million barrels of daily production and the most efficient hedging tool for hundreds of commercial oil companies. Since the mid-1980s, benchmark crude oil prices such as West Texas Intermediate (WTI) in the United States and Brent crude oil in Europe have served as reference points that the market uses for pricing other crude oils. Since late 2010, however, WTI has been selling at a large discount to Brent, and has become less useful as an indicator for US petroleum product prices. Beginning with the July 2012 Short-Term Energy Outlook (STEO), the US Energy Information Administration (EIA) will supplement its traditional WTI and average refiner acquisition cost (RAC) forecasts with a forecast of the Brent crude oil spot price that will directly enter into price forecasts for gasoline and other refined products in the STEO (see Brent Crude Oil Spot Price Added to Forecast). EIA currently expects the Brent crude oil price will average USD99 per barrel over the second half of 2012 and USD98 per barrel in 2013. Until 2008, all North American crude oil grades broadly tracked fluctuations in the WTI price and were clustered within about USD8 per barrel of the WTI spot price (Today in Energy, June 21, 2012). Pricing differences between crude oil grades were explained largely by the different quality characteristics of the crude oil in each location and relative transportation costs. Between January 2004 and late 2010, WTI consistently sold at about a USD1 to USD2 premium to Brent as the two crude oil prices closely tracked each other. Starting in late 2010, WTI began to sell at a discount to Brent due to rapid increases in crude oil production from tight oil formations (This Week In Petroleum, March 14, 2012), primarily from the Bakken formation in North Dakota and the Eagle Ford shale in Texas, which led to transportation bottlenecks in and around the Cushing, Oklahoma storage hub where WTI oil is traded (This Week In Petroleum, May 16, 2012). In addition, Brent prices were being positively impacted by supply disruptions in the waterborne light-sweet crude oil markets (e.g., outages in Libya, Nigeria). The WTI discount to Brent continued to widen in 2011, reaching a monthly average high of about USD27 per barrel in September 2011, before falling back to around USD13 per barrel in June 2012. With limited pipeline capacity, the additional crude oil volumes have been moved out of the region by rail and to a lesser extent by truck. The USD6 to USD12 per barrel cost of transportation by rail and truck has been cited by some analysts as a floor for the Brent-WTI spread. With the large gap between Brent and WTI prices, WTI is no longer representative of the marginal crude oil price driving petroleum product prices in the US market. A comparison of Reformulated Gasoline Blendstock for Oxygenate Blending (RBOB) spot prices – which represent wholesale gasoline prices – to the Brent, WTI, and RAC crude oil prices in the largest US refining region, the Gulf Coast, illustrates the growing disconnect of gasoline prices from both WTI and RAC prices since late 2010. The spreads between Gulf Coast RBOB and the Brent, WTI, and RAC crude oil prices tracked each other closely, averaging 27 cents per gallon from 2006 through 2010. Since the end of 2010, only Brent has held near its historical average spread, averaging 18 cents per gallon, while the WTI and RAC spreads have averaged 57 cents per gallon and 42 cents per gallon, respectively. Thus, Brent has become more representative of the marginal cost of crude oil for the majority of refiners in the Atlantic Basin. In the Rocky Mountain region and the Midwest, discounted inland crudes are widely used by refiners. However, because Midwest product markets also rely on products produced outside of that region, product prices still reflect the price of waterborne crudes that are best represented by the Brent benchmark. Why is WTI No Longer a Global Benchmark? It's been a long time coming, but Brent crude may finally top the light sweet crude from Texas – known as Western Texas Intermediate – as the global oil benchmark. Typically, WTI crude from Cushing, Oklahoma, holds a higher price than Brent crude. The difference is in the quality:- the less sulfur, the easier it is to refine the crude into gasoline. WTI is both lighter and sweeter, containing about 0.24% sulfur. Brent crude has about 0.37% sulfur and is still classified as a sweet crude. Now compare that with the world's heavier deposits of oil .... Heavy crude oil produced from Venezuela's Orinoco Belt contains approximately 4.5% sulfur. Even the mighty OPEC – which produces about 40% of the world's oil supply – doesn't have the same quality. So you can see why WTI is highly sought after. Recently, however, there have been concerns that WTI should no longer be considered the best reflection for global oil demand. For starters, there were Enbridge's recent pipeline troubles .... The company was forced to shut down one of its pipelines after a leak was discovered. The pipeline was part of the Lakehead System, which transports up to 670 000 barrels of oil to Midwest refineries, as well as the Cushing hub. (That's one of the reasons we've seen oil prices spike to USD78 per barrel recently (2010-September-28).) The company expects to restart the pipeline today. WTI is currently trading at a USD2.15/bbl discount to Brent crude. Last May, the spread between the two was more than USD5 per barrel. The concern is that WTI is losing its connection to global markets, particularly the supply-demand issue. The WTI discount comes at a time of near-record inventory levels. I'll let you connect the dots for yourself .... Losing its global reputation:- last month, Reuters reported Asia is trying to ditch its regional oil benchmarks for Brent crude, stating that Brent is a closer match to the region's light, sweet crude than WTI. Even OPEC has shown concern that WTI may be an inaccurate benchmark. You might remember about a year ago, when we talked about Saudi Aramco's decision to ditch WTI for the Argus Sour Crude Index .... According to the Saudis, the Argus was a better reference for the heavier, more sour crude which the country exports. The low-hanging fruit is gone. The idea of WTI losing its status as a global benchmark is downright scary. For decades, WTI has been sought after for its light, sweet qualities. The fact that the world's exporters have lost faith in the Texas-grade crude shows us how far global production has come. Think about it .... How many times have you heard us say that the cheap, easy-to-get oil is a thing of the past? Even the light, sweet crude in the United States is losing its quality. You know there's a veritable oil boom happening right now in North Dakota. The Bakken oil has a gravity between 38–40, and sulfur ranging from 0.2% to 0.5%. Unfortunately, producing this North Dakota oil isn't as easy as drilling a vertical well; horizontal drilling technology is now used, and wells can cost millions of Dollars. The reality is that oil is becoming harder to get. At current consumption levels, the world is using more than 31 billion barrels of oil each year. With the world's oil supply becoming more expensive to extract, it makes me wonder how long it will be until Brent is considered an 'inaccurate reference' for world oil supplies. North Sea production:- Brent crude comes from the North Sea. That in and of itself is cause for concern. Oil production in the North Sea peaked during the 1990s. Producing oil in the rough Atlantic waters is much more difficult compared to a conventional field. It isn't the most optimal place to hold the bulk of UK's oil reserves. You can see how production has declined – even despite oil's historic run-up to USD150 per barrel in 2008. It didn't matter how high the price of oil climbed; nothing could turn around oil production in the UK. Oil production will only get worse from here on out for the United Kingdom .... So far, the biggest North Sea oil discovery within the last three decades has been the Buzzard field. Located in the Central North Sea, the Buzzard field was discovered in 2001 and produces more than 200 000 barrels of oil per day. Now factor in the cost of developing Brent crude .... An Oil and Gas UK survey released earlier this year suggested 17 new fields in the UK Continental Shelf are 20% more expensive to develop – not to mention 25 billion pounds (or approximately USD36.6 billion) must be spent by 2016 in order to put the infrastructure in place. It's enough to make the last deposits of light, sweet easy-to-extract crude even more valuable for producers – and that's assuming you know where to look. When investors do find those plays, however, the payoff can even more lucrative. Key Factors (on 2013-June-05) Behind The Recent Narrowing In The Brent-WTI Spread:- the Brent-WTI spread, the difference between the spot prices of Brent and West Texas Intermediate (WTI) crude oils, has narrowed considerably over the past several months. The spread, which was more than USD23 per barrel in mid-February, fell to under USD9 in April, and has ranged between USD7 and USD10 since then. The narrowing of the spread is supported by several factors that have depressed Brent prices or strengthened WTI prices, including the displacement of Brent-quality crude imports into North America by increased US production that is flowing to refiners through expanded crude-by-rail and pipeline infrastructure, seasonal European refinery maintenance and tariff policy changes in South Korea. Recent expansions in midstream crude oil infrastructure have eased downward pressure on the WTI price. Before mid-2012, only one 96 000-barrel-per-day (bbl/d) pipeline delivered crude oil from the Midwest to the Gulf Coast. Since then, significant new takeaway capacity from Cushing has come on line, starting with the 150 000-bbl/d Seaway Pipeline reversal in

May 2012 and its 250 000-bbl/d expansion in January 2013. Sunoco's Permian Express Pipeline and the reversal of Magellan Midstream Partners' Longhorn Pipeline are expected to add 315 000 bbl/d of pipeline capacity that bypasses Cushing, taking Permian Basin crude directly to the Gulf Coast. These projects, along with an additional 760 000 bbl/d of pipeline capacity debottlenecking Cushing, are expected to come on line by the end of 2013. With expanded pipeline and crude-by-rail capacity, competitively-priced US crude oil production is backing out imports of Brent-like crude oil, especially crudes from Nigeria, Angola, and Algeria. In 2010, the US imported 886 000 bbl/d of light sweet crude oil to the Gulf Coast; by March 2013, imports had fallen to less than 40 000 bbl/d. Crude-by-rail is also displacing imports on both the West and East coasts. In addition, US crude oil exports to Canada have increased from an historical average of 24 000 bbl/d to 100 000 bbl/d over the first quarter of 2013, replacing Brent-quality crude imports to Canada's East Coast refineries. Taken together, these changes have diverted almost 1 million bbl/d of Brent-like crude away from North America into other regions of the global crude market. Pending changes in tariff policy in South Korea, the world's third largest petroleum importer, are also affecting the demand for Brent crude. South Korea imposes a 3-percent tariff on crude oil imports but rebates the tariff if refined petroleum products are exported. Although the crude oil tariff is not levied on imports from countries that have a free trade agreement (FTA) with South Korea, the rebate has still been paid for exports of product, effectively providing a 3-percent subsidy to crude imports from FTA partner countries. According to trade press, South Korea's imports of crude oil from European Union (EU) member countries increased eight-fold since an FTA with the EU was signed in mid-2011. Beginning in July 2013, the rebate will no longer be paid for export volumes made from FTA crude imports, eliminating the implicit 3-percent subsidy. Downward pressure on Brent prices has possibly been mitigated by the very recent announcement that South Korea may incentivize refiners to process more Brent-price-based crude oil. The future of the Brent-WTI spread will be determined in part by the balance between future growth in midcontinent crude production on the one hand and in midstream infrastructure to move that crude to refiners on the other. Over the next two years, about 2 million bbl/d of new or diverted pipeline takeaway capacity from Cushing to the Gulf Coast is planned, significantly more than the 1.2 million bbl/d of new incoming capacity. In its May 2013 Short-Term Energy Outlook EIA forecasts the Brent-WTI spread to average USD13 per barrel in 2013 and decline to an average USD9 per barrel in 2014. West Texas Intermediate (WTI) crude oil is of very high quality. Its API gravity is 39.6 degrees (making it a light crude oil), and it contains only about 0.24 percent of sulphur (making a sweet crude oil). WTI is generally priced at about a USD2–4 per-barrel premium to OPEC Basket price and about USD1–2 per barrel premium to Brent, although on a daily basis the pricing relationships between these can very greatly. WET = WASTE EXTRACTION TEST

WET = WHOLE EFFLUENT TOXICITY TEST

WET = МОКРАЯ – A sample of grain is identified as Wet if the moisture content exceeds the moist range established for that class of grain. With increasing moisture content, grain is graded straight, tough, damp, moist, and wet. / Проба зерна идентифицируется как мокрая, если содержание влаги превосходит установленный диапазон влажности для такого класса зерна. В случае увеличения содержания влаги зерно будет последовательно отсортировано как сухое или твёрдое (straight), средней сухости или мягкое (tough), влажное или вязкое (damp), сырое (moist) и мокрое (wet).

WETBACK BOILER = ЭКРАНИРОВАННЫЙ КОТЁЛ (или ХХ) – Wetback Boiler:- firetube boiler design wherein the back portion of the boiler has a water jacket.

WET BARREL = МОКРЫЙ БАРРЕЛЬ – Wet Barrel is a physical barrel of crude oil or refined product as opposed to a Paper Barrel. / Фактический баррель нефти или очищенного продукта в противоположность Бумажному Баррелю (Paper Barrel).

WETBED METHOD = МЕТОД УВЛАЖНЁННОЙ ГРЯДЫ (или МЕТОД УВЛАЖНЁННОЙ ГРЯДКИ) – Wetbed Method:- raising seedlings on a seedbed where land is prepared and puddled.

WETBED SEEDING = СЕВ В УВЛАЖНЁННУЮ ГРЯДУ (или ОБСЕМЕНЕНИЕ В УВЛАЖНЁННУЮ ГРЯДКУ) – Wetbed Seeding is a planting of pregerminated seed or small seedlings into a wet seedbed. / Под Посевом понимается заделка семян в верхние слои почвы для их прорастания. Способы:- квадратно-гнездовой, перекрёстный, разбросной, рядовой (ленточный, узкорядный, широкорядный) и другие. Проводится сеялками, иногда с самолёта.

WET BOTTOM BOILER = КОТЁЛ С ЖИДКИМ ШЛАКОУДАЛЕНИЕМ (или ХХ) – Wet Bottom Boiler:- slag tanks are installed usually at the furnace throat to contain and remove molten ash.

WET–BULB TEMPERATURE = ТЕМПЕРАТУРА ПО ВЛАЖНОМУ ТЕРМОМЕТРУ (или ТЕМПЕРАТУРА МОКРОГО ТЕРМОМЕТРА, или ТЕМПЕРАТУРА ПСИХРОМЕТРА) – Wet-Bulb Temperature is the temperature at which water, by evaporating into air, can bring the air to saturation at the same temperature. Wet-bulb temperature is measured by a wet-bulb psychrometer. Wet-Bulb Temperature is the lowest temperature which a water wetted body will attain when exposed to an air current. This is the temperature of adiabatic saturation, and can be used to measure humidity.

WET COTTON = ВЛАЖНЫЙ ХЛОПОК (или МОКРЫЙ ХЛОПОК) – Wet Cotton means a bale of cotton that, at a gin, has 7.5 percent or more moisture, wet basis, at any point in the bale.

WET DECATING = МОКРАЯ ДЕКАТИРОВКА – Wet Decating is a finishing process to add luster to wool fabrics. In the wet decating method, the material is tightly wrapped on a perforated roller and immersed in a trough of hot water. In dry decating, steam is used instead of hot water. / Мокрая Декатировка горячей водой. Декатировка, от Французского слова Decatir, означающее (основное значение) Уничтожать Блеск, обработка шерстяных тканей паром или горячей водой для предотвращения усадки при последующей обработке и носке и улучшения внешнего вида. Декатировка производится на специальных аппаратах – декатирах. Различают декатиры для сухой и мокрой декатировки. Декатир для сухой декатировки представляет собой герметически закрывающийся цилиндрический котёл, внутри которого находится вращающийся полый цилиндр с перфорированной поверхностью, приспособленный для наматывания ткани. Подаваемый в котёл пар проходит через слои ткани, намотанной с минимальным натяжением, внутрь цилиндра и отсасывается через его открытый конец. В декатире для мокрой декатировки цилиндр с намотанной на нём тканью вращается в корыте с горячей (50–60 °C) водой. Декатир соединён не только с паропроводом, но и с водопроводом.

WET FORMING = МОКРОЕ ФОРМОВАНИЕ – Wet Forming is the production of a nonwoven fabric web from an aqueous suspension of fibers by filtering the short fibers onto a screen belt or perforated drum.

WET GAS = ЖИРНЫЙ ГАЗ – Wet Gas is a raw natural gas with a relatively high concentration of natural gas liquids (ethane, propane, butane, pentanes and condensates). Wet Gas is a natural mixture of hydrocarbons that may be gaseous or both liquid and gaseous in the reservoir and that contains an appreciable proportion of compounds heavier than ethane (e.g., propane or butane) that are condensable when brought to the surface. Such gases usually are characterized by the volume or weight of the condensables contained in a given volume of total gas produced. This figure, computed for volumes at 15 °C (59 °F) and 750 mm of mercury, is usually expressed either in gallons per 1 000 cubic feet or in grams per cubic meter; for a gas to be classified as wet, it must contain more than 0.3 gallon of condensables per 1 000 cubic feet of gas. The condensables are recovered, the propane being marketed as liquefied petroleum gas and the heavier hydrocarbons being made into gasoline. Compare Dry Gas. Natural gas containing condensable hydrocarbons. Wet Gas is a natural gas that contains an appreciable proportion of hydrocarbon compounds heavier than methane, e.g., ethane, propane, and butane. The mixture may be gaseous or both liquid and gaseous in the reservoir; the heavier hydrocarbons are condensable when brought to the surface and are frequently separated as natural gas liquids (NGLs). Alternatively, the propane and other lighter compounds may be marketed as liquefied petroleum gas (LPG), and heavier hydrocarbons may be made into gasoline (petrol). Wet gases usually are characterized by the volume or weight of the condensables contained in a given volume of total gas produced. Wet Gas is the unprocessed natural gas containing more than 20% of impurities and heavier hydro-carbons. Wet Gas is:- (1) methane (dry gas) mixed with other hydrocarbons; and (2) gas with a high liquid content, which often needs to be dried using a dehydration process. Wet Gas is a natural gas that contains less methane (typically less than 85% methane) and more ethane and other more complex hydrocarbons. / Природный газ, содержащий конденсируемые (сжиженные) углеводороды. Жирный Газ (ЖГ) – обычно природный горючий нефтерастворённый газ, который в стандартных условиях содержит много гомологов метана – С2+, и С5+, тяжёлых углеводородов от С3 и выше. Такой состав газов характерен для газоконденсатных и нефтяных месторождений. Подсчёт тяжёлых углеводородов и состав газов учитывают раздельно по С2, С3, С4 и С5+высшие. Газы соответственно называются этановыми, содержащими широкую фракцию лёгких углеводородов (С3 и С4), и конденсат содержащими (С5+высшие). В магистральные газопроводы подача жирного газа невозможна. Жирный газ обычно не используется как топливо, он перерабатывается на газоперерабатывающих заводах (ГПЗ). Технология переработка жирного газа более экономична, чем переработка бензиновых фракций. Жирный газ формируются либо в условиях высокотемпературных залежей, когда происходит естественная деструкция ретроградной системы. Либо из керогена болотного типа.

WETHER = ВАЛУХ – Wether is a male sheep or goat castrated before sexual maturity. Because it's (the operative phrase) isn't caught up breeding, all of it's nutrition goes into the fiber thus producing a better quality fiber. Fleeces from wethers can't be entered into most wool shows but are worth watching for. Wether is a castrated male sheep. / Под Валухом понимается кастрированный баран. Всех баранчиков, не используемых на племя, кастрируют в возрасте 2–3 недель (баранчиков, подлежащих реализации на мясо в год рождения, оставляют некастрированными). Валухи менее требовательны к условиям кормления (хорошо откармливаются) и содержания, хорошо нагуливаются и дяют мясо лучшего качества. Настриг шерсти с тонкорунных взрослых валухов на 1.5–2 килограмма больше, а качество шерсти выше, чем у маток. На откорм выгоднее ставить валухов в 4-месячном возрасте. В стадах шёрстного направления валухов держат до 3–4 лет, шёрстно-мясного и мясо-сального – до 8–18 месяцев.

WETHER WOOL = ШЕРСТЬ ВАЛУХА – Wether Wool:- any fleece clipped after the first shearing is called Wether Wool. This wool is usually taken from sheep older than fourteen months, and these fleece contains much soil and dust.

WET–LAID NONWOVEN = ВЛАЖНО–СФОРМИРОВАННЫЙ (или ГИДРАВЛИЧЕСКИ–СФОРМИРОВАННЫЙ, или МОКРОВЫЛОЖЕННЫЙ) НЕТКАНЫЙ МАТЕРИАЛ – Wet-Laid Nonwoven is a fabric made by the wet-forming process. The short fibers typically have more random orientation in the web and the web has more isotropic properties than carded webs.

