (1 800 °F) in a few minutes. Ultrasonic Welding:- ultrasonic joining is achieved by clamping the two pieces to be welded between an anvil and a vibrating probe or sonotrode. The vibration raises the temperature at the interface and produces the weld. The main variables are the clamping force, power input, and welding time. A weld can be made in 0.005 second on thin wires and up to 1 second with material 1.3 mm (0.05 inch) thick. Spot welds and continuous seam welds are made with good reliability.

Applications include extensive use on lead bonding to integrated circuitry, transistor canning, and aluminum can bodies. Explosive Welding:- explosive welding takes place when two plates are impacted together under an explosive force at high velocity. The lower plate is laid on a firm surface, such as a heavier steel plate. The upper plate is placed carefully at an angle of approximately 5° to the lower plate with a sheet of explosive material on top. The charge is detonated from the hinge of the two plates, and a weld takes place in microseconds by very rapid plastic deformation of the material at the interface. A completed weld has the appearance of waves at the joint caused by a jetting action of metal between the plates. Weldability Of Metals:- carbon and low-alloy steels are by far the most widely used materials in welded construction. Carbon content largely determines the weldability of plain carbon steels; at above 0.3 percent carbon some precautions have to be taken to ensure a sound joint. Low-alloy steels are generally regarded as those having a total alloying content of less than 6 percent. There are many grades of steel available, and their relative weldability varies. Aluminum and its alloys are also generally weldable. A very tenacious oxide film on aluminum tends to prevent good metal flow, however, and suitable fluxes are used for gas welding. Fusion welding is more effective with alternating current when using the gas-tungsten arc process to enable the oxide to be removed by the arc action. Copper and its alloys are weldable, but the high thermal conductivity of copper makes welding difficult. Refractory metals such as zirconium, niobium, molybdenum, tantalum, and tungsten are usually welded by the gas-tungsten arc process. Nickel is the most compatible material for joining, is weldable to itself, and is extensively used in dissimilar metal welding of steels, stainlesses, and copper alloys. Welding:- there are two basic methods for applying bonding or welded seams. The first method uses an adhesive film, and the application of heat to glue or laminate two substrates together. The second method involves gluing or attaching two fabrics, using ultrasonic technology. The creation and channeling of high frequency vibratory waves cause a rapid buildup of heat in synthetic fabrics to create the bonding. Welding:- one of the most significant changes in the technology of metals fabrication has been the introduction of fusion welding during the XX century. Before this, the main joining processes were riveting and forge welding. Both had limitations of scale, although they could be used to erect substantial structures. In 1895 Henry-Louis Le Chatelier stated that the temperature in an oxyacetylene flame was 3 500 °C (6 300 °F), some 1 000 °C higher than the oxyhydrogen flame already in use on a small scale for brazing and welding. The first practical oxyacetylene torch, drawing acetylene from cylinders containing acetylene dissolved in acetone, was produced in 1901. With the availability of oxygen at even lower cost, oxygen cutting and oxyacetylene welding became established procedures for the fabrication of structural steel components. The metal in a join can also be melted by an electric arc, and a process using a carbon as a negative electrode and the workpiece as a positive first became of commercial interest about 1902. Striking an arc from a coated metal electrode, which melts into the join, was introduced in 1910. Although it was not widely used until some 20 years later, in its various forms it is now responsible for the bulk of fusion welds. / , изобретённая в 1877 родившимся в Англии Американским инженером и изобретателем Элихью Тчомсэн (Elihu Thomson; 1853-Март-29–1937-Март-13), . Под Сваркой понимается процесс получения неразъёмных соединений металлических деталей при их местном нагреве. Сварка – процесс получения неразъёмного соединения деталей машин, конструкций и сооружений при их местном или общем нагреве, пластическом деформировании или при совместном действии того и другого в результате установления межатомных связей в месте их соединения. Сваривают детали из металлов, керамических материалов, пластмасс, стекла, биологической ткани и другого. Существуют способы сварки, при которых материал расплавляется (дуговая, электрошлаковая, электроннолучевая, плазменная, лазерная, газовая и другие), нагревается и пластически деформируется (контактная, высокочастотная, газопрессовая и другие) или деформируется без нагрева (холодная, взрывом и другие), способ диффузионного соединения в вакууме. Различают также сварку:- (i) по виду используемого источника энергии – дуговая, газовая, электроннолучевая и другие; (ii) по способу защиты материала – под флюсом, в защитных газах, вакууме и другие; (iii) по степени механизации – ручная, полуавтоматическая и автоматическая.

WELFARE = ПОСОБИЕ – Welfare is the organized public or private social services for the assistance of disadvantaged groups. Aid could include general Welfare payments, health care through Medicaid, food stamps, special payments for pregnant women and young mothers, and federal and state housing benefits. The Welfare system in the United States began in the 1930s, during the Great Depression. Opponents of Welfare argue that it affects work incentives. Social Welfare can be taken to mean 'the welfare or well-being of a society'. In economics, the utility of people considered in aggregate. For social welfare in the economic sense, see Welfare Economics and Social Welfare Function. The provision of a wide range of social services, for the benefit of individual citizens. This usage is closely related to the idea of the welfare state. Welfare is the provision of a minimal level of well-being and social support for all citizens, sometimes referred to as Public Aid. In most developed countries, welfare is largely provided by the government, in addition to charities, informal social groups, religious groups, and inter-governmental organizations. The welfare state expands on this concept to include services such as universal healthcare. In the United States, Welfare is most often used to refer to means-tested cash benefits, especially the Aid to Families with Dependent Children (AFDC) program and its successor, the Temporary Assistance for Needy Families Block Grant. Sometimes, especially by critics of government social spending, it is used to refer to all means tested programs, including for example, healthcare through Medicaid and food and nutrition programs (SNAP (short for the Supplemental Nutrition Assistance Program)). AFDC (originally called Aid to Dependent Children) ADC was created during the Great Depression to alleviate the burden of poverty of families with children and allow widowed mothers to maintain their households. (New Deal employment program such as the Progress Administration primarily served men.) Prior to the New Deal, anti-poverty programs were primarily operated by private charities or state or local governments; however, these programs were overwhelmed by the depth of need during the Depression. The United States has no national program of cash assistance for non-disabled poor individuals who are not raising children. The exception to this is permanent alimony, which is still administered in a handful of states including New Jersey, Florida and Oregon. Alimony Reform movements in these states are attempting to end this form of private welfare. In 1996, the Personal Responsibility and Work Opportunity Reconciliation Act changed the structure of Welfare payments and added new criteria to states that received Welfare funding. After reforms, which President Clinton said would 'end Welfare as we know it', amounts from the federal government were given out in a flat rate per state based on population. Each state must meet certain criteria to ensure recipients are being encouraged to work themselves out of Welfare. The new program is called Temporary Assistance for Needy Families (TANF). It encourages states to require some sort of employment search in exchange for providing funds to individuals, and imposes a five-year lifetime limit on cash assistance. In FY 2010, 31.8% of TANF families were white, 31.9% were African-American, and 30.0% were Hispanic. According to the US Census Bureau data released September 13, 2011, the nation's poverty rate rose to 15.1% (46.2 million) in 2010, up from 14.3% (approximately 43.6 million) in 2009 and to its highest level since 1993. In 2008, 13.2% (39.8 million) Americans lived in relative poverty. / Президент Бил Клынтчэн (Bill Clinton). Хиллари Клынтчэн (Hillary Clinton). В России пособие назначается:- (i) единовременные пособия, например, на рождение ребёнка; (ii) многодетным и одиноким матерям; (iii) на детей в малообеспеченных семьях; (iv) на детей военнослужащих срочной службы; (v) по безработице; (vi) по беременности и родам

(всем женщинам в размере, устанавливаемом законом); (vii) по временной нетрудоспособности (при болезни, увечье, при уходе за больным членом семьи, карантине и в некоторых других случаях). В ряде случаев назначается инвалидам и престарелым, не имеющим права на государственную пенсию.

WELFARE ECONOMICS = ЭКОНОМИКА БЛАГОСОСТОЯНИЯ (или ЭКОНОМИЧЕСКАЯ ТЕОРИЯ БЛАГОСОСТОЯНИЯ) – Welfare Economics is a branch of economics dealing with human welfare, the defining of wealth, and the establishment of guides for social policy aiming at the maximization of total individual utilities. Welfare Economics:- branch of economics that seeks to evaluate economic policies in terms of their effects on the well-being of the community. It became established as a well-defined branch of economic theory during the XX century. Earlier writers conceived of welfare as simply the sum of the satisfactions accruing to all individuals within an economic system. Later theorists became skeptical of the possibility of measuring even one person's satisfactions and argued that it was impossible to compare with precision the states of well-being of two or more individuals. In simple terms, the long-standing assumption that a poor man would derive more additional satisfaction than a rich man from any given increase in income could not be precisely maintained. On the level of social policy, this meant that measures redistributing resources from rich to poor (as in the case of progressive income taxation) could not be said to increase the sum of individual satisfactions. A new and more limited criterion was then developed for judging economic policy:- one economic situation was judged superior to another only if at least one person had been made better off without anyone else being made worse off. Alternatively, one economic state might be judged superior to a previous one even though some consumers were made worse off if the gainers could compensate the losers and still be better off than before. There would, however, be no way of judging among several alternatives of which all fulfilled this condition. Welfare Economics:- cost-benefit analysis of the allocation of resources, economic activity, and distribution of the resulting output on a society's welfare. See also Welfare State. Welfare Economics is a branch of economics that focuses on the optimal allocation of resources and goods and how this affects social welfare. Welfare economics analyzes the total good or welfare that is achieve at a current state as well as how it is distributed. This relates to the study of income distribution and how it affects the common good. Welfare economics is a subjective study that may assign units of welfare or utility in order to create models that measure the improvements to individuals based on their personal scales. Welfare economics uses the perspective and techniques of microeconomics, but they can be aggregated to make macroeconomic conclusions. Because different 'optimal' states may exist in an economy in terms of the allocation of resources, welfare economics seeks the state that will create the highest overall level of social welfare. Some people object to the idea of wealth redistribution because it flies in the face of pure capitalist ideals, but economists suggest that greater states of overall social good might be achieved by redistributing incomes in the economy. / Экономика Благосостояния – раздел экономической науки, изучающий нормативные вопросы (смотрите Нормативная Экономика (Normative Economics)), относящиеся к благосостоянию общества в целом; в частности, эта теория старается классифицировать различные способы распределения ресурсов в терминах благосостояния. К сожалению, единственным общепризнанным критерием для альтернатив является Оптимальность по Парето (Pareto Optimality), которая крайне недостаточна для вынесения суждения. Таким образом, хотя экономическая теория благосостояния связана с такими важными вопросами, как налогообложение, распределение, регулирование внешних эффектов экономической деятельности, государственная политика и так далее, её практическое использование весьма ограничено.

WELFARE STATE = СОЦИАЛЬНО ОБЕСПЕЧЕННОЕ ГОСУДАРСТВО (или ГОСУДАРСТВО БЛАГОСОСТОЯНИЯ, или ГОСУДАРСТВО ВСЕОБЩЕГО БЛАГОДЕНСТВИЯ) – Welfare State is a state whose government devotes a very large proportion of its activities and expenditures to the direct provision of personal benefits to be consumed by qualifying individuals or families (as contrasted with such more traditional and less individually divisible government activities as national defense, law enforcement, controlling the money supply, economic regulation, maintaining transportation and communications nets, administering the public lands, etc). Welfare benefits to individuals may be in the form either of bureaucratically supplied professional services of government employees or in the form of government-issued stipends or allowances or subsidies (transfer payments) to help qualifying households pay for general subsistence or for specific categories of state-favored expenses (merit goods). Examples of such social welfare programs would include old age and disability pensions, unemployment benefits, aid to families with dependent children, income supplements for the poor, public housing and housing vouchers, health care provided in state hospitals or clinics and reimbursement for the costs of privately-provided health care, government-funded drug abuse rehabilitation programs, food stamps, public education and child care, etc. Advocacy of extensive 'Welfare State' programs was at first associated mainly with socialist movements, but in most Western industrial societies today many welfare state programs are endorsed as well by non-socialist parties that nevertheless still continue to reject the socialists' traditional demands for much more extensive state ownership, state planning, and state administration of industry and commerce. Xxxx. Welfare State:- concept of government in which the state plays a key role in the protection and promotion of the economic and social well-being of its citizens. It is based on the principles of equality of opportunity, equitable distribution of wealth, and public responsibility for those unable to avail themselves of the minimal provisions for a good life. The general term may cover a variety of forms of economic and social organization. A fundamental feature of the welfare state is social insurance, a provision common to most advanced industrialized countries (e.g., National Insurance in the United Kingdom, Old-Age, Survivors, Disability, and Health Insurance in the United States). Such insurance is usually financed by compulsory contributions and is intended to provide benefits to persons and families during periods of greatest need. It is widely recognized, however, that in practice these cash benefits fall considerably short of the levels intended by the designers of the plans. The welfare state also usually includes public provision of basic education, health services, and housing (in some cases at low cost or without charge). In these respects the welfare state is considerably more extensive in western European countries than in the United States, featuring in many cases comprehensive health coverage and provision of state-subsidized tertiary education. Antipoverty programs and the system of personal taxation may also be regarded as aspects of the welfare state. Personal taxation falls into this category insofar as its progressivity is used to achieve greater justice in income distribution (rather than merely to raise revenue) and also insofar as it used to finance social insurance payments and other benefits not completely financed by compulsory contributions. In socialist countries the welfare state also covers employment and administration of consumer prices. The modern use of the term is associated with the comprehensive measures of social insurance adopted in 1948 by Great Britain on the basis of the report on Social Insurance and Allied Services (1942) by Sir William (later Lord) Beveridge. In the XX century as the earlier concept of the passive, laissez-faire state was gradually abandoned, almost all states have sought to provide at least some of the measures of social insurance associated with the welfare state. Thus, in the United States, the New Deal of President Franklin D. Roosevelt, the Fair Deal of President Harry S. Truman, and a large part of the domestic programs of later presidents were based on welfare state principles. In its more thoroughgoing form the welfare state provides state aid for the individual in almost all phases of his life – 'from the cradle to the grave' – as exemplified in The Netherlands and the Social Democratic governments of the Scandinavian countries. Many less developed countries have the establishment of some form of welfare state as their goal. The principal problems in the administration of a welfare state are:- determining the desirable level of provision of services by the state; ensuring that the system of personal benefits and contributions meets the needs of individuals and families while at the same time offering sufficient incentives for productive work; ensuring efficiency in the operation of state monopolies and bureaucracies; and the equitable provision of resources to finance the services over and

above the contributions of direct beneficiaries. / домогательство (abuse). коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Теория Государства Всеобщего Благоденствия – одна из современных буржуазно-реформистских апологетических теорий о сущности капиталистического общества и буржуазного государства, которое изображается как сила, устраняющая несправедливость капиталистического строя и обеспечивающая рост благосостояния широких масс населения. Является частью ложной идеи о трансформации капитализма в новый общественный строй. Её теоретическим источником явились кейнсианство и реформистская идеология. Как самостоятельное понятие концепция Государства Всеобщего Благоденствия получила распространение после 2-й Мировой Войны 1939–45 и стала неотъемлемым элементом официальной буржуазной пропаганды, а также различных партийных платформ и программ (например, Лейбористской Партии в Великобритании, Либерально-Демократической Партии – в Японии и других). Согласно этой концепции, в прошлом буржуазное государство стояло на позициях невмешательства и не боролось с социальными несправедливостями капиталистического строя, а ныне оно превратилось в силу, которая якобы противостоит монополиям и добивается социальной гармонии. Развитие государственно-монополистического капитализма после 2-й Мировой Войны, сопровождавшееся усиленным вмешательством буржуазного государства в экономику, добытые в борьбе трудящимися социальные завоевания в ряде капиталистических стран были использованы для пропаганды идей Государства Всеобщего Благоденствия. Сторонники этой ‘теории’, видя притягательную силу идей социализма, стремились также создать впечатление, будто его возможности присущи и ‘новому’ капиталистическому государству. В действительности Теория Государства Всеобщего Благоденствия представляет собой завуалированную форму защиты государственно-монополистического капитализма, при котором буржуазное государство используется монополиями для укрепления своей экономической мощи и усиления эксплуатации трудящихся. Имеющее место в некоторых случаях ограничение деятельности отдельных монополий буржуазным государством направлено на соблюдение интересов класса капиталистов в целом. Социально-экономические завоевания трудящихся в капиталистических странах – не следствие деятельности буржуазного государства, а результат ожесточённой классовой борьбы. Коммунистические и рабочие партии, борясь против буржуазной и реформистской идеологии, разоблачают апологетическую сущность концепции Государства Всеобщего Благоденствия.