WETLAND = ИЗБЫТОЧНО УВЛАЖНЁННАЯ ЗЕМЛЯ (или СИЛЬНО УВЛАЖНЁННАЯ ЗЕМЛЯ, или ВОДНО–БОЛОТИСТОЕ УГОДЬЕ, или СЫРОЙ УЧАСТОК, или ЗАБОЛОЧЕННОЕ МЕСТО) – Wetland:- terrestrial ecosystem characterized by poor drainage and the consequent presence most or all of the time of sluggishly moving or standing water saturating the soil. Wetlands are usually classified, according to soil and plant life, as bog, marsh, or swamp. In the United States, types of Wetlands:- over the thousands of years that people have been living with wetlands, many terms have been developed to describe them. Here are those that are common in the Midwest. (i) Aquatic Bed:- areas of shallow permanent water dominated by plants that grow on or below the surface of the water. (ii) Bog:- a peat-accumulating wetland that has no significant inflow or outflow of water and supports acidophilic vegetation, particularly sphagnum. (iii) Bottomland:- lowlands (usually forested) along streams and rivers that are periodically flooded. (iv) Fen:- a peat-accumulating wetland that receives some water from surrounding mineral soils and usually supports grasslike vegetation. (v) Interdunal Swale Wetland:- a wetland dominated by grasslike vegetation that occurs in the low areas between sand dunes or beach ridges along the Great Lakes shoreline. (vi) Marsh:- a frequently or continually inundated wetland characterized by grasslike and other emergent vegetation adapted to saturated soil conditions. (vii) Muskeg:- large expanses of peatlands. (viii) Peatland:- a generic terms for any peat-accumulating wetland. (ix) Poor Fen:- a peat-accumulating wetland that is transitional between a true bog and a true fen. (x) Pothole:- a shallow pond dominated by grasslike vegetation. (xi) Slough:- a swamp or shallow lake system. (xii) Swamp:- a wetland dominated by tress or shrubs. (xiii) Wet Meadow:- grassland with saturated soil near the surface but without standing water for most of the year. (xiv) Wet Prairies:- intermediate between a marsh and a wet meadow. Wetland:- generally, a land that is characterized by an abundance of moisture and that is inundated by surface or groundwater often enough to support a prevalence of vegetation typically adapted for life in saturated soil conditions. See also Hydrophytic Vegetation. Wetland:- the US Army Corps of Engineersand the Environmental Protection Agency (COE and EPA) have adopted a regulatory definition for administering the Section 404 permit program of the Clean Water Act of 1972. Under these regulations, Wetlands are those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas. Wetland is:- (1) pertaining to soils flooded for at least several weeks each year, or to crops growing in such soils. (2) Land of which the rooting zone can be kept saturated for a substantial part of the growing season, where necessary, by encouraging accumulation of water on the soil through puddling and the use of bunds or levees. Wetland:- the Natural Resources Conservation Service (NRCS) definition is used for identifying wetlands on agricultural land in assessing producer eligibility for USDA program benefits under the swampbuster provision of the Food Security Act of 1985. As amended in 1990, the Food Security Act states that a wetland, except when considered a converted wetland, is land that (a) has a predominance of hydric soil; (b) is inundated or saturated by surface or groundwater at a frequency and duration sufficient to support a prevalence ofhydrophytic vegetation typically adapted for life in saturated soil conditions; and (c) under normal circumstances, does support a prevalence of such vegetation. For purposes of the Food Security Act, as amended, and any other act, the term wetland does not include lands in Alaska identified as having high potential for agricultural development which have a predominance of permafrost soils. Wetland is the terrestrial ecosystem characterized by poor

drainage and the consequent presence most or all of the time of sluggishly moving or standing water saturating the soil. Wetlands are usually classified, according to soil and plant life, as bog, marsh, or swamp. A Wetland is a land area that is saturated with water, either permanently or seasonally, such that it takes on the characteristics of a distinct ecosystem. Primarily, the factor that distinguishes wetlands from other land forms or water bodies is the characteristic vegetation that is adapted to its unique soil conditions:- Wetlands consist primarily of hydric soil, which supports aquatic plants. The water found in wetlands can be saltwater, freshwater, or brackish. Main wetland types include swamps, marshes, bogs and fens. Sub-types include mangrove, carr, pocosin, and varzea. Wetlands play a number of roles in the environment, principally water purification, flood control, and shoreline stability. Wetlands are also considered the most biologically diverse of all ecosystems, serving as home to a wide range of plant and animal life. Wetlands occur naturally on every continent except Antarctica. They can also be constructed artificially as a water management tool, which may play a role in the developing field of water-sensitive urban design. The largest wetlands in the world include the Amazon River basin and the West Siberian Plain. Another large wetland is the Pantanal, which straddles Brazil, Bolivia, and Paraguay in South America. The UN Millennium Ecosystem Assessment determined that environmental degradation is more prominent within wetland systems than any other ecosystem on Earth. International conservation efforts are being used in conjunction with the development of rapid assessment tools to inform people about wetland issues. A patch of land that develops pools of water after a rain storm would not be considered a 'wetland', even though the land is wet. Wetlands have unique characteristics: they are generally distinguished from other water bodies or landforms based on their water level and on the types of plants that thrive within them. Specifically, wetlands are characterized as having a water table that stands at or near the land surface for a long enough period each year to support aquatic plants. A more concise definition is a community composed of hydric soil and hydrophytes. Wetlands have also been described as ecotones, providing a transition between dry land and water bodies. Mitsch and Gosselink write that wetlands exist '... at the interface between truly terrestrial ecosystems and aquatic systems, making them inherently different from each other, yet highly dependent on both'. In environmental decision-making, there are subsets of definitions that are agreed upon to make regulatory and policy decisions. Technical Definitions:- a Wetland is 'an ecosystem that arises when inundation by water produces soils dominated by anaerobic processes, which, in turn, forces the biota, particularly rooted plants, to adapt to flooding'. There are four main kinds of wetlands – marsh, swamp, bog and fen (bogs and fens both being types of mires). Some experts also recognize wet meadows and aquatic ecosystems as additional wetland types. The largest wetlands in the world include the swamp forests of the Amazon and the peatlands of Siberia. Ramsar Convention (The Convention on Wetlands of International Importance, especially as Waterfowl Habitat is an international treaty; it is named after the city of Ramsar in Iran, where the Convention was signed in 1971) Definition:- under the Ramsar international wetland conservation treaty, wetlands are defined as follows:- (i) Article 1.1:- '... wetlands are areas of marsh, fen, peatland or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed six meters'. (ii) Article 2.1:- 'Wetlands may incorporate riparian and coastal zones adjacent to the wetlands, and islands or bodies of marine water deeper than six meters at low tide lying within the wetlands'. Regional Definitions:- although the general definition given above applies around the world, each county and region tends to have its own definition for legal purposes. For example, in the United States, Wetlands are defined as 'those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs and similar areas'. This definition has been used in the enforcement of the Clean Water Act. Some US states, such as Massachusetts and New York, have separate definitions that may differ from the federal government. Ecology:- the most important factor producing wetlands is flooding. The duration of flooding determines whether the resulting wetland has aquatic, marsh or swamp vegetation. Other important factors include fertility, natural disturbance, competition, herbivory, burial and salinity. When peat accumulates, bogs and swamps arise. Characteristics:- wetlands vary widely due to local and regional differences in topography, hydrology, vegetation, and other factors, including human involvement. Wetlands can be divided into two main classes:- tidal and non-tidal areas. Hydrology:- wetland hydrology is associated with the spatial and temporal dispersion, flow, and physiochemical attributes of surface and ground water in its reservoirs. Based on hydrology, wetlands can be categorized as riverine (associated with streams), lacustrine (associated with lakes and reservoirs), and palustrine (isolated). Sources of hydrological flows into wetlands are predominately precipitation, surface water, and ground water. Water flows out of wetlands by evapotranspiration, surface runoff, and sub-surface water outflow. Hydrodynamics (the movement of water through and from a wetland) affects hydroperiods (temporal fluctuations in water levels) by controlling the water balance and water storage within a wetland. Landscape characteristics control wetland hydrology and hydrochemistry. The O_2 and CO_2 concentrations of water depend on temperature and atmospheric pressure. Hydrochemistry within wetlands is determined by the pH, salinity, nutrients, conductivity, soil composition, hardness, and the sources of water. Water chemistry of wetlands varies across landscapes and climatic regions. Wetlands are generally minerotrophic with the exception of bogs. Bogs receive their water from the atmosphere and therefore their water has low mineral ionic composition because ground water has a higher concentration of dissolved nutrients and minerals in comparison to precipitation. The water chemistry of fens ranges from low pH and low minerals to alkaline with high accumulation of calcium and magnesium because they acquire their water from precipitation as well as ground water. Role of Salinity:- salinity has a strong influence on wetland water chemistry, particularly in wetlands along the coast. In non-riverine wetlands, natural salinity is regulated by interactions between ground and surface water, which may be influenced by human activity. Soil:- carbon is the major nutrient cycled within wetlands. Most nutrients, such as sulfur, phosphorus, carbon, and nitrogen are found within the soil of wetlands. Anaerobic and aerobic respiration in the soil influences the nutrient cycling of carbon, hydrogen, oxygen, and nitrogen, and the solubility of phosphorus thus contributing to the chemical variations in its water. Wetlands with low pH and saline conductivity may reflect the presence of acid sulfates and wetlands with average salinity levels can be heavily influenced by calcium or magnesium. Biogeochemical processes in wetlands are determined by soils with low redox potential. Biota:- the biota of a wetland system includes its vegetation zones and structure as well as animal populations. The most important factor affecting the biota is the duration of flooding. Other important factors include fertility and salinity. In fens, species are highly dependent on water chemistry. The chemistry of water flowing into wetlands depends on the source of water and the geological material in which it flows through as well as the nutrients discharged from organic matter in the soils and plants at higher elevations in slope wetlands. Biota may vary within a wetland due to season or recent flood regimes. Flora:- there are four main groups of hydrophytes that found in wetland systems throughout the world. Submerged water plants. This type of vegetation is found completely underwater. Submerged wetland vegetation can grow in saline and fresh-water conditions. Some species have underwater flowers, while others have long stems to allow the flowers to reach the surface. Submerged species provide a food source for native fauna, habitat for invertrebrates, and also possess filtration capabilities. Examples include seagrasses and eelgrass. Floating water plants. Floating vegetation is usually small although it may take up a large surface area in a wetland system. These hydrophytes have small roots and are only found in slow-moving water with rich-nutrient level water Floating aquatic plants are a food resource for avian Species. Examples include water lilies lily pad and duckweed. Emergent water plants. Emergent water plants can be seen above the surface of the water but whose roots are completely submerged. Many have aerenchyma to transmit oxygen from the atmosphere to their roots. Extensive areas of emergent plants are usually termed marsh. Examples include cattails (Typha) and arrow arum (Peltandra Virginica). Surrounding trees and shrubs. Forested wetlands are generally known as Swamps. The upper level of these

swamps is determined by high water levels, which are negatively affected by dams. Some swamps can be dominated by a single species, such as silver maple swamps around the Great Lakes. Others, like those of the Amazon Basin, have large numbers of different tree Species. Examples include cypress (Taxodium) and mangrove. Fauna:- (i) Fish:- fish are more dependent on wetland ecosystems than any other type of habitat. 75% of the United States' commercial fish and shellfish stocks depend solely on estuaries to survive. Tropical fish Species need mangroves for critical hatchery and nursery grounds and the coral reef system for food. (ii) Amphibians:- Frogs are the most crucial amphibian species in wetland systems. Frogs need both terrestrial and aquatic habitats in which to reproduce and feed. While tadpoles control algal populations, adult frogs forage on insects. Frogs are used as an indicator of ecosystem health due to their thin skin which absorbs both nutrient and toxins from the surrounding environment resulting in an above average extinction rate in unfavorable and polluted environmental conditions. (iii) Reptiles:- Alligators and crocodiles are two common reptilian Species. Alligators are found in fresh water along with the fresh water Species of the crocodile. The saltwater crocodile is found in estuaries and mangroves and can be seen in the coastline bordering the Great Barrier Reef in Australia. The Florida Everglades is the only place in the world where both crocodiles and alligators co-exist. Snakes, lizards, goannas, and turtles also can be seen throughout wetlands. Snapping turtles are one of the many kinds of turtles found in wetlands. (iv) Mammals:- multiple small mammals as well as large herbivore and apex species such as the Florida Panther live within and around wetlands. The wetland ecosystem attracts mammals due to its prominent seed sources, invertebrate populations, and numbers of small reptiles and amphibians. (v) Monotremes:- the platypus (Ornithorhynchus Anatinus) is found in eastern Australia living in freshwater rivers or lakes, and much like the beaver creates dams, create burrows for shelter and protection. The platypus swims through the use of webbed feet. Platypuses feed on insect larvae, worms, or other freshwater insects hunting mainly by night by the use of their bill. They turn up mud on the bottom of the lake or river, and with the help of the electroreceptors located on the bill, unearth insects and freshwater insects. The platypus stores their findings in special pouches behind their bill and consumes its prey upon returning to the surface. (vi) Insects and Invertebrates:- these species total more than half of the 100 000 known animal species in wetlands. Insects and invertebrates can be submerged in the water or soil, on the surface, and in the atmosphere. Algae:- Algae are diverse water plants that can vary in size, color, and shape. Algae occur naturally in habitats such as inland lakes, inter-tidal zones, and damp soil and provide a dedicated food source for animals, fish, and invertebrates. There are three main groups of algae:- Plankton are algae which are microscopic, free-floating algae. This algae is so tiny that on average, if fifty of these microscopic algae were lined up end-to-end, it would only measure one millimeter. Plankton are the basis of the food web and are responsible for primary production in the ocean using photosynthesis to make food. Filamentous algae are long strands of algae cells that form floating mats. Chara and Nitella algae are upright algae that look like a submerged plant with roots. Climates:- (i) Temperature:- temperatures vary greatly depending on the location of the wetland. Many of the world's wetlands are in temperate zones (midway between the North or South Pole and the equator). In these zones, summers are warm and winters are cold, but temperatures are not extreme. However, wetlands found in the tropic zone, around the equator, are warm year round. Wetlands on the Arabian Peninsula, for example, can reach 50 °C (122 °F) and would therefore be subject to rapid evaporation. In northeastern Siberia, which has a polar climate, wetland temperatures can be as low as −50 °C (−58 °F). In a moderate zone, such as the Gulf of Mexico, a typical temperature might be 11 °C (51 °F). (ii) Rainfall:- the amount of rainfall a wetland receives varies widely according to its area. Wetlands in Wales, Scotland, and Western Ireland typically receive about 1 500 mm (or 60 in) per year. In some places in Southeast Asia, where heavy rains occur, they can receive up to 10 000 mm (about 200 in). In the northern areas of North America, wetlands exist where as little as 180 mm (7 inches) of rain fall each year. (iii) Temporal Variation:- perennial systems; seasonal systems; episodic (periodic or intermittent) system of the down; surface flow may occur in some segments, with subsurface flow in other segments; ephemeral (short-lived) systems; and migratory species. (iv) Human-Disturbance:- (a) Encroachment:- drainage, development, over-grazing, mining, and unsustainable water use; (b) Ecosystem Stress:- water scarcity, endangered species, disruption of breeding grounds, and Imbalance in sediment load and nutrient filtration. Peatswamps of South-east Asia:- in Southeast Asia, peatswamp forests and soils are being drained, burnt, mined, and overgrazed contributing severely to climate change. As a result of peat drainage, the organic carbon that was built up over thousands of years and is normally under water, is suddenly exposed to the air. It decomposes and turns into carbon dioxide (CO_2), which is released into the atmosphere. Peat fires cause the same process and in addition create enormous clouds of smoke that cross international borders, such as happen every year in Southeast Asia. Peatlands form only 3% of all the world's land area, however, their degradation equals 7% of all fossil fuel CO_2 emissions. Through the building of dams, Wetlands International is halting the drainage of peatlands in Southeast Asia, hoping to mitigate CO_2 emissions. Concurrent wetland restoration techniques include reforestation with native tree species as well as setting up community fire brigades. This sustainable approach can be seen in Central Kalimantan and Sumatra, Indonesia. Aquaculture:- concerns are developing over certain aspects of farm fishing, which uses natural waterways to harvest fish for human consumption and pharmaceuticals. This practice has become especially popular within Asia and the South Pacific. Its impact downstream upon much larger water ways has negatively influenced many small island developing states. The function of natural wetlands can be classified by their ecosystem benefits. United Nations Millennium Ecosystem Assessment and Ramsar Convention found wetlands to be of biosphere significance and societal importance in the following areas:- flood control; groundwater replenishment; shoreline stabilization and storm protection; water purification; reservoirs of biodiversity; wetland products; cultural values; recreation and tourism; and climate change mitigation and adaptation. The economic worth of the ecosystem services provided to society by intact, naturally functioning wetlands is frequently much greater than the perceived benefits of converting them to 'more valuable' intensive land use – particularly as the profits from unsustainable use often go to relatively few individuals or corporations, rather than being shared by society as a whole (Ramsar convention). Wetland is an area that is regularly saturated by surface or ground water and subsequently is characterized by a prevalence of vegetation that is adapted for life in saturated soil conditions. Examples include swamps, bogs, fens, marshes, pocosins and estuaries. Wetland:- the US Fish and Wildlife Service (USFWS) defines wetlands as lands transitional between terrestrial and aquatic systems, where the water table is usually at or near the surface, or the land is covered by shallow water. For purposes of this classification, wetlands must have one or more of the following three attributes:- (a) at least periodically, the land supports predominantly hydrophytes; (b) the substrate is predominantly undrained hydric soils; and (c) the substrate is nonsoil and is saturated with water or covered by shallow water at some time during the growing season of each year. / Ромсарская Конвенция (Ramsar Convention). WETLAND BANKING = ОБУСТРОЙСТВО ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ОБУСТРОЙСТВО СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Banking is a term used to describe actions required to be taken on the part of developers to mitigate and replace the loss of wetlands. Through various federal and state regulations governing land use on wetlands, when impacts to wetlands cannot be avoided or minimized wetlands must be replaced. The replacement process allows for the creation or restoration of any number of wetlands to provide replacement credit for future wetlands impacts.

WETLAND CONSERVATION = СОХРАНЕНИЕ ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или КОНСЕРВАЦИЯ СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ, или ОХРАНА СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Conservation is:- (1) Wetlands Protection:- the principle USDA programs for wetland conservation are swampbuster, the Wetlands Reserve Program, and the

Farmable Wetlands Pilot Program. (2) The Food Security Act of 1985 swampbuster provision discouraged the alteration of wetlands for agricultural purposes. Producers who drained, dredged, filled, leveled, or otherwise altered wetlands to make possible the production of an agricultural commodity after November 28, 1990, or who planted an agricultural commodity on a wetland that was converted after December 23, 1985, lost eligibility for most USDA program benefits. The provisions were further amended by the Food, Agriculture, Conservation, and Trade Act of 1990 and the Federal Agriculture Improvement and Reform Act of 1996. The Farm Security and Rural Investment Act of 2002 (Sec. 2002) reauthorized the provision and amended the program to prohibit the USDA from delegating the ability to make compliance determinations to any person or entity. / сохранение (conservation).

WETLAND CREATION = СОЗДАНИЕ ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или СОЗДАНИЕ СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Creation:- a wetland that has been created on a site location that historically was not a wetland, or is a wetland but the site will be converted to a wetland with a different hydrology, vegetation type, or function than naturally occurred on the site.

WETLAND DELINEATION = ОЧЕРЧИВАНИЕ ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ОЧЕРЧИВАНИЕ СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Delineation is the determination of wetland status on both agricultural and nonagricultural lands. For agricultural lands, the Natural Resources Conservation Service is the lead federal agency responsible for determining wetland status under both swampbuster and Section 404. The US Army Corps of Engineers is the lead federal agency responsible for determining wetland status on nonagricultural lands for those not participating in USDA programs. See also Isolated Waters, Section 404, and Swampbuster. A Wetland Delineation is a more detailed process that specifically defines the legal boundary of jurisdictional wetlands on a property. This boundary separates the regulated wetland from the upland areas on site. It is critical to identify the exact wetland boundary and acreage for permitting of impacts to wetlands or other regulated waters. It is often prudent to have a wetland delineation carried out to provide documentation that you have avoided impacts to wetlands. / Служба Сохранения Природных Ресурсов.

WETLAND DETERMINATION = УСТАНОВЛЕНИЕ ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или УСТАНОВЛЕНИЕ СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Determination (sometimes called Identification) is simply the determination of whether an area is a wetland. Wetland delineation is the actual determination and establishment of wetland boundaries. For landowners who want to protect the natural resources on their property, just knowing that a wetland exists may be enough information for a hands-off form of stewardship. However, if you want to 'do something' in or adjacent to your wetland that might impact the wetland's function (or is a regulated activity), then knowing the wetland boundaries is essential. Who Determines Wetlands? On the state level, the Michigan Department of Environmental Quality (MDEQ) is responsible for determining wetland boundaries pursuant to Michigan's Wetland Protection statute. On the federal level, the US Environmental Protection Agency (EPA), the US Army Corps of Engineers (Corps), the US Fish and Wildlife Service (FWS) and the Natural Resources Conservation Service (NRCS) all play a role is delineating wetlands in the administration of Federal law that addresses wetlands. Currently, the Michigan Department of Environmental Quality delineates wetlands according to The Michigan Department of Natural Resources Wetland Determination Draft Manual for Field Testing. The purpose of this manual is to formalize the process used to delineate wetlands as they are defined by state law:- 'Wetland' means land characterized by the presence of water at a frequency and duration sufficient to support, and that under normal circumstances does support, wetland vegetation or aquatic life, and is commonly referred to as a Bog, Swamp, or Marsh. (Section 30301(d), Part 303, Wetland Protection Act 451 of 1994). Where are Wetlands Usually Found? Wetlands are typically found in depressions, the lowest portion of the landscape, or adjacent to lakes, rivers, or streams. Landscape position, climate, and soil type all influence wetland formation. You can expect to find wetlands in the following places:- (i) in low areas with a high water table; (ii) on slopes where groundwater breaks out as springs or seeps; (iii) near rivers, streams, lakes, and the Great Lakes; (iv) in flat areas where clayey soils or bedrock close to the surface form an impervious layer that creates a 'perched' water table; and (v) in abandoned ditches or stream channels. Also Certified Wetland Determination. See also Wetland Delineation. To obtain cost effective preliminary information early in a project, clients request a wetland determination where we:- (i) evaluate available maps of the property to initially determine if wetlands may be present; (ii) inspect the site to verify whether regulated wetlands are present; and (iii) establish their general extent and location. / Служба Сохранения Природных Ресурсов.

WETLAND ENHANCEMENT = ПОВЫШЕНИЕ (или УСИЛЕНИЕ) ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ПОВЫШЕНИЕ (или УСИЛЕНИЕ) СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Enhancement is the modification or rehabilitation of an existing or degraded wetland where specific functions or values are modified for the purpose of meeting specific project objectives.

WETLAND ENROLLMENT PILOT PROGRAM = ПИЛОТНАЯ ПРОГРАММА ПО ПРИЁМУ ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ПИЛОТНАЯ ПРОГРАММА ПО ПРИЁМУ СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – In the United States, Wetland Enrollment Pilot Program:- (a) Program Required:- (1) in general, during the 2008 through 2012 fiscal years, the Secretary shall carry out a program in each State under which the Secretary shall enroll eligible acreage described in subsection (b). (2) Participation among States:- the Secretary shall ensure, to the maximum extent practicable, that owners and operators in each State have an equitable opportunity to participate in the program established under this section. (b) Eligible Acreage:- (1) wetland and related land:- subject to subsections (c) and (d), an owner or operator may enroll in the conservation reserve, pursuant to the program established under this section, land:- (A) that is wetland (including a converted wetland described in section 3822 (b)(1)(A) of this title) that had a cropping history during at least 3 of the immediately preceding 10 crop years; (B) on which a constructed wetland is to be developed that will receive flow from a row crop agriculture drainage system and is designed to provide nitrogen removal in addition to other wetland functions; (C) that was devoted to commercial pond-raised aquaculture in any year during the period of calendar years 2002 through 2007; or (D) that, after January 01, 1990, and before December 31, 2002, was:- (i) cropped during at least 3 of 10 crop years; and (ii) subject to the natural overflow of a prairie wetland. (2) Buffer Acreage:- subject to subsections (c) and (d), an owner or operator may enroll in the conservation reserve, pursuant to the program established under this section, buffer acreage that:- (A) with respect to land described in subparagraph (A), (B), or (C) of paragraph (1):- (i) is contiguous to such land; (ii) is used to protect such land; and (iii) is of such width as the Secretary determines is necessary to protect such land, taking into consideration and accommodating the farming practices (including the straightening of boundaries to accommodate machinery) used with respect to the cropland that surrounds such land; and (B) with respect to land described in subparagraph (D) of paragraph (1), enhances a wildlife benefit to the extent practicable in terms of upland to wetland ratios, as determined by the Secretary. (c) Program Limitations:- (1) Acreage limitation:- the Secretary may enroll in the conservation reserve, pursuant to the program established under this section, not more than:- (A) 100 000 acres in any State; and (B) a total of 1 000 000 acres. (2) Relationship to maximum enrollment:- subject to paragraph (3), any acreage enrolled in the conservation reserve under this section shall be considered acres maintained in the conservation reserve. (3) Relationship to other enrolled acreage:- acreage enrolled in the conservation reserve under this section shall not affect for any fiscal year the quantity of:- (A) acreage enrolled to establish conservation buffers as part of the program announced on March 24, 1998 (63 Fed. Reg. 14109); or (B) acreage enrolled into the conservation reserve enhancement program announced on May 27, 1998 (63 Fed. Reg. 28965). (4) Review; potential increase in enrollment acreage:- the Secretary shall conduct a review of the program established under this section with respect to each State that has enrolled land in the conservation reserve pursuant to the program. As a result of the review, the

Secretary may increase the number of acres that may be enrolled in a State under the program to not more than 200,000 acres, notwithstanding paragraph (1)(A). (d) Owner or operator enrollment limitations:- (1) wetland and related land:- (A) wetlands and constructed wetlands:- the maximum size of any land described in subparagraph (A) or (B) of subsection (b)(1) that an owner or operator may enroll in the conservation reserve, pursuant to the program established under this section, shall be 40 contiguous acres. (B) Flooded farmland:- the maximum size of any land described in subparagraph (D) of subsection (b)(1) that an owner or operator may enroll in the conservation reserve, pursuant to the program established under this section, shall be 20 contiguous acres. (C) Coverage:- all acres described in subparagraph (A) or (B), including acres that are ineligible for payment, shall be covered by the conservation contract. (2) Buffer acreage:- the maximum size of any buffer acreage described in subsection (b)(2) that an owner or operator may enroll in the conservation reserve under this section shall be determined by the Secretary in consultation with the State Technical Committee. (3) Tracts:- except for land described in subsection (b)(1)(C) and buffer acreage related to such land, the maximum size of any eligible acreage described in subsection (b)(1) in a tract of an owner or operator enrolled in the conservation reserve under this section shall be 40 acres. (e) Duties of owners and operators:- during the term of a contract entered into under the program established under this section, an owner or operator shall agree:- (1) to restore the hydrology of the wetland within the eligible acreage to the maximum extent practicable, as determined by the Secretary; (2) to establish vegetative cover (which may include emerging vegetation in water and bottomland hardwoods, cypress, and other appropriate tree species) on the eligible acreage, as determined by the Secretary; (3) to a general prohibition of commercial use of the enrolled land; and (4) to carry out other duties described in section 3832 of this title. (f) Duties of the Secretary:- (1) in general, except as provided in paragraphs (2) and (3), in return for a contract entered into under this section, the Secretary shall:- (A) make payments to the owner or operator based on rental rates for cropland; and (B) provide assistance to the owner or operator in accordance with sections 3833 and 3834 of this title. (2) Contract offers and payments:- the Secretary shall use the method of determination described in section 3834 (c)(2)(B) of this title to determine the acceptability of contract offers and the amount of rental payments under this section. (3) Incentives:- the amounts payable to owners and operators in the form of rental payments under contracts entered into under this section shall reflect incentives that are provided to owners and operators to enroll filterstrips in the conservation reserve under section 3834 of this title. Also Pilot Program for Enrollment of Wetland and Buffer Acreage in the Conservation Reserve. See also Farmable Wetland Pilot Project (FWP). / сохранение (conservation).

WETLAND MITIGATION = ОСЛАБЛЕНИЕ (или СМЯГЧЕНИЕ) ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ОСЛАБЛЕНИЕ (или СМЯГЧЕНИЕ) СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Mitigation:- those actions taken to avoid, minimize, or deter the need to adversely impact existing wetlandsand similar habitats. Wetland mitigation deals in three fundamental areas:- (a) avoidance – a comprehensive evaluation to find the least environmentally damaging practicable alternative; (b) minimization – if adverse actions are unavoidable, then steps must be taken to insure that such adverse effects are minimized to every extent possible; and (c) compensatory mitigation B adding new areas to the existing wetland inventory. See also Mitigate, Mitigation, and Wetland Banking.

WETLAND RESTORATION = ВОССТАНОВЛЕНИЕ (или РЕСТАВРАЦИЯ) ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ВОССТАНОВЛЕНИЕ (или РЕСТАВРАЦИЯ) СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetland Restoration is a rehabilitation of a drained or degraded wetland, where the soils, hydrology,vegetative community, and biological habitat are returned to the natural condition to the extent practicable.

WETLANDS RESERVE PROGRAM = ПРОГРАММА ПО РЕЗЕРВАМ ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ПРОГРАММА ПО РЕЗЕРВАМ СИЛЬНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ) – Wetlands Reserve Program (WRP):- authorized by the Food Security Act of 1985 (Sec. 1237), as amended by the Federal Agriculture Improvement and Reform Act of 1996 (Sec. 333) and the Farm Security and Rural Investment Act of 2002 (Sec. 2201). A program to take wetlands out of production for a period of 30 years or more. Priority is given to enrolling wetlands that enhance wildlife habitat. The USDA purchases easements from willing owners of land that can be restored to a wetland. The USDA also provides cost-share assistance to restore these wetlands. The Natural Resources Conservation Service, in cooperation with the Fish and Wildlife Service, determines land eligibility and prepares a Wetland Reserve Plan of Operation that will restore and protect the wetlands. Producers enrolling in the program must agree to implement an approved wetlands restoration and protection plan, and grant either a permanent easement or a 30-year easement, or enter into a restoration cost-share agreement. In return, participating producers16 will receive payments over a 5- to 30-year period. The USDA has an enrollment cap of 2 275 000 acres of which, to the maximum extent practicable, the USDA will enroll 250 000 acres in each calendar year. The USDA is no longer instructed to make equal use of permanent easements, 30-year easements, and restoration cost-share agreements. The WRP is part of the new Comprehensive Conservation Enhancement Program that replaced the Environmental Conservation Acreage Reserve Program. The Farm Security and Rural Investment Act of 2002 reauthorized the WRP as a mandatory program under the Commodity Credit Corporation (subject to available appropriations) through FY2007. / Служба Сохранения Природных Ресурсов. сохранение (conservation).

WETLAND TILLAGE = ВСПАШКА ИЗБЫТОЧНО УВЛАЖНЁННЫХ ЗЕМЕЛЬ (или ВСПАШКА СИЛЬНО УВЛАЖНЁННОЙ ЗЕМЛИ, или ОБРАБОТКА СИЛЬНО УВЛАЖНЁННОЙ ПОЧВЫ) – Wetland Tillage is a preparing the soil by plowing of lowland fields and harrowing the soil in a saturated or flooded condition.

WET LEASE = МОКРАЯ АРЕНДА (или АРЕНДА С ЭКИПАЖЕМ) – The Wet Lease of an aircraft is an arrangement whereby the lessor provides at least some crew, maintenance and fuel. The last of these is now uncommon despite being origin of the term. There are various variations possible on the lease terms, but the common element is that the lessor retains some responsibility for supplying and operating the aircraft. The payment for a wet lease partly a fixed amount per period of the lease and an hourly rate for hours flown. A wet lease needs to be distinguished from:- (i) a dry lease:- the simple lease of only an aircraft; and (ii) a charter where the owner of the aircraft retains complete responsibility for operating it and provides it, and is paid, per flight. Because of the possible variations and grey areas, the following terms may also be used:- (i) damp lease:- a lease with less than a full cabin crew; and (ii) ACMI (short for the Aircraft, Crew, Maintenance and Insurance) lease:- aircraft, crew maintenance and insurance, a more specific term than wet lease. Wet Lease is an arrangement for renting an aircraft under which the owner provides crews, ground support equipment, fuel and so on (of dry lease). Wet Lease is an arrangement that covers all facets of operating an airplane on a carrier's behalf. Includes the airframe, crew, and most, if not all, of the airplane-related expense items.

WET MEADOWS = ВЛАЖНЫЕ ЛУГА – Wet Meadows are the wetlands vegetated with grasses, sedges, and showy flowering plants, but with the absence of woody plants. Standing water is present only after heavy rains. Wet meadows serve as buffers between uplands and waterways where their dense vegetation trap sediments and take up nutrients, retain floodwaters, and provide wildlife habitat. Wet Meadow:- grassland with saturated soil near the surface but without standing water for most of the year.

WET MILLED = ВЛАЖНОГО РАЗМОЛА – Wet Milled:- steeped in water with or without sulfur dioxide to soften the kernel in order to facilitate the separation of the various components.

WET MILLING = ВЛАЖНЫЙ РАЗМОЛ – Wet Milling is a milling process for corn in which the kernel is steeped in water, with or without sulfur dioxide, to soften the kernel in order to facilitate the separation of the various component parts. The process begins with shelled yellow dent corn that has been removed from the cob during harvesting. The corn is cleaned and steeped then milled, breaking the germ loose. Mechanical and solvent processes during germ separation extract oil from the germ. The corn leaves the germ separator in a water suspension for further grinding to release starch and gluten from the kernel fiber. The starch and gluten slurry is piped to starch separators. The fiber, steepwater, and germ residue are sold as animal feed. The extracted gluten meal is used as poultry feed and in pet food. Starch is collected and washed to produce a high-quality starch. Starch is either dried and then marketed, modified into specialty starches, or converted into corn syrups and other sweeteners.

WET MODULUS = МОДУЛЬ МОКРОТЫ – Wet Modulus is the modulus determined when the material is completely wet. In the definition of the generic name 'Modal', the term 'Wet Modulus' is defined as the tenacity required to produce an elongation of 5% when the specimen is completely immersed in water.

WET NATURAL GAS = ЖИРНЫЙ ПРИРОДНЫЙ ГАЗ – Wet Natural Gas is a mixture of hydrocarbon compounds and small quantities of various nonhydrocarbons existing in the gaseous phase or in solution with crude oil in porous rock formations at reservoir conditions. The principal hydrocarbons normally contained in the mixture are methane, ethane, propane, butane, and pentane. Typical nonhydrocarbon gases that may be present in reservoir natural gas are water vapor, carbon dioxide, hydrogen sulfide, nitrogen and trace amounts of helium. Under reservoir conditions, natural gas and its associated liquefiable portions occur either in a single gaseous phase in the reservoir or in solution with crude oil and are not distinguishable at the time as separate substances. Note:- The Securities and Exchange Commission and the Financial Accounting Standards Board refer to this product as natural gas.

WETNESS = ВЛАЖНОСТЬ (или СЫРОСТЬ) – Wetness is a term used to designate the percentage of water in steam. Also used to describe the presence of a water film on heating surface interiors.

WETOX = WET AIR OXIDATION

WET PRAIRIES = ВЛАЖНЫЕ ПРЕРИИ – Wet Prairies:- intermediate between a marsh and a wet meadow.

WET SERVICE CONDITION = УСЛОВИЕ ВЛАЖНОЙ ЭКСПЛУАТАЦИИ – All service conditions other than dry. The Wet Service Factor (or C_M for short) is used to signify wood that will not be used in a dry condition, e.g., covered structures. Note that wood that cycles between wet/dry conditions will degrade in condition faster than wood that is subject to continuous wet or dry conditions. For example, a column supporting a wood pier under water will retain it's strength longer than the part of the column that is stuck between the tide (as tide goes up it will be wet, and as the tide goes down it will then dry). This is because the transition between wet and dry will deteriorate the wood faster than a constantly wet, or constantly dry member. The Wet Service Factor, C_M, applies to dimension lumber (including those preservatively treated). Reference design values for structural sawn lumber are based on the moisture service conditions (19% or less for lumber). When the moisture content of the structural members in use differs from these moisture service conditions, reference design values shall be multiplied by the wet service factors, C_M. Wet Service Factor, C_M:- it's important to consider the moisture content in the wood both at the time of fabrication and while in service. Dry use describes sawn wood elements with moisture content of 19% or less. Since most covered structures will remain continuously dry for the service life of the structure, the issue of dry wood at fabrication pertains mostly to sawn lumber, which may have higher moisture content. Most glued engineered wood products require a low moisture content for good adhesion in their manufacture; therefore, engineered wood elements will almost always be dry at time of fabrication. Many engineered wood products, such as I-joists, are manufactured for specific end-use applications and are intended to remain dry at all times. Nominal design values must be multiplied by the appropriate wet service factors. / Например, древесина, используемая для поддержки водных подмостков под водой будет .

WET SOLIDS = ВЛАЖНЫЕ ТВЁРДЫЕ ТЕЛА – Wet Solids:- condensed milk, skim milk, or whey, as distinguished from dry solids in the form of nonfat dry milk or dried whey powder.

WET SPINNING = МОКРОЕ ПРЯДЕНИЕ – The first step of Wet Spinning is similar to solvent spinning. The plastics is dissolved in chemical solvents. This fluid solution is forced out through the spinneret into a coagulating bath that makes the plastics gel into a solid filament form. Some members of the cellulosic, acrylic, and polyvinyl plastics families may be processed by wet spinning. Wet Spinning is the process in which a solution of the fiber-forming substance is extruded into a liquid coagulating medium where the polymer is regenerated, as in the manufacture of viscose or cuprammonium rayon. There are four types of spinning for polymers- wet spinning, dry spinning, melt spinning, and gel spinning. Wet Spinning:- of all the four processes, wet spinning is the oldest process. It is used for polymers that need to be dissolved in a solvent to be spun. The spinneret remains submerged in a chemical bath that leads the fiber to precipitate, and then solidify, as it emerges out of the spinneret holes. The name of the process, i.e. wet spinning has got its name from this 'wet' bath only. Acrylic fiber, rayon fiber, aramid fiber, modacrylic fiber, and spandex fibers, all are manufactured through wet spinning. / осадок (precipitate).

WET–SPUN FLAX = МОКРО ВЫПРЯДЕННЫЙ ЛЁН – Wet-Spun Flax:- the process of spinning line flax where the fibers are smoothed by moistening them as they are spun. Traditionally, spinners licked their fingers and drank a lot of beer. More prosaically, you can get little wooden buckets to hold the water and can hang by a leather thong from the wheel. Or even a bowl of water. You should coat the inside part of the bobbin (where the fibers wind around) with paraffin or some other sealant if you don't want to damage your bobbin. / увлажнение (или эмульсирование) . При выработке пряжи из чёсаного льна применяют два способа прядения:- мокрое и сухое. Способ прядения определяет характер вытягивания в вытяжных приборах прядильных машин и их конструкцию. При мокром способе прядения пряжа формируется из элементарных волокон или из небольших их комплексов, а при сухом – из технических волокон. При мокром способе прядения ровница проходит через корыто с горячей водой (45–75 °С), установленное перед вытяжным прибором. Горячая вода способствует размягчению клеящих пектиновых веществ, которыми склеены элементарные волокна льна, и обеспечивает сдвиг элементарных волокон друг относительно друга в вытяжном приборе. Мокрый способ прядения позволяет получать более тонкую, ровную, гладкую пряжу. Сухое прядение применяют для выработки пряжи большой и средней линейной плотности.

WET STEAM = ВЛАЖНЫЙ ПАР (или СЫРОЙ ПАР) – Wet Steam is a mixture of steam and liquid water. It exists at a saturation temperature containing more than 5% water. It is said to be a two-phase mix:- steam contains droplets of water that have not changed phase. Wet steam may cause corrosion in vulnerable equipment such as turbine blades, low-pressure steam piping and heat exchangers. Wet steam lowers the heat transfer efficiency of steam, which results in an inefficient sterilization procedure. Wet steam is also known as Supersaturated Steam. Wet Steam is a steam containing moisture. Wet Steam is generated by heating water, which then turns to steam at the first stage. If additional heat is added to wet steam at a set pressure, the temperature remains the same until all the liquid is evaporated. Only then does the temperature rise above saturation, allowing the formation of wet steam. The quantity of water in wet steam is designated by the quality. The superiority of steam refers to the percent of steam flow that is steam and water by weight. Steam that is 90% steam and 10% water is known as 90% quality steam. Wet steam is the most difficult type of steam to

measure. Problems that are caused by wet steam in a steam system include:- (i) Hydraulic Water Hammer:- an accumulation of condensate or humidity in pipelines or appliances is carried by rapidly moving steam; (ii) Erosion:- excessive presence of water in steam lines promotes erosion; (iii) Deposits Of Water-Treatment Chemicals:- degrade heat transfers by forming deposits in heat exchangers; (iv) Contamination:- traces of treated water in the steam can contaminate the product; and (v) Destruction Of Turbines:- water droplets literally destroy the vanes of a turbine. It is very important that the boiler, steam traps and piping be routinely maintained so that the problem of wet steam caused by the distribution system can be avoided. If they become filled with water and dirt, they may not work effectively, or at all. / Известен также как Пересыщенный Пар (Supersaturated Steam).

WET STRENGTH = ВЛАГОПРОЧНОСТЬ – Wet Strength is the measurement of the strength of a material when it is saturated with water, normally relative to the dry strength. / Прочность на разрыв во влажном состоянии.

WET SUIT = ВЛАЖНЫЙ КОСТЮМ (или ГИДРОКОСТЮМ) – Wet Suit is a close-fitting suit made of material, as sponge rubber, that traps a thin layer of water against the body to retain body heat and that is worn, as by a skin diver, especially in cold water. Surfers generally wear wet suits when surfing. The suit protects the body from the board as well as maintains body temperature.

WETT = WHOLE EFFLUENT TOXICITY TESTING

WETTABLE POWDER = РАЗМОКАЕМЫЙ ПОРОШОК (или ВПИТЫВАЕМЫЙ ВЛАГУ ПОРОШОК, или СМАЧИВАЕМЫЙ ПОРОШОК) – Wettable Powder (WP) is a pesticide formulation consisting of talc or clay and a wetting agent mixed with the pesticide. When water is mixed with the formulation, a suspension is formed and is used to spray on the target pest. Wettable Powder (WP) is a finely divided dry formulation that can be readily suspended in water. Wettable Powders (WP) are the concentrated dusts impregnated with an insecticide concentrate. While the water from a WP mixture will penetrate porous materials, the powder usually does not. Most of the insecticide is left on the surface where it can be picked up by a passing insect.

WETTING AGENT = СМАЧИВАЮЩИЙ АГЕНТ (или СМАЧИВАЮЩЕЕ СРЕДСТВО, или СМАЧИВАТЕЛЬ) – Wetting Agent is:- (i) a substance that serves to reduce the interfacial tensions and causes spray solutions or suspensions to make better contact with treated surfaces (see also Surfactant); and (ii) a substance in a wettable powder formulation that causes it to wet readily when added to water. Wetting Agent is a substance that renders a surface non-repellent to a wetting liquid. Wetting Agent is a chemical that helps water penetrate a material or form a film over its surface; usually a surfactant. Wetting agents are often used in dyeing to help the dye solution penetrate to the individual fibers (they don't usually help the dye penetrate from the surface of the fiber to the interior of the fiber). They can help in some fiber arts dyeing processes, but too much in a dye solution used for direct application may make the dye spread more than is wanted.