WELL = СКВАЖИНА – (1) An oil Well is an instrument which, when a driller taps it, brings oil from the ground to the Earth’s surface. The oil itself, according to the United States Department of Energy, exists as small droplets in the pores of rocks. As an oil producer, you need to know about the size and number of pores in a rock, and the speed at which the oil can flow through these pores. Also, you need to know about the different types of wells. (i) Injection Well:- an injection well is one in which a worker might inject water or gas into the well to stimulate oil production. Two types of injection wells exist – a water injection well and a gas injection well. In the former type, you inject water into the ground to bring the oil out of the well. A gas injection well uses gas to increase the pressure underground to extract the oil. (ii) Appraisal Well:- the purpose of an appraisal well is evaluation. Oil rig workers use this type of well to run buildup tests, to test the stems of drills, and to gather fluid and core samples, among other evaluative functions. (iii) Satellite Well:- this type of well is one that an offshore drilling unit digs to produce hydrocarbons that well diggers cannot otherwise produce from development wells from a platform rig, or other permanent drilling source. Well diggers will drill several of these as a cost-cutting measure to avoid the expense of building a new platform. (iv) Offset Well:- an offset well is a well that a driller may place next to another one. As the Babylon Dictionary points out, the distance between the two wells depends upon factors such as the spacing regulations that region has in force, or whether the adjoining well produces oil or gas. (v) Flowing Well:- this term refers to a well that produces oil naturally. A flowing well is one that produces without the aid of a pump. Hydrocarbons naturally flow through this structure between the formation of the well to the wellhead. Well is a hole drilled in the earth for the purpose of (1) finding or producing crude oil or natural gas; or (2) producing services related to the production of crude or natural gas. Well Types:- there are a number of different types of wells that can be drilled, and these are described below. A particular well type may be best suited or most economic in the efforts to drain a specific configuration of hydrocarbons. Various drilling strategies can be adopted to place wells in specific patterns with the aim of optimizing production from a field. Conventional Wells:- in the early days of the oil industry, drilling wells was a simple operation. A well location was picked at top reservoir, and the well was drilled directly down to the target as a vertical well. Then drilling became more sophisticated when the art of deviating wells was perfected. Here, the drill bit is deflected at an angle from the vertical toward a specific target. Deviated wells are commonly drilled from fixed drilling locations such as an offshore platform. One method of directional drilling uses an assembly with a mud turbine and a bit. The flow of mud through the turbine causes the attached bit to rotate while the drill string remains stationary. Drillers refer to this type of drilling as being in sliding mode because the drill pipe slides along the hole behind the turbine. To deflect the bit in the appropriate direction, a bent sub is used; this is a piece of drill pipe bent to about 1–2° angle, which is inserted behind the mud turbine and oriented from the surface along the planned direction for the well. A more recent technique for deviating a well involves using a rotary steerable assembly. Signals from the surface can be sent to the tool to deflect the bit in the appropriate direction while it is still drilling ahead in rotary mode. Drilling can be more efficient this way because there is less risk that the drill pipe will get stuck, it turns instead of slides, and the rate of penetration is faster. Vertical and moderately deviated wells are called Conventional Wells. They are the most common well configurations because they are relatively cheap to drill. Sidetrack Wells:- a typical operation is to sidetrack a well. This is where a well has already been drilled or partly drilled and there is a need to exit out of one side of the well to a different target. A sidetrack may be required if there is an object stuck in the original hole, which cannot be fished out. In producing fields, an existing well may be sidetracked if there is no further use for that well, e.g., the oil well has watered out. A window will be cut in the casing of the original well by a special milling assembly, and drilling will then proceed out of the window toward a new target. Horizontal Wells:- horizontal wells are wells where the reservoir section is drilled at a high angle, typically with a trajectory to keep the well within a specific reservoir interval or hydrocarbon zone. In a strict sense, these wells are rarely perfectly horizontal, but they tend to be near horizontal mostly, generally at an angle greater than 80° from vertical. Horizontal wells are drilled in a specific configuration. The tangent section of the well is drilled along a deviated well path to just above the reservoir section, to what is known as the kick off point. From the kick off point, the well is drilled at an increasingly higher angle, arcing around toward an angle close to horizontal. The point at which the well enters (or lands on) the reservoir is called the Entry Point. From there on, the well continues at a near-horizontal orientation with the intention of keeping it substantially within the reservoir target until the desired length of horizontal penetration is reached. One problem in drilling a horizontal well is in locating the kick off point at about the right distance above the reservoir. The kick off point will be planned for a specific depth above the prognosed target zone depth, such that there will be enough room to turn the well around, so as to enter the target at a near horizontal angle. If the target zone comes in high on prediction, the chances are that the well will be drilled all the way through the reservoir before being able to turn round quickly enough to establish a horizontal trajectory. If the target zone is deeper than expected, then quite a long distance of well can be drilled at a very high angle before the reservoir is entered. Given the normal uncertainty on establishing the depth of a target zone from the seismic data, it is common for a pilot hole to be drilled first to get this information directly. Pilot holes may be vertical, although it is better to

deviate the pilot hole in the direction of the horizontal well path, and closer to the planned entry point for the horizontal section. If a horizontal well is planned near an appraisal well, then this can be used as a proxy for a pilot hole. A horizontal well can be drilled geometrically where there is a reasonable confidence in the expected reservoir geometry. The targets are defined at the entry point and at total depth, and the well is drilled according to a set geometrical plan between them. The alternative is to geosteer a horizontal well, particularly where there is less confidence in predicting the reservoir geology. Geosteering involves using geological information obtained as the well is being drilled to try and keep the well path within the target. This can involve the use of real-time log data but may also include input while drilling from well-site biostratigraphy or from examination of drill cuttings if the lithologies at the top and base of the reservoir are distinctive. The main technique in geosteering involves the use of a real-time log data display while the horizontal well is being drilled. The downhole log data can be directly transmitted to a computer screen in the geologist's office from the well site. This allows the geologist to establish which part of the reservoir is being drilled through and then decide where the well should be steered to next. This is done by comparing the real-time logs with data from nearby wells. Log responses in horizontal wells can look different from that in conventional wells. A catalog of expected log responses, as they would appear in a horizontal trajectory, can be created by computer modeling. If the geologist thinks that the well is above the target zone, they will ask the directional driller at the rig site to steer down; if the geologist believes they are below the target, they will ask the driller to steer up. Geosteering is at times a high-risk operation, and it can be stressful. In the early days of drilling horizontal wells, it was found that just under half of all the horizontal wells that were drilled ended up as failures or underperformed compared to expectation. The record may have improved since then; nevertheless outright failures still occur today. Frequently, when drilling new well locations, the geology will turn out quite different from what was expected and this reflects the nature of reservoir uncertainty. Even so, the outcome from the vertical penetration of a reservoir interval is a lot more predictable than when a horizontal well is drilled. Random geological uncertainties that will have a relatively trivial effect on the drilling outcome of a vertical well can cause serious problems with a horizontal well operation. At very high angles, if the top reservoir is 15 m (49 ft) deeper than predicted, the target will be penetrated much later than planned, or maybe missed altogether. Sometimes, after tracking the target interval, the well may then cross an unexpected subseismic fault and exit out of the target zone. It may not be clear which stratigraphic interval has been found on the other side of the fault. The geologist monitoring the well may not know if the target is above or below the well path. Another problem that can occur is that the predicted formation dip angle is wrong by a few degrees. In this instance, the well will quickly exit out of the top or base of a thin target. It can take a long section of the drilled interval before it can be steered back into the target horizon again. Some geologists refer to the steering efficiency of a horizontal well; the percentage of the total well length within the target zone beyond the entry point. Modern logging-while-drilling resistivity logs used in geosteering assemblies have some degree of look-ahead capability to try and maximize the steering efficiency. The current created by the tool can have a sufficient depth of penetration to detect if the drilling assembly is converging on a bed boundary. This can give enough warning to allow the well to be steered away from the bed boundary. Despite these problems, horizontal wells often end up as the best producers in a field. There are many reasons for drilling a horizontal well as opposed to a conventional well. They can produce considerable volumes of incremental reserves from what would otherwise be an underperforming area of the reservoir. Although they are more expensive to drill and are more prone to failure, horizontal wells often produce at several times the rate of an equivalent conventional well in the same reservoir. For example, experience in the heavy oil belt of Venezuela has shown that flow rates are increased significantly by producing from horizontal wells, yet they cost only 1.5 times more than vertical wells. In the Widuri and adjacent fields, offshore Sumatra, 15% of the producers are horizontal wells, yet these provide 30% of the oil production volume. Reservoirs tend to be much longer and wider laterally compared to their thickness, so a horizontal well is more likely to be in significantly greater contact with a given length of reservoir than a vertical well. Another feature of a horizontal well is that, for a given flow rate, a longer well needs less pressure drawdown to produce at that rate. All this can create the outcome by which horizontal wells are much more productive or economic than conventional wells. This tends to be true of the following situations:- (i) Thin Reservoirs:- a conventional well will intersect a relatively thin section of the reservoir, whereas a horizontal well can run the length of the reservoir and produce much more hydrocarbons; (ii) Horizontal Wells can target long, narrow macroforms such as channel fill sandstones; (iii) Fractured Reservoirs:- a horizontal well has a much greater chance of intersecting vertical or steeply dipping natural fractures compared to conventional wells. This can be a particularly effective way of producing fractured reservoirs with very low matrix permeabilities. (iv) Low-Permeability Reservoirs:- where an interval shows low permeabilities, horizontal wells can make up for this by maximizing the contact length with the reservoir. This means that low-permeability rocks such as chalk can produce at economic rates that would be marginal to uneconomic with conventional wells. (v) Reservoirs Prone To Coning:- because of the lower drawdown, horizontal wells may be less prone to water or gas coning behavior. For example, horizontal wells have been drilled in the Widuri field, offshore Sumatra, so as to minimize water coning. High vertical permeabilities and viscous oil are factors likely to promote coning behavior in the vertical wells in the field. (vi) Similarly, individual horizontal wells produce more oil in heavy oil reservoirs because the lower pressure drawdown tends to keep water and gas away from the well longer. For example, a total of 110 horizontal wells had been drilled prior to 2002 in the Hamaca field in Venezuela's Orinoco heavy oil belt. The development plan is to ultimately drill over 1 000 horizontal laterals to produce the 8–10° API gravity oil. (vii) Oil rims, thin oil columns typically lying below a gas cap, can be targeted with horizontal wells. The reduced drawdown minimizes the chances of coning water up from the water leg or drawing gas down from the gas cap. In certain parts of the world, horizontal wells are the well type of preference, whereas conventional wells are much less common. This is true of the Danish North Sea, where chalk is the main reservoir interval, and also in parts of the Middle East such as Qatar, Abu Dhabi, and Oman. There are situations where it is not advantageous to drill horizontal wells. In reservoirs where there is a very low Kv/Kh (vertical permeability/horizontal permeability) because of small-scale bedding-parallel baffles, bedding-parallel horizontal wells are not effective. Numerous baffles parallel to the wellbore will severely restrict the contactable drainage volume. It is better to drill strongly layered reservoirs like these with slanted instead of horizontal wells. Some subsurface professionals will advise against drilling horizontal wells if it can be more practical to drill a slant well. These are less risky to drill, and there is a better chance of establishing which part of the reservoir stratigraphy has been penetrated by the well. Slant wells may be a better option for drilling injection wells where it is important to ensure waterflood support to a specific reservoir interval. Designer Wells are types of high-angle or horizontal wells that have more than one intended target. This makes them more cost effective because the individual targets would have otherwise required several conventional wells to drain them effectively. One aim of a designer well could be to penetrate and drain more than one fault block. In mature fields, multitarget infill wells can increase the chances of finding an economic volume of oil. For example, in the Oseberg field, Norwegian North Sea, a designer well successfully targeted and lined up several fluvial channel sandstone bodies. Multilateral Wells are wells that have more than one branch radiating from the main borehole. Each branch can drain a separate part of the reservoir and produce into a common single wellbore. The advantage of multilateral wells is that, for the same number of drainage points, they can be somewhat cheaper than if separate wells had been drilled. Coiled Tubing Drilling:- coiled tubing is continuous, small-diameter steel pipe stored on a reel at the surface in lengths of up to 6 000 m (19 685 ft) long. Coiled tubing can be used in place of drill pipe for new wells and short-length to medium-length horizontal sidetracks (typically with a step-out of less than 800 m (2 625 ft)). A mud turbine and drill bit combination is used for coiled tubing drilling. The turbine is powered by the mud moving through it; the tubing itself does not rotate. The advantage of coiled tubing drilling is that the drilling operation is quicker than normal drilling in that the connection time involved with a jointed drill pipe is

eliminated. The tubing is simply rolled in and out of the well. Through Tubing Rotary Drilling is a relatively inexpensive method of creating a short-length to moderate-length sidetrack of an existing well (with a step-out of up to 1 000 m (3 381 ft), sometimes longer). Slim-bore drill pipe is used to drill the well, and the benefit of this is that the drill pipe is narrow enough to be run through the existing production tubing. This eliminates the time and cost involved with pulling the completion in an existing well to start drilling and then rerunning it after the well has reached total depth. Through tubing rotary drilling has been used in the Gullfaks field in the Norwegian North Sea. 4-D seismic data is used to identify remaining oil targets. Many of these targets are small but can be drilled cheaply by the use of through tubing rotary drilling. This has contributed to a reversal of the oil production decline at the late mature stage of field life. Well:- a bored, drilled, or driven shaft, or a dug hole, whose depth is greater that the largest surface dimension and whose purpose is to reach underground water supplies or oil, or to store or bury fluids below ground. Well:- oil is without a doubt one of the driving forces of the XXI century economy. It's used to power a plethora of different applications and despite common misconception, not all oil is created equal. On the contrary, oil comes in many different varieties and is sourced from a range of different wells. The three major players Oil wells are generally classified into three different categories. Those that exclusively produce oil, those that exclusively produce natural gas and those that produce both oil and natural gas. As natural gas is a common by-product of oil production most sites will need to have a strategy in place to manage its presence. What to do with the natural gas? While some extraction sites can sell on natural gas for a profit, unwanted natural gas can pose as a serious problem, both logistically and financially. If producers can't find a buyer it has to be either burned, which is environmentally controversial, or pumped back into the well. Alternatively, natural gas can be transformed into a liquid which makes for easier transportation. Using the German the Fischer-Tropsch process gas to liquid (GTL) technology converts natural gas into synthetic gasoline, diesel or jet fuel. This can then be easily moved on tankers or through pipelines. According pro-GTL advocates GTL is a much cleaner fuel with better eco-friendly credentials than its petroleum counterparts. Onshore or offshore? Another key way of categorising oil wells is to look at whether or not they are located onshore or offshore. While the reservoirs themselves are more or less identical the layout, build and cost can differ quite significantly. Because of the need for advanced infrastructure offshore oil drilling is often far more expensive than onshore projects. A sense of purpose? As well as looking at physical aspects wells can also be classified according to their purpose. These sorts of wells fall into five major categories. Wildcat wells are projects located outside of already established oil and gas fields. Exploration wells are tentative ventures that drill in new areas with the hope of discovering untouched resources. Appraisal wells are used to evaluate the characteristics of existing hydrocarbon accumulation, production wells are constructed specifically for harvesting oil and gas while abandoned wells have been permanently sealed. Lahee classification explained in the US, and in other countries that drill for oil the Lahee classification system is widely adopted. Established in 1944 by Frederic H. Lahee, the system encompasses a variety of categories which are assigned to each well before drilling commences. The classifications are allocated according to the degree of geological control, pre-determined hydrocarbon potential of the drilling location and the extent of operational risk. Well is an opening in the ground made by drilling or boring and from which oil or gas is obtained. Wells:- oil and gas wells are classified as either exploration or development wells. Exploration wells are wells drilled to find a new field or to find a new reservoir in a field previously found to be productive of oil and gas in another reservoir. Appraisal wells are exploration wells drilled to confirm the results of a discovery well. Delineation wells are exploration wells drilled to determine the boundaries of a productive formation or to delineate the extent of a find. Development wells are wells drilled in an existing reservoir in a proved oil- or gas-producing area. Completed wells are wells in which drilling work has been completed and that are capable of producing. Dry wells are wells completed as dry holes, that is, wells not capable of producing in commercial quantities. / месторождение Видури (Widuri field) в Индонезии. месторождение Амака (Hamaca field) в Венесуэле. месторождение Усэбарьг (Oseberg field) в Норвегии . месторождение Гюльфакс (Gullfaks field). Доктор Фрэдэрик Хэнри Лэйхи (Dr Frederic Henry Lahee; 1884–1968) в США. Скважина буровая, горная выработка круглого сечения глубиной свыше 5 метров (м) и диаметром обычно 75–300 миллиметров (мм), проводимая с помощью буровой установки. Скважины проходят с поверхности земли и из подземных горных выработок под любым углом к горизонту. Различают начало скважины (устье), дно (забой) и ствол. Глубины скважин составляют от нескольких м до 9 и более километров (км). При бурении разведочных скважин на твёрдые полезные ископаемые их диаметр обычно 59 и 76 мм, на нефть и газ – 100–400 мм. По назначению скважины подразделяются на:- Разведочные Скважины для геологических целей, инженерно-геологических и гидрологических изысканий, изучения структур, геофизических работ, поисков и разведки полезных ископаемых; Эксплуатационные Скважины – для добычи нефти и газа, подземных вод, минеральных солей и другого; Вспомогательные Скважины – нагнетательные, наблюдательные, пьезометрические, вентиляционные, водоотливные, дегазационные; Специальные Скважины – замораживающие, тампонажные, дренажные и тому подобные; Взрывные Скважины – для размещения в них зарядов взрывчатых веществ. Скважина создаётся последовательным разрушением (смотрите Бурение) горных пород, удалением выбуренной породы и, при необходимости, закреплением стенок скважины от обрушения. Удаление выбуренной породы производится промывочной жидкостью, газом и механическими устройствами. В разведочных скважинах при неустойчивых верхних породах применяют тонкостенные обсадные трубы (в устойчивых породах – без крепления). В сильнотрещиноватых породах и зонах поглощения тампонируют быстросхватывающимися смесями. Эксплуатационные и глубокие разведочные скважины крепят металлическими обсадными трубами и цементируют. Обсадные трубы свинчиваются или свариваются; в неглубоких скважинах на воду применяют трубы из пластмассы, асбоцемента и другого. Технология крепления скважины на нефть и газ включает установку в устье первой обсадной колонны длиной обычно до 20 м, называемой Направлением. Для обеспечения вертикальности или наклонной направленности последующему стволу скважины и для перекрытия неустойчивых верхних пород и изоляции газоводяных притоков спускают вторую колонну обсадных труб – так называемый Кондуктор длиной от десятков до сотен м. В кольцевое (затрубное) пространство между стенками скважины и кондуктором с помощью промывочной или специальной жидкости через кондуктор закачивается цементный раствор. После окончания бурения до проектной глубины и проведения геофизических работ, выявляющих наличие продуктивных горизонтов (нефть, газ и другое), в скважину спускают эксплуатационную колонну обсадных труб. Во избежание перетоков нефти или газа в вышележащие горизонты, а воды в продуктивные пласты пространство скважины за эксплуатационной колонной также заполняется цементным раствором. В сложных геологических условиях (водоносные, поглощающие горизонты и другие), когда проходка скважины без дополнительного крепления невозможна, между кондуктором и эксплуатационной колонной спускается промежуточная (техническая) колонна. Если после кондуктора спускается только эксплуатационная колонна, конструкция скважины называется Одноколонной (при одной или двух промежуточных колоннах конструкция скважины называется Двух- или Трёхколонной). Для извлечения из пластов жидких и газообразных полезных ископаемых существуют различные методы вскрытия и оборудования забоя скважины. В большинстве случаев в нижней зацементированной части эксплуатационной колонны, находящейся в продуктивном пласте, простреливают (перфорируют) ряд отверстий в стенке обсадных труб и цементной оболочке. В устойчивых породах призабойную зону скважины оборудуют различного типа фильтрами и не цементируют или обсадную колонну спускают до кровли продуктивного пласта, а его разбуривание и эксплуатацию производят без крепления ствола скважины. Устье скважины в зависимости от её назначения оборудуют арматурой (колонная головка, задвижки, крестовина и другое).

Скважина – это цилиндрическая горная выработка, у которой длина ствола гораздо больше, чем её диаметр. Какие ещё признаки делают скважину скважиной? Мы знаем, что есть такие сооружения как колодцы, шахты. В эти сооружения человек может попасть. В скважину – нет. Таким образом, скважина – это горная выработка без доступа в неё человека. В некоторых книгах ещё дают дополнительное условие:- с диаметром ствола не более 0.75 м. Но это, как говорят Американцы, optional. Верхняя часть скважины называется Устье, нижняя – Забой. Стенки скважины – это Ствол Скважины. Мы привыкли говорить, что скважины бурят. На самом же деле скважины строят. Скважины – это сложные капитальные сооружения. Их, кстати говоря, относят к основным средствам предприятия, а затраты на бурение скважин и их обустройство – к капитальным вложениям. Конструкция Скважины:- при проектировании конструкции нефтяной скважины исходят из следующих основных требований:- (i) конструкция скважины должна обеспечивать свободный доступ к забою глубинного оборудования и геофизических приборов; (ii) конструкция скважины должна предотвращать обрушение стенок скважины; (iii) конструкция скважины должна обеспечивать надёжное разобщение всех пластов друг от друга, то есть она должна предотвращать перетекание флюидов из одного пласта в другой; и (iv) кроме того, она должна обеспечивать возможность герметизации устья скважины при необходимости. Давайте разберём, как строят скважины и какова их типовая конструкция на примере нефтяных скважин, которые бурят на месторождениях Удмуртии. Сначала бурят ствол большого диаметра глубиной порядка 30 метров. Спускают металлическую трубу диаметром 324 мм, которая называется Направление, и цементируют пространство между стенками трубы и стенками горной породы. Направление нам необходимо для того, чтобы верхний слой почвы не размывался при дальнейшем бурении. Далее продолжают бурение ствола меньшим диаметром до глубины примерно 500–800 м. Снова спускают колонну труб диаметром 168 мм и также цементируют пространство между колонной труб и стенками породы по всей длине. Это у нас Кондуктор. Далее бурение возобновляют и бурят скважину уже до целевой глубины. Снова спускают колонну труб диаметром 146 мм, которая называется Эксплуатационной Колонной. Пространство между стенками труб и горной породой опять же цементируется от забоя скважины и вплоть до устья. Зачем нам нужен кондуктор? До глубины порядка 500 метров расположена зона пресных вод с активным водообменном. Ниже глубины 500 м (глубина может быть различна для разных регионов) идёт зона затруднённого водообмена с солёными водами, а также другими флюидами (нефтью, газами). Кондуктор нам необходим в качестве дополнительной защиты, предотвращающей возможность засолонения пресных вод и попадания в них вредных веществ с нижележащих пластов. Между кондуктором и эксплуатационной колонной в некоторых случаях (например, при большой глубине скважины) спускают промежуточную (техническую) колонну. Типы Скважин:- в зависимости от геологических условий нефтяного месторождения бурят различные типы скважин. Нефтяная скважина может быть пробурена как:- (i) вертикальная; (ii) наклонно-направленная; (iii) горизонтальная; и (iv) многоствольная или многозабойная. Вертикальная Скважина – это скважина, у которой угол отклонения ствола от вертикали не превышает 5°. Если угол отклонения от вертикали больше 5°, то это уже Наклонно-Направленная Скважина. Горизонтальной Скважиной (или Горизонтальным Стволом Скважины) называют скважину, у которой угол отклонения ствола от вертикали составляет 80–90°. Но здесь есть один нюанс. Так как ‘в природе нет прямых линий’ и продуктивные нефтенасыщенные пласты залегают в недрах земли, как правило, с некоторым наклоном, а часто с довольно крутым наклоном, то на практике получается, что нет никакого смысла бурить горизонтальную скважину под углом приблизительно равным 90°. Логичнее пробурить ствол скважины вдоль пласта по наиболее оптимальной траектории. Поэтому в более широком смысле, под Горизонтальной Скважиной понимают скважину, имеющую протяжённую фильтровую зону – ствол, пробуренный преимущественно вдоль напластования целевого пласта в определённом азимутальном направлении. Скважины с двумя и более стволами называют Многоствольными (Многозабойными). Чем отличается многоствольная скважина от многозабойной? Многоствольные Скважины, также как и Многозабойные Скважины, имеют основной ствол и один или несколько дополнительных. Ключевым отличием является расположение точки разветвления стволов. Если точка находится выше продуктивного горизонта, на который пробурена скважина, то скважину называют Многоствольной Скважиной (МСС). Если же точка разветвления стволов находится в пределах продуктивного горизонта, то скважину называют Многозабойной Скважиной (МЗС). Другими словами, если основной ствол скважины пробурен вплоть до продуктивного горизонта и уже в самом продуктивном горизонте из него пробурен один или несколько дополнительных стволов, то это многозабойная скважина (МЗС). В этом случае скважина пересекает верхнюю границу продуктивного горизонта только в одной точке. Если же дополнительные стволы скважины забурены из основного ствола выше продуктивного горизонта и, таким образом, скважина имеет больше одной точки пересечения с продуктивным горизонтом или, как вариант, дополнительные стволы пробурены на разные горизонты, то это Многоствольная Скважина (МСС). Категории Скважин:- по своему назначению скважины подразделяются на следующие категории:- (i) поисковые; (ii) разведочные; и (iii) эксплуатационные. Поисковые Скважины – это скважины, которые бурят с целью поиска новых залежей (месторождений) нефти и газа. Разведочные Скважины бурят на площадях с уже установленной нефтегазоносностью для уточнения запасов нефти и газа, а также для сбора и уточнения исходных данных, необходимых для составления проекта (технологической схемы) разработки месторождения. При проектировании и разработке нефтяных месторождений выделяются следующие группы эксплуатационных скважин:- (i) основной фонд добывающих и нагнетательных скважин; (ii) резервный фонд скважин; (iii) контрольные (наблюдательные и пьезометрические) скважины; (iv) оценочные скважины; (v) специальные (водозаборные, поглощающие и другие) скважины; и (vi) скважины-дублёры. Добывающие (нефтяные и газовые) Скважины предназначены для извлечения из залежи нефти, нефтяного и природного газа, газоконденсата и других сопутствующих компонентов. В зависимости от способа подъёма жидкости добывающие скважины подразделяются на Фонтанные, Газлифтные и Насосные Скважины. Нагнетательные Скважины предназначены для воздействия на продуктивные пласты путём нагнетания в них воды, газа, пара и других рабочих агентов. В соответствии с принятой системой воздействия нагнетательные скважины могут быть законтурными, приконтурными и внутриконтурными. В процессе разработки в число нагнетательных скважин в целях переноса нагнетания, создания дополнительных и развития существующих линий разрезания, организации очагового заводнения могут переводиться в добывающие скважины. Часть нагнетательных скважин может временно использоваться в качестве добывающих. Резервный Фонд Скважин предусматривается с целью вовлечения в разработку отдельных линз, зон выклинивания и застойных зон, которые не вовлекаются в разработку скважинами основного фонда в пределах контура их размещения. Количество резервных скважин обосновывается в проектных документах с учётом характера и степени неоднородности продуктивных пластов (их прерывистости), плотности сетки скважин основного фонда и так далее. Контрольные (наблюдательные и пьезометрические) Скважины предназначаются:- (i) Наблюдательные – для периодического наблюдения за изменением положения водонефтяного, газонефтяного и газоводяного контактов, за изменением нефтеводогазонасыщенности пласта в процессе разработки залежи; и (ii) Пьезометрические – для систематического измерения пластового давления в законтурной области, в газовой шапке и в нефтяной зоне пласта. Количество и местоположение контрольных скважин определяется в проектных документах на разработку. Оценочные Скважины бурятся на разрабатываемых или подготавливаемых к пробной эксплуатации месторождениях (залежах) с целью уточнения параметров и режима работы пластов, выявления и уточнения границ обособленных продуктивных полей, оценки выработки запасов нефти отдельных участков залежи в пределах контура запасов категории

A+B+C1. Специальные Скважины предназначаются для добычи технической воды, сброса промысловых вод, подземного хранения газа, ликвидации открытых фонтанов. К специальным относятся водозаборные, поглощающие скважины:- (i) Водозаборные Скважины предназначаются для водоснабжения при бурении скважин, а также систем поддержания пластового давления в процессе разработки; и (ii) Поглощающие Скважины предназначены для закачки промысловых вод с разрабатываемых месторождений в поглощающие пласты. Скважины-Дублёры предусматриваются для замены фактически ликвидированных из-за старения (физического износа) или по техническим причинам (в результате аварий при эксплуатации) добывающих и нагнетательных скважин.

(2) Wells are used all over the world and are an important source of water for many people. In this video lesson you will identify different types of wells, as well understand their underground source of water. Have you ever tried to dig a hole at the beach, just to have it keep filling up with water? Or maybe you thought you could dig a hole to China through your backyard, again, just to find that at some point, your hole started filling with water? In both instances, you couldn't get too far because you had reached the water table. This is the level underground that is saturated with water. As we learned in another lesson, this water is called Groundwater, and it makes up almost all of the liquid freshwater on Earth's surface – 98.5% of it! Access to the water table has always provided an important source of drinking water, most often through wells. A well is a human-made hole in the ground specifically used for accessing groundwater. Wells come in different shapes and sizes, but their use is generally the same. In fact, for many people in both developed and developing countries, well water is still the main supply of water for home uses, irrigation and drinking water. Groundwater is even more important in areas that lack surface water, such as deserts. Types of Wells:- there are three main ways that wells are created. Originally, all wells were Dug Wells. These are wells that are created by digging it out by hand. Wells are rarely made this way anymore, because let's face it, who wants to spend all day digging a hole in the ground with a shovel? Dug wells are dug down below the water table and lined with a material, like stone or brick. This helps support the well and keep it from collapsing. Driven Wells are much more common in today's society than dug wells because they are wells that are created with a small pipe driven into the ground. The pipe has a filter over the bottom to keep out as much sediment as possible, and that pipe is driven down into the ground until it reaches the water table. Once the well is deep enough, all of the dirt is washed out of the inside of the pipe, and a pump is installed so that water can be removed from the well. Finally, we have Drilled Wells. These are how most modern wells are created because these wells are created by digging a hole in the ground with machinery and can reach deeper into the ground than both dug and driven wells. A large bit drills into the ground, much like your drill creates a hole in your wall for hanging a picture. These wells can be drilled more than 1 000 feet deep. Pumps are used with drilled wells, too, since it would take a really long rope to reach a bucket down that far! Artesian Wells:- there is one more type of well, but this one is special. Groundwater is usually held underground in a reservoir called an Aquifer. Normally, an aquifer gets filled with water when rainwater soaks into the ground and collects in these underground locations. This is called an Unconfined Aquifer because it is not confined, as it is open to receiving water through the soil above. All the wells you have learned about in this lesson are wells that tap into unconfined aquifers in the ground. Sometimes, though, an aquifer is below an area of ground that doesn't let water soak through. When this happens, we call this a confined aquifer because it is confined under an impermeable layer of soil. All aquifers are unconfined in some location; otherwise they wouldn't be able to fill with water! Types of Wells:- (i) Drilled Wells are constructed by either cable tool (percussion) or rotary-drilling machines. Drilled wells that penetrate unconsolidated material require installation of casing and a screen to prevent inflow of sediment and collapse. They can be drilled more than 1 000 feet deep. The space around the casing must be sealed with grouting material of either neat cement or bentonite clay to prevent contamination by water draining from the surface downward around the outside of the casing. (ii) Driven Wells are constructed by driving a small-diameter pipe into shallow water-bearing sand or gravel. Usually a screened well point is attached to the bottom of the casing before driving. These wells are relatively simple and economical to construct, but they can tap only shallow water and are easily contaminated from nearby surface sources because they are not sealed with grouting material. Hand-driven wells usually are only around 30 feet deep; machine-driven wells can be 50 feet deep or more. (iii) Dug Wells:- historically, dug wells were excavated by hand shovel to below the water table until incoming water exceeded the digger's bailing rate. The well was lined with stones, bricks, tile, or other material to prevent collapse, and was covered with a cap of wood, stone, or concrete tile. Because of the type of construction, bored wells can go deeper beneath the water table than can hand-dug wells. Dug and bored wells have a large diameter and expose a large area to the aquifer. These wells are able to obtain water from less-permeable materials such as very fine sand, silt, or clay. Disadvantages of this type of well are that they are shallow and lack continuous casing and grouting, making them subject to contamination from nearby surface sources, and they go dry during periods of drought if the water table drops below the well bottom. Wells are extremely important to all societies. In many places wells provide a reliable and ample supply of water for home uses, irrigation, and industries. Where surface water is scarce, such as in deserts, people couldn't survive and thrive without groundwater. Types of Wells:- digging a well by hand is becoming outdated today (would you want to do it?). Modern wells are more often drilled by a truck-mounted drill rig. Still, there are many ways to put in a well – here are some of the common methods. (i) Dug Wells:- hacking at the ground with a pick and shovel is one way to dig a well. If the ground is soft and the water table is shallow, then dug wells can work. Historically, dug wells were excavated by hand shovel to below the water table until incoming water exceeded the digger's bailing rate. The well was lined with stones, brick, tile, or other material to prevent collapse, and was covered with a cap of wood, stone, or concrete. They cannot be dug much deeper than the water table – just as you cannot dig a hole very deep when you are at the beach ... it keeps filling up with water! (ii) Driven Wells:- driven wells are still common today. They are built by driving a small-diameter pipe into soft earth, such as sand or gravel. A screen is usually attached to the bottom of the pipe to filter out sand and other particles. Problems? They can only tap shallow water, and because the source of the water is so close to the surface, contamination from surface pollutants can occur. (iii) Drilled Wells:- most modern wells are drilled, which requires a fairly complicated and expensive drill rig. Drill rigs are often mounted on big trucks. They use rotary drill bits that chew away at the rock, percussion bits that smash the rock, or, if the ground is soft, large auger bits. Drilled wells can be drilled more than 1 000 feet deep. Often a pump is placed in the well at some depth to push the water up to the surface. Water Levels in Wells:- groundwater users would find life easier if the water level in the aquifer that supplied their well always stayed the same. Seasonal variations in rainfall and the occasional drought affect the 'height' of the underground water level. Withdrawing water from a well causes the water levels around the well to lower. The water level in a well can also be lowered if other wells near it are withdrawing water. When water levels drop below the levels of the pump intakes, then wells will begin to pump air – they will 'go dry'.

WELL AREA = XX АРЕАЛ (или АРЕАЛ ВПАДИНЫ, или АРЕАЛ ЯМЫ, или АРЕАЛ СКВАЖИНЫ) – Well Area is an area identified as a danger to maritime navigation containing one or more wells.

WELLBORE = СТВОЛ СКВАЖИНЫ – Wellbore is a physical hole that makes up the well, and can be cased, open or a combination of both. Wellbore is a channel created by drilling. / Стенки скважины – это ствол скважины.

WELL CAR = ФИТИНГОВАЯ ПЛАТФОРМА – Well Car is a drop-frame rail flat car. Also known as Stack Car. Well Car is a car for carrying containers. These have a very low center of gravity since the containers are carried in a deep 'well' in the car. / пониженная рама (drop-frame). Платформа – грузовой вагон открытого типа с небольшими бортами; с расширением специализации

вагонов применяются платформы для большегрузных контейнеров, двухъярусные платформы для перевозки легковых автомобилей и другие.

WELL COMPLETION = ЗАКАНЧИВАНИЕ СКВАЖИНЫ – Well Completion is the process of making a well ready for production or injection.

WELL DENSITY = ПЛОТНОСТЬ СКВАЖИН – Well Density:- xxxxx. / Плотность Бурения или Плотность Скважин (Well Density) – отношение числа всех пробуренных скважин к площади разбуриваемого объекта.