W FORMATION = ФОРМИРОВАНИЕ ДАБЛ.Ю. (или ФОРМАЦИЯ ДАБЛ.Ю.) – In technical analysis, W Formation is a price trend characterized by a sharp fall, then a sharp rise, then a second sharp fall, and finally a second sharp rise. It is called a W Formation because the series of rises and falls vaguely looks like the letter W. Technical analysts may consider a W formation a buy signal if the second sharp rises outpaces the two previous price highs. In technical analysis, W Formation is a chart formation caused by a sharp decline, a sharp upward movement, and then a second sharp decline and sharp upward movement. The resultant chart pattern is similar to the letter W. In general, if the second upward movement surpasses each of the two previous high points, the W formation is a bullish sign. The double top and double bottom are another pair of well-known chart patterns whose names don't leave much to the imagination. These two reversal patterns illustrate a security's attempt to continue an existing trend. Upon several attempts to move higher, the trend is reversed and a new trend begins. These chart patterns formed will often resemble what looks like a 'W' (for a double bottom) or an 'M' (double top). The Double Top pattern is found at the peaks of an upward trend and is a clear signal that the preceding upward trend is weakening and that buyers are losing interest. Upon completion of this pattern, the trend is considered to be reversed and the security is expected to move lower. The first stage of this pattern is the creation of a new high during the upward trend, which, after peaking, faces resistance and sells off to a level of support. The next stage of this pattern will see the price start to move back towards the level of resistance found in the previous run-up, which again sells off back to the support level. The pattern is completed when the security falls below (or breaks down) the support level that had backstopped each move the security made, thus marking the beginnings of a downward trend. It's important to note that the price does not need to touch the level of resistance but should be close to the prior peak. Also, when using this chart pattern one should wait for the price to break below the key level of support before entering. Trading before the signal is formed can yield disastrous results, as the pattern is only setting up the possibility for the trend reversal and could trade within this banded range for some time without falling through. This pattern is a clear illustration of a battle between buyers and sellers. The buyers are attempting to push the security but are facing resistance, which prevents the continuation of the upward trend. After this goes on a couple of times, the buyers in the market start to give up or dry up, and the sellers start to take a stranglehold of the security, sending it down into a new downtrend. Again, volume should be an important focus as one should look for an increase in volume when the security falls below the support level. Also, as in other chart patterns, do not be alarmed if there is a return to the previous support level that has now become a resistance level in the newly established trend. Double Bottom is the opposite chart pattern of the double top as it signals a reversal of the downtrend into an uptrend. This pattern will closely resemble the shape of a 'W'. The double bottom is formed when a downtrend sets a new low in the price movement. This downward

move will find support, which prevents the security from moving lower. Upon finding support, the security will rally to a new high, which forms the security's resistance point. The next stage of this pattern is another sell-off that takes the security down to the previous low. These two support tests form the two bottoms in the chart pattern. But again, the security finds support and heads back up. The pattern is confirmed when the price moves above the resistance the security faced on the prior move up. Remember that the security needs to break through the support line to signal a reversal in the downward trend and should be done on higher volume. As in the double top, do not be surprised if the price returns to the breakout point to test the new support level in the upward trend. Price Objective and Adjustments:- it's important to get an idea as to the size of the resulting move once the signal has been formed. In both the double top and double bottom, the initial price objective can be measured by taking the price distance between the support and resistance levels or the range that chart pattern trades. For example, assume in a double top that the upward trend peaks at USD50 and retraces to USD40 to form the support level. Assuming everything follows through on the chart pattern and the support level is broken at USD40, the initial price objective should be set at USD30 (USD40 – USD10). Often in technical analysis and chart patterns, we're presented with an ideal chart setup; but in reality the pattern doesn't always look as perfect as it's supposed to. In double tops and double bottoms one thing to remember is that the price on the second test does not always need to reach the same distance as the first test. Another problem that can occur is the second testing point, where the top or bottom actually breaks the level that the first top or bottom test created. If this occurs, it can give a signal that the previous trend will continue – instead of reverse – as the pattern suggests. However, don't be too quick to abandon the pattern as it could still materialize. If the price does, in fact, move above the prior test, look to see if the move was accompanied by large volume, suggesting a trend continuation. For example, if on the second test of a double bottom the price falls below the support line on heavy volume, it is a good sign the downward trend will continue and not reverse. If the volume is very weak, it could just be a last attempt to continue the downward trend, but the trend will ultimately reverse. The double tops and double bottoms are strong reversal patterns that can provide trading opportunities. But it is important to be careful with these patterns as the price can often move either way. Consequently, it's important that the trade is implemented once the support/resistance line is broken. W Formation is a technical analysis term used to describe a chart on which the price of a security has made two approximately equal bottoms over a period of time. Technical analysts try to buy at one of the bottoms in anticipation of a rise (which would make the shape of a 'W' on the chart). Also called Double Bottom. Opposite of Double Top. / Формирование Дабл.Ю. – графическая модель в техническом анализе, когда цена формирует Английскую букву Дабл.Ю. (W). Иными словами тенденция технического графика динамики цены акции, облигации или сырья, показывающая, что цена дважды достигла уровня поддержки и движется выше. Перевёрнутая буква Дабл.Ю. означает, что цена достигла уровня противодействия и понижается. Смотрите также Двойное Дно (Double Bottom). W-Образная Модель – модель технического графика, отражающего цены на акции, облигации или товарно-сырьевую продукцию, которая показывает, что цены достигли уровня поддержки (support level) дважды и движутся вверх; также называется двойным локальным минимумом (double bottom) или двойным дном. Модель, обратная W-образной модели, отражает противоположную ситуацию:- цена достигла уровня сопротивления и падает. Это называется Двойной Вершиной (Double Top).

WHARF = ПРИСТАНЬ (или ПРИЧАЛ, или ВЕРФЬ) – Wharf is the oldest term in English referring to port structures. It denotes any structure of timber, masonry, cement, or other material built along or at an angle to the navigable waterway, with sufficient depth of water to accommodate vessels and receive and discharge cargo or passengers. The term can be substituted for Quay when applied to great solid structures in large ports. The area between the quay wall (made of solid masonry) and the nearby warehouse or storage facility is ca1led the Quay Apron. A landing place or pier where ships may tie up and load or unload. A Wharf or Quay is a structure on the shore of a harbor or on the bank of a river or canal where ships may dock to load and unload cargo or passengers. Such a structure includes one or more berths (mooring locations), and may also include piers, warehouses, or other facilities necessary for handling the ships. A wharf commonly comprises a fixed platform, often on pilings. Commercial ports may have warehouses that serve as interim storage areas, since the typical objective is to unload and reload vessels as quickly as possible. Where capacity is sufficient a single wharf with a single berth constructed along the land adjacent to the water is normally used; where there is a need for more capacity multiple wharves, or perhaps a single large wharf with multiple berths, will instead be constructed, sometimes projecting into the water. A pier, raised over the water rather than within it, is commonly used for cases where the weight or volume of cargos will be low. Smaller and more modern wharves are sometimes built on flotation devices (pontoons) to keep them at the same level as the ship, even during changing tides. In everyday parlance the term Quay is common in the United Kingdom, Canada, Australia, and many other Commonwealth countries, and the Republic of Ireland, whereas the term wharf is more common in the United States. In some contexts wharf and quay may be used to mean pier, berth, or jetty. In old ports such as London (which once had around 1700 wharves) many old wharves have been converted to residential or office use. Etymology:- the word Wharf comes from the Old English Hwearf, meaning Bank or Shore, and its plural is either wharfs or wharves; collectively a group of these is referred to as a Wharfing or Wharfage. Wharfage also refers to a fee charged by ports for the cargo handled there. In the northeast and east of England the term Staithe or Staith (from the Norse for landing stage) is also used. For example Dunston Staiths in Gateshead and Brancaster Staithe in Norfolk. However, the term Staithe may also be used to refer only to loading chutes or ramps used for bulk commodities like coal in

loading ships and barges. It has been suggested that wharf actually is an acronym for ware-house at river front, but it is actually a backronym created by Thames river boat guides. Another explanation may be that the word wharf comes from the Dutch word Werf which means Yard, an outdoor place where work is done, like a shipyard or a lumberyard. Wharf is a place for berthing vessels to perform loading and discharging of cargo. Wharf is a general term for any structure at which vessels berth or tie-up. The term is also used specifically for a berthing structure of open piling construction, aligned parallel with the shoreline, and referred to as a Marginal Wharf. See also Dock, Marina, Pier, and Wharfage. Wharf is a landing place where vessels may tie up for loading and unloading of cargo. Wharf is a structure built alongside the water or perpendicular to the shore where ships berth for loading or discharging goods. See also Wharfage. Wharf is a structure built on the shore of a harbor extending into deep water so that vessels may lie alongside. Wharf is a structure built along a shore, and often into the water, at which boats can be docked and loaded or unloaded. Also known as Pier or Quay. Wharf is a quay alongside which vessels berth. / Данстон Стэйсс в Гэйтсхэде (Dunston Staiths in Gateshead) и Бранкэстёр Стэйс в Нофоке (Brancaster Staithe in Norfolk). Под Причалом понимается совокупность сооружений и устройств для стоянки и обслуживания судов, посадки и высадки пассажиров, грузовых операций и тому подобного. Причальные сооружения (набережные, пирсы) оборудуют тумбами для закрепления судовых швартовов и отбойными приспособлениями (привальными брусьями, кранцами и другими), предохраняющими причал и борта судна от повреждений при навале. На причале располагают грузоподъёмные механизмы, склады и прочее. Причал, комплекс сооружений и устройств, предназначенных для подхода, швартовки, стоянки, обработки и обслуживания судов, посадки и высадки пассажиров, грузовых операций и тому подобного. Различают грузовые, пассажирские, судоремонтные и другие причалы. Под Пристанью понимается специально оборудованное место на внутренних водных путях для стоянки речных судов у берега. Предназначена для посадки и высадки пассажиров, перегрузочных и других операций. Пристани бывают стационарными и плавучими. Под Пристанью понимается небольшой порт на внутренних водных путях, имеющий обычно 1–2 причала. Причалы, к которым пристают суда, вместе с прилегающими складами, где хранятся товары до погрузки или после разгрузки. Верфь – предприятие для постройки судов, которое, в отличие от судостроительных заводов, не имеет цехов по изготовлению изделий машиностроения и получает эти изделия в виде поставок с других предприятий. По характеру выполняемых работ верфи подразделяют на судостроительные и судосборочные. Судостроительные верфи выполняют полный цикл работ по постройке судна. Судосборочные верфи, в отличие от судостроительных, осуществляют только сборку судов, получая с других верфей или заводов готовые к сборке насыщенные блоки корпуса и агрегаты механизмов и энергетических установок. Основными цехами судостроительной верфи, строящей суда из стали, являются:- корпусообрабатывающий цех, изготавливающий детали корпуса судна (в этот цех включается также склад стали, участок первичной обработки металла и плаз – специальное помещение, где на полу вычерчивают обводы судна и отдельные детали); сборочно-сварочный цех, в котором собирают и сваривают из деталей узлы, секции и блоки корпуса; стапельный цех, где формируется корпус судна и осуществляется его спуск на воду; механомонтажный цех, выполняющий монтаж главных двигателей, механизмов машинного отделения и гребных валов; слесарно-корпусной цех, изготавливающий и монтирующий вентиляцию, мелкие устройства, кожухи; деревообрабатывающий цех, изготавливающий и монтирующий обшивку помещений, мебель и тому подобное; малярно-заготовительный цех, выполняющий работы по изготовлению и монтажу изоляции и защитных покрытий; такелажно-корпусной цех, изготавливающий такелаж, тенты и тому подобное; цех гальванопокрытия, обеспечивающий цинкование, хромирование, никелирование, омеднение, кадмирование труб, крепежа и других изделий; достроечный цех, выполняющий работы по достройке судов на плаву с их испытаниями и сдачей. Судно – наиболее сложное инженерное сооружение, и для его постройки верфи оснащают уникальным оборудованием и применяют наиболее современные высокопроизводительные технологии. При постройке судна на верфи выделяются три этапа:- предстапельный, стапельный и достроечный. На предстапельном этапе после изготовления деталей проводится поточно-позиционная сборка плоских и полуобъёмных секций корпуса, сборка объёмных блоков, укрупнение массы секций и блоков, их насыщение трубопроводами, механизмами, изоляцией и окраска. В отдельные агрегаты собираются механизмы машинного отделения для последующего монтажа на стапеле. На стапельном этапе производится формирование судна из отдельных сборочных блоков, обстройка корпуса, проводятся механические испытания, окраска; этап заканчивается спуском остова судна на воду. На достроечном этапе завершаются работы по достройке судна, его испытания и сдача в эксплуатацию. Стапельный этап в зависимости от размеров судна может выполняться на наклонном стапеле с продольным спуском, горизонтальном стапеле с поперечным механизированным спуском по наклонным путям (на слипе), на горизонтальном стапеле в сухом доке (со всплытием построенного судна). Помещение, в котором производится стапельная сборка, называется эллингом. В цехах постройки блоков и в эллингах ширина пролётов достигает 60–120 метров (м) при высоте 60 м. Крановое оборудование может иметь грузоподъёмность более 1 000 тонн. Сухие доки имеют размеры в плане до 950 х 592 м, в них могут строиться суда дедвейтом до 1 000 000 тонн.

WHARFAGE = ПРИСТАНСКИЙ СБОР (или ПРИЧАЛЬНЫЙ СБОР, или ПОРТОВЫЙ СБОР) – Wharfage is the charge that an owner of a facility (terminal or port) charges for the movement of cargo through that facility. See also Wharf. Wharfage (or Whfge.) is a charge assessed by a pier or dock owner for handling incoming or outgoing cargo. Wharfage is a charge assessed by a pier or dock owner against freight handled over the pier or dock or against a steamship company using the pier or dock. See also Berth, and Dockage. Wharfage is a fee charged for the use of a wharf for mooring, loading or discharging a vessel or for storing goods. Wharfage is a charge for handling traffic on the wharf or for docking vessels at the wharf. Wharfage is a charge, usually made by a port authority, for cargo being unloaded from a ship. Wharfage is a charge assessed by a pier or dock owner against the cargo or a steamship company for use of the pier or dock. Wharfage is a cost of utilization of wharves. / Под Пристанскими Сборами (Wharfage) понимаются:- (i) плата, взимаемая с судна, причалившего к пристани; (ii) плата, взимаемая с судна, осуществляющего обработку грузов на пристани; и (iii) синоним Dockage или Moorage. Под Причальным Сбором понимается плата, взимаемая управляющим пристани за использование причала для погрузки на судно или разгрузки с судна товара.

WHARF DEMURRAGE = ПРИСТАНСКИЙ ДЕМЕРРЕДЖ (или ПРИСТАНСКАЯ ПЛАТА ЗА ПРОСТОЙ) – Wharf Demurrage is a charge assessed against cargo remaining in or on terminal facilities after the expiration of free time, unless arrangements have been made for storage.

WHARFINGER = НАЧАЛЬНИК ПРИСТАНИ (или НАЧАЛЬНИК ПРИЧАЛА, или НАЧАЛЬНИК ВЕРФИ) – Wharfinger is an archaic term for a person who is the keeper or owner of a wharf. The wharfinger took custody of and was responsible for goods delivered to the wharf, typically had an office on the wharf or dock, and was responsible for day-to-day activities including slipways, keeping tide tables and resolving disputes. The word's etymology is probably Elizabethan-era English. An 1844 usage appears in Pigot's Directory of Dorset in which Beales and Cox are noted to be wharfingers for the Port of Weymouth. In some regions, the term has not fallen out of use. For example, in the town of Saint Andrews in the Canadian province of New Brunswick, wharfinger is the name for the official responsible for the municipal wharf. Wharfinger is the person in charge of a wharf. Wharfinger is:- (1) one who owns or keeps a wharf, for the purpose of receiving and shipping merchandise to or from it, for hire. (2) Like a warehouseman, (q.v.) a wharfinger is responsible for ordinary neglect, and is therefore required to take ordinary, care of goods entrusted to him as such. The responsibility of

a wharfinger begins when he acquires, and ends when he ceases to have the custody of the goods in that capacity. (3) When he begins and ceases to have such custody depends generally upon the usages of trade and of the business. When goods are delivered at a wharf, and the wharfinger has agreed, expressly or by implication, to take the custody of them, his responsibility commences; but a mere delivery at the wharf, without such assent, does not make him liable. When goods are in the wharfinger's possession to be sent on board of a vessel for a voyage, as soon as he delivers the possession and the care of them to the proper officers of the vessel, although they are not actually removed, he is, by the usages of trade, deemed exonerated from any further responsibility. / в Справочнике Пигэта (Pigot's Directory) Билз (Beales) и Кокс (Cox). Лицо, ответственное за руководство пристанью. Начальник Пристани – это фирма или отдельное лицо, которое отвечает за функционирование пристани.

WHARFINGER'S RECEIPT = РАСПИСКА НАЧАЛЬНИКА ПРИСТАНИ – Wharfinger's Receipt is an acknowledgement of the receipt of goods at the wharf. It is issued by the wharfinger. It has a legal value similar to that of a warehouse receipt. Bills of lading and wharfingers' receipts are commercial instruments, and their transferability, or, as it is sometimes termed, their 'quasi negotiability', depends on the custom of merchants and the conveniences of trade. WHEAT = ПШЕНИЦА – The three principal types of Wheat used in modern food production are Triticum Vulgare (or Aestivum), Triticum Durum, and Triticum Compactum. Triticum Vulgare provides the bulk of the Wheat used to produce flour for bread making and for cakes and biscuits (cookies). It can be grown under a wide range of climatic conditions and soils. Although the yield varies with climate and other factors, it is cultivated from the southernmost regions of America almost to the Arctic and at elevations from sea level to over 10 000 feet. Triticum Durum, longer and narrower in shape than Triticum Vulgare, is mainly ground into semolina (purified middlings) instead of flour. Durum semolina is generally the best type for the production of pasta foods. Triticum Compactum is more suitable for confectionery and biscuits than for other purposes. In the Wheat industry of the United States, grain that, before the removal of dockage, consists of 50 percent or more common Wheat (Triticum Aestivum L.), club Wheat (Triticum Compactum Host.), and Durum Wheat (Triticum Durum Desf.) and not more than 10 percent of other grains for which standards have been established under the United States Grain Standards Act and that, after the removal of the dockage, contains 50 percent or more of whole kernels of one or more of these Wheats. The Kansas City Board of Trade (KCBT), established near one of the world's most fertile growing regions, is the largest free market for hard red winter Wheat. Prices negotiated in the KCBT Wheat futures trading pit are the benchmark for Wheat prices around the world. The role of the KCBT has evolved since the exchange was founded more than 120 years ago as a central market for Wheat grown in the Great Plains. The KCBT has become an international market force, influencing Wheat prices in Australia and Argentina as well as Kansas and Oklahoma. The KCBT also became a financial market leader with the introduction of its Value Line stock index futures contract in 1982, and extended its leadership to energy in 1995 with the introduction of western natural gas futures and options. But the exchange has not lost sight of its original purpose:- to provide price protection for Wheat producers, handlers and processors. Traders in the KCBT Wheat pit typically represent interests that handle and process Wheat – producers, exporters, millers and bakers – and whose inventories are subject to price change. They use futures contracts to minimize the risk of price change, a procedure called Hedging. Speculators also are represented in the KCBT Wheat pit. They perform the crucial role in any futures market of assuming risk from hedgers. These investors neither own nor plan to own commodities, but hope to profit from price changes in the futures contracts they buy and sell. Wheat is a palatable grain and should be fed coarsely ground or crushed for best results. It should not be fed whole or ground finely. Finely ground Wheat is powdery and unpalatable. Wheat should not make up more than 50 percent of the grain mix (a maximum of 33 percent is common) nor be fed at a rate greater than 12 pounds (5.5 kg) per cow per day. Unseasonably rainy weather occasionally will cause Wheat to sprout after it has been cut and is lying in the swath or even while still standing. Sprouted Wheat is an acceptable feed, although it is somewhat damaged Wheat. Rolled sprouted Wheat should be prepared every two days to avoid spoilage. The primary use of Wheat is to produce food for humans. Grain that is not good enough for human food is used for animal feed. Many different food products are made from the different classes of Wheat. Durum Wheat is used to make pastas. Hard red Wheat is used to make loaf bread and other products. The soft red winter Wheat grown in Ohio is used to make cookies, cakes, donuts, and other fine pastries. Often, flour from different classes of Wheat is blended to make special flours for unique food products. There are several classes of Wheat:- (i) Durum Wheat, the hardest of all US Wheats, is seeded in the spring and contains a high amount of protein (1 216%), which is good for pasta products macaroni, spaghetti, and other noodles. Durum Wheat is grown mainly in North Dakota and has subclasses such as Hard Amber Durum, Amber Durum, and Durum Wheats; (ii) Hard Red Spring Wheat contains the highest protein content (1 316.5%) making it an excellent bread wheat with superior milling and baking characteristics. Hard red spring Wheat is grown mostly in Montana, the Dakotas, and Minnesota. This Wheat is seeded in the spring and may have either a hard or a soft endosperm. Subclasses are Dark Northern Spring, Northern Spring, and Red Spring Wheats; (iii) Hard Red Winter Wheat is the class of Wheat used mostly for bread and all-purpose flour. This Wheat is fall-seeded, has medium to high protein content (10–13.5%), and can have either hard or soft endosperm. Hard red winter Wheat accounts for more than 40% of the US Wheat crop and half of US Wheat exports. This Wheat is produced in the Great Plains, between the Mississippi River and the Rocky Mountains, and from Texas to the Dakotas and Montana. It has a wide range of protein and good milling and baking qualities. The flour is used to produce bread, rolls, some sweet goods, and all-purpose flour; (iv) Hard White Wheat is the newest class of Wheat to be grown in the United States. Hard white Wheat is closely related to red Wheats except for the color genes and has a milder, sweeter flavor, equal fiber, and similar milling and baking qualities. Hard white Wheat is used in yeast breads, hard rolls, bulgur, tortillas, and oriental noodles. This Wheat is used in domestic markets and is exported in limited amounts. There are no subclasses; (v) Soft Red Winter Wheat is seeded in the fall, has a low to medium protein content with soft endosperm, and is used to make cakes, pastries, flat breads, and crackers. It is grown east of the Mississippi and has no subclasses. Ohio is the leading producer of soft red winter Wheat followed by Arkansas, Illinois, and Missouri. Ohio Wheat is known for making higher-quality flour than that coming from any other soft red winter wheat-producing state; and (vi) Soft White Wheat is used much the same way as soft red wheat (for bakery products other than bread) and is grown mostly in the Pacific Northwest and to a lesser extent in California, Wisconsin, Michigan, and New York. Soft white Wheat has low protein and high yields. Subclasses are Soft White, White Club, and Western White Wheats. See also Red Wheat. Wheat is a a whole grain cultivated for human consumption due to its high protein content. It is used for flour to be used in baking goods, pastas, snacks, etc. Lower quality grains are used as animal feed. It is also used to make alcoholic beverages and biofuel through a process of fermentation. Wheat straw can be used as a construction material for roofing thatch. Major Wheat producers include the EU, China, India, Russia, the United States, France and Canada, among others. Different classes of Wheat include:- Durum, hard red spring, hard red winter, hard white, soft red winter and soft white. Soft red winter Wheat is traded at the CBOT® under ticker symbol W. Hard red winter Wheat is traded at the KCBT under ticker symbol KW. Wheat is a cereal grass of the Gramineae (Poaceae) Family and of the Genus Triticum and its edible grain, one of the oldest and most important