WELL DIVERSIFIED PORTFOLIO = ХОРОШО ДИВЕРСИФИЦИРОВАННЫЙ ПОРТФЕЛЬ – Well Diversified Portfolio is a portfolio that has invested in many different types of security in order to hedge against the securities already in the portfolio. Ideally, this reduces the risk inherent in any one investment, and increases the possibility of making a profit, or at least avoiding a loss. This may also reduce the expected return on the fund, but it depends on level and type of diversification. There are two main types of diversification that a well-diversified portfolio may utilize. Horizontal diversification involves investing in similar types of investments. Examples include investing in several technology companies or in different types of bonds. Vertical diversification involves investing in very different securities; for example, one may choose to invest in securities traded in different countries or in both winter clothing and swimsuit companies. Both types of diversification may be as broad or narrow as the fund's manager chooses. In general, the broader the diversification, the less risk and less return. Well Diversified Portfolio is a portfolio that includes a variety of securities so that the weight of any security is small. The risk of a well-diversified portfolioclosely approximates the systematic risk of the overall market, and the unsystematic risk of each security has been diversified out of the portfolio. A Well-Diversified Portfolio contains a very large number of individual stocks and/or bonds that are selected without bias toward particular economic segments. A fully diversified portfolio will approximate the global publicly traded securities markets. The question about diversification most frequently asked by individual investors is 'how many stocks or bonds do I need to be well-diversified'? While the answer to this question is important, the caveats surrounding the answer are even more important. There are large numbers of scientific investment studies addressing the question of the number of stocks required to be well diversified. It is important that both the stock and bond portions of one's portfolio be very well diversified. However, because stocks and bonds have very different characteristics, diversification considerations vary between these types of securities. Most of the scientific literature focuses on equities diversification, and there are relatively few studies on bond diversification. Because bond pricing is quite complex and bond markets transaction costs are relatively high for individual investors, the logic of investing through bond funds is extremely compelling. The Skilled Investor has summarized several different diversification research papers, because of their points-of-view and educational value to individual investors. This article summarizes key observations of 'Diversification and the Reduction of Dispersion:- An Empirical Analysis' by Professors John Evans and Stephen Archer of the University of Washington is an early study on the number of stocks required to be well diversified. While this is an older study (1968), it is worth understanding, because Professors Evans and Archer went into some detail about what a well-diversified portfolio depends upon. From the S&P 500 stock list, Professors Evans and Archer developed a model to test diversification using the 470 stocks that had complete data for the period 1958 to 1967. They randomly selected 60 different portfolios of 40 stocks each and compared these portfolios with the returns and price volatility of the S&P 500 index. They ran statistical tests to determine both the incremental value and costs of adding more stocks to a portfolio. Concerning the number of stocks needed largely to eliminate unsystematic or company specific risk from a stock portfolio, they did not intend to come up with a single magic threshold number. Instead, they tested the number of additional stocks needed to achieve a statistically important gain in diversification. The Evans and Archer study made the point that increasing diversification by purchasing additional stocks was not costless. Of course, when Professors Evans and Archer published their study in 1968, financial market transaction costs were far higher, and one had to be much more concerned with the cost of building a diversified portfolio. At that time, one could argue that a lower number of stocks achieved a sufficiently well diversified portfolio on a cost-adjusted basis, because per unit transaction costs were so much higher than today. Now, the ability of portfolio managers to pay attention to a large number of potential portfolio holdings is much more a limiting factor than trading costs. During the last twenty-five years of the XX century, mutual fund and exchange traded fund portfolio assembly costs declined dramatically. Brokerage commissions were deregulated in 1975, and transaction costs have fallen very dramatically since then. Furthermore, well-diversified, low-cost index mutual funds have now become commonplace, while none existed in 1968. The mutual fund industry was still in its relative infancy. For example, there were 361 US-based mutual funds of all kinds in 1970 with only USD48 billion in assets, and there were no exchange-traded funds. In contrast, at the end of 2010, there were 7 581 US-based mutual funds of all kinds (in 21 971 different share classes) with USD11.8 Trillion in assets, and there were also 923 US-based exchange-traded funds with USD1.0 Trillion in assets. Now, very low cost index mutual fund and ETF investing is a much more efficient and effective way to achieve full market diversification. Because investment costs have declined dramatically, higher levels of diversification can be achieved far more cost-effectively through mutual funds and ETFs today. Of course, you need to be very careful to keep the total fund expenses that you pay very low. While a minority of available mutual funds and ETFs have pursued a low cost strategy, one of the primary reasons why the number of funds has grown so phenomenally is that they are very profitable. Unfortunately, this profit to the ETF and mutual fund industry comes at the expense of individual investors, who are ostensibly 'shareholders' in these excessively costly investment funds. For many mutual funds large scale has meant large profits, because savings from these economies of scale have not been passed on to the shareholders of the funds. This is a very stark example of an industry with what is know as an 'agency' problem. When there is an agency problem, the agents of the shareholders do not act in the best interests of the shareholders. In theory, the interests of fund shareholders are supposed to be paramount in mutual funds. In practice the boards of many mutual funds and not truly independent and serve primarily the for-profit interests of the large investment fund family companies that either employ fund directors or that pay fees to supposedly 'independent' outside directors to sit on the boards of funds. Unfortunately, there are two boards of directors and two sets of shareholders whose interests are in conflict – the board of each individual mutual fund and the board of the overall fund company with their respective sets of shareholders with conflicting interests. In reality, for many mutual funds it seems that the profit interests of the shareholders of the overall fund company dominates and supplants the interests of the shareholders of the individual investment funds. This is a clear breakdown in corporate governance. Unfortunately, these agency problems are systematic across most of the industry. The only real solution that individual investors have is to decide to patronize only fund companies with very low fees that respect their obligations to fund shareholders. In addition to showing that large numbers of additional stocks are required to achieve measurable improvements in diversification, the Evans and Archer study clarified other requirements for a well-diversified portfolio. The number of stocks selected for a highly diversified portfolio also depends on what one actually means by 'the market'. To achieve full diversification, as the scope of your definition of the 'securities market' increases, you need to hold an increasing number of representative individual securities. If one means the market for the largest US companies, then the S&P 500 is one of several competing indexes and represents about 70% of total US equity market capitalization. If one means the entire investable US equities market, then the Wilshire 5000 is one of several that could be used. A global index would have many more stocks and would cover an even broader economic base. Therefore, the number of stocks to be well diversified would depend on what one means by the 'market'. Within the meaning of finance literature, the full equity securities 'market' portfolio is the global equities market and includes all investment styles and all countries. In addition, to the numbers of different securities and their

weighting, Evans and Archer indicated that you need to ensure that your securities selection process is random, if you wish to be fully diversified. Your diversified investment portfolio construction methods should not biased toward one or another decision factor, such as being skewed toward a single industry or a subset of all industries. Unless you buy the entire global market through an index fund or exchange-traded fund, your random selection of a subset of the whole market might be a method such as a 'toss of the darts' at a capitalization-weighted stock page. This would mean that each security would have an equal chance of being selected for inclusion on a capitalization-weighted portfolio basis. Unless this random selection condition is met, the goal of constructing a highly-diversified portfolio would be disrupted, because you introduced a bias or skew through your selection methods. Fundamental indexing investment product alternatives have received attention recently. Fundamental indexes select securities based on various company economic metrics rather than on a company's securities market capitalization. Concerning the use of capitalization weighting as the index benchmark for the full market and for full diversification, The Skilled Investor is well aware of the controversy percolating in the industry and in financial journals about the possible advantages and disadvantages of market capitalization weighting of mutual funds and ETFs. Supposedly 'new' fundamental indexing methods are based upon various measures of a company's economic impact, such as revenues, dividends, book value, number of employees, etc. A detailed analysis of this 'market capitalization' versus business or fundamental indexing metrics dispute is beyond the scope of this diversification article. In short, however, well-constructed statistical investment analyses of the past several decades have shown that other factors affect securities prices, in addition to the economic risk factors that affect the overall markets. In particular, a 'value stock' versus 'growth stock' factor seems to exist. In general, over much longer periods value stocks tend to out-perform growth stocks. However, for shorter periods there is a cyclical and unpredictable ebb and flow, concerning when one or the other strategy produces superior returns. Whether you should have a 'value' versus 'growth' emphasis in your investment portfolio selection has been debated for much longer than this more recent debate about 'fundamental' indexing. In fact, fundamental indexing might just primarily be a better method to introduce a 'value tilt' into an investment program. However, the higher current fee structure associated with fundamental indexing investment vehicles on the market could nullify its potential risk-adjusted return advantage – partially or fully. There are very broadly diversified capitalization weighted market index funds and ETFs available with annual management fees of only 0.1% and total costs around 0.2% annually. Fundamentally indexed products have annual management fees that typically are 0.5% to 1.0% higher – not including other less visible costs, such as incremental trading expenses. You have to be very confident in your convictions about the superiority of fundamentally indexed funds to choose them over much cheaper capitalization weighted index mutual funds and ETFs. / Вилшир Эсошиэтс, Инк. (Wilshire Associates, Inc.). Хорошо Диверсифицированный Портфель (Well Diversified Portfolio) – инвестиционный портфель, составленный из большого количества ценных бумаг таким образом, что доля каждой бумаги сравнительно невелика. Риск хорошо диверсифицированного портфеля приближен к систематическому риску рынка в целом. При этом несистематический риск каждой бумаги ликвидируется посредством диверсификации.

WELL ENOUGH = ДОВОЛЬНО ХОРОШО (или ХХ) – Well Enough is an order meaning sufficient (enough).

WELLHEAD = ТОЛКОВАЯ ГОЛОВА (или УСТЬЕ (СКВАЖИНЫ)) – (1) Wellhead is the point at which the crude (and/or natural gas) exits the ground. Following historical precedent, the volume and price for crude oil production are labeled as Wellhead, even though the cost and volume are now generally measured at the lease boundry. In the context of domestic crude price data, the term Wellhead is the generic term used to reference the production site or lease property. Slang in energy industries. The 'Wellhead' is the point where crude oil and natural gas leave a well. A Wellhead is the component at the surface of an oil or gas well that provides the structural and pressure-containing interface for the drilling and production equipment. The primary purpose of a wellhead is to provide the suspension point and pressure seals for the casing strings that run from the bottom of the hole sections to the surface pressure control equipment. While drilling the oil well, surface pressure control is provided by a blowout preventer (BOP). If the pressure is not contained during drilling operations by the column of drilling fluid, casings, wellhead, and BOP, a well blowout could occur. Once the well has been drilled, it is completed to provide an interface with the reservoir rock and a tubular conduit for the well fluids. The surface pressure control is provided by a Christmas tree, which is installed on top of the wellhead, with isolation valves and choke equipment to control the flow of well fluids during production. Wellheads are typically welded onto the first string of casing, which has been cemented in place during drilling operations, to form an integral structure of the well. In exploration wells that are later abandoned, the wellhead may be recovered for refurbishment and re-use. Offshore, where a wellhead is located on the production platform it is called a Surface Wellhead, and if located beneath the water then it is referred to as a Subsea Wellhead or Mudline Wellhead. A wellhead serves numerous functions, some of which are:- (i) provide a means of casing suspension. (Casing is the permanently installed pipe used to line the well hole for pressure containment and collapse prevention during the drilling phase). (ii) Provides a means of tubing suspension. (Tubing is removable pipe installed in the well through which well fluids pass). (iii) Provides a means of pressure sealing and isolation between casing at surface when many casing strings are used. (iv) Provides pressure monitoring and pumping access to annuli between the different casing/tubing strings. (v) Provides a means of attaching a blowout preventer during drilling. (vi) Provides a means of attaching a Christmas tree for production operations. (vii) Provides a reliable means of well access. (viii) Provides a means of attaching a well pump. The primary components of a wellhead system are:- casing head; casing spools; casing hangers; packoffs (isolation) seals; bowl protectors/wear bushings; test plugs; mudline suspension systems; tubing heads; tubing hangers; and tubing head adapters. The oil industry specifications for wellhead systems (materials, dimensions, test procedures and pressure ratings etc) are:- (i) API 6A Specification for Wellhead and Christmas Tree Equipment; and (ii) ISO 10423 Wellhead and Christmas Tree Equipment. In general well heads are 5 nominal ratings of wellheads 2, 3, 5, 10 and 15 (x 1 000) psi working pressure. they have an operating temperature range of –50 to +250 degrees Fahrenheit. they are used in conjunction with ring type seal gaskets. In general the yield strength of the materials range from 36 000 to 75 000 psi. Wellhead is the control equipment placed at the top of the well casing. / Толковая Голова это жаргонный термин в энергетических отраслях, под которым подразумевается пункт, где нефть или природный газ покидают скважину. Скважина – искусственная цилиндрическая горная выработка глубиной от нескольких метров до 10 километров и более и диаметром обычно 75–800 миллиметров. Скважины разделяются на взрывные, вспомогательные (вентиляционные, водоотливные и так далее), разведочные, специальные (дренажные, замораживающие и тому подобные), эксплуатационные (для добычи воды, газа, нефти и так далее). Проходка скважины осуществляется буровыми установками. Элементы скважины:- забой – дно; ствол или стенки – боковая поверхность; устье – выход на поверхность скважины. Буровая Скважина – цилиндрическая горная выработка, имеющая относительно малое поперечное сечение (обычно 75–350 миллиметров). Различают горнотехнические, исследовательские, строительные и эксплуатационные скважины.

(2) Wellhead is the physical structure, facility, or device at the land surface from or through which groundwater flows or is pumped from subsurface, water-bearing formations. See also Groundwater.

WELLHEAD PRICE = ПРОМЫСЛОВАЯ ЦЕНА (или ЦЕНА НА УСТЬЕ (СКВАЖИНЫ)) – Wellhead Price is the value at the mouth of the well. In general, the wellhead price is considered to be the sales price obtainable from a third party in an arm's length transaction. Posted prices, requested prices, or prices as defined by lease agreements, contracts, or tax regulations should be used

where applicable. Wellhead Price is the value of crude oil or natural gas at the mouth of the well (or wellhead). Wellhead Price represents the sales price, including charges for natural gas plant liquids subsequently removed from the gas, gathering and compression charges, and State (in the United States) production, severance and/or similar charges. / Стоимость нефти или природного газа на устье скважины. Цена Франко-Скважина (Wellhead Price) – цена нефти, газа или конденсата на устье скважины, то есть без учёта расходов на транспортировку добытого углеводородного сырья.

WELLHEAD PRODUCTION = ДОБЫЧА НА УСТЬЕ (СКВАЖИНЫ) – Wellhead Production is all oil which exits the ground (wellhead). When the crude oil has been brought to the surface, it requires further treatment so that it can be sent to refineries for processing. The oil produced at the well-head varies considerably from field to field, due not only to the physical characteristics, but also to the amount of gas and water which it contains. Before the oil can be sold, the remaining gas, water and other impurities need to be removed. Once this is done, the oil is stored at the terminal before transport to refineries. It is at this point that the produced oil becomes marketable (production).

WELLHEAD PROTECTION AREA = АРЕАЛ ЗАЩИТЫ СКВАЖИН – Wellhead Protection Area (WHPA) is the surface and subsurface area surrounding a water well, through which contaminants are reasonably likely to move toward and reach such water well.

WELLHEAD PROTECTION PROGRAM = ПРОГРАММА ЗАЩИТЫ СКВАЖИН – In the United States, Wellhead Protection Program (WHPP) is a pollution prevention and management program used to protect underground-based sources of drinking water. The national WHPP was established in 1986 by the Safe Drinking Water Act. The law specified that certain program activities, such as delineation, contaminant source inventory, and source management, be incorporated into state wellhead protection programs, which are approved by the Environmental Protection Agencyprior to implementation. While the authorization for the program applies only to states, a number of tribes are implementing the program as well.

WELLHEAD UNIT VALUE = СТОИМОСТЬ ЕДИНИЦЫ НА СКВАЖИНЕ – Wellhead Unit Value is the wellhead sales price, including charges for natural gas plant liquids subsequently removed from the gas; gathering and compression charges; and state production, severance, and/or similar charges.

WELLHEAD VALUE = СТОИМОСТЬ НА УСТЬЕ СКВАЖИНЫ – The Wellhead Value is derived by taking the gross value of petroleum recovered and deducting all costs incurred between a defined valve on the christmas tree and the point of sale. Deductible costs are normally confined to the processing, storage and transport of the petroleum recovered by the producer to the point of sale. All other costs, including costs associated with exploration, drilling, recovery and abandonment are not deductible. In Australia, Geothermal Energy:- (i) Royalty on Geothermal Energy is 2.5% of the Wellhead Value of the geothermal energy; (ii) the value at the well head of geothermal energy is a value calculated by subtracting from the price (exclusive of any Goods and Services Tax (GST) component) that could reasonably be realised on sale of the energy to a genuine purchaser at arms length from the producer all reasonable expenses (exclusive of any GST component) reasonably incurred by the producer in getting the energy to the point of delivery to the purchaser; and (iii) the value at the well head of a regulated substance or geothermal energy is to be assessed by the Minister. / Цена На Устье Скважины (Wellhead Value):- (1) Выручка на устье скважины. Валовые поступления от реализации углеводородного сырья по ценам франко-скважина. (2) Смотрите также Wellhead Price (Cost).

WELLINGTON = ВЭЛИНТЭН (или ВЫСОКИЙ САПОГ) – Wellington is a leather boot having a loose top with the front usually coming above the knee (usually used in plural).

WELL INJECTION = НАГНЕТАНИЕ СКВАЖИНЫ – Well Injection is a subsurface emplagement of fluids in a well.

WELL LOGGING = КАРОТАЖ СКВАЖИН – Well Logging:- field technique used in mineral exploration to analyze the geologic formations penetrated by a drill hole. When electrical instruments are employed, the technique involves the recording of variations in the natural electrical properties of subsurface formations. Changes in the porosity, fluid content, or lithology (rock character) of the formation are indicated as variations in resistivity or conductivity. A driller's log records occurrences during drilling of such factors as the pump pressure, the action of the tools, and the rate of drilling. In core logging, samples of the core are extracted from the drill hole and subjected to physical and chemical tests. Borehole camera logging is employed when the condition of the rock strata must be analyzed before major drilling can be undertaken. In this method a camera is lowered into a pilot hole. The camera can take either black-and-white or color photographs or can transmit television images to a monitor on the surface, where they are then photographed. Radioactivity logging is the method in which natural or induced radioactivity in subsurface formations is measured and recorded. Variations in the radioactive gamma rays emitted from formations reveal the character of the rock because of the presence of uranium, thorium, or potassium minerals. Visual wall logging, as the name implies, is the actual examination of the wall of the hole by a geologist. Cuttings-analysis logging involves cuttings recovered from the drilling fluid; when combined with other logging methods, it can furnish valuable data. / Под Каротажем, от Французского слова Кяротаж (Carottage), понимается исследование горных пород в буровых скважинах электрическими, магнитными, радиоактивными и акустическими и другими методами. Каротаж используется для изучения геологического разреза и выявления полезных ископаемых.

WELL–MILLED KERNELS = КАЧЕСТВЕННО ОБРУШЕННАЯ ЗЕРНОВКА (или КАЧЕСТВЕННО ОБРУШЕННЫЕ ЯДРА) – Well-Milled Kernels are whole or broken kernels of Rice from which the hulls and practically all of the germs, the embryos and the bran layers have been removed.

WELL MONITORING = НАБЛЮДЕНИЕ ЗА СКВАЖИНАМИ – Well Monitoring:- the measurement, by on-site instruments or laboratory methods, of the quality of water in a well.

WELL OUT IN RIVER = ХХ НА РЕКЕ – Well Out In River is a channel report term meaning nearer to the middle of the river than to the bank.

WELL PAD = КУСТ СКВАЖИН – Well Pad is the area that has been cleared for a drilling rig to work on a plot of land designated for natural gas or oil extraction. The pad is constructed by clearing all trees and obstacles to allow for engineering of a foundation usually made of local rock from a quarry. An area typically is 3–5 acres of cleared land. The pad is then ready for the drilling derrick and all of it's supporting equipment. Many suppliers with trucks will transport supplies needed by the drilling company to complete drilling, successfully. The area will be set up for such transportation needs and housing for the on site crews will also be made available on the pad. Well Pad is the area that has been cleared for a drilling rig to work on a plot of land used for oil or gas extraction. Well Pad is a synonym for 'Cluster' which is a group of wells usually ten or so, depending on the configuration. The wells within the cluster (or well pad) are grouped to share common processing facilities (separators, gathering pipelines and so on). / Куст Скважин:- бурение скважины кустовым способом подразумевает, что устья скважин располагаются рядом друг с другом, а их залежи в различных углах разрабатываемого месторождения. Современные нефтедобывающие предприятия предпочитают бурение скважин кустовым методом. Такое предпочтение объясняется тем фактом, что на данную разработку необходимо меньше

сопутствующих коммуникаций:- дорог, трубопроводов, линий электропередач. Объём же добываемых полезных ископаемых эквивалентен. Наиболее предпочтительно использовать кустовое бурение на плодородных или заповедных землях, где поверхностный слой оберегается, и на его полное восстановление потребуются многие десятилетия. При бурении скважин на болотистых землях бурение кустом применяют для снижения количества отсыпных работ и удешевления процесса добычи нефти. При обнаружении залежей полезных ископаемых под сооружениями, реками и озёрами или в зоне шельфа кустовое бурение скважин также предпочтительно по сравнению с другими. Прекрасным примером применения кустового бурения для разработки нефте- и газоносных залежей в России являются территории Тюменской, Томской областей и всей Западной Сибири, так как стала возможна разработка залежей, находящихся на болотистой местности, с помощью минимальных вложений по постройке отсыпанных островов по добыче полезных ископаемых. Существует два основных типа куста в зависимости от соотношения базы и самого куста:- (i) Локальные Кусты – это разработки, не связанные с базой; там скважины расположены веером для получения максимально возможного количества источников; и (ii) Базовые Кусты – это места добычи, расположенные рядом с основной магистралью. Для увеличения производительности выработки всё буровое оборудование доставляется на неё после окончания всех скважин на кусте. Затем все насосы, оборудование для химической обработки и изготовления промывочной жидкости перемещаются на следующую скважину. Одна скважина может содержать от двух до тридцати кустов. При чрезмерном количестве скважин увеличиваются затраты на прокладку следующего источника, также риск встречи стволов растёт пропорционально количеству скважин. Поэтому при проектировании куста для успешной добычи полезных ископаемых необходимо тщательно продумывать расположение скважин. Для осуществления кустового бурения необычайно важны общий дебит всех скважин на кусте и газовый фактор нефти. Знание этих особенностей позволяет рассчитать суммарную пожароопасность скважины при возникновении возможного фонтанирования нефти на поверхность земли. После определения числа скважин переходят к разработке проекта куста. Планом куста является изображение в горизонтальной проекции стволов скважин, расположенных в этой разработке. Также в него включают местоположение устьев скважин, порядок их бурения и углы смещения забоев. После определения всех параметров строится схема куста.

WELL PERMIT = РАЗРЕШЕНИЕ НА СКВАЖИНУ – Well Permit:- Permit Requirements in the United States:- (i) no person may drill or alter a well unless that person has first obtained a permit from the Department of Energy and Environment; and (ii) no person may operate a well unless one of the following conditions has been met:- (a) the person has obtained a permit under the act, (b) the person has registered the well under the act, and (c) the well was in operation on April 18, 1985, under a permit that was obtained under the Gas Operations Well-Drilling Petroleum and Coal Mining Act. Compliance With Permit:- a person may not drill, alter or operate an oil or gas well except in accordance with a permit or registration issued under the act and in compliance with the terms and conditions of the permit, this chapter and the statutes under which it was promulgated. A copy of the permit shall be kept at the well site during drilling or alteration of a well. Permit Transfers:- (i) No transfer, assignment or sale of rights granted under a permit or registration may be made without prior written approval of the Department. Permit transfers may be denied for the reasons set forth in section 201(e)(4) and (5) of the act (58 P.S. § 601.201(e)(4) and (5)). (ii) The Department may require the transferee to fulfill the drilling, plugging, well site restoration, water supply replacement and other requirements of the act, regardless of whether the transferor commenced the activity and regardless of whether the transferor failed to properly perform the transferor's obligations under the act. Transfer of Well Ownership or Change of Address:- (i) within 30 days after the sale, assignment, transfer, conveyance or exchange of a well, the new owner or operator shall notify the Department, in writing, of the transfer of ownership; (ii) the notice shall include the following information:- (a) the names, addresses and telephone numbers of the former and new owner, and the agent if applicable, (b) the well permit or registration number, (c) the effective date of the transfer of ownership, and (d) an application for a well permit transfer if there is a change in the well operator; and (iii) the permittee shall notify the Department of a change in address or name within 30 days of the change. Water Well Permits are governed by state and local laws, which vary by jurisdiction. The process of obtaining a water well permit involves primarily identifying potential sources of contamination and then maintaining separation distances to protect the water quality. Well permits are required to assure construction consistent with regulations for the safeguarding of persons and property from hazards arising from unsanitary and unhealthy drinking water and to assure an adequate supply of water. Water well permits are required prior to commencing construction. Well permits may be required for commercial, industrial, municipal, irrigation, feed lot, geothermal, recovery wells, and other uses. In some cases, permits are not required for test holes, temporarily dewatering wells with a short-term use, or water wells designed and constructed to pump (yield) under a certain number of gallons per minute. The permit process may require site inspection and water quality testing. Local laws should be consulted for specific requirements in your area. / Лицензия на Бурение Скважины (Well Permit) – официальное разрешение на проходку единичной скважины (поисково-разведочной, эксплуатационной или вспомогательной) выдаваемое властями соответствующего штата (при проведении буровых работ на землях, находящихся под юрисдикцией последнего).

WELLS FARGO = ВЭЛЗ ФАРГОУ – Wells Fargo is an American financial services company with banks in many states, especially in the West. The founders of the original company were Henry Wells (1805–78) and William George Fargo (1818–81), who had earlier helped establish the American Express Company. They and other investors established Wells, Fargo & Company in March 1852, to handle the banking and express business prompted by the California Gold Rush. In California the company handled the purchase, sale, and transport of gold dust, bullion, and specie and other goods that moved from the West to the East Coast by ship, via the Isthmus of Panama. In the decade following 1855, Wells Fargo expanded into the staging business with overland routes from Missouri and the Midwest to the Rockies and the Far West. In 1866 a grand consolidation brought almost all Western stagecoach lines under the Wells Fargo name. The days of stagecoaching gradually declined, however, after completion of the first transcontinental railroad in 1869. In 1905 Wells Fargo's banking operations (in California) were separated from its express operations and merged with the Nevada National Bank (founded 1875) to form the Wells Fargo Nevada National Bank. In 1923 this bank merged with the Union Trust Company (founded 1893) to form the Wells Fargo Bank & Union Trust Co., a name that was shortened to Wells Fargo Bank in 1954. In 1960 it merged again, this time with the giant American Trust Company (dating to 1854), to form the Wells Fargo Bank American Trust Company. In 1968 the holding company Wells Fargo & Company was created to own all shares of Wells Fargo Bank, NA, as the bank was renamed. In the late XX century Wells Fargo Bank (headquartered, as was the holding company, in San Francisco) had more than 300 branches throughout California, as well as subsidiaries, affiliates, and branches worldwide. In 1986 Wells Fargo & Company acquired the Crocker National Corporation for approximately USD1 billion. The following decade brought mergers with First Interstate Bancorporation (1996) and Norwest Corporation (1998). The contemporary Wells Fargo, one of the largest banks in the United States, provides services including banking, mortgages, insurance, and financial management. Other companies have also possessed rights to use the Wells Fargo name. Wells Fargo the express carrier eventually disappeared; in 1918 its domestic operations were taken over by

American Railway Express (reorganized in 1929 as Railway Express Agency, Inc., and fading into bankruptcy in 1975 as REA Express, Inc.). Wells Fargo's foreign express business continued independently until 1924, when the American Express Company acquired a controlling interest in Wells Fargo stock and absorbed the remaining Wells Fargo express business. During the years under American Express, however, Wells Fargo also developed security services; these, together with rights to the Wells Fargo name, were sold in 1967 to Baker Industries, Inc., and survived through subsidiary Wells Fargo Armored Service Corp., which included Wells Fargo Guard Services and Wells Fargo Alarm Services. The merger of Loomis Armored Inc. and Wells Fargo Armored Service Corp. in 1997 created Loomis, Fargo & Co., a division of Securitas AB, a Swedish company. / Вэлз Фаргоу (Wells Fargo). WELL WATER FOR COOLING = ПОДХОДЯЩАЯ ВОДА ДЛЯ ОХЛАЖДЕНИЯ – Well Water For Cooling:- a means of cooling that uses water from a well drilled specifically for that purpose. The subterranean temperature of the water stays at a relatively constant temperature. Where water is abundant, it provides a means of getting 55-degree Fahrenheit water with no mechanical cooling. Used usually for heat rejection in a water source heat pump.

WELT = ОБШИВКА (или ОТОРОЧКА, или ОКАНТОВКА, или ЛИСТОЧКА (кармана), или КАЙМА, или БОРТ, или ОБТАЧКА, или ФАЛЬЦ, или КАНТ, или СТЕЛЬКА) – Welt is:- (1) a strip of material seamed to a pocket opening as a finishing, as well as a strengthening device. (2) A raised or swelled lap or seam. (3) A covered cord or ornamental strip sewed on a border or along a seam. (4) In knitting, it is flat-knitted separately and then joined to the fabric by looping or hand knitting, as the heel to the stocking. (5) A ribbed piece of knit goods used in forming the end of a sleeve or sock to prevent rolling or raveling. Welt is:- (1) a finished edge on knit goods, especially hosiery. In women's stockings, it is a wide band knitted from heavier yarn than the leg and folded on itself. (2) A small cord covered with fabric and sewn along a seam or border to add strength. (3) A seam made by folding the fabric double, generally over a cord, and sewing it. (4) A term sometimes used for Piqué. / (1) ластик носка или борт чулка. (4) Пике с поперечным рубчиком.

WELTING = ОБШИВКА (или БОРТОВКА, или КАЙМА) – Welting is a decorative edging. It gives strength to the area in which it is sewn. Welting is made by covering cord with bias strips of matching or contrasting fabric. It is a popular finish for seams on upholstery. Occasionally is used on clothing, too. Welting is the same as Piping. See also Cording, and Piping. / Бортовка, плотная полульняная или хлопчатобумажная ткань полотняного переплетения, употребляется при шитье верхней одежды в качестве прокладки, придающей устойчивость её формам (борта, грудь, плечи и так далее). WEST AFRICA ECONOMIC COMMUNITY = ЭКОНОМИЧЕСКОЕ СООБЩЕСТВО ЗАПАДНОЙ АФРИКИ – The Economic Community Of West African States (ECOWAS) or in French, Communauté Economique de l'Afrique de l'Ouest (CEAO), created in 1974, includes:- Benin, Burkina Faso, Cote d'Ivoire, Mali, Mauritania, Niger and Senegal; Togo has observer status. The CEAO operates as a free trade area for agricultural products and raw materials and as a preferential trading area for approved industrial products, with a regional cooperation tax (Taxe de Coopération Régionale or TCR) replacing import duties and encouraging trade among member states. In order to ensure that benefits of the regional grouping flow to all members, especially the least developed ones (Burkina Faso, Mali, Mauritania and Niger), the CEAO has established the solidarity and action fund for the development of the community, Fonds de Solidarité et d'Intervention pour le Développement de la Communauté (FOSIDEC) to provide financial services and guarantees to development lenders in both public and private sectors for projects in member states. In addition, CEAO has the long-term objective of creating a customs union with extensive harmonization of fiscal policies between member states, though no concrete achievements in this direction have been recorded. Headquartered in Abuja, Nigeria. The Economic Community Of West African States (ECOWAS) is a regional group of fifteen countries, founded on 1975-May-28. Its mission is to promote economic integration in 'all fields of economic activity, particularly industry, transport, telecommunications, energy, agriculture, natural resources, commerce, monetary and financial questions, social and cultural matters ...'. The Institutions of the Economic Community Of West African States (ECOWAS) are as follows:- (i) The Commission; (ii) The Community Parliament; (iii) The Community Court OF Justice; and (iv) ECOWAS Bank for Investment and Development (EBID). The ECOWAS Commission and the ECOWAS Bank for Investment and Development, more often called The Fund are its two main institutions designed to implement policies, pursue a number of programmes and carry out development projects in Member States. Such projects include intra-community road construction and telecommunications; and agricultural, energy and water resources development. The fifteen (in 2011) West African States that constitute ECOWAS:- Benin, Burkina Faso, Cabo Verde, Cote d'Ivoire, Gambia, Ghana, Guinee, Guinee Bissau, Liberia, Mali, Niger, Nigeria, Senegal, Sierra Leone, and Togo. West Africa Economic Community (WAEC) is the international organization established in 1975 to end barriers in trade and to achieve cooperation in development. Members include Burkina Faso, Côte d'Ivoire, Mali, Mauritania, Niger, and Senegal; Benin and Togo have observer status. West Africa Economic Community (WAEC) or in French – Communauté Économique de l'Afrique de l'Ouest (CEAO):- this organization has acted on behalf of member countries to establish freedom of movement and freedom of trade in the region since 1973. The members of WAEC are Cote d'Ivoire, Mali, Mauritania, Niger, and Senegal. The activities of WAEC include one of the first common customs systems between all members, along with a standardized tax on commodities. WAEC is also largely responsible for establishing freedom of movement of citizens of member countries throughout the West Africa Economic Community. Although the importance of WAEC has been supplanted by the newer and larger Economic Community of Western African States (ECOWAS), its importance as a pioneer in freedom of international trade and movement of member citizens still stands. Notes:- (i) superseded the West African Customs and Economic Union on coming into force of the Treaty of Abidjan, 01 January 1974; (ii) superseded by the West African Monetary Union first and, in 1994, by the West African Economic and Monetary Union. / Экономическое Сообщество Западной Африки или Экономическое Сообщество Западно-Африканских Государств или, как это звучит на Французском языке по месту регистрации сообщества, Комюнотэ Экономик дё л'Яфрик' дё л'Юэст (Сэ.Е.А.О.; Communauté Economique de l'Afrique de l'Ouest (CEAO)) была создана 28 Мая 1975. Под Экономическим Сообществом Западной Африки (ЭСЗА; West Africa Economic Community (WAEC)) понимается региональная международная торговая группировка, образованная в 1973. Штабквартира расположена в Уагадугу, Буркина Фасо. Представляет собой таможенный союз между государствами-членами:- Кот д'Ивуар, Мавритания, Мали, Нигер и Сенегал.

WEST AFRICAN DEVELOPMENT BANK = ЗАПАДНО–АРИКАНСКИЙ БАНК РАЗВИТИЯ – The West African Development Bank (WADB) or in French – Banque Ouest Africaine de Développement (BOAD) / pt. Banco de Desenvolvimento do Oeste Africano (BDOA) is an international Multilateral Development Bank established in 1973 to serve the nations of Francophone and Lusophone West Africa. The BOAD is organized by the Central Bank of West African States and its eight member governments:- Benin, Burkina-Faso, Côte d'Ivoire, Guinea Bissau, Mali, Niger, Senegal and Togo. It is funded by member states, foreign governments and international agencies. Its headquarters are in Lomé, Togo. The BOAD was created 14 November 1973 by member states of the West African Monetary Union (WAMU). The original charter focused on development of member economies towards balanced development and to prepare economies for future West African economic integration. In 1994, it became the development arm of the West African Economic and Monetary Union (WAEMU/UEMOA). Since that time several international organisations have become members of the bank, adding funding and sitting on the board. These include The African Development Bank, the European Investment Bank, the Export and Import Bank of India (Exim Bank), and the People's Bank of China. The president of the bank's board is chosen by the heads of state of UEMOA, and since January 2008, Abdoulaye Bio-Tchane. The Bank's day to day operations are carried out by the President and the Bank adminmanager, cabinet, directorships of departments based in Lome, and mission offices based in the member nations. The BOAD released a revised mission statement in 2001, refocusing their funding on three development goals: poverty reduction, economic integration and promotion of private sector activity. The bank disburses long- and medium-term loans, previously available only to BOAD member governments and public institutions, are since 2002 also offered to private businesses involved in development projects of regional importance as well as lines of credit to finance Micro-credit projects and small to medium private enterprises. The BOAD also funds debt-relief programs to member governments with the agreement that funds are instead diverted to health programmes particularly those dealing with HIV/AIDS, education and infrastructure improvements. Xxxxx. The West African Development Bank (WADB) or Banque Ouest Africaine de Développement (BOAD) was established in 1973 following an agreement signed by the member countries of the West African Monetary Union (WAMU). The aim of the WADB is to promote balanced development of its member countries and to achieve West African economic integration. The member countries are Benin, Burkina-Faso, Côte d'Ivoire, Guinea Bissau, Mali, Niger, Senegal and Togo. Mission:- in 2001, WADB established priority working areas with particular emphasis on poverty reduction, economic integration and promotion of private sector activity. (i) Poverty reduction:- WADB aims to decrease poverty in the region by improving living conditions for the rural poor. In 2002, WADB financed several poverty reduction projects amounting to 28 billion Francs Colonies Françaises d'Afrique (Francs CFA). Of this total, 33% was earmarked for improvement of production systems and drinking water access as well as mechanisms to fight desertification and soil erosion. WADB gave debt relief to some of its member countries and ensured that the funds were instead spent on health programmes particularly those dealing with HIV/AIDS, education and infrastructure improvements. (ii) Economic integration:- one of WADB's central goals is to improve regional economic integration. In 2002, WADB financed seven projects with a regional focus through a 41 billion

Francs CFA investment. Projects included regional telecommunications and energy initiatives as well as the modernization of airports and regional road networks. (iii) Support to the private sector:- WADB supports member government policy on liberalization of economies and promotion of private sector investment. New financing in 2002 of approximately 23 billion Francs CFA went to ten projects that focused on food and beverage production, construction, cellular telephone technology, tourism and the promotion of small- and medium-sized businesses. Support to small- and medium-sized businesses is an essential factor in improving general economic performance particularly growth and labor flexibility. (iv) Technical assistance:- WADB gives technical assistance to member countries in several areas but with a particular emphasis on organizing meetings with a regional scope and supporting the New Partnership for Africa's Development (NEPAD). In 2002, WADB provided 120 million Francs CFA in loans to the NEPAD initiative. Financial products:- (i) long- and medium-term loans for financing investment projects and recapitalization funding; and (ii) financing to national financing institutions:- (a) lines of credit to assist in financing of micro-projects and the development of small and medium businesses, and (b) financing of feasibility studies. Eligible sectors:- (i) WAMU member countries; (ii) public institutions in member countries; and (iii) organizations and businesses involved in the development of regional economic initiatives. Headquartered in Lomé, Togo. / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Западно-Африканский Банк Развития (ЗАБР) был учреждён в 1973. Функционирует с 1976. Штабквартира расположена в Ломе, Того. Учредителями банка выступили правительства Бенина, Берега Слоновой Кости, Верхней Вольты, Нигера, Сенегала, Того, а также Центральный Банк Западно-Африканских Государств. Цель банка – содействовать экономическому развитию, торговле и интеграции в Западной Африке. Западно-Африканский Банк Развития – инвестиционный институт Западно-Африканского Валютного Союза (У.Эм.О.А.), обеспечивающий кредитное сотрудничество Бенина, Буркина-Фасо, Кот д'Ивуара, Нигера, Сенегала, Того. Банк был учреждён в Ноябре 1973, однако приступил к операциям лишь в Марте 1977. Общее руководство и контроль за деятельностью БОАД осуществляет Совет Министров У.Эм.О.А.. Банк призван оказывать содействие экономическому развитию стран-членов У.Эм.О.А., при этом особый приоритет имеет кредитование проектов, содействующих развитию экономической интеграции упомянутых стран. В соответствии с Уставом БОАД осуществляет кредитование лишь рентабельных объектов, исключается возможность финансирования социально-культурных учреждений. Отдельным направлением деятельности банка является содействие выкупу иностранной недвижимости на территории Западной Африки, для чего создан специальный фонд содействия выкупу иностранного имущества.