of the cereal crops. Wheat is treated in several articles in the Macropaedia. For treatment of its cultivation, see Farming and Agricultural Technology:- Crop-farming. For the processing of wheat grain, see Food Processing:- Cereals and other starch products. The Wheat plant has long, slender leaves, stems that are hollow in most varieties, and heads composed of varying numbers of flowers, ranging from 20 to 100. The flowers are grouped together in spikelets, each having two to six flowers. In most spikelets, two or three of the flowers become fertilized, producing grains. Of the thousands of varieties of Wheat known, the most important are Triticum Aestivum, used to make bread; Triticum Durum, used in making pasta (alimentary pastes) such as spaghetti and macaroni; and Triticum Compactum, or Club Wheat, a softer type, used for cake, crackers, cookies, pastries, and family flours. Though grown under a wide range of climates and soils, Wheat is best adapted to temperate regions with rainfall between 30 and 90 cm (12 and 36 inches). Winter and spring Wheat are the two major types of the crop, with the severity of the winter determining whether a winter or spring type is cultivated. Winter Wheat is always sown in the fall; spring wheat is generally sown in the spring but can be sown in the fall where winters are mild. Some Wheat is simply prepared by soaking and cooking the grain for use in porridge, broth, or pudding. Most food uses, however, require more processing. The grain is cleaned and then conditioned by the addition of water, so that the kernel breaks up properly. In milling, the grain is cracked and then passed through a series of rollers. As the smaller particles are sifted out, the coarser particles pass to other rollers for further reduction. About 72 percent of the milled grain is recovered as white flour. When a higher percentage is extracted, the flour is darker in color. Flour made from the whole kernel is called Graham Flour and becomes rancid with prolonged storage because of the germ-oil content retained. White flour, which does not contain the germ, preserves longer. The greatest portion of the wheat flour produced is used for breadmaking. Wheats grown in dry climates are generally hard types, having protein content of 11–15 percent and strong gluten (elastic protein). The hard type produces flour best suited for breadmaking. The Wheats of humid areas are softer, with protein content of about 8–10 percent and weak gluten. The softer type of Wheat produces flour suitable for cakes, crackers, cookies, and pastries and household flours. Durum Wheat semolina (from the endosperm) is used for making pastas, or alimentary pastes. Although most Wheat is grown for human food, and about 10 percent is retained for seed, small quantities are used by industry for production of starch, paste, malt, dextrose, gluten, alcohol, and other products. Inferior and surplus Wheats and various milling byproducts are used for livestock feeds. The composition of the Wheat grain, a major source of energy in the human diet, varies somewhat with differences in climate and soil. On an average, the kernel contains 12 percent water, 70 percent carbohydrates, 12 percent protein, 2 percent fat, 1.8 percent minerals, and 2.2 percent crude fibers. A pound of wheat contains about 1 500 calories (100 grams contains about 330 calories). Thiamine, riboflavin, niacin, and small amounts of vitamin A are present, but the milling processes remove the bran and germ, where these vitamins are found in the greatest abundance. More of the world’s farmland is devoted to wheat than to any other food crop; in the late XX century about 570 000 000 acres (230 000 000 hectares) were sown annually, with a total production of almost 600 000 000 metric tons. The world’s largest producer is China, with an estimated annual yield of almost 100 000 000 metric tons. Other leading producers are the United States, Russia, India, Ukraine, France, Canada, Kazakstan, and Turkey. Wheat refers to a family of related small grains that are descended from the natural crossing of three Middle East grasses (Triticum Monococcum, Aegilops Speltoids, and Triticum Tauscii) centuries ago. As a result, Wheat’s genome is triploid (i.e. it incorporates three complete sets of deoxyribonucleic acid (DNA)), and contains approximately 17 billion base pairs (bp). Wheat is historically an annual plant that can attain a height of four feet (1.2 meters), although variations (e.g., shorter) have been bred. / содержит 50% и более целиковой зерновки (целых ядер) . Под Пшеницей понимается род одно- и многолетних трав семейства злаков. Около 20 видов в Австралии, Америке, Африке, Евразии. Возделывают в основном мягкую Пшеницу и твёрдую Пшеницу (озимые и яровые формы). В культуре с 7–6 тысячелетия до Нашей Эры (Передняя Азия, Туркменистан, Южная Европа). В Северной Америке с XVII века. Из зерна делают муку, крупу, макароны, крахмал, комбикорма и другое. Зелёная масса, сено, солома, зерно, отруби – корм для скота. В 1978 мировая посевная площадь (наибольшая в Индии, Канаде, КНР, СССР, США) составляла 232 миллиона гектаров (га), средняя урожайность составляла 19 центнеров (ц) с 1 га. Под Пшеницей (Triticum) понимается род травянистых растений семейства Мятликовых, ведущая зерновая культура во многих странах. Около 30 дикорастущих и культурных видов; в бывшем СССР – 19 видов. Некоторые из них – Пшеница Араратская (Triticum Araraticum), Пшеница Урарту (Triticum Urartu), Пшеница Беотийская (Triticum Boeoticum), Пшеница Тимофеева (Triticum Timopheevii) – в Красной Книге СССР. В мировом земледелии наиболее распространены голозёрные виды:- Пшеница Мягкая, или Обыкновенная (Triticum Aestivum, Triticum Vulgare), и Пшеница Твёрдая (Triticum Durum); возделывают также Пшеницу Шарозёрную (Triticum Sphaerococcum), в Индии, Пакистане; Полбу-Эммер, или Двузернянку (Triticum Dicoccum), в Индии, СССР, Эфиопии; Пшеницу Плотноколосую, или Карликовую (Triticum Compactum), в Армении, Афганистане, Сирии; Пшеницу Персидскую, дику (Triticum Persicum), в СССР (Армения, Грузия, Дагестан) и Турции и другие. В зависимости от остистости колоса, его окраски и опушённости колосковых чешуёй, окраски остей и зерна виды Пшеницы подразделяют на разновидности. Распространённые разновидности Мягкой Пшеницы – Альбидум, Барбаросса, Грекум, Лютесценс, Мильтурум, Ферругинеум, Цезиум, Эритролеукон, Эритроспермум и другие; Твёрдой Пшеницы – Гордеиформе, Леукурум, Мелянопус. Пшеница – однолетнее растение. Путём гибридизации различных видов и форм создана многолетняя Пшеница. У Пшеницы различают Озимые и Яровые, Полуозимые формы и Двуручки (дают урожай при весеннем и осеннем посеве). За период вегетации для Озимой Пшеницы нужна сумма среднесуточных температур около 2 100 °С, Яровой Пшеницы – не менее 1 300 °С. Для успеха культуры Озимой Пшеницы большое значение имеют устойчивость к сильным морозам, выпреванию, вымоканию, ледяной корке. Пшеница довольно требовательна к влаге, особенно в период выхода в трубку – налива зерна. Засуха значительно снижает урожайность зерна. Яровая Пшеница более засухоустойчива. Вегетационный период Яровой Пшеницы 70–110 суток, Озимой Пшеницы – 45–50 суток осенью (развиваются вегетативные органы) и 75–100 суток весной и летом (формируются генеративные органы, растение даёт урожай). Пшеница – самоопылитель. Лучшие почвы – чернозёмы, на дерновоподзолистых хорошие урожаи получают при внесении удобрений; культура не выносит кислых почв. Пшеница – одна из основных продовольственных культур многих стран мира, важнейший предмет вывоза (или экспорта). Зерно её перерабатывают на муку, крупу и другие продукты, используют для приготовления комбикормов. Отруби и другие отходы помола – концентрированный корм. Солому используют на подстилку, для изготовления бумаги, картона, плетёных изделий, в качестве грубого корма для сельскохозяйственных животных; зелёную массу – для весенней подкормки скота. Родиной многих видов Пшеницы (в том числе многих разновидностей Мягкой и Твёрдой Пшеницы) является Закавказье. В Ираке, Иране, Сирии, Туркменистане, Турции выращивали с 7–6-го тысячелетия до Нашей Эры, в странах Западной Европы – 6–2-го тысячелетия до Нашей Эры, на Северном Кавказе – с 1-го тысячелетия до Нашей Эры, на территории Беларуси и стран Прибалтики – IV–V веков Нашей Эры. В Южную Америку Пшеница завезена в 1528, на территорию США – в 1602, в Канаде её стали возделывать с 1802, в Австралии – с 1788. Общий ареал Пшеницы охватывает все земледельческие районы мира. На Севере граница её возделывания доходит до 66° северной широты (в Швеции), в СССР опытные посевы культуры – до 76°44’ северной широты (Мурманская Область). На Юге она доходит до южных границ Австралии, Южной Америки, Африки. Пшеница – преимущественно степная культура. В Европе она занимает главным образом зоны степи и лесостепи, в Северной Америке – прерии, в Южной Америке (Аргентина) – пампу, в Австралии – степные и полупустынные пространства. Пшеницу

выращивают также в предгорных районах на высоте до 4 000 метров. В Европейских странах в основном выращивают Озимую Мягкую Пшеницу, в северных районах – Яровую, на Юге континента – также Твёрдую Пшеницу. В Азии наибольшие площади заняты Яровой Мягкой Пшеницей, здесь значительны и посевы Твёрдой Пшеницы. В Северной Америке возделывают Яровую Мягкую Пшеницу (Канада, США) и Озимую Мягкую Пшеницу (США), а также Твёрдую. В Южной Америке (Аргентина) и Австралии преобладает Яровая Мягкая Пшеница, в Африке – Яровая Мягкая и Твёрдая. Посевы других видов Пшеницы небольшие. В бывшем СССР Озимую Мягкую Пшеницу выращивали во всех земледельческих районах; наибольшие площади на Украине, Северном Кавказе, в Центральночернозёмных областях, на Юге Казахстана; Озимую Твёрдую Пшеницу возделывали главным образом в Азербайджане. Районы возделывания Яровой Мягкой Пшеницы:- Казахстан, лесостепные с степные районы Сибири, Урал, Поволжье, Центральночернозёмные области, Нечернозёмная зона; Яровой Твёрдой Пшеницы:- Поволжье, Урал, Казахстан и другие. В 1985 Озимой Пшеницей было занято 18 000 000 гектаров (га), Яровой – 32 300 000 га, средняя урожайность соответственно 21.6 и 12 центнеров с одного гектара (ц/га). Урожайность Озимой Пшеницы в передовых хозяйствах (например, в Краснодарском Крае, в Украине) достигала 50–70 ц/га, Яровой Пшеницы – 20–30 ц/га. В связи с освоением интенсивных технологий возделывания Пшеницы особое внимание уделяется выведению сортов интенсивного типа, отзывчивых на высокие дозы удобрений, не восприимчивых к болезням и вредителям, устойчивых к засухе, низким температурам и другим неблагоприятным факторам среды, неполегающих, дающих зерно высокого качества, пригодное для длительного хранения. Этим требованиям отвечают:- Озимые сорта Мягкой Пшеницы – Бригантина (потенциальная урожайность свыше 80 ц/га), Донская безостая, Обрий, Партизанка, Безостая 1, Надзея, Прометей; Озимые сорта Твёрдой Пшеницы – Коралл Одесский, Парус; Яровые сорта Мягкой Пшеницы – Жигулёвская, Иртышанка 10, Сибирка, Омская 17; Яровые сорта Твёрдой Пшеницы – Светлана, Безенчукская 139, Алмаз и другие. Озимую Пшеницу высевают по чёрным и занятым парам, многолетним травам, после Люпина, Гороха и других культур. Предшественники для Яровой Пшеницы – чистый пар, Кукуруза, Подсолнечник, Зернобобовые, Картофель, Озимые Зерновые и другие. Для основного удобрения Озимой Пшеницы используют навоз или компосты 20–60 тонн на один гектар (т/га) (особенно эффективны в Нечернозёмной зоне), минеральные удобрения (40–100 кг/га N, 40–80 кг/га P_2O_5 и до 60 кг/га K_2O). В рядки при посеве вносят до 40 кг/га P2O5, в ранневесеннюю подкормку – 30–60 кг/га N и 30 кг/га P_2O_5. Яровую Пшеницу удобряют преимущественно минеральными туками:- основное удобрение – 20–30 кг/га N, 30–45 кг/га P_2O_5 и 20–35 кг/га K_2O; в рядки при посеве вносят 10–15 кг/га P_2O_5. В поливных условиях и при выращивании сортов интенсивного типа дозы удобрений увеличивают. Сеют Пшеницу рядовым (междурядья 15 сантиметров (см)) и узкорядным (7–8 см) способами; норма посева семян 1.8–2.5 ц/га (4–7.5 миллиона семян), глубина посева 3–8 см. Убирают Пшеницу раздельным способом и прямым комбайнированием. Подготовку почвы проводят машинами общего назначения (борона, культиватор, плуг), сеют зерновыми сеялками, для уборки используют зерноуборочные комбайны и жатки. Интенсивные технологии возделывания Пшеницы (разработаны для различных зон бывшего СССР) включают:- (i) выращивание сортов интенсивного типа; (ii) размещение посевов по лучшим предшественникам; (iii) тщательную дифференцированную обработку почвы; (iv) обеспечение растений питательными веществами и влагой в соответствии с запланированной урожайностью; (v) первоклассные семена; (vi) интегрированную систему защиты растений от болезней, вредителей и сорняков; (vii) прогрессивные методы уборки урожая; и (viii) строгое соблюдение технологической дисциплины. Вредители Пшеницы – Зерновая Совка, Гессенская и Шведская Мухи, Зеленоглазка, Вредная Черепашка и другие; болезни Пшеницы – головни, ржавчины, мучнистая роса и другие. Мягкая Пшеница (Soft Wheat), наиболее распространённый вид Пшеницы. Свыше 250 разновидностей (Альбидум, Лютесценс, Мильтурум, Эритроспермум и другие) во всех земледельческих регионах мира. Из зерна мягкой Пшеницы изготавливается мука для выпечки хлеба, манная крупа и комбикорма. Сильные Пшеницы, сорта мягкой Пшеницы со стекловидным на изломе зерном и высоким содержанием прочной эластичной клейковины; дают высококачественную муку. Твёрдая Пшеница (Hard Wheat), распространённый вид Пшеницы, зерно с высоким содержанием белка и особым качеством клейковины. Более 120 разновидностей (Гордеиформе, Мелянопус и другие) во многих земледельческих регионах мира. Сырьё для макаронной промышленности. 2015-Сентябрь-08:- Россия вот уже пятнадцать лет планомерно усиливает свои позиции на мировом рынке Пшеницы, отвоевывая долю у лидера – США. За последние пять лет эта тенденция стала ещё более явной, а теперь серьёзно ускорилась. Российскую Пшеницу стали предпочитать даже некоторые традиционные покупатели Американского зерна. Яркий пример – Мексика, которая сократила привоз (или импорт) Пшеницы от своих Североамериканских соседей на 7.5% в прошлом году, а продажи с начала текущего рыночного года (начался с 01 Июня 2015) упали на 29%. Черноморский регион (где главный игрок – это Россия вкупе с Украиной) увеличил свою долю на Мексиканском рынке с нуля до 12% за два последних года. За 11 месяцев прошедшего сезона 2014/15 Мексика привезла (или импортировала) 406 000 тонн Российской Пшеницы. Это в полтора раза больше, чем в предыдущем сезоне. А до этого Пшеница из России в Мексику вообще не поставлялась. На втором месте по привозу (или импорту) Российской Пшеницы в регионе (Южная, Центральная и Северная Америка) Перу, которая купила в прошедшем сезоне 180 000 тонн Российской Пшеницы (правда, годом ранее приобрела в 1.8 раза больше). Замыкает тройку импортёров в этом регионе Никарагуа, купившая 81 000 тонн Российской Пшеницы. Привозит (или импортирует) её также Эквадор. Россия в последние годы стала особенно активна и в Африке. Нигерия, один из главных покупателей Пшеницы в США, за последние пять лет вдвое сократила свои закупки у Американской стороны. По данным Американского Министерства Сельского Хозяйства, 17% своей Пшеницы Нигерия закупает теперь у России и Украины, хотя ещё два года назад эта доля составляла не более 1%. Некогда Египет закупал у США до 90% своего привоза (или импорта) Пшеницы. В прошлом году эта цифра снизилась до 7%, тогда как доля России возросла до 25%. В Российском Зерновом Союзе уверены, что ежегодные конференции, которые они стали проводить в Египте с 2004, сыграли не последнюю роль в расширении географии поставок Российской Пшеницы. За 15 лет Россия среди основных стран-экспортёров переместилась с шестой позиции на третье-четвёртое места с небольшим отрывом от Франции, США и Канады. Доля США на глобальном рынке зерна сократилась до 16% с 30% в 2008. Россия же, наоборот, нарастила долю рынка Пшеницы до 13.6% в сезоне 2014/15, тогда как в первой половине 2000-х её доля не поднималась выше 9%. К 2020 планируется довести долю поставок Российской Пшеницы и Ячменя до 20% мирового рынка. Причины нового рекорда:- В сезоне 2014/15, который закончился в Июне, поставки Российской Пшеницы достигли очередного исторического рекорда в 22.3 миллиона тонн. Что помогает Российской Пшенице отвоёвывать позиции на мировом рынке, в том числе у США? В первую очередь это слабеющая национальная валюта и падение фрахтовых ставок. Только в прошлом году Рубль потерял 45% своей стоимости, что сделало вывоз (или экспорт) зерна из России более конкурентоспособным. ‘Сырьевые экспортёры действительно чувствуют себя крайне комфортно из-за девальвации Рубля. Они могут варьировать цены и давать дисконт на продукцию даже там, где ранее даже не стали бы обсуждать эту тему – и всё равно остаются в плюсе. Поэтому Российские зерновики сейчас активно ‘двигают’ на рынке других игроков’, – говорит Анна Бодрова, старший аналитик компании Альпари. Сейчас цена Российской Пшеницы является самой низкой за пять лет и составляет около 179 Долларов за тонну, отмечает она. Для сравнения, в 2014 средняя цена на FOB составляла 247 Долларов за тонну, в 2013 – не менее 310 Долларов за тонну. Российская Пшеница дешевле Американской примерно на 20 Долларов, поэтому именно сейчас наши фермеры занимают доминирующее положение на рынках, отмечает Мадина Абаева из QB Finance. Неудивительно, что небогатые Мексика, Нигерия и Египет