WEST AFRICAN ECONOMIC AND MONETARY UNION = ЗАПАДНО–АФРИКАНСКИЙ ЭКОНОМИЧЕСКИЙ И ВАЛЮТНЫЙ СОЮЗ – The West African Economic and Monetary Union (WAEMU) or, in French, Union Économique et Monétaire Ouest Africaine (UEMOA) was created by treaty signed at Dakar, Senegal on 1994-January-10. WAEMU comprises seven French-speaking African countries:- Benin, Burkina Faso, Cote d'Ivoire, Mali, Niger, Senegal, and Togo. Within WAEMU, these countries share a common currency (CFA Franc; ISO Code – XOF/952) freely convertible into the French Franc at a fixed parity, and a common central bank, Banque Centrale des États de l'Afrique de l'Ouest (BCEAO) responsible for the conduct of the Union's monetary and credit policies. There is a common regional development bank, Banque Ouest Africaine de Développement (BOAD). See also CFA Franc. Headquartered in Ouagadougou, Burkina Faso. West African Economic and Monetary Union (WAEMU):- Formerly known as the West African Monetary Union (WAMU/UMOA), the West African Economic and Monetary Union (UEMOA) was founded on 10 January 1994 in response to the devaluation of the common currency, the CFA Franc, on 11 January 1994. The Treaty establishing UEMOA (the Dakar Treaty of 10 January 1994) theoretically came into effect on 01 August 1994 after ratification by the seven member countries, thereby also replacing the since then dissolved West African Economic Union (WAEU/CEAO). This new regional economic organization was to a large extent the brainchild of Mr Charles Konan Banny, Governor of the Central Bank of West African States (BCEAO), whose experts have played a major role in establishing the guiding principles and institutional framework of UEMOA. Because of its important role in especially the initial phases of the establishment of the new Union, this Bank, as well as the West African Development Bank (BOAD) are and will remain inextricably linked to it. The UEMOA Council of Ministers met in Ouagadougou on 06 August 1999, focusing on the economic situation within member states and trade relations between the union and other countries. The UEMOA Inter-Parliamentary Committee adopted a draft treaty on the creation of a regional parliament. The UEMOA Summit convened in Lomé in December 1999, immediately prior to the ECOWAS Summit and announced the take off of their common monetary zone in January 2000. 8 Members in 2011:- Benin, Burkina Faso, Cote d'Ivoire, Guinee Bissau, Mali, Niger, Senegal, and Togo. / Западно-Африканский Экономический и Валютный Союз (ЗАЭВС) или, как это звучит на Французском языке по месту регистрации, Юньо Экономик и Монетэр Вэст Африкен (У.Ё.Эм.О.А.; Union Économique et Monétaire Ouest Africaine (UEMOA)), был создан в Дакаре, Сенегал 10 Января 1994 на основе подписанного договора. ЗАЭВС состоит из семи Франкоговорящих Африканских стран:- Бенина, Буркина Фасо, Кот Д'Ивуара, Мали, Нигера, Сенегала и Того. В пределах ЗАЭВС ти страны используют общую валюту (Сэ.Эф.А. Франк; Код МОС – XOF/952), свободно обратимую (конвертируемую) во Французский Франк по фиксированной ставке, и общий центральный банк, Банк Сотраль деЗета дё л'Яфрик дё л'Юэст (по-Французски – Banque Centrale des États de l'Afrique de l'Ouest, сокращённо – BCEAO), отвечающий за руководство денежной массой и кредитную политику этого Союза. В этом Союзе имеется также общий региональный банк развития – Западно-Африканский Банк Развития или Банк Вэст Африкен дё Девэлёпмо (Бэ.О.А.Дэ.; Banque Ouest Africaine de Développement (BOAD)). (UEMOA – на Французском языке)) создан при активном участии Франции на базе существовавшего с 1962 Западно-Африканского Валютного Союза (ЗВС), объединявшего государства субрегиона. Договор об учреждении У.Ё.Эм.О.А. был подписан в Дакаре 10 Января 1994 и вступил в силу 01 Августа того же года. В настоящее время (2009-Июнь) членами У.Ё.Эм.О.А. являются 8 государств – Бенин, Буркина-Фасо, Кот д'Ивуар, Мали, Нигер, Сенегал, Того, Гвинея-Бисау (последняя – с Января 1997). Территория входящих в Союз стран составляет 3.47 миллионов квадратных километров, население – более 70 миллионов человек. Деятельность У.Ё.Эм.О.А., ориентирующегося на пример Европейского Союза, предусматривает унификацию законодательной базы в экономической, валютной, фискальной сферах, создание многосторонних механизмов контроля за исполнением принимаемых решений. Положения основополагающих документов У.Ё.Эм.О.А. имеют преимущество по отношению к нормам национального законодательства стран-членов. Цели У.Ё.Эм.О.А. – создание общего рынка на основе свободного перемещения рабочей силы, товаров, услуг и капиталов; проведение единой торговой политики; установление общих правил конкуренции и оказания господдержки производителям; гармонизация макроэкономической политики стран-членов; разработка общих подходов к вопросам развития конкретных отраслей; согласование национальных бюджетных программ с денежно-кредитной политикой Союза. Руководящими органами У.Ё.Эм.О.А. являются:- (i) Конференция Глав Государств и Правительств:- собирается не реже одного раза в год. Решения Конференции обязательны к исполнению всеми органами Союза и национальными властями входящих в него государств. Председатель У.Ё.Эм.О.А. – Президент Мали Амаду Тумани Туре (Amadou Toumani Touré; избран в Марте 2009). (ii) Совет Министров:- собирается не реже 2 раз в год. Обеспечивает исполнение решений, принимаемых Конференцией глав государств и правительств. (iii) Комиссия Союза:- Председатель Комиссии – бывший Министр Финансов Мали Сомаила Сиси (Soumaila Cissé) и по одному представителю от каждой из стран-членов, назначаемых Конференцией Глав Государств и Правительств на четырёхлетний срок. Занимается координацией отраслевой политики, унификацией

законодательной базы. (iv) В Августе 1999 образован Политический Совет, состоящий из министров иностранных дел стран-членов, в функции которого входит выработка рекомендаций политического, дипломатического и стратегического характера по вопросам поддержания мира, стабильности и безопасности. В рамках Союза функционируют также Верховный Суд и Счётная Палата. Местопребывание Комиссии, Верховного Суда и Счётной Палаты У.Ё.Эм.О.А. – Уагадугу, Буркина Фасо. Предусматривается создание Парламента У.Ё.Эм.О.А., призванного осуществлять контроль за деятельностью органов Союза. В настоящее время соответствующие функции возложены на Межпарламентский Комитет (5 парламентариев от каждой страны, собирается раз в год, постоянный секретариат расположен в Бамако), который заслушивает доклады Комиссии о деятельности У.Ё.Эм.О.А.. Автономными специализированными учреждениями У.Ё.Эм.О.А. являются Центральный Банк Государств Западной Африки (субрегиональный эмиссионный институт) и Западно-Африканский Банк Развития с офисами, соответственно, в Дакаре (Сенегал) и Ломе (Того). Единой внутризональной валютой является Франк КФА (1 Доллар США = около 500 Франков КФА). С 1998 в Абиджане (Кот-д'Ивуар) действует Региональная Фондовая Биржа – прообраз будущих единых фондового и финансового рынков. Сформирована Региональная Консульская Палата. Бюджет Союза формируется за счёт отчислений от таможенных пошлин на товары, привозимын (или импортируемые) из третьих стран, в размере 0.5% от их стоимости. Однако на практике основные расходы У.Ё.Эм.О.А. финансируются Европейским Союзом, с которым подписаны соответствующие конвенции. В 1996 на Конференции Глав Государств и Правительств стран-членов У.Ё.Эм.О.А. была принята Программа приоритетных действий по реализации целей Союза, направленная на ускорение сближения законодательств и формирования единой законодательной базы. Был также принят ряд мер по обеспечению свободного обращения капиталов и унификации налогообложения, согласованию отраслевых программ развития. Интеграционные процессы в торгово-экономической области в рамках У.Ё.Эм.О.А. заметного развития не получили. Для Союза по-прежнему характерен низкий объём внутризональной торговли (менее 10% от совокупного внешнеторгового оборота) и взаимных инвестиций. Основная причина – неравномерность экономического развития государств-членов. Последствия осуществления интеграционных мероприятий неоднозначны. Либерализация торговли ставит в тяжёлое положение промышленные предприятия в наименее развитых странах субрегиона. Не менее сложный характер имеет проблема компенсации потерь национальных бюджетов от снижения таможенных поступлений. Трудности связаны и с одновременным членством многих стран У.Ё.Эм.О.А. в нескольких субрегиональных организациях (Буркина Фасо, например, состоит в 8 структурах). В 2000 положено начало процессу гармонизации деятельности У.Ё.Эм.О.А. и Экономического Сообщества Западно-Африканских Государств (ЭКОВАС) с прицелом на слияние в перспективе этих организаций. В середине 2002 между У.Ё.Эм.О.А. и США было подписано первое в своем роде соглашение о развитии торговли и инвестиций. Его главной задачей является содействие развитию стран-участниц союза путём облегчения доступа Африканской продукции на Американский рынок, а также обеспечение получения инвестиций в экономику государств региона для разработки их неиспользуемых ресурсов, в частности, в области сельского хозяйства, энергетики, поиска полезных ископаемых, транспорта и связи. Стороны взяли на себя обязательства принять необходимые меры для обеспечения свободной циркуляции товаров и услуг, а также гарантировать создание условий для размещения долгосрочных инвестиций. В конце Октября 2002 состоялось подписание меморандума о сотрудничестве между У.Ё.Эм.О.А. и Исламским Банком Развития (ИБР). Договорённости с ИБР предусматривают:- обмен информацией и исследованиями по различным аспектам экономического и социального сотрудничества; сотрудничество между ответственными лицами и техническими экспертами двух организаций, проведение совместных коллоквиумов, стажировок и взаимное приглашение на мероприятия, организуемые У.Ё.Эм.О.А. или ИБР; координацию разработок, проектов и программ развития; организацию совместных миссий по разработке и поддержке программ и проектов развития стран-участниц; совместное финансирование проектов развития в интересах одной или нескольких стран-участниц. Тяжёлым бременем на экономиках стран-участниц Союза лежит внешняя задолженность, составляющая от 60% до более 330% ВВП. Главными задачами в экономической составляющей деятельности У.Ё.Эм.О.А. являются консолидация таможенной политики, углубление сотрудничества по линии частнопредпринимательских структур, диверсификация торгово-экономического сотрудничества стран Союза (проекты с партнёрами из США, Марокко, Египта, Туниса), обеспечение роста ВВП. Пока с трудом реализуются программы по свободному передвижению товаров, услуг, капиталов и людей в рамках экономического пространства Сообщества. В качестве наиболее важных на ближайшую перспективу целей обозначены формирование Общего рынка государств-участников и реализация всех положений, предусмотренных при создании Таможенного Союза. Пробуксовывает вопрос о запуске Единого парламента, договор о котором не ратифицировали Бенин, Гвинея-Бисау, Кот д'Ивуар и Сенегал. На саммите У.Ё.Эм.О.А. в Уагадугу в Январе 2007 основное внимание было уделено вопросу о назначении управляющих Центральным Банком Государств Западной Африки и Западно-Африканским Банком Развития. Утверждён бюджет организации на 2007 – 170 миллионов Долларов США. На саммите У.Ё.Эм.О.А. в Уагадугу в Январе 2008 рассматривались вопросы создания общего рынка, реформирования Центрального Банка Государств Западной Африки, развития Регионального Банка Солидарности. Президент Буркина-Фасо Блез Купауре (Blaise Compaoré) переизбран Председателем У.Ё.Эм.О.А.. Последний саммит организации прошёл в Уагадугу в Марте 2009. Председателем У.Ё.Эм.О.А. избран Президент Мали Амаду Тумани Туре. Рассматривались вопросы социально-экономического развития субрегиона, намечены планы расширения стратегических рамок процесса региональной интеграции. Следующий саммит состоится в Бамако (Мали) в 2010. Основным внешним партнёром У.Ё.Эм.О.А. является Франция. Подписаны документы о сотрудничестве с Европейским Союзом.

WEST CENTRAL ATLANTIC FISHERY COMMISSION = ЗАПАДНО–ЦЕНТРАЛЬНАЯ АТЛАНТИЧЕСКАЯ КОМИССИЯ ПО РЫБОЛОВСТВУ – The West Central Atlantic Fishery Commission (WCAFC) is an inter-governmental organization established in 1973 under the auspices of the United Nations Food and Agriculture Organisation (FAO). Its functions include:- facilitating the co-ordination of research; assisting member governments in establishing rational policies; and promoting the rational management of resources of interest in two or more countries. Its area of competence is the western central Atlantic.

WESTERN ACCOUNT = ЗАПАДНЫЙ СЧЁТ – Western Account is an agreement among underwriters regarding liability, in which each member of the syndicate is liable only for the amount of its participation in, but not for the unsold portion of, the issue. See also Severally But Not Jointly, and Syndicate. / Западный Счёт:- техника организации синдиката, при которой каждый член синдиката андеррайтеров несёт ответственность только за своё размещение и не отвечает за размещение любым другим членом. WESTERN AREA = ЗАПАДНЫЙ АРЕАЛ – Western Area (in the United States in 1900's) is the newest Cotton producing section in this country including parts of Southern California, Arizona and New Mexico. Irrigation is required and the Cotton is of two types, American-Egyptian and Upland.

WESTERN AREA POWER ADMINISTRATION = АДМИНИСТРАЦИЯ ПО ЭНЕРГЕТИКЕ ЗАПАДНОГО РАЙОНА – In the United States, Western Area Power Administration (WAPA) markets and delivers cost-based hydroelectric power and related services within a

15-state region of the central and western United States. The Western Area Power Administration (WAPA) is one of four federally-owned power marketing administrations in the United States.

WESTERN ASSOCIATION FOR TRANSMISSION SYSTEM COORDINATION = ЗАПАДНАЯ АССОЦИАЦИЯ ПО КООРДИНАЦИИ СИСТЕМ ПЕРЕДАЧИ (или XX) – In the United States, the Western Association for Transmission System Coordination (WATSCO):- Assembly Bill 2933 (Moore):- this bill requires municipal electric utilities, investor owned electric utilities, state agencies owning an interest in electric transmission facilities to form a voluntary association to be known as the Western Association for Transmission System Coordination (WATSCO) to coordinate the planning and operating of bulk, wholesale electrical transmission systems. / Mo (Moore).

WESTERN BLOT TEST = ЗАПАДНЫЙ БЛОТ ТЕСТ – Western Blot Test:- a test that is performed on biological samples such as blood (after centrifugation to remove red blood cells from the blood) to detect proteins (e.g., AIDS-rel. antibodies) individually. Gel electrophoresis is used to separate the AIDS antigen proteins of killed (known) AIDS viruses. Next the protein bands (resulting from the gel electrophoresis) are exposed to the blood being tested and (AIDS) antibodies stick to specific individual antigens (bands), which are then identified (as being present in the tested blood) via dyes.

WESTERN BLOTTING = ЗАПАДНЫЙ БЛОТИНГ – Western Blotting (WB) is a core technique in cell and molecular biology. Western blotting, also known as Immunoblotting or Protein Blotting, is a core technique in cell and molecular biology. In most basic terms, it is used to detect the presence of a specific protein in a complex mixture extracted from cells. Three Key Elements:- the Western blotting procedure relies upon three key elements to accomplish this task:- (i) the separation of protein mixtures by size using gel electrophoresis; (ii) the efficient transfer of separated proteins to a solid support; and (iii) the specific detection of a target protein by appropriately matched antibodies. Once detected, the target protein will be visualized as a band on a blotting membrane, X-ray film, or an imaging system. Since Western blotting is accomplished rapidly, using simple equipment and inexpensive reagents, it is one of the most common laboratory techniques. The results achieved are also easy to interpret, unique, and unambiguous. Therefore, it is routinely used on its own, or along with other immunoassays, in research and clinical settings. Why use a Western Blot? Western blots are in wide use across a broad range of scientific and clinical disciplines. Their ability to clearly show the presence of a specific protein both by size and through the binding of an antibody makes them well-suited for evaluating levels of protein expression in cells, and for monitoring fractions during protein purification. Likewise, they are helpful for comparing expression of a target protein from various tissues, or seeing how a particular protein responds to disease or drug treatment. In many cases, Western blots are used in combination with other key antibody based detection techniques, such as ELISAs (short for the enzyme-linked immunosorbent assays) or immunohistochemistry. Western Blotting Antibodies:- antibodies selected for immunodetection should be Western blot tested if possible, with attention paid to the experimental conditions recommended by the antibody supplier. Usually, Western blot positive antibodies recognize a short linear sequence of amino acids found within the target protein that remains intact, or becomes visible, when the target protein is fully unraveled. This is because most Western blots are carried out under denaturing and reducing conditions which remove all higher order protein structure. In contrast, some epitopes can be conformational, forming a three dimensional structural configuration of amino acids that will be lost upon denaturation of the protein. Thus, not all antibodies work in a typical Western blot. Since Western blot procedures allow for flexibility in choosing gel electrophoresis and blotting conditions, it is possible to modify buffers to retain enough higher order protein structure for detection by some antibodies. Bio-Rad is one of the world's leading manufacturers of primary and secondary antibodies for Western blot anaylsis. In addition, we offer ISO-certified pre-made buffers to simplify immunostaining and make results more consistent from blot to blot. Our 100% Satisfaction Guarantee is backed by our quality, which makes ordering from Bio-Rad totally risk free! See also Western Hybridization. Western Blotting (WB) is a widely used technique for the detection and analysis of proteins. It is frequently used to study single proteins but the advent of multiplexed, fluorescence-based detection enables the simultaneous detection of several proteins. Western blotting, or immunoblotting, is used for both qualitative and quantitative analysis of protein expression in a wide variety of biological samples. The Amersham Western blotting portfolio provides optimal solutions for routine protein identification with chemiluminescence as well as for accurate and reproducible quantitative WB with fluorescence detection. In Western blotting, native or denatured proteins are first separated by gel electrophoresis according to polypeptide length (under denaturing conditions) or by the three-dimensional structure of the protein (under native/non-denaturing conditions). The separated proteins are then transferred to a membrane, typically made of nitrocellulose or polyvinylidene difluoride (PVDF), where they are probed using antibodies specific to the target protein. The target protein is then detected and visualized using an imaging system. Western Blotting:- Western blot analysis can detect one protein in a mixture of any number of proteins while giving you information about the size of the protein. It does not matter whether the protein has been synthesized in vivo or in vitro. This method is, however, dependent on the use of a high-quality antibody directed against a desired protein. So you must be able to produce at least a small portion of the protein from a cloned DNA fragment. You will use this antibody as a probe to detect the protein of interest. Western blotting tells you how much protein has accumulated in cells. If you are interested in the rate of synthesis of a protein, Radio-Immune Precipitation (RIP) may be the best assay for you. Also, if a protein is degraded quickly, Western blotting won't detect it well; you'll need to use (RIP). See the section on RIP for more information, as well as a helpful comparative chart that illustrates the differences between these two techniques. Let's look at this technique in greater detail:- (1) Separate The Proteins using SDS-polyacrylamide gel electrophoresis or sodium dodecyl sulfate-polyacrylamide gel electrophoresis (also known as SDS-PAGE). This separates the proteins by size. (2) Place A Nitrocellulose Membrane On The Gel and, using electrophoresis, drive the protein (polypeptide) bands onto the nitrocellulose membrane. You want the negative charge to be on the side of the gel and the positive charge to be on the side of the nitrocellulose membrane to drive the negatively charged proteins over to the positively charged nitrocellulose membrane. This gives you a nitrocellulose membrane that is imprinted with the same protein bands as the gel. One thing to be aware of is that proteins bind better to nitrocellulose at a low pH. You may need to go through some trial-and-error to find the optimal pH. You also need to be sure there are no air bubbles between the nitrocellulose and the gel or your proteins will not transfer. (3) Incubate The Nitrocellulose Membrane With A Primary Antibody:- the primary antibody, which is the specific antibody mentioned above, sticks to your protein and forms an antibody-protein complex with the protein of interest. (4) Incubate The Nitrocellulose Membrane With A Secondary Antibody:- this antibody should be an antibody-enzyme conjugate. The secondary antibody should be an antibody against the primary antibody. This means the secondary antibody will 'stick' to the primary antibody, just like the primary antibody 'stuck' to the protein. The conjugated enzyme is there to allow you to visualize all of this. It's kind of like a molecular flare stuck on the antibodies so you can visualize what s going on. (5) To Actually See Your Enzyme In Action, you'll need to incubate it in a reaction mix that is specific for your enzyme. If everything worked properly, you will see bands wherever there is a protein-primary antibody-secondary antibody-enzyme complex, or, in other words, wherever your protein is. (6) Put X-Ray Film On Your Gel to detect a flash of light, which is given off by the enzyme. The reaction usually runs out in about an hour. Making A Primary Antibody:- this description assumes you have available purified protein. Run the protein on an SDS-PAGE (SDS-polyacrylamide gel electrophoresis or sodium dodecyl sulfate-polyacrylamide gel electrophoresis) gel. Stain the gel with KCl (калий хлор). The KCl forms a precipitate with the SDS. Since the area with the protein has a low concentration of SDS, the area with the protein will not show a precipitate. This will allow you to see the protein band as a clear band against a milky white precipitate on the rest of the gel. Carefully cut out the band and

soak it in 1 mL phosphate-buffered saline (PBS) buffer. Crush it and make an emulsion with 1 mL Freund's Complete Adjuvant (which is an oily substance). The complete adjuvant contains microbacteria (an immune stimulant) to increase the immune response. Inject this subscapularly into a rabbit. This is your first inoculation. Only use the complete adjuvant for the first inoculation. Never inject a rabbit with complete adjuvant more than one time. Rest the rabbit for one month, then repeat the process using an incomplete adjuvant. You can expect to see good antibody titers about 10 days after the second booster. Bleed the rabbit. You can expect about 30 to 40 mL per bleeding, and about 50 percent of the volume is serum. Now you have rabbit antisera. To get your primary antibody, dilute the rabbit antisera in blotto (aka Carnation Nonfat Dry Instant Milk) and apply it to your nitrocellulose blot. Make sure you dilute 1:500 to 1:100 in blotto; less dilution will give you background binding and really muddy up your results. Secondary Antibody:- this is much easier than the procedure for the primary antibody. Grab a catalogue and look for a goat-anti-rabbit antibody conjugated to horseradish peroxidase (HRP). The goat-anti-rabbit is your secondary antibody (the one that 'sticks' to the primary antibody) and the HRP is the conjugated enzyme that will allow you to visualize your protein. Western Blotting is an important technique used in cell and molecular biology. By using a western blot, researchers are able to identify specific proteins from a complex mixture of proteins extracted from cells. The technique uses three elements to accomplish this task:- (1) separation by size, (2) transfer to a solid support, and (3) marking target protein using a proper primary and secondary antibody to visualize. This paper will attempt to explain the technique and theory behind western blot, and offer some ways to troubleshoot. Western blot is often used in research to separate and identify proteins. In this technique a mixture of proteins is separated based on molecular weight, and thus by type, through gel electrophoresis. These results are then transferred to a membrane producing a band for each protein. The membrane is then incubated with labels antibodies specific to the protein of interest. The unbound antibody is washed off leaving only the bound antibody to the protein of interest. The bound antibodies are then detected by developing the film. As the antibodies only bind to the protein of interest, only one band should be visible. The thickness of the band corresponds to the amount of protein present; thus doing a standard can indicate the amount of protein present. The paper will first describe the protocol for western blot, accompanied by pictures to help the reader and theory to rationalize the protocol. This will be followed by the theoretical explanation of the procedure, and in the later section, troubleshooting tips for common problems. / Западный Блотинг – метод определения искомого белка в сложной белковой смеси путём гибридизации разделённых электрофорезом белков с меченым зондом, например, антителом.

WESTERN EUROPEAN UNION = ЗАПАДНОЕВРОПЕЙСКИЙ СОЮЗ (или ЗАПАДНЫЙ ЕВРОПЕЙСКИЙ СОЮЗ) – Western European Union (WEU):- association of 10 countries (Belgium, France, Germany, Greece, Italy, Luxembourg, The Netherlands, Portugal, Spain, and the United Kingdom) that operates as a forum for the coordination of matters of European security and defense. It contributed to the creation of the North Atlantic Treaty Organization (NATO) and works in cooperation with that organization. The WEU became the primary defense institution of the European Union in the 1990s, though it gave up that role in 2001. The WEU grew out of the Brussels Treaty of 1948 – an agreement between Belgium, France, Luxembourg, The Netherlands, and the United Kingdom to provide for collective defense and to facilitate cooperation in economic, social, and cultural matters. NATO and the Council of Europe, both of which were formed in 1949, developed out of that framework. In 1954 the Brussels Treaty was strengthened and modified to include West Germany and Italy, to end the occupation of West Germany, and to include West Germany in NATO; and the WEU came into being on May 06, 1955. In 1960 the activities of committees for social and cultural affairs were transferred to the Council of Europe. In 1984 the union was 'reactivated' and a new agenda established: it recognized the significance of US arms to the defense of Europe and resolved to increase regional military cooperation. In 1988 Portugal and Spain joined the union; Greece joined in 1992. There are also six associate members (Czech Republic, Hungary, Iceland, Norway, Poland, and Turkey), five observer countries (Austria, Denmark, Finland, Ireland, and Sweden), and seven associate partners (Bulgaria, Estonia, Latvia, Lithuania, Romania, Slovakia, and Slovenia). The WEU is administered by a council consisting of the ministers of foreign affairs and of defense of the member countries. The council is responsible for policy formulation and is headed by a secretary-general. Three internal agencies are also involved. The assembly of the WEU, which has a number of permanent committees (political defense, technological and aerospace, rules of procedure and privileges, and parliamentary and public relations), consists of the delegates of the member countries to the Parliamentary Assembly of the Council of Europe; it meets at least twice each year (normally in Paris). Headquarters of the WEU are in Brussels. / Западноевропейский Союз (ЗЕС) – военно-политическая организация в составе Бельгии, Великобритании, Италии, Люксембурга, Нидерландов, Федеративной Республики Германии, и Франции. Создан в Мае 1955 путём преобразования и расширения Западного Союза (образован в 1948) в соответствии с Парижскими соглашениями 1954. Связан с НАТО.

WESTERN HYBRIDIZATION = ЗАПАДНАЯ ГИБРИДИЗАЦИЯ – Western Hybridization is a method to detect protein by use of an antibody directed against it. Also known as Western Blotting. / Известна также как Западный Блотинг (Western Blotting). Гибридизация с использованием Вэстёрн Блотинга (перенос белков с геля на фильтр). Под Гибридизацией, от Латинского слова Hibrida, означающее Помесь, понимается скрещивание разнородных в наследственном отношении организмов. Один из важнейших факторов эволюции биологических форм в природе. Применяют для получения хозяйственных ценных форм животных и растений. Скрещивание особей одного и того же вида (различных подвидов, сортов, пород или линий) называется внутривидовой гибридизацией, а различных видов или родов – отдалённой гибридизацией.

WESTERN REGIONAL TRANSMISSION ASSOCIATION = РЕГИОНАЛЬНАЯ ЗАПАДНАЯ АССОЦИАЦИЯ ПО ПЕРЕДАЧЕ (или XX) – The Western Regional Transmission Association (WRTA) is an regional transmission group (RTG). See also Western Systems Coordinating Council. 2002-May-09:- at a landmark meeting on April 18, 2002, the Western Systems Coordinating Council (WSCC), Southwest Regional Transmission Association (SWRTA), and Western Regional Transmission Association (WRTA) merged to form the Western Electricity Coordinating Council (WECC). The new organization, WECC, will continue to be responsible for coordinating and promoting electric system reliability as has been done by WSCC since its formation nearly 35 years ago. In addition to promoting a reliable electric power system in the Western Interconnection, WECC will support efficient competitive power markets, assure open and non-discriminatory transmission access among members, and provide a forum for resolving transmission access disputes. This is truly a historical milestone for the electric system customers and stakeholders in Western North America, said Dennis E. Eyre, WECC Executive Director. As a result of the merger, WECC will reduce overlap and duplication between organizations that have been performing similar tasks. While providing significant improvements in efficiency, WECC also has been formed with a superior governance structure. The new WECC Board consists of twenty-seven Director positions, including twenty Member Class Directors and seven Non-Affiliated Directors. The Non-Affiliated Directors are:- Janice B. Case, former Senior Vice President of Florida Power Corporation; John T. Coughlin, former Utility Commissioner in the State of Wisconsin; Jack L. King, former President of Oglethorpe Power; Tim Newton, former Vice President of Powerex; Maria C. Richter, former Managing Director of Morgan Stanley; Jananne Sharpless, former Commissioner of the California Energy Commission; and James H. Young, Jr., former Senior Vice President of

South Carolina Electric & Gas and currently Chairman of the Midwest ISO. The Member Class Directors are:- Class 1 – Jack E. Davis, President of Arizona Public Service Company; Thomas A. Delawder, Vice President of Tucson Electric Power Company; Ronald D. Nunnally, Director, Southern California Edison Company; and William A. Pascoe, Vice President of NorthWestern Energy. Class 2 – Richard G. Ferreira, consultant, Transmission Agency of Northern California; Maude Grantham-Richards, Director, Farmington Electric Utility System; Charles J. Hosken, General Manager, Public Utility District No. 1 of Chelan County; and Steve R. Mendoza, Executive Director, Arizona Power Authority. Class 3 – Rick A. Bowen, Executive Vice President of Dynegy Power Corp.; Anne M. Cleary, President – west region of Mirant Americas Inc.; Ken Peterson, President and CEO of Powerex; and John H. Stout, Senior Vice President of Reliant Energy Services. Class 4 – Scott Cauchois, Chief of the Electricity Resources and Pricing Branch, California Office of Ratepayer Advocates; Scott A. Gutting, President of Energy Strategies LLC; Nancy L. Kelly, Economist, Utah Committee Consumer Services; and Steven E. LaFond, electricity resource management, The Boeing Company. Class 5 – William M. Chamberlain, Chief Counsel, California Energy Commission; Denise Mullen-Dalmer, Director, British Columbia Ministry of Energy; R. Prasad Potturi, electrical engineering bureau Chief, New Mexico Public Regulation Commission; and Marsha H. Smith, Commissioner, Idaho Public Utilities Commission. The formation of the Western Electricity Coordinating Council (WECC) was accomplished over a four-year period through the cooperative efforts of WSCC, SWRTA, WRTA and other regional organizations in the West. WECC's interconnection-wide focus is intended to complement current efforts to form Regional Transmission Organizations (RTO) in various parts of the West. For more information on WECC and its formation, visit WECC's web site (http://www.wecc.biz). The web site also includes information on the electric industry's electricity supply and delivery programs and activities in the West. WECC – one of the 10 electric reliability councils in North America, encompassing a geographic area equivalent to over half the United States – is responsible for promoting electric system reliability, competitive electricity markets, access to the transmission grid, and providing a forum for coordinating the operating and planning activities of its 145 members. The members, representing all segments of the electric industry, provide electricity to 71 million people in 14 Western states, two Canadian provinces, and portions of one Mexican state. / Дэнис И. WECC is the Regional Entity responsible for compliance monitoring and enforcement. In addition, WECC provides an environment for the development of Reliability Standards and the coordination of the operating and planning activities of its members as set forth in the WECC Bylaws. WECC is geographically the

largest and most diverse of the eight Regional Entities with delegated authority from the North American Electric Reliability Corporation (NERC) and Federal Energy Regulatory Commission (FERC). The WECC Region extends from Canada to Mexico and includes the provinces of Alberta and British Columbia, the northern portion of Baja California, Mexico, and all or portions of the 14 Western states between. Membership in WECC is open to all entities who meet the qualifications in the WECC Bylaws. WECC strives for transparency and open participation in all of its meetings and processes. WECC has a long history of assuring reliability in the West that began when it was originally formed in 1967 by 40 power systems, then known as the Western Systems Coordinating Council (WSCC). Thirty-five years later in 2002, the WSCC became WECC when three regional transmission associations merged. WECC was designated a Regional Entity for the Western Interconnection in 2007 after the North American Electric Reliability Corporation (NERC) delegated some of the authority it had received from the Federal Energy Regulatory Commission (FERC) to create, monitor and enforce reliability standards. Today, WECC is an independent organization that works with entities across the West to further the common theme of grid reliability. Through its various reliability-related activities, WECC provides critical support to the Reliability Coordinator and the resource owners/operators throughout the Western Interconnection. WECC's strength and value lie it its ability to consistently leverage the Interconnection-wide perspective in its day-to-day activities, as well as its forward-thinking products and services.

WESTERN SYSTEMS POWER POOL = ЭНЕРГЕТИЧЕСКИЙ ПУЛ ЗАПАДНЫХ СИСТЕМ (или ХХ) – The Western Systems Power Pool (WSPP) is a Federal Energy Regulatory Commission (FERC) approved industry institution that provides a forum for short-term trades in electric energy, capacity, exchanges and transmission services. The pool consists of approximately 50 members and serves 22 states, a Canadian province and 60 million people. The WSPP headquartered in Phoenix, Arizona. The Western Systems Power Pool (WSPP) was formed in 1987 as an experiment and in 1991 became a more permanent entity for the purpose of sharing electric power between multiple power companies in the Western United States, and British Columbia. Western Systems Power Pool (WSPP) is an organization of more than 300 electricity utilities and power marketers throughout the US operating under an umbrella marketing agreement. The WSPP Agreement is open to power sellers and customers, though it provides only for wholesale and not retail sales. It established the WSPP electricity spot market contract, the standard contract for short-term power trading across the US. The contract traded on a trial basis in May 1987 and was given final approval on July 1991 by the Federal Energy Regulatory Commission (FERC). The Western Systems Power Pool is a spot energy market and trading forum centered in Phoenix, AZ. It serves approximately 50 members in 22 US states and Canada who participate in energy production, transmission and resale. The WSPP covers a region that serves approximately 60 million people.