предпочитают Российское Американскому. ‘Российская Пшеница намного дешевле, – заявил агентству Блумбёг (Bloomberg) Гафай Усман, Временный Поверенный Посольства Нигерии в Москве. – Всё больше пшеницы будет привозиться (или импортироваться) из России. По большей части сельскохозяйственное население Нигерии не может позволить себе покупать продукты, изготовленные из Американской Пшеницы’. Россия отбирает покупателей и у других экспортёров. Как рассказывает Бодрова, в Августе с Российскими поставщиками пытались конкурировать Французские производители зерна, предлагая тонну Пшеницы за 174.5 Доллара. Однако для них логистическая цепочка оказалась слишком длинной и дорогой, поэтому Российское сырьё оставалось в приоритете у покупателей. Конечно, помимо девальвации Рубля, на руку сыграл хороший урожай зерна в сезоне 2014/15, который оказался примерно на 10–12% лучше, чем годом ранее, отмечает эксперт. О том, как хорошо себя чувствовали в сезоне 2014/15 (с Июня по Июнь) экспортёры зерна, говорит то, что на рынок вышли сотни новых игроков. Зерно вывозили более 560 компаний, тогда как сезоном ранее их было чуть более 400. Основной объём зерна (23 миллиона тонн из 31.8 миллиона тонн), как и раньше, поставили за рубеж экспортёры из первой двадцатки крупнейших, но появилось и много мелких игроков. Россия активно наращивает объёмы производства и вывоза (или экспорта) Пшеницы, тогда как США стали снижать её вывоз (или экспорт), потому что сосредоточились на удовлетворении растущих потребностей внутреннего рынка. Однако, с другой стороны, они активно наращивают производство и вывоз (или экспорт) других агрокультур, в частности Кукурузы. И здесь Россия им не конкурент. У России продовольственная Пшеница 4-го класса – это основной продукт на вывоз (или экспорт). Её доля в общем вывозе (или экспорте) занимает аж 70%. Впрочем, Россия тоже начала постепенно заниматься другими культурами. Так, поставки Ячменя в прошедшем сезоне выросли до исторически рекордных 5.4 миллиона тонн. В 2008 пошли первые поставки на вывоз (или экспорт) Российской Кукурузы, сейчас её объёмы выросли до 4 миллионов тонн. ‘В Советское время мы ввозили 30–40 миллионов тонн Кукурузы, сейчас мы её вывозим (или экспортируем). Около 1 миллиона тонн Кукурузы отправили в Южную Корею – уже неплохо. Всего поставляем пока немного – 4 миллиона тонн, но со временем будет больше, – уверен Вице Президент Российского Зернового Союза Александр Корбут. – Сельхозпроизводители адаптируются к конъюнктуре рынка, увеличивают производство высокодоходных культур, хотя это ни в коем случае не приводит к дефициту по другим культурам. Интересно стало производить, потому что можно заработать. Стимул один – доход’. Будет ли новый рекорд? Министерство Сельского Хозяйства США прогнозирует, что в этом сезоне (2015/16) Россия отгрузит рекордные 23 миллиона тонн зерна (против 22.3 миллионов сезоном ранее). Это будет лишь немного ниже ожидаемого вывоза (или экспорта) из США в 25.2 миллионов тонн. Сможет ли Россия в новом сезоне удержать свои позиции и показать новый рекорд по вывозу (или экспорту)? Несмотря на все выгоды, которые даёт девальвация Российским аграриям, ответ на этот вопрос не так однозначен. Вице Президент Российского Зернового Союза Александр Корбут говорит, что Россия могла бы вывозить (или экспортировать) и 23–27 миллиона тонн Пшеницы (то есть даже перегнать США), если будет изменена вывозная (или экспортная) пошлина, введённая Россией с 01 Июля 2015. Если этого сделано не будет, то вывоз (или экспорт) может опуститься до 17–18 миллионов тонн, прогнозируют в Российском Зерновом Союзе. Как говорит Корбут, Россия может вывозить (или экспортировать) 23–27 миллиона тонн зерна ‘абсолютно безболезненно, потому что валовый сбор в этом году у нас будет 61.5 миллион тонн, это перекрывает все наши потребности’. ‘При таком валовом сборе надо вывозить (или экспортировать) эти 23–27 млн тонн зерна, чтобы не упали закупочные цены и чтобы не были утрачены стимулы для сельхозпроизводителей’, – считает он. ‘Сместить какого-то – такую цель никто не ставит. Наша цель – обеспечить такой сбыт нашей Пшеницы, чтобы крестьянин получал доход и ему было выгодно производить. Сместится ли при этом доля США – неважно, важна доходность сельскохозяйственной деятельности’, – говорит он. Поэтому Российский Зерновой Союз инициирует обсуждения об изменении введённой пошлины. Речь идёт о введённой с 01 Июля формуле вывозной (или экспортной) пошлины на все виды Пшеницы:- 50% минус 5 500 Рублей за тонну, но не менее 50 Рублей. Пошлина фактически будет работать, когда курс Доллара будет за 60 Рублей, пояснил глава Минсельхоза Александр Ткачёв. То есть её цель – нивелировать выгоду вывоза (или экспорта) при падении Рубля. Чем ниже падает Рубль, тем выше цена зерна на вывоз (или экспорт) в Долларах. При цене до 11 000 Рублей за тонну пошлина равна минимальным 50 Рублям, в диапазоне от 11 000 до 13 000 носит фискальный характер, а регулирующее (с точки зрения объёмов вывоза (или экспорта)) воздействие, по оценке правительства, оказывает при цене свыше 13 000 Рублей. Понятно, что пошлина снижает выгоду сельхозпроизводителей при резком падении курса Рубля. Однако, с другой стороны, позволяет избежать рисков дефицита и роста цен на зерно (и, соответственно, хлеб) внутри страны. ‘Если бы не было этой формулы (вывозной (или экспортной) пошлины), то цена на зерно была бы больше 15 Рублей за килограмм, а это означает:- первое – у нас бы был неудержимый рост цены на хлеб, второе – кратно подорожали бы комбикорма’, – объяснил Министр на прошлой неделе. Однако производители зерна продолжают обращаться к властям страны с просьбой пересмотреть механизм пошлины, указывая, что на выходе получается так, что им выгоднее хранить зерно и не продавать его вообще никуда, в том числе на внутренний рынок. С 01 Июля по 09 Августа вывоз (или экспорт) Пшеницы из России действительно сократился в 2.2 раза. Однако Ткачёв на прошлой неделе заявил, что, пока ситуация на рынке нестабильная, пошлина будет работать. Ограничения на вывоз (или экспорт) иногда вводятся властями, и это действительно может слегка ослабить позиции страны на мировом рынке, но социальная стабильность внутри страны в таких ситуациях ставится на первое место. К примеру, в 2010 из-за эмбарго на вывоз (или экспорт) зерна Россия вывалилась из четвёрки лидеров на мировом рынке. Но тогда эмбарго было необходимо из-за низкого урожая в силу засушливого сезона. Без него зерно могло утечь на вывоз (или экспорт), спровоцировав дефицит зерна внутри России и рост цен на хлеб. Сейчас риски те же, только причина в девальвации, которая толкает фермеров продавать зерно за рубеж. Понятно, что ограничения на вывоз (или экспорт) невыгодны сельхозпроизводителям, особенно учитывая, что девальвация Рубля серьёзно увеличивает себестоимость производства. В Марте 2015 Министр Сельского Хозяйства Кубани Сергей Гаркуша указывал, что рост цен на три составляющие – удобрения, средства защиты и ГСМ – поднял себестоимость производства Кубанского зерна почти в полтора раза. По экспертным оценкам, в структуре себестоимости производства зерна 30–50 процентов приходится на привозную (или импортную) или номинированную в валюте составляющую. С одной стороны, регулирование вывоза (или экспорта) зерна необходимо сейчас, но, с другой стороны, пошлина не должна приводить к резкому обвалу вывоза (или экспорта) и доходов сельхозпроизводителей. Стоит сказать, что после провального для вывоза (или экспорта) 2010 Россия восстановила свои позиции на мировом рынке.

WHEAT AND FEED GRAIN EXPORT CERTIFICATE PROGRAMS = ПРОГРАММЫ ПО ВЫВОЗНЫМ СВИДЕТЕЛЬСТВАМ НА ПШЕНИЦУ И КОРМОВОЕ ЗЕРНО (или ПРОГРАММЫ ПО ЭКСПОРТНЫМ СЕРТИФИКАТАМ НА ПШЕНИЦУ И КОРМОВОЕ ЗЕРНО) – Wheat And Feed Grain Export Certificate Programs are two discretionary programs for the 1986–90 crop years designed to encourage exports of wheat and feed grains from private stocks. Under the Cash Export Certificate Program and the Export Marketing Certificate Program, the USDA could have issued wheat and feed grain export certificates to all eligible producers. The programs were not implemented.

WHEAT BELT = ПШЕНИЧНЫЙ ПОЯС – (1) Wheat Belt is the part of the North American Great Plains where Wheat is the dominant crop. The belt extends along a North-South axis for more than 1 500 miles (2 400 km) from central Alberta, Canada, to central Texas,

the United States. It is subdivided into winter Wheat and spring Wheat areas. The southern area, where hard red winter Wheat is grown, includes parts of the states of Kansas, Oklahoma, Texas, Nebraska, and Colorado. A hard red spring Wheat is grown in parts of Montana, North Dakota, South Dakota, Minnesota and in the Canadian provinces of Alberta, Saskatchewan, and Manitoba, where the climate is more severe.

(2) Wheat Belt is the principal crop-growing region of Western Australia, occupying about 60 000 square miles (160 000 square km) in the Southwestern section of the state. Served by the Perth-Albany Railway, the crescent-shaped belt is delineated on the West by a line drawn from Geraldton South through Moora, Northam, and Katanning to the Western end of the Great Australian Bight. The Eastern boundary of the belt bulges as Far East as Southern Cross. The Wheat Belt receives as much as 20 inches (500 mm) of rainfall annually in the West, declining to 10 inches (250 mm) in the East. In addition to Wheat, the area yields Oats, Barley, and wool. The Wheat Belt developed after the decline of gold mining in 1905 and was aided by the introduction of superphosphate fertilizers, new breeds of livestock, machinery, government loans, surveys, railway feeder-line construction, immigration, and 'soldier settlement schemes' for military veterans after both World Wars.

WHEAT CLASSES = КЛАССЫ ПШЕНИЦЫ – (1) In the United States, there are eight classes for Wheat:- Durum Wheat, Hard Red Spring Wheat, Hard Red Winter Wheat, Soft Red Winter Wheat, Hard White Wheat, Soft White Wheat, Unclassed Wheat, and Mixed Wheat. / Выращиваемая в Соединённых Штатах Америки Пшеница подразделяется на восемь классов (в России они идентифицируются как типы):- Пшеница Дурум (Durum Wheat), Твёрдая Яровая Краснозёрная Пшеница (Hard Red Spring Wheat), Твёрдая Озимая Краснозёрная Пшеница (Hard Red Winter Wheat), Мягкая Озимая Краснозёрная Пшеница (Soft Red Winter Wheat), Твёрдая Белозёрная Пшеница (Hard White Wheat), Мягкая Белозёрная Пшеница (Soft White Wheat), Неклассифицируемая или Не Подпадающая Под Классификацию Пшеница (Unclassed Wheat), и Смесь Пшеницы (Mixed Wheat). Основой существующей в США товарной классификации зерна, установленной Стандартами США на Зерно, является система сортов (grades) или классов, в которой показатели качества для каждого вида зерна регламентированы. Американскими стандартами предусмотрено также унифицированное обозначение класса зерна, применяемое для всех видов зерна, на которые действуют стандарты. Обозначение класса производится в следующем порядке:- буквы US (США), номер класса, подтип, тип или вид зерна, содержание докеджа (Американский стандарт определяет Докедж как весь материал, отличный от Пшеницы, легко и быстро отделяемый от неё, для удаления которого не требуется сложного оборудования, используемого в зерноочистительных отделениях мельниц. К докеджу относят также недоразвитые, сморщенные зерновки и мелкие частицы зерна Пшеницы, удаляемые с непшеничными примесями и не остающиеся при повторном просеивании или очистке. Содержание докеджа определяется для всех типов и подтипов Пшеницы в соответствии с методическими инструкциями Федеральной Зерновой Инспекции при помощи устройства именуемого докедж тестером, состоящего из системы регулирования скорости подачи зерна, аспиратора и набора сит. Устройство обеспечивает отделение примесей, которые по весу легче и по размеру больше или меньше, чем пшеничные зерна. Содержание докеджа в Пшенице указывается с округлением до десятой доли процента, например, 0.86% округляется до 0.9%; 1.34% округляется до 1.3%). Например, US #2 HRW, dockage 0.7% (твёрдозёрная краснозёрная озимая Пшеница, Американский класс № 2, докедж 0.7%). Допускается следующее обозначение, например, US #2 or better HRW, что обозначает, что требуемая Пшеница может иметь характеристики класса № 2 или класса № 1. В случае невозможности отнести зерно к одному из пяти классов в связи с наличием особых признаков или состояния, указываются специальные классы или класс по образцу. В Российской Федерации Пшеницу делят на пять типов. В основу деления на типы положены следующие признаки:- цвет (белозёрная, краснозёрная), ботанический вид (мягкая, твёрдая) и биологическая форма (яровая, озимая); I, II, III и IV типы делят на подтипы. В основу деления зерна Пшеницы на подтипы положены оттенок цвета (тёмно-красная, светло-красная и так далее) и стекловидность. Все возделываемые на земном шаре сорта Пшеницы в основном относятся к двум ботаническим видам:- Пшеница Мягкая и Пшеница Твёрдая. Типовые особенности по существу, являются сортовыми признаками, что наглядно видно при использовании в названных признаках определений Твёрдозёрная и Мягкозёрная. Эти два вида Пшеницы различаются как по химическому составу и биохимическим свойствам зерна, так и по технологическим достоинствам. Для хлебопечения используют муку из зерна мягкой стекловидной Пшеницы в основном I, III и IV типов или из мягкой Пшеницы с примесью не более 20% твёрдой Пшеницы II типа. Типовой состав Пшеницы:- хлебопекарную пшеничную муку вырабатывают с достаточным (около 14%) содержанием белка и клейковиной хорошего качества. Твёрдая Пшеница является основным сырьём для изготовления высококачественных макаронных изделий. Цвет зерна в основном янтарно-жёлтый. Консистенция зерна, как правило, стекловидная. Общая стекловидность не менее 70%. Различия в строении зерна мягкой и твёрдой Пшеницы легко усматриваются. Продовольственное зерно, в свою очередь, дифференцируется на Классы, качество которых обеспечивает возможность выработки муки, крупы высокого качества при хорошем выходе. Первые классы используются как улучшители, а низшие классы – в подсортировку. В основу товарной классификации Пшеницы (ГОСТ 9353-90 Пшеница. Требования При Заготовках И Поставках.) положены показатели, характеризующие мукомольные (натура, стекловидность) и хлебопекарные свойства (сорт, количество и качество клейковины, содержание проросших и фузариозных зёрен, степень обесцвеченности), что обусловливает целевое назначение класса. Например, высший, 1-й и 2-й классы (Сильная Пшеница) предназначены для использования в качестве улучшителя Слабой Пшеницы. К ним относятся лишь партии сортов, включённых в список сильных и по всем показателям отвечающих требованиям высшего, 1-го и 2-го классов. Целевое назначение Пшеницы этих классов – служить улучшителями для партий зерна 3-го класса (с пониженным содержанием клейковины 23–24%), а также 4-го класса. Пшеница 3-го класса (с количеством клейковины 23% и выше) не ниже II группы качества пригодна для выработки стандартной сортовой хлебопекарной муки. Пшеницу 4-го класса без подсортировки к ней значительного количества высококачественного зерна сильной Пшеницы для получения стандартной хлебопекарной муки использовать затруднительно. В связи с острым дефицитом высококлейковинной пшеницы в 1995 4-й класс мягкой Пшеницы в соответствии с введенными временными техническими условиями дифференцирован на 2 группы:- с содержанием клейковины 21–23% и 18–21%. Классификация твёрдой Пшеницы по качеству предусматривает деление её на 5 классов. В основу этой классификации положены также технологические признаки, характеризующие зерно как сырьё для получения муки, пригодной для выработки макаронных изделий (количество и качество клейковины, содержание зёрен других типов, проросших зёрен, состояние зерна, его цвет и запах). При недостатке твёрдой Пшеницы макаронную муку вынуждены вырабатывать из мягкой, тогда подбираются партии Пшеницы с высокой стекловидностью. Мягкая и твёрдая Пшеница всех классов, кроме 5-го, предназначена для использования на продовольственные цели, а Пшеница 5-го класса – на непродовольственные цели. Каждому классу соответствует определённый подтип типового состава, состояние зерна, количество и качество (группа) клейковины, стекловидность и содержание трудноотделимой примеси. Класс Пшеницы определяют по наихудшему значению одного из показателей качества зерна, указанных в таблицах ГОСТа.

WHEAT CROP YEAR = ГОД УРОЖАЯ ПШЕНИЦЫ – Wheat Crop Year refers to the crop marketing year beginning 01 April for Japan, 01 June for the United States, 01 July for the European Union and New Zealand, 01 August for Canada and 01 October for Australia.

WHEATEN = XX (или ПШЕНИЧНОЕ) – Wheaten is a pale yellowish to ruddy fawn color characteristic of the coat of some dogs.

WHEAT GERM = ПШЕНИЧНЫЙ ЗАРОДЫШ (или ЗАРОДЫШ ПШЕНИЦЫ) – Wheat Germ is the seed embryo of Wheat. Oil can be extracted from whole or rolled Wheat germ by use of solvents. Flaked or ground Wheat germ is used in baking goods, dietetic preparations, feed supplements, and pharmaceutical preparations.

WHEATGRASS = ПЫРЕЙ (или ЖИТНЯК, или ПШЕНИЧНАЯ ТРАВА) – Wheatgrass:- (Genus Agropyron), any of a number of species of wheatlike grasses in the Family Poaceae, found throughout the North Temperate Zone. The plants are perennials, 30 to 100 cm (about 12 to 40 inches) tall; many have creeping rhizomes (underground stems). The most important forage species are Bluebunch Wheatgrass (Agropyron Spicatum) and Western Wheatgrass (Agropyron Smithii). Crested Wheatgrass (Agropyron Cristatum), Desert Wheatgrass (Agropyron Desertorum), and Slender Wheatgrass (Agropyron Trachycaulum) are good forage plants and are often used as soil binders in the Western United States. / Пырей – Род Многолетних Трав Семейства Злаков. Около 150 Видов, в Северном Полушарии; в бывшем Союзе Советских Социалистических Республик (СССР) насчитывалось около 50 Видов. Многие Пыреи – кормовые Растения; Пырей Ползучий – кормовое растение, в посевах – злостный Сорняк. Несколько Видов скрещено с Пшеницей (Пшенично-Пырейные гибриды). Пырей (Agropyron), Род Растений Семейства Злаков. Многолетние Травянистые Растения часто с ползучим корневищем. Соцветие – двурядный колос. Колоски дву- и многоцветковые, сжатые с боков, расположены по одному на выступах оси и обращены к ней широкой стороной. Колосковые чешуи, заострённые сверху или переходящие в ость. Известно около 150 видов (включая Регнерию (или Рэгнерию (Roegneria)), которую иногда относят к Роду Пырей, иногда выделяют в самостоятельный Род). В бывшем СССР 51 вид Пырея (без Регнерии). Встречаются почти всюду:- на полях, лугах, в садах, огородах, степях, лесах, оврагах и так далее. Род Пырей подразделяется на 2 Подрода:- Пырей Настоящий (Elytrigia; в бывшем СССР 38 Видов) и Житняк. Многие виды Пырея – ценные кормовые растения, некоторые – злостные Сорняки. Несколько Видов Пырея (Agropyron Glaucum, Agropyron Clongatum и другие) успешно использованы для скрещивания с Пшеницей (смотрите Пшенично-Пырейные Гибриды). Наиболее распространён Пырей Ползучий (Agropyron Repens) – длиннокорневищевый Злак, произрастающий в различных экологических условиях. Предпочитает рыхлые, богатые азотом почвы. Распространён на залежах, в поймах рек, входит в состав травостоев лугов, в горных районах поднимается до субальпийской зоны. Зимостоек и засухоустойчив. Кормовое растение; поедается сельскохозяйственными животными на пастбищах (до цветения) и в сене (до цветения и в фазе цветения). В 100 килограммах (кг) сена 51.7 кормовой единицы и 6.7 кг переваримого протеина. Урожай сена до 80 центнеров с одного гектара (ц/га). В посевах Пырей Ползучий – трудноискоренимый Сорняк. Засоряет полевые, огородные, плодовые и другие культуры, в большом количестве встречается вдоль дорог, изгородей, канав и тому подобного. Глубина залегания корневищ на рыхлых почвах 20 сантиметров (см) и более, на уплотнённых – 10–15 см. Корневища и молодые побеги хорошо переносят суровые зимы. Разрезанные на части при обработке почвы корневища способны отрастать и давать новые растения. Распространяется Пырей и с семенным материалом других трав, от которых его семена трудноотделимы (Костёр Безостый, Житняк), а также при перевозке сена, убранного в период созревания семян Пырея. Меры Борьбы:- система обработки почвы, направленная на истощение корневищ с последующим подавлением сорняка посевами сельскохозяйственных культур; применение гербицидов. Из других Видов Подрода Настоящих Пыреев в бывшем СССР наибольшее кормовое значение имели Пырей Средний (Agropyron Intermedium) и Пырей Волосоносный (Agropyron Trichophorum). Из Рода Регнерия кормовое значение имеет Пырей Бескорневищевый, или Пырей Нежный (Agropyron Tenerum-Raegneria Trachycaulon), введённый в СССР в культуру как кормовое растение (завезён из Северной Америки); в диком виде не встречается.

WHEAT HEAD BLIGHT = XX (или ФУЗАРИОЗ ПШЕНИЦЫ, или ГИББЕРЕЛЛЁЗ ПШЕНИЦЫ) – Wheat Head Blight:- xxxxx. / Фузариоз Пшеницы:- возбудитель – Fusarium Roseum. Гиббереллёз Пшеницы:- Возбудитель – Gibberella Reae.