WESTERN TEXAS INTERMEDIATE = ЗАПАДНО–ТЕХАССКАЯ СРЕДНЯЯ – West Texas Intermediate (WTI) is the most important US benchmark crude oil. WTI crude oil is of high quality and can produce a high proportion of petrol. A light sweet (low sulpher) crude oil. WTI is widely traded, as are derivatives based on it, for example through the CME and it is very often used as the benchmark for US oil prices. Historical prices are available on the web through the US Energy Information Administration. Because ot its low API gravity (lightness) and sulpher content, WTI generally trades at higher prices than other major benchmarks such as Brent (itself a light crude), however, as it is a US measure, geographical differences in supply or demand can sometimes reverse this. The Western Texas Intermediate (WTI), also known as Texas Light Sweet, is a light crude oil low in wax and sulphur content which makes it light and sweet. It is usually refined into gasoline, kerosene and diesel. It is used as a benchmark in US crude oil pricing. Usually WTI commands a higher price in the market than its Brent counterpart. Light Sweet Crude Oil WTI is traded at the NYMEX® under ticker symbol CL and at the ICE Futures Europe® under symbol T. Contract size in both exchanges is 1 000 barrels with a contract price quoted in US Dollars and Cents per barrel. Delivery dates take place every month of the year. West Texas Intermediate (WTI) crude oil is of very high quality and is excellent for refining a larger portion of gasoline. Its API gravity is 39.6 degrees (making it a 'light' crude oil), and it contains only about 0.24 percent of sulfur (making a 'sweet' crude oil). This combination of characteristics, combined with its location, makes it an ideal crude oil to be refined in the United States, the largest gasoline consuming country in the world. Most WTI crude oil gets refined in the Midwest region of the country, with some more refined within the Gulf Coast region. Although the production of WTI crude oil is on the decline, it still is the major benchmark of crude oil in the Americas. WTI is generally priced at about a USD2–per–barrel premium to the OPEC basket price and about USD1–per–barrel premium to Brent, although on a daily basis the pricing relationships between these can vary greatly. / 2016-Январь-15:- Качество нефти сильно отличается от сорта к сорту. Некоторые её виды могут быть вязкими, как смола, или чрезвычайно 'лёгкими' (даже легче воды). Сильно варьируется и содержание серы:- от едва фиксируемого до сильнокислого. И хотя на рынке продаются и покупаются сотни сортов нефти, торговцы используют в своих контрактах лишь несколько эталонных видов. Брэнт (Brent) из Северного Моря – самый распространённый стандарт в мире. Американцы предпочитают использовать похожую по качеству нефть, известную как Западно-Техасская Средняя (ЗТС или Дабл.Ю.Ти.Ай. (WTI)). WTI когда-то была базовым сортом нефти на мировом рынке. Она имеет ряд преимуществ над Брэнт. Во-первых, из-за того что ЗТС поступает в распределительный центр (Кушинг, Штат Оклахома (Cushing, State of Oklahoma)) по нефтепроводу, её можно продавать в различных объёмах. Брэнт на контрасте продаётся лишь танкерами, для чего приходится заключать большое количество мелких контрактов. Кроме того, Брэнт неразрывно связана с небольшим числом увядающих нефтяных месторождений, отмечает Британский журнал Зи Иканэмист (The Economist). Но ЗТС имела один серьёзный недостаток. Запрет на вывоз (или экспорт) означал, что этот базовый сорт мог быть отключён от мировых нефтяных цен, если Америка производила больше нефти, чем ожидалось, так как переизбыток не мог идти на вывоз (или экспорт). Большую часть XX века эта угроза была гипотетической, так как добыча 'чёрного золота' в Америке неуклонно падала. Но в последние несколько лет сланцевая революция резко увеличила Американское производство. Излишки сырой нефти сначала появились в Кушинге, а затем через сеть нефтеперерабатывающих заводов и в Мексиканском Заливе. Всё это привело к тому, что цены на Американский базовый сорт стали ниже, чем за Брэнт. Разрыв в 2011 достиг 28 Долларов США за баррель. В связи с тем, что ЗТС всё меньше и меньше отражала истинное положение дел на мировом рынке, торговцы всё чаще предпочитали Брэнт. Объёмы покупки-продажи Североморского сорта превзошли все сделки по ЗТС в начале 2012. Возобновление (запрет на вывоз (или экспорт) действовал сорок лет) Американского вывоза (или экспорта) в 2016 изменило ситуацию. Два базовых сорта теперь торгуются примерно по одинаковой цене. ЗТС вновь становится одним из самых популярных сортов нефти в торговых операциях. Но ситуация на рынке может вскоре измениться, так как его центр упорно движется на Восток. ОПЭК прогнозирует, что спрос на 'чёрное золото' в Азии увеличится на 16 миллионов баррелей в сутки к 2040. Если это произойдёт, то Азия будет потреблять в общей сложности более 46 миллионов баррелей в сутки (в четыре раза больше, чем Европа). С такими темпами Азия вскоре станет доминирующей силой на мировом нефтяном рынке.

WESTERN UNION CORPORATION = КОРПОРАЦИЯ ВЭСТЭН ЮНИЭН (или КОРПОРАЦИЯ ЗАПАДНЫЙ СОЮЗ) – Western Union Corporation:- former telecommunications company that was the largest provider of telegraphic services in the United States. The company was founded in 1851, when the New York and Mississippi Valley Printing Telegraph Company was formed to build a telegraph line from Buffalo, State of New York, to St. Louis, State of Missouri, the United States. Five years later, with the acquisition of several other independent lines, the company reorganized to become the Western Union Telegraph Company. By the end of 1861, Western Union had built the first transcontinental telegraph line. The company made a brief foray into the telephone field but lost a

legal battle with Bell Telephone in 1879 and thereafter concentrated solely on telegraphy. It grew rapidly and absorbed more than 500 other companies, including its chief competitor, Postal Telegraph Inc., in 1943. As telegraphy was increasingly replaced by other methods of telecommunication, Western Union diversified its operations to include automatic teletypewriter services, leased private-line circuitry, and a money order service, as well as telegrams and mailgrams. Western Union's Telex and TWX systems made it the chief operator of teleprinter networks in the United States in the 1960s and '70s, and its Westar communications satellite (1974) made it a major participant in the American satellite communications industry. Later in the century, the advent of high-speed digital data transmission and modern fax machines supplanted some of the company's most important services, notably telegrams, TWX, and Telex. In the face of rapidly changing technology, the Western Union Telegraph Co. was reorganized in 1988 as the Western Union Corp. to handle money transfers and related services. Parts of the company were sold to AT&T and GM Hughes Electronics Corp., among other buyers, and the company's name was changed to New Valley Corp. in 1991. The company entered bankruptcy proceedings in 1993 and shortly thereafter sold the last of its major holdings, Western Union Financial Services Inc., to First Financial Management Corp.. / Нью Йок энд Мисысыпи Вэлы Прынтинь Тчэлыграф Кампэни (New York and Mississippi Valley Printing Telegraph Company). WEST NILE VIRUS = ЗАПАДНЫЙ НИЛЬСКИЙ ВИРУС (или ВИРУС ЗАПАДНОГО НИЛА) – West Nile Virus (WNV) is a potentially serious illness. Experts believe WNV is established as a seasonal epidemic in North America that flares up in the summer and continues into the fall. This fact sheet contains important information that can help you recognize and prevent West Nile virus. Prevention measures consist of community-based mosquito control programs that are able to reduce vector populations, personal protection measures to reduce the likelihood of being bitten by infected mosquitoes, and the underlying surveillance programs that characterize spatial/temporal patterns in risk that allow health and vector control agencies to target their interventions and resources. The easiest and best way to avoid WNV is to prevent mosquito bites:- (i) When you are outdoors, use insect repellent containing an EPA-registered active ingredient. Follow the directions on the package. (ii) Many mosquitoes are most active at dusk and dawn. Be sure to use insect repellent and wear long sleeves and pants at these times or consider staying indoors during these hours. (iii) Make sure you have good screens on your windows and doors to keep mosquitoes out. (iv) Get rid of mosquito breeding sites by emptying standing water from flower pots, buckets and barrels. Change the water in pet dishes and replace the water in bird baths weekly. Drill holes in tire swings so water drains out. Keep children's wading pools empty and on their sides when they aren't being used. The Symptoms of WNV:- (i) Serious Symptoms in a Few People:- about one in 150 people infected with WNV will develop severe illness. The severe symptoms can include high fever, headache, neck stiffness, stupor, disorientation, coma, tremors, convulsions, muscle weakness, vision loss, numbness and paralysis. These symptoms may last several weeks, and neurological effects may be permanent. (ii) Milder Symptoms in Some People:- up to 20 percent of the people who become infected have symptoms such as fever, headache, and body aches, nausea, vomiting, and sometimes swollen lymph glands or a skin rash on the chest, stomach and back. Symptoms can last for as short as a few days, though even healthy people have become sick for several weeks. (iii) No Symptoms in Most People:- approximately 80 percent of people (about 4 out of 5) who are infected with WNV will not show any symptoms at all. How Does West Nile Virus Spread? (i) Infected Mosquitoes:- most often, WNV is spread by the bite of an infected mosquito. Mosquitoes become infected when they feed on infected birds. Infected mosquitoes can then spread WNV to humans and other animals when they bite. (ii) Transfusions, Transplants, and Mother-to-Child:- in a very small number of cases, WNV also has been spread through blood transfusions, organ transplants, breastfeeding and even during pregnancy from mother to baby. (iii) Not Through Touching:- WNV is not spread through casual contact such as touching or kissing a person with the virus. How Soon Do Infected People Get Sick? People typically develop symptoms between 3 and 14 days after they are bitten by the infected mosquito. How Is WNV Infection Treated? There is no specific treatment for WNV infection. In cases with milder symptoms, people experience symptoms such as fever and aches that pass on their own, although even healthy people have become sick for several weeks. In more severe cases, people usually need to go to the hospital where they can receive supportive treatment including intravenous fluids, help with breathing and nursing care. What Should I Do if I Think I Have WNV? Milder WNV illness improves on its own, and people do not necessarily need to seek medical attention for this infection though they may choose to do so. If you develop symptoms of severe WNV illness, such as unusually severe headaches or confusion, seek medical attention immediately. Severe WNV illness usually requires hospitalization. Pregnant women and nursing mothers are encouraged to talk to their doctor if they develop symptoms that could be WNV. What Is the Risk of Getting Sick from WNV? People over 50 at higher risk to get severe illness. People over the age of 50 are more likely to develop serious symptoms of WNV if they do get sick and should take special care to avoid mosquito bites. Being outside means you're at risk. The more time you're outdoors, the more time you could be bitten by an infected mosquito. Pay attention to avoiding mosquito bites if you spend a lot of time outside, either working or playing. Risk through medical procedures is very low. All donated blood is checked for WNV before being used. The risk of getting WNV through blood transfusions and organ transplants is very small, and should not prevent people who need surgery from having it. If you have concerns, talk to your doctor. Pregnancy and nursing do not increase risk of becoming infected with WNV. The risk that WNV may present to a fetus or an infant infected through breastmilk is still being evaluated. Talk with your care provider if you have concerns. What Is the Centers for Disease Control and Prevention (CDC) Doing About WNV? CDC is working with state and local health departments and other government agencies, as well as private industry, to prepare for and prevent new cases of WNV. Some things CDC is doing include:- (i) manage and maintain ArboNET, a nation-wide electronic surveillance system where states share information about WNV and other arboviral diseases; (ii) support states develop and carry out improved mosquito prevention and control programs; (iii) developing better, faster tests to detect and diagnose WNV; (iv) prepare updated prevention and surveillance information for the media, the public, and health professionals; and (v) working with partners on the development of vaccines. What Else Should I Know? If you find a dead bird:- don't handle the body with your bare hands. Contact your local health department for instructions on reporting and disposing of the body. They may tell you to dispose of the bird after they log your report. West Nile Virus (WNV) is a potentially deadly exotic disease of horses, humans, and wild birds. No cases of WNV infection have ever been found in any commercial poultry in the United States. See also Poultry. West Nile Virus is a mosquito-borne zoonotic arbovirus belonging to the genus Flavivirus in the family Flaviviridae. This flavivirus is found in temperate and tropical regions of the world. / Западный Нильский Вирус передаётся людям чаще всего через укус москита, но им также можно заразиться при переливании заражённой крови. Большинство людей, заражённых Западным Нильским вирусом, никогда не обнаруживают у себя признаки этой болезни или же полностью излечиваются после преодоления симптомов, сходных с симптоматикой гриппа. Однако некоторые симптомы этого заболевания могут нанести и серьёзный вред здоровью. В США существуют центры крови, которые предотвращают дальнейшую передачу этого потенциально смертельного вируса и обеспечивают безопасное кровоснабжение больных. Для обнаружения Западного Нильского вируса используют технологию цепной реакции, в которой ведущей становится нуклеиновая кислота, а также технологию усиления. Благодаря таким мерам генетический материал Западного Нильского вируса обнаруживается в донорской крови, сданной людьми, у которых

отсутствовали яркие симптомы болезни. Центры по Контролю и Профилактике Заболеваний (Centers for Disease Control and Prevention (CDC)) Соединённых Штатов заявили, что скрининг донорской крови на присутствие Западного Нильского вируса с применением нуклеиновой кислоты значительно снижает риск передачи заражённой крови. Согласно данным CDC, центры скрининга крови идентифицировали более 340 доноров в 2006, чья кровь дала положительный результат на Западный Нильский вирус. В Июне 2003 были начаты клинические испытания по анализу Западного Нильского вируса для того, чтобы решить проблемы Американского Управления по Контролю за Продуктами и Лекарствами и Центра по Контролю и Профилактике Заболеваний. Технология цепной реакции на основе нуклеиновой кислоты была одобрена в США, Европе для диагностики донорской крови на присутствие ВИЧ, вируса гепатита С и гепатита В.

WEST REGION = ЗАПАДНЫЙ РЕГИОН – West Region:- in align with the American Gas Association definition, the Energy Information Administration adopted three natural gas storage regions:- the West Region, the East Region, and the Producing Region. The West Region includes the following states:- Arizona, California, Colorado, Idaho, Minnesota, Montana, Nevada, North Dakota, Oregon, South Dakota, Washington, Wyoming, and Utah. See also Map.

WEST TEXAS INTERMEDIATE CRUDE OIL = ЗАПАДНО–ТЕХАССКАЯ СРЕДНЯЯ НЕФТЬ – The ICE (IntercontinentalExchange, Inc) Futures West Texas Intermediate (WTI) Light Sweet Crude Oil futures contract provides participants with the opportunity to trade one of the world's most liquid commodities in a fully electronic marketplace. In addition to bringing the benefits of electronic trading to US light sweet crude trading, this contract brings together the world's two most significant oil benchmarks on a single exchange. This offers a number of benefits to participants, including reductions in collateral requirements through the offsetting of margins. The ICE WTI Crude futures contract is cash settled. See also Western Texas Intermediate. West Texas Intermediate (WTI) is the US crude oil used as a benchmark for pricing much of the world's crude oil production. WTI is a relatively low specific gravity 'intermediate' crude with low sulphur content ('sweet'). West Texas Intermediate (WTI) is the benchmark for approximately 12 to 15 million barrels of crude oil produced or sold each day in the Western Hemisphere. Except for crude oil produced in Alaska, nearly all of the crude oil produced in the United States is priced off WTI. About 80 percent of the crude oil imported into the United States is priced off WTI. Because WTI is the benchmark for most of the crude oil consumed in the United States, exporters of North Atlantic basin crudes priced off Brent often will quote the prices in relation to WTI to facilitate price comparisons for US importers. Although more crude oil worldwide is priced off Brent than WTI, the standard NYMEX® WTI contract is the most widely traded commodity futures contract in the world. Approximately 150 000 contracts for WTI are traded daily on the NYMEX®, representing a volume of crude oil equal to nearly twice the world's daily production. WTI is actually a blend of crude oils produced in oil fields in Texas, New Mexico, Oklahoma, and Kansas. These crude oils all have relatively low sulfur levels and are relatively low in density. Like Brent, the production of WTI is dwindling. Ten years ago, around 750 000 barrels of WTI were produced daily; presently, around 400 000 barrels of WTI are produced daily. Future production is expected to decline. As a result of the historical development of Cushing, Oklahoma, as a transportation and storage hub for crude oil produced in the region, the standard NYMEX® futures contract for light sweet crude oil provides for the delivery of WTI or several comparable alternative grades at that location. Presently, there are about 20 million gallons of storage capacity at Cushing and an extensive network of crude oil pipelines leading into and out of these facilities. However, Cushing is landlocked, far from the ports handling oil imports and exports, and no longer the central distribution point it once was for crude oil produced in the United States. Numerous industry participants are concerned about the potential for distortion – either intentional or unintentional – of WTI pricing due to the limited volume of WTI produced each month, the relative isolation of Cushing from global trade, and limits on Cushing's pipeline and storage capacity. Like Brent, the production of WTI is half of what it once was. Like Brent, the constrained logistics of WTI production, transport, and storage can make the availability of WTI subject to artificial bottlenecks or surges in supply. One of the most frequently raised issues regarding the WTI benchmark is that 80 percent of the tank storage capacity at Cushing, Oklahoma is controlled by two companies, BP and Shell. Because crude oil inventories in the Midwest strongly affect WTI prices, the concern is that the actions of these two firms regarding their storage tanks at Cushing may have a disproportionate impact on Midwestern supplies and inventories and hence on the price of WTI. West Texas Intermediate (WTI), a light sweet US crude oil, is a common benchmark (reference) crude, and is traded in the futures market on the NYMEX®. It is commonly used as a price reference, with adjustments for quality and transportation, for other crude oils sold in North America. References to the oil prices are usually either references to the spot price of either WTI/Light Crude as traded on New York Mercantile Exchange (NYMEX®) for delivery in Cushing, Oklahoma; or the price of Brent as traded on the Intercontinental Exchange (ICE, which the International Petroleum Exchange has been incorporated into) for delivery at Sullom Voe. The price of a barrel (which is 42 gallons) of oil is highly dependent on both its grade (which is determined by factors such as its specific gravity or API and its sulphur content) and location. The vast majority of oil will not be traded on an exchange but on an over-the-counter basis, typically with reference to a marker crude oil grade that is typically quoted via pricing agencies such as Argus Media Ltd and Platts. For example in Europe a particular grade of oil, say Fulmar, might be sold at a price of 'Brent plus USD0.25/barrel' or as an intra-company transaction. ICE claim that 65% of traded oil is priced off their Brent benchmarks. Other important benchmarks include Dubai, Tapis, and the OPEC basket. The Energy Information Administration (EIA) uses the Imported Refiner Acquisition Cost, the weighted average cost of all oil imported into the US as their 'world oil price'. West Texas Intermediate (WTI) is a grade of crude oil deliverable against the New York Mercantile Exchange (NYMEX®) light, sweet crude oil contract. Nominally, the benchmark crude of the US oil industry. Crude oil is the world's most actively traded commodity, and the NYMEX® Division light sweet crude oil futures contract is the world's most liquid form for crude oil trading, as well as the world's largest-volume futures contract trading on a physical commodity. Additional risk management and trading opportunities are offered through options on the futures contract; calendar spread options; crack spread options on the pricing differential of heating oil futures and crude oil futures and gasoline futures and crude oil futures; and average price options. The contract trades in units of 1 000 barrels, and the delivery point is Cushing, Oklahoma, the United States which is also accessible to the international spot markets via pipelines. The contract provides for delivery of several grades of domestic and internationally traded foreign crudes, and serves the diverse needs of the physical market. West Texas Intermediate crude oil is deemed to be traded at Cushing, Oklahoma. Traders typically refer to the NYMEX® Light Sweet Crude futures contract as the WTI contract, although the contract allows delivery of other grades. Traders around the world know where they can turn to manage risk and access market opportunities in the crude oil market. Because of its liquidity and transparency, our physically delivered Light Sweet Crude Oil (WTI) contract is recognized as the global standard pricing benchmark. WTI crude is a blend of several US domestic streams of light sweet crude oil. For WTI crude, the delivery point in Cushing, Oklahoma, is a vital transshipment point, where storage facilities and intersecting pipelines provide easy access to refiners and suppliers. Crude flows inbound to Cushing from around the country, and outbound through dozens of pipelines. Naturally, Light Sweet Crude Oil (WTI) has become a significant physical market price reference – it serves as benchmark for approximately 5 million barrels of daily production and the most efficient hedging tool for hundreds of commercial oil companies.