WHEAT MIDDLINGS = ПШЕНИЧНЫЕ ОТРУБИ – Wheat Middlings (also known as Wheat Midds) are a by-product of Wheat milling. During milling, 70 to 75 percent of the Wheat grain becomes flour, and the remaining 25 to 30 percent results in by-products. Wheat middlings consist of fine particles of wheat bran, wheat shorts, wheat germ, wheat flour, and some of the by-product from the tail of the mill. Wheat middlings cannot contain more than 9.5 percent crude fiber and must have minimums of 14 percent protein and 3 percent fat. As is common with by-products, the nutritive value of Wheat middlings varies considerably. The nutrient content varies with the variety of Wheat milled and the type of milling process used. Typically, nutrient variation of Wheat middlings from a single source is low. When changing from one supplier to another, however, it is best to analyze the product for protein and fiber content. Surprisingly, little published information is available regarding the feeding of Wheat middlings to poultry. Early research suggested that Wheat middlings can serve as an alternative to corn in layer diets when included to at least 43 percent. The current interest in Wheat middlings is in their use as a nonfeed removal method for molting laying hens. Wheat middlings are a bulky, low-nutrient-density feedstuff. Feeding more than 89 percent Wheat middlings has been shown to put a flock of laying hens out of egg production. Research also has shown, however, that the level of hunger in hens given Wheat middlings to induce a molt is the same as in hens deprived of feed. There has been interest in using Wheat middlings to control odors in a poultry house as well. Including about 7 percent Wheat middlings in layer diets has been shown to reduce ammonia emissions without a loss in egg production. Wheat

Middlings are the fine particles of wheat bran, shorts, germ, and flour recovered from milling Wheat grain. Wheat Middlings are the left over crap after the Wheat is processed to be bread or cereal or whatever else it is going to be. Distillers grains are the left over stuff in the bottom of the barrel after they make whiskey or whatever booze they make, then they dry it and use it in feed. / Пшеничные Отруби являются побочным продуктом мукомольной промышленности, однако диетологи во всём мире признают их полезные свойства. Отруби Пшеницы – это плодовые оболочки зёрен, которые удаляются производителями при переработке зерновых культур, что делает рафинированные (очищенные) продукты внешне более привлекательными и вкусными, лишая их ценных питательных качеств. В первую очередь зерно лишается большей части клетчатки (пищевых волокон), а также минеральных веществ и витаминов. Конечно, испечённый из очищенного зерна хлеб более сдобный, пышный, мягкий и красивый, но для здоровья человека он практически бесполезен. Таким образом, современная выпечка, богатая крахмалом и лишённая отрубей, содержит минимальное количество полезных веществ и максимальное количество калорий. В результате ежедневного потребления рафинированных (очищенных) продуктов растёт заболеваемость сахарным диабетом, атеросклерозом, ишемической болезнью сердца, желчекаменной болезнью, дисбактериозом, развивается ожирение, рак толстой и прямой кишки. Исходя из вышесказанного цельнозерновые продукты, к которым относятся также пшеничные отруби должны стать незаменимой составляющей рациона каждого человека. В ходе изготовления пшеничной муки высшего сорта продуктами отхода – отрубями считаются зерновой зародыш, алейроновый слой эндосперма и цветочная оболочка зерна. Именно в отрубях содержится больше 90% всех биологически ценных веществ Пшеницы. Производители удаляют зародыш Пшеницы для того, чтобы мука могла храниться долгое время и не прогоркать, в то же время алейроновый слой эндосперма сделает муку тёмной, придавая ей бурый оттенок. Пшеничные отруби считаются превосходным источником клетчатки, а также витаминов А, Е, группы В и ценных микро- и макроэлементов. Клетчатка благотворно влияет на деятельность всей системы пищеварения, а особенно на работу кишечника. Витамины группы В активно участвуют в энергетическом, углеводном, жировом, белковом и водно-солевом обмене в организме, благоприятно влияют на кроветворение, так как эти витамины участвуют в синтезе белка гемоглобина, который входит в состав эритроцитов. Витамины группы В участвуют в регуляции деятельности пищеварительной, мышечной, сердечно-сосудистой, нервной системы и гормонального баланса. Содержанием витаминов в отрубях обусловлено и то, что они содействуют быстрой регенерации тканей, улучшая состояние и внешний вид кожи, ногтей и волос. Употребляя в пищу отруби, человек укрепляет иммунную защиту организма и зрение. Помимо витаминов и клетчатки в отрубях содержатся и такие ценные элементы как сера, марганец, фосфор, медь, цинк и йод, необходимые организму. Лечебные свойства пшеничных отрубей известны уже давно. Ещё в древности такие целители как Авиценна и Гиппократ назначали отруби, хлеб, изготовленный из муки грубого помола и цельнозерновые каши, тем, кто страдал от проблем с кишечником и системой пищеварения. Сегодня в народной медицине отруби применяют в качестве профилактики онкологических заболеваний. Благодаря высокому содержанию клетчатки, попадая в организм, отруби удерживают большое количество воды, и далее двигаясь в кишечнике и толстой кишке, оказывают очищающее действие. Поэтому отруби особенно полезны при запорах. Клетчатка как губка буквально впитывает и выводит из организма токсины и шлаки, благодаря чему вредные вещества не соприкасаются со слизистой оболочкой кишечника, сводя к минимуму риск развития геморроя и рака толстой кишки. Содержащаяся в отрубях клетчатка – это также отличная питательная среда для полезной микрофлоры кишечника, что делает этот продукт ценным для профилактики и лечения дисбактериоза. Отмечено благотворное влияние клетчатки и на процесс желчевыделения, а также выведения из организма ‘плохого’ холестерина. Отруби показаны при желчекаменной болезни, дискинезии желчных путей, других болезнях желчевыводящих путей, желчного пузыря и печени. Употребление в пищу отрубей нормализует деятельность сердечно-сосудистой системы, благодаря способности снижать уровень ‘плохого’ холестерина, препятствуя образованию атеросклеротических бляшек в сосудах. Для работы сердца важен и витамин В1, а также магний и калий, содержащиеся в пшеничных отрубях. Регулярное употребление в пищу пшеничных отрубей поможет сохранить здоровым сердце и сосуды, а также избежать таких заболеваний, как аритмия, тахикардия, атеросклероз, нарушения коронарного кровообращения, инсульт и инфаркт миокарда. Содержащаяся в пшеничных отрубях клетчатка замедляет усвоение углеводов, благодаря чему замедляется повышение уровня сахара в крови, что полезно для больных сахарным диабетом и способствует уменьшению количества применяемых инсулинсодержащих препаратов. Пшеничные отруби для женской красоты и стройности:- Попадая в желудок человека, отруби разбухают, значительно увеличиваясь в объёме. Таким образом, в организме возникает ощущение сытости, что предохраняет от переедания и как следствие от набора лишних килограммов. Содержащиеся в пшеничных отрубях вещества способствуют нормализации в организме женщины баланса эстрогенов, что важно для профилактики и лечения таких женских заболеваний, как эндометриоз, миома матки и рак молочной железы. Для мужчин важен входящий в состав отрубей витамин Е, помогающий восстановить и сохранить потенцию. Употребление пшеничных отрубей:- Пшеничные отруби могут входить в состав самых разных блюд. Их добавляют в салаты, супы, фарш, тесто, в каши, вторые блюда, а также в напитки (коктейли, кисели, компоты). В пшеничных отрубях можно панировать котлеты, битки, мясо или овощи. Если Вы решили включить пшеничные отруби в какое-либо блюдо, то предварительно залейте их горячей водой на полчаса, слейте жидкость и используйте в приготовлении пищи. Если же Вы употребляете их в сухом виде, то запивайте пшеничные отруби большим количеством жидкости. Начинайте употреблять в пищу цельнозерновые продукты с небольших порций – от 1 до 3 чайных ложек в день. Если Вы стараетесь не есть вечером, а чувство голода постоянно преследует Вас, то залейте пару ложек пшеничных отрубей стаканом кефира или йогурта и съешьте. Такой ужин будет очень полезен и некалориен. Из пшеничных отрубей можно приготовить разнообразные лечебные и общеукрепляющие отвары и настои. Противопоказания к применению пшеничных отрубей:- Пшеничные отруби противопоказаны при язве желудка и двенадцатиперстной кишки, спаечной болезни брюшной полости и язвенном колите. Их следует с осторожностью употреблять при обострениях холецистита, панкреатита, хронического гастрита, гастродуоденита. Важно знать о том, что слишком большое количество пшеничных отрубей в рационе может привести к дисбалансу кальция в организме, а также нарушить соотношение других минеральных веществ. Максимальной суточной дозой потребляемых пшеничных отрубей считается 3–4 столовые ложки этого продукта.

WHEAT PIT = ЯМА ПО ПШЕНИЦЕ – Wheat Pit is a market or exchange where Wheat stocks are bought and sold. / рынок Пшеницы.

WHEAT SCAB = ПАРША ПШЕНИЦЫ (или КЛАДОСПОРИОЗ ПШЕНИЦЫ, или ПЬЯНЫЙ ХЛЕБ) – Wheat Scab is a destructive disease of Wheat caused by Fungi of the Genera Fusarium and Gibberella and characterized by bleached blighted heads and kernels with a scabby appearance from the tufted mycelia outgrowths. Compare Head Blight. Fusarium Head Blight, or Scab, is a fungal disease that attacks wheat around the time of heading and flowering. The disease can reduce grain yield and test weight as well as grain quality. Affected grain may also be contaminated with a toxin called Vomitoxin, or Deoxynivalenol (DON). DON can be harmful to some animals and humans and often reduces the market value of grain. Wheat scab and associated mycotoxins are generally most severe under wet weather conditions (frequent rain, high humidity), and especially when those conditions occur as the crop is heading or flowering. The scab fungus Fusarium Graminearum (also known as Gibberella Zeae) is very common throughout the cereal- and corn-growing regions of the United States. It is usually found in abundance on corn and small grain stubble left in the field after harvest.

The fungus colonizes corn stalks and ear residue in the summer and fall. Spores of the fungus are produced from the affected residues in the spring and summer after the soil has warmed and when wet conditions keep the soil surface and crop residues moist for long periods. Infection occurs on flowering wheat heads during warm, wet periods. Ideal conditions for infection are around 60 to 85 F with at least 90% relative humidity. Longer durations of high humidity are the most favorable, thus the disease is often a problem when frequent rains occur over several days at or near flowering time. In some years, favorable weather conditions may occur after flowering stage, which can result in less disease symptom development on wheat heads, but may occasionally be associated with elevated DON levels in grain. Symptoms:- the disease is most easily recognized on immature wheat heads where one or more spikelets (or the entire head) appear prematurely ripened or bleached. Where the rachis is infected, all portions of the head above that point may be blighted. The disease also can move down the head and infect the upper part of the stem as well. Fungal mycelium and pink or orange spore masses may be seen on or at the base of infected spikelets, along with small, dark purple to black-colored fruiting bodies called Perithecia. Infected spikelets generally are sterile or contain shriveled kernels. Fusarium-damaged kernels are often chalky pink in appearance and shriveled. These grains are often called 'Tombstones' because of their diseased appearance and extremely poor viability. Yield And Quality Impacts:- When disease pressure is high, susceptible wheat varieties may experience significant yield losses (up to 50% or greater) due to blighted or sterile florets and poor grain fill. Moderately resistant varieties often yield considerably more than susceptible ones in high-disease environments. Vomitoxin is also a problem, reaching 2 to10 ppm in grain taken from scabby fields. Scabby grain can present major problems in marketing, storage and utilization. Local elevators often have discount schedules for Fusarium-damaged kernels (FDK) or vomitoxin contamination based on ppm DON present in sampled grain. And since scab often reduces test weight, there may be discounts for that as well. Many grain buyers will severely discount or reject grain with DON levels above a threshold, often set at 1 to 3 ppm, depending on end use. It's wise to check with grain markets to determine if discounts or buying restrictions would warrant additional cleaning steps prior to delivery. Some scabby kernels may be cleaned out by increasing airflow rates while combining, or by processing grain through a clean-up step prior to marketing. If discounts are severe for test weight, DON and FDKs, the increased quality after cleaning may make up for a loss of some bushels and the cost of cleaning. Conversely, if discounts are slight, extra cleaning may not be necessary or worthwhile. Storage Concerns:- It is important to remember that if the scabby wheat is to be stored for future delivery or utilization, the grain must be kept dry (and cool if possible) to avoid increases in DON and damaged kernels. The scab fungus can continue to grow on high-moisture (14% or higher) grain between about 55 and 85 F and may produce more toxin contamination during storage. Wheat seed crops affected by scab may tend to have low germination rates immediately following harvest, but may improve as much as 10 to 20% with short-term storage (3 to 4 weeks). However, germination tends to decrease after a year or more in storage. Livestock Impacts:- Certain livestock may tolerate low levels of vomitoxin in feed while swine and other non-ruminants are very sensitive. There are no FDA 'action thresholds' at which DON-contaminated grain is illegal to feed, however there are 'advisory levels' recommended (Henry, 2006). According to those levels, beef cattle could receive grain at around 10 ppm DON if it makes up no more than 50% of their ration, or 5 ppm DON in finished feed. Research suggests that dairy cattle also can tolerate similar levels and that the toxin is not carried into milk. Swine can tolerate 5 ppm DON in not more than 20% of their ration (1 ppm in finished feed), but may refuse the feed or regurgitate it, reducing gain. Chickens tend to be more tolerant than beef cattle but FDA advises similar threshold levels. Signs of vomitoxin poisoning generally include vomiting, diarrhea, reduced feed intake, malaise and other gastric distress signs. Management Strategies:- (i) Cultural Practices:- Successful management of wheat scab requires an integrated approach to achieve acceptable levels of suppression. A combination of varietal resistance to scab, crop rotation, tillage and foliar fungicides applied at the proper time can provide good management of this difficult disease. Varieties with the highest level of available resistance to scab should be selected for scab-prone areas or when wheat is grown in rotation with corn. Although no highly resistant or immune varieties are available, the best performing varieties may reduce scab and vomitoxin by about 50% or more over the most susceptible varieties1. Pioneer provides scab resistance ratings on all its wheat varieties. Scores are assigned relative to other Pioneer varieties using a 1 to 9 scale (9 = excellent, 1 = poor). Pioneer's best varieties for scab resistance are rated a 7 or 8 on this scale. Wheat planted on corn stubble may develop more disease during epidemics than wheat on Soybean or other non-host residue. Tillage may also reduce locally developing inoculum by burying colonized residues; however, in the more open geography of the Great Plains, spores may travel for many miles and tillage may be an impractical management strategy for scab in those areas. (ii) Risk Assessment:- Since scab is highly weather-dependent, it's possible to estimate the risk of severe infection based on weather prior to and following flowering stage. The US Wheat and Barley Scab Initiative supports a website that provides site-specific risk assessments for most of the US Wheat-growing areas prone to scab development:- www.wheatscab.psu.edu. In general, risk is high when weather has been warm and wet for several days prior to and at heading/flowering. If wet weather is forecast to continue, the risk goes up as well. These risk assessments can aid growers in scheduling fungicide applications to at-risk crops. (iii) Chemical Management:- According to multiyear data reported by the University of Illinois, foliar fungicides such as Prosaro® (active ingredient prothioconazole) and Caramba® (active ingredient metconazole) have proven to be the most effective products available against scab when applied correctly (Bradley, 2011). Tebuconazole fungicides have also been widely used but were less effective against scab in the Illinois trials. The study demonstrated about a 60 to 70% reduction in disease and vomitoxin over untreated wheat when the most effective products were applied correctly at the peak of flowering. Recommended ground-based application directions include use of directed spray (angled nozzles) in 10 gallons per acre (gpa) carrier applied when most of the field is actively flowering (Eversgerd, 2012). Aerial applications should be made using no less than five gallons/acre carrier volume. Strobilurin-containing products such as Headline®, Quadris®, Quilt®, Stratego®, and TwinLine® are not recommended for scab management or for application to wheat heads if scab is a threat. In fact, vomitoxin (DON) levels may actually increase in grain following application of these products to Wheat heads (Bradley, 2011). The US Wheat and Barley Scab Initiative maintains a website with more information about wheat scab and variety testing programs:- www.scabsmart.org. / Пайэниэ (Pioneer). WHEATS OF OTHER CLASSES = ПШЕНИЦА ИНЫХ КЛАССОВ – Other Classes of Wheat are all classes of wheat including non-registered varieties, other than the predominant class in the sample. Contrasting classes are classes of a different colored Wheat; for example, Canada Western Amber Durum (CWAD) is a contrasting class in Canada Western Red Spring (CWRS). / К Иным Классам Пшеницы относятся классы Пшеницы, включающие незарегистрированные разновидности, отличающиеся от преобладающего в пробе класса. К контрастирующим классам (contrasting classes) относятся классы с различным окрасом зерновки Пшеницы; например, Канадская Западная Янтарнозёрная Дурум (КЗЯД; Canada Western Amber Durum (CWAD)) является контрастирующим классом по отношению к Канадской Западной Яровой Краснозёрной (КЗЯК; Canada Western Red Spring (CWRS)). В России классы идентифицируются как типы Пшеницы.

WHEAT TAKE–ALL DISEASE = БОЛЕЗНЬ, ОХВАТЫВАЮЩАЯ ВСЮ ПШЕНИЦУ – Wheat Take-All Disease is a fungal disease that attacks Wheat (Triticum Aestivum).

WHEEL = КОЛЕСО (или ПРЯЛКА, или МОТОВИЛО) – Wheel:- an image of a wheel from the Carr House Museum in Canada.

WHEELBASE = КОЛЁСНАЯ БАЗА – Wheelbase is the distance from the center line of the front axle to the center line of the rear axle.

WHEEL BEARINGS = КОЛЁСНЫЕ ПОДШИПНИКИ (или КОЛЁСНЫЕ ВТУЛКИ, или КОЛЁСНЫЕ ОПОРЫ) – Wheel Bearings:- the leather, brass, or plastic part of the wheel that holds the axle. / Колёсные Подшипники обеспечивают вращение колеса (приводного или неприводного) относительно ходовой части автомобиля, выдерживая при этом воздействующие на колесо нагрузки. Первое Поколение Колёсных Подшипников:- Изначально использовались однорядные подшипники, устанавливающиеся парами. По сравнению с этими стандартными подшипниками, колёсные подшипники первого поколения были двухрядными, причём они не требовали предварительной регулировки. Преимущества:- Компактные размеры, повышенная надёжность, простота установки. Это одни из наиболее распространённых колёсных подшипников. Второе Поколение Колёсных Подшипников:- В целях упрощения конструкции, а также снижения веса, что ожидалось производителями автомобилей, некоторые компании стали предлагать колёсные подшипники нового типа. Внутренние и внешние кольца этих подшипников имеют особую конструкцию, со ступицей в сборе, фланцами и крепёжными отверстиями, что упрощает их установку. Преимущества:- снижение количества деталей, повышенная жёсткость, повышенная точность, большее соответствие рабочим условиям. Третье Поколение Колёсных Подшипников:- Подшипники 3-го поколения поддерживают две функции:- возможность соединения с ходовой частью с одной стороны и с тормозным и колесным дисками – с другой. Всё это возможно благодаря наличию фланцев на внутреннем и наружном кольцах. Кроме того, интеграция подшипника с автомобилем позволяет выполнять функции трансмиссии на ведущей оси (за счёт шлицевого или планетарного соединения). Преимущества:- простота установки за счёт предварительного натяга, отрегулированного на заводе-изготовителе.

WHEELCHAIR = КРЕСЛО КОЛЯСКА – Wheelchair:- a mobility aid belonging to any class of three or four wheeled devices, usable indoors, designed for and used by individuals with mobility impairments, whether operated manually or powered. A ‘common wheelchair’ is such a device which does not exceed 30 inches in width and 48 inches in length measured two inches above the ground, and does not weigh more than 600 pounds when occupied.

WHEELCHAIR ACCESSIBLE VEHICLE = ТРАНСПОРТНОЕ СРЕДСТВО, ДОСЯГАЕМОЕ ДЛЯ КРЕСЛА КОЛЯСКИ – Wheelchair Accessible Vehicle is a vehicle that a wheelchair-bound person may enter either (1) via an on-board retractable lift or ramp; and (2) directly from a station platform reached by an elevator or a ramp that is either level with the vehicle floor or can be raised to floor level.

WHEELING = ПЕРЕКАТЫВАНИЕ (или ТРАНСПОРТИРОВКА) – Wheeling:- one utility transmitting electric power over its lines on behalf of a second utility. Wholesale wheeling is used to indicate bulk transactions in the wholesale market, whereas retail wheeling allows power producers direct access to retail customers. This term is often used colloquially to mean Transmission. Slang in energy industries. Electricity ‘Wheeling’ is when electricity is moved through a local grid for use in another area. In reference to electricity, the carriage of electricity from one supplier across the transmission lines of an intermediate utility for delivery to a third party. Wheeling:- using a utility’s lines to transport power from one neighboring system to another. Wheeling is:- (1) the delivery, and more specifically refers to delivery of energy across transmission systems. In some contexts it is used synonymously with Transmission, although this use is somewhat misleading since energy can be wheeled through distribution systems as well. Wheeling across transmission systems is generally referred to as Wholesale Wheeling since wholesale transactions are nearly always limited to sales made on the transmission grid. (2) Any movement of energy between parts of the system, or within the same part of the system, that involves a change of ownership for the energy. Wholesale Wheeling is the sale and delivery of energy among buyers and sellers in the wholesale market, usually to parties who take delivery of the energy on the transmission system. When a utility or energy distribution company delivers, or wheels, energy from the transmission system to an end-use customer, it is referred to as Retail Wheeling. When a customer who also generates energy produces energy at one site, transports it across someone else’s facilities and consumes it at another site, it is referred to as Self-Service Wheeling. Wheeling is the transmission of electricity by an entity that does not own or directly use the power it is transmitting. / По отношению к электричеству, передача электричества от одного поставщика по линиям электропередачи посреднической энергетической компании для поставки третьей стороне.

WHEELING CHARGE = СБОР ЗА ПЕРЕКАТЫВАНИЕ – Wheeling Charge is an amount charged by one electrical system to transmit the energy of, and for, another system or systems.

WHEELING SERVICE = УСЛУГА ПЕРЕКАТЫВАНИЯ – Wheeling Service:- the movement of electricity from one system to another over transmission facilities of intervening systems. Wheeling service contracts can be established between two or more systems.

WHEEL–THROUGH = XX – Wheel-Through:- an energy transaction fl owing through a transmission grid whose origination and destination are outside of the transmission grid.

WHEEL TRACK PLANTING = ПОСАДКА В КОЛЕЮ (или ПОСАДКА В БОРОЗДЫ, или ТОЧНЫЙ ВЫСЕВ В КОЛЕЮ, или ТОЧНЫЙ ВЫСЕВ В БОРОЗДЫ) – Wheel Track Planting is a practice of planting in which the seed is planted in tracks formed by wheels rolling immediately ahead of the planter. / сеялка точного высева (planter). Под Посадкой понимается размещение рассады (Капусты, Табака, Томата), саженцев плодовых, декоративных и лесных культур, клубней Картофеля, луковиц Лука, Тюльпана и других по площади поля с заделкой в почву. Проводят рассадо-посадочными машинами, картофелесажалками и вручную.

WHEN, AS AND IF ISSUED = КОГДА, КАК ТОЛЬКО И ЕСЛИ БУДУТ ВЫПУЩЕНЫ – When, As And If Issued is a term referring to a transaction made conditionally because a security, although authorized, has not yet been issued. See also When Issued. ‘When, As And If Issued’ (commonly known as ‘When-Issued’ (WI)) security refers to a security that has been authorized for issuance but not yet actually issued. ‘WI’ trading takes place between the time a new issue is announced and the time it is actually issued. All ‘When Issued’ transactions are on an ‘if’ basis, to be settled if and when the actual security is issued. / Термин, относящийся к условно состоявшейся сделке с ценной бумагой, которая хотя и была зарегистрирована, но ещё не была выпущена. Смотрите также По Выпуску или По Факту Выпуска (When Issued).

WHEN DISTRIBUTED = ПО РАСПРЕДЕЛЕНИИ – When Distributed (in stock listings of newspapers):- conditional buy and sell orders in a fixed-income market for a new issue that cannot be completed or transferred to another party until the offering has taken place. These transactions are labeled as ‘When Distributed’ because there is a possibility that they will not occur if the offering is cancelled. When Distributed is a term used in the fixed-income market that indicates a buy or sell transaction can be transferred to the counter-party only after another one has occurred. When Distributed:- (i) used to refer to a security that trades after the date of issue but before the time at which the certificates are delivered; and (ii) of or relating to a security on which a distribution is scheduled but has not yet occurred. When Distributed:- transactions conditional on the secondary distribution of shares issued and outstanding but closely held, as those of a wholly owned subsidiary, for example. See also When Issued. / По Распределении:- сделки с новой ценной бумагой, которая распределяется в результате одобрения владельцами акций. По Распределении:- сделки, зависящие от вторичного

размещения акций (secondary distribution), выпущенных и находящихся на руках акционеров (issued and outstanding) компаний с небольшим числом владельцев (closely held). Например, это могут быть акции филиала, находящегося в полной собственности головной компании. Смотрите также When Issued.

WHEN HALFWAY OVER = КОГДА ПОЛПУТИ ПРОЙДЕНО (или ХХ) – When Halfway Over is a channel report term used in crossings meaning when halfway across the river, put head of tow on the next mark listed in the channel report.

WHEN ISSUED = ПО ВЫПУСКУ (или ПО ФАКТУ ВЫПУСКА) – When Issued (WI) is a short form of 'When, As And If Issued'. The term indicates a conditional transaction in a security authorized for issuance but not as yet actually issued. All 'When Issued' transactions are on an 'if' basis, to be settled if and when the actual security is issued and the exchange or National Association of Securities Dealers rules the transactions are to be settled. When Issued is short form of 'When, As And If Issued'. The term indicates a conditional transaction in a security authorized for issuance but not as yet actually issued. All 'When Issued' transactions are on an 'If' basis, to be settled if and when the actual security is issued and the exchange or National Association of Securities Dealers rules the transactions are to be settled. When Issued:- referring to a conditional offer for a new security, subject to the security actually being issued. Before a new issue, underwriters canvass potential investors, who may or may not book an order to buy a portion the new issue. Orders made are said to be effective 'When Issued' because they may not be completed, especially if the offering is cancelled. Less formally, orders when issued are referred to as Orders 'With Ice' or Orders 'When Distributed'. When-Issued Trading:- off-exchange trading in newly issued securities prior to availability for delivery (or settlement). Often referred to as the 'Gray Market'. Not to be confused with the 'Gray Capital Market' and its often dubious sales techniques. When Issued (WI):- a transaction that is made conditionally because a security has been authorized but not yet issued. Treasury securities, stock splits, and new issues of stocks and bonds are all traded on a when-issued basis. Prior to a new issue's offering, underwriters solicit potential investors who may elect to book an order to purchase a portion of the new issue. These orders are made conditionally – 'When Issued' – because they may not be completed, particularly in the event the offering is canceled. Orders when issued are sometimes called Orders 'With Ice' or Orders 'When Distributed'. The term is short for 'When, As And If Issued'. Securities trade on a when issued basis when they have been announced, but not yet issued. The transaction is settled only after the security has been issued. A when-issued market exists where when issued instruments are traded. When issued markets can provide an indication regarding the level of interest that a new issue will attract. When issued transactions are dependent upon the actual security being issued and the exchange or National Association of Securities Dealers ruling that the transactions will be settled. A term When Issued (WI) refers to a transaction made conditionally, because a security, although authorized, has not yet been issued. Treasury securities, new issues of stocks and bonds, stocks that have split, and in-merger situations after the time the proxy has become effective but before completion are all traded on a when-issued basis. Also known as With Ice. When Issued (WI) is a transaction or trade in securities that are not yet issued, on the understanding that the trade will settle once the securities have actually been issued; this is a special kind of forward transaction; active WI markets exist for Treasury securities. They sometimes exist for Freddie Mac securities that are to be issued in an auction, e.g., Reference Bills. / По Выпуску – краткая форма выражения 'Когда, Как Только и Если Будут Выпущены' ('When, As And If Issued'), означающая условную сделку с ценной бумагой, получившей разрешение на эмиссию, но в действительности ещё не выпущенной. Все сделки с условием По Выпуску заключаются на условной основе, что они будут совершены, если и когда реальная ценная бумага будет выпущена в соответствии с правилами биржи или Национальной Ассоциации Дилеров по Ценным Бумагам, и что сделки могут совершаться. По Выпуску – сокращение от 'когда, поскольку и если выпуск (ценных бумаг) состоится'. Термин, который относится к сделке, совершённой условно, поскольку выпуск ценных бумаг, хотя и разрешён, но реально ещё не состоялся. Сделки с новыми выпусками (new issues) акций и облигаций, а также с разделёнными (split) акциями и казначейскими ценными бумагами всегда совершаются 'по выпуску'. В приводимых в газетах таблицах символ WI указывается рядом с ценой таких бумаг. Смотрите также По Распространении (When Distributed).

WHEN ISSUED BASIS = БАЗИС ПО ВЫПУСКУ (или БАЗИС ПО ФАКТУ ВЫПУСКА) – When Issued Basis:- trades on a when issued basis is a purchase or sale of a security to be issued pursuant to:- (i) a prospectus offering where a receipt for the final prospectus for the offering has been issued by the applicable securities regulatory authority but the offering has not closed and settled; (ii) a proposed plan of arrangement, an amalgamation or a take-over bid prior to the effective date of the amalgamation or the arrangement or the expiry date of the takeover bid; or (iii) any other transaction that is subject to the satisfaction of certain conditions, and the trade is to be settled only if the security is issued and the trade in the security prior to the issuance would not contravene the applicable securities legislation. Essentially, if the condition for the issuance or distribution of the security is not satisfied, all trades which have been executed on a 'when issued' basis will be cancelled. / Базис По Выпуску:- котировки ценных бумаг, по которым заключаются сделки до их реального выпуска. Причины происхождения этого типа акций различные, но обычно они появляются в результате реорганизаций корпораций, слияний, финансирования прав акционеров на покупку акций из новых выпусков на льготных условиях и дроблений акций.

WHEN–ISSUED SECURITY = ЦЕННАЯ БУМАГА ПО ВЫПУСКУ – When-Issued Security:- an authorized but not yet issued security that is traded conditionally ('when, as, and if issued') in the period between the announcement date and the auction date. New corporate-bond and Treasury-security issues are often traded on a when-issued basis. To model a when-issued security, create a user security.

WHEN WELL OVER = КОГДА ЗНАЧИТЕЛЬНО БОЛЬШЕ (или ХХ) – When Well Over is a channel report term used in describing courses steered in crossings when more than halfway across or halfway over the reach.

WHERE AWAY = МЕСТО ПОКИНУТО (или ХХ) – Where Away is a call requesting direction in answer to the report of a lookout that an object has been sighted.

WHEY = СЫВОРОТКА – Whey is a watery fraction that forms along with curd when milk coagulates. It contains the water-soluble constituents of milk and is essentially a 5 percent solution of lactose in water, with some minerals and lactalbumin. The whey is removed from the curd during the process of making cheese; then it is centrifuged to remove fat, concentrated or dried, and used for human food in processed cheese products, baking, and candy making. Whey is used for animal feed as a liquid, concentrate, or dry powder. Whey is:- (1) the water and solids of milk that remain in cheese-making after the curd is removed. It contains about 93.3 percent water; 6.5 percent lactose, protein, minerals, enzymes, and water-soluble vitamins; and 0.2 percent fat. There are two general types of whey:- acid and sweet. Acid whey is produced from cheeses such as cottage and cream. Sweet whey is from cheeses such as Cheddar and Mozzarella. (2) A classification of cheeses such as Ricotta made predominantly from the whey. See also Dry Whey. / Смотрите также Сухая Сыворотка (Dry Whey). Молочная Сыворотка – это продукт, образующийся при сворачивании молока. Само молоко при этом образует густую массу, из которой готовят творог или некоторые другие молочные продукты, а сыворотка остаётся в виде жидкости. Чтобы получить самостоятельный продукт, массу процеживают. При производстве сыра и казеина эта жидкость является побочным продуктом. Она нашла широкое применение в пищевой промышленности и диетологии, так как она низкокалорийна, и полезные свойства её весьма многочисленны. Помимо обычной, существует ещё и

сыворотка сладкая – побочный продукт производства твёрдых сыров, таких как Швейцарский и Чеддер; кислая – побочный продукт производства прессованного творога, кислых сыров. В основе методики получения лежат естественные процессы. Когда молоко свёртывается под воздействием молочной кислоты, вырабатываемой микроорганизмами или вносимой искусственным путём, либо под воздействием сычужного фермента, pH молока падает до 4.6. Именно в этот момент происходит отделение молочного белка и сыворотки друг от друга. Путём процеживания казеин и жидкость отделяют друг от друга, а затем пускают их в производство. В состав молочной сыворотки входят следующие элементы:- белки (17%); жиры (10%); углеводы (74%); лактоза; пробиотические бактерии; витамины:- A, группа B, C, E, H, PP, холин; биотин; никотиновая кислота; фосфор; магний; калий; натрий; сера; хлор; железо; молибден; кобальт; йод; цинк; медь; кальций. Калорийность молочной сыворотки – 18–27 ккал на 100 граммов. Сыворотка применяется очень широко, и не только в кулинарии. Она является необходимым компонентом при промышленном производстве коричневых сыров, козьего сыра Рикотта. Она входит в состав некоторых рецептов хлебобулочных изделий, кормов для домашних животных. Выделенные из состава сыворотки белки, в первую очередь альфа- и бета-лактоглобулины, являются самостоятельной биодобавкой, которая популярна в среде бодибилдеров. На основе этого продукта, особенно в тех регионах, где налажено производство сыров, изготавливают газированные напитки. Так как в состав сыворотки молочной входит множество элементов, имеющихся в грудном молоке, она стала основой искусственного детского питания. Баланс углеводов, жиров и белков оптимален для усваивания желудком и кишечником ребёнка. Приём такой продукции способствует укреплению иммунитета. Отмечено улучшение состояния здоровья у малышей с дисбактериозом и повышенным газообразованием. Сыворотка является ещё и косметическим продуктом:- из неё делают питательные коктейли для кожи, примочки, ванночки и маски. Жидкость способствует обновлению клеток, нормализации обменных и метаболических процессов, выведению шлаков и продуктов биологического распада. Это естественное сырьё входит в состав натуральной косметики, ухаживающей за кожей, разглаживающей морщины, укрепляющей волосы, производящей омолаживающий эффект. Согласно легенде, знаменитые ванны Клеопатры содержали в себе сыворотку. Полезные свойства сыворотки изучены очень хорошо. Выявлено, что она оказывает положительное влияние на:- пищеварение; почки; печень; нервную систему; кожу; сердечно-сосудистую систему; иммунную систему; кроветворение. Регулярное потребление сыворотки благотворно сказывается на работе почек и печени, они начинают функционировать существенно активнее. Постепенно нормализуется количество воды в тканях, выводится всё лишнее, в том числе токсины и шлаки, уменьшается отёчность. Это также хорошо отражается на состоянии кожи, она становится более чистой, приобретает равномерный оттенок, уменьшается количество кожного сала, являющегося причиной угревой сыпи. Содержащиеся в составе напитка аминокислоты повышают выработку серотонина, что помогает бороться с депрессией, повышает болевой порог и уменьшает раздражительность. Состав сыворотки оказывает успокаивающее действие на нервную систему. Регулярный приём нормализует деятельность желудочно-кишечного тракта (ЖКТ), что также приводит к нормализации веса, постепенному похудению, восстановлению обмена веществ. Польза сыворотки для сердца при регулярном приёме однозначна – улучшается кровообращение, кроветворение, купируется развитие атеросклероза, очищаются сосуды, уменьшаются проявления гипертонии. Жидкость включают в качестве очищающего элемента во многие диеты, она показана в таких случаях:- (i) заболевания ЖКТ (гастрит, панкреатит, энтероколит, энтерит, дисбактериоз кишечника, хронический запор, пиелонефрит, гломерулонефрит, пищевая токсикоинфекция); (ii) проблемы с сосудами головного мозга (церебральный атеросклероз, проблемы мозгового кровообращения); (iii) эндокринные проблемы; (iv) заболевания сердечно-сосудистой системы (атеросклероз, стенокардия, ишемическая болезнь, недостаточность кровообращения, кардиосклероз); (v) воспаления дыхательных путей (бронхит, фарингит, тонзиллит, гайморит, пневмония); (vi) кожные заболевания (аднексит, молочница, кольпит, цервицит, генитальный герпес, эрозия шейки матки, нарушения вагинальной флоры); и (vii) женские болезни (жирная кожа, диатез, акне, псориаз, демодикоз, нейродермит, пищевая аллергия). Противопоказания:- Единственная причина, по которой стоит отказаться от приёма сыворотки – индивидуальная непереносимость лактозы. У человека с такой проблемой могут иметь место аллергические реакции, отёчность, расстройство кишечника, сильный метеоризм. Другая опасность – неправильное хранение. Пропавший натуральный продукт – среда для развития болезнетворных бактерий. Несмотря на противопоказания, молочная сыворотка является очень полезным и вкусным напитком, который можно применить десятками способов. Обязательно стоит включить её в свой рацион!

WHEY PROTEIN = СЫВОРОТОЧНЫЙ БЕЛОК (или СЫВОРОТОЧНЫЙ ПРОТЕИН) – Whey Protein is one of two major groups of protein present in milk.

WHEY PROTEIN CONCENTRATE = СЫВОРОТОЧНЫЙ БЕЛКОВЫЙ КОНЦЕНТРАТ (или СЫВОРОТОЧНЫЙ ПРОТЕИНОВЫЙ КОНЦЕНТРАТ) – Whey Protein Concentrate (WPC) is a product resulting from the ultra-filtration of raw liquid whey and the subsequent evaporation and spray drying to a powder. The protein content typically ranges from 34 percent to less than 90 percent. When the protein concentration exceeds 90 percent, the product is known as a Whey Protein Isolate (WPI). Whey protein concentrate is a source of milk protein in feeds, milk replacers, and pet foods and can be used as an alternative to nonfat dried milk.

WHEY PROTEIN ISOLATE = СЫВОРОТОЧНЫЙ БЕЛКОВЫЙ ИЗОЛЯТ (или СЫВОРОТОЧНЫЙ ПРОТЕИНОВЫЙ ИЗОЛЯТ) – Whey Protein Isolate (WPI) is the holy grail of protein powders, most pure form of whey protein available. Whey protein isolate has the highest amount of pure protein, typically containing around 85% to 98% pure protein. Not only whey protein isolate the most pure form of protein, but it also has the highest biological value (BV). Biological value is a measure of how fast your body can use a fuel source. Whey protein isolate is great for both fat loss and muscle gain. Out of all the protein whey sources, isolate has the lowest the lowest amount of fat and lactose. See also Whey Protein Concentrate (WPC). A Whey Protein Isolate (often Whey Isolate) is a dietary supplement created by filtering milk protein. Whey is a by-product of the cheese-making process. Whey can be processed to yield whey protein in three forms:- whey isolate, whey concentrate, or whey hydrolysate. Whey proteins are highly bioavailable, are very quickly absorbed into the body, and have a high concentration of branched-chain amino acids (BCAAs) which are highly concentrated in muscle tissue, and are used to fuel working muscles and stimulate protein synthesis. The difference between the whey protein forms is the process used to filter the proteins. Whey isolates yield a higher percentage of pure protein and can be filtered enough to be virtually lactose free, carbohydrate free, fat free, and cholesterol free. Whey isolates have had their base component (water) removed and are generally considered almost lactose and cholesterol free – they are at least 90% protein by weight. Two filtration methods are widely used. One method, utilizes ion exchangers which denature the proteins with heat, and may or may not damage the proteins. The second method, microfiltration, uses other filtration methods. Both methods yield a very high protein to non-protein product ratio. Whey and other protein powders can be reconstituted at the time of usage by the addition of a solvent such as water, juice, milk, or other liquid. Whey protein is popular among athletes today because of its ability to be digested very rapidly and help return the post-workout body back from a catabolic (muscle-wasting) state to an anabolic (muscle-building) state. Because of their filtration methods, whey isolates tend to be less allergenic than concentrates and other bovine milk or dairy products. Dehydrated (powdered) concentrates and isolates have reduced packaging and shipping requirements, and extended shelf lives. They are readily available.

WHFGE. = WHARFAGE

WHFIT = WIDELY HELD FIXED INVESTMENT TRUST

WHIP = WILDLIFE HABITAT INCENTIVES PROGRAM

WHIPCORD = ЖЁСТКАЯ БЕЧЁВКА (или ПЛАЩЁВАЯ ТКАНЬ, или ГАБАРДИН, или ОСНОВНАЯ САРЖА 3/1) – Whipcord is a woven fabric with a very steep and compacted twill appearance on the face of the goods. End-uses for the fabric include dress woolens, worsteds, or wool blends, and many types of uniforms. Whipcord is a cloth that is made of hard-twisted yarns and has fine diagonal cords or ribs. Whipcord:- cotton, rayon, worsted or woolen. Twill weave. Very much like gabardine, but the yarn is bulkier and much more pronounced. The twill is steep 63 degrees and goes from left to right (except for cotton). It is very durable, rugged and stands hard usage and wear. In time, it shines a bit with wear. Sometimes back is napped for warmth. So named because it stimulates the lash of a whip. Whipcord is a compact woven fabric having a very steep twill on the face of the goods. Whipcord is used in dress woolens, worsteds, or wool blends and in many types of uniforms. Whipcord is an extremely strong, twill-weave worsted fabric made in fairly heavy weights of cotton, wool worsted, and fabrics of man-made fibers and blends. It is similar to gabardine, but heavier and with a more pronounced diagonal rib on the right side. It is so named because it simulates tlre lash of a whip. Cotton whipcotds are often four-harness warp-twill weaves. It is used for draperies and upholstery, uniforms, riding clothes, and other wearing apparel where a strong fabric is required.

WHIPPED CREAM = ОБМЁТАННЫЙ (или КЕТЛЁВАННЫЙ) КРИМ – Whipped Cream is a type of crêpe fabric produced from false-twist textured polyester yarn.

WHIPPED–IN FILLING = СГОННАЯ УТОЧИНА – Whipped-In Filling:- xxxxx. See also Pulled-In Filling.

WHIPPING = КЕТЛЁВКА (или ОБМАТЫВАНИЕ, или ОБВИВАНИЕ, или ОПЛЕТАНИЕ) – Whipping is a method of preventing the ends of a line from unlaying or fraying by turns of small stuff, stout twine or seizing wire with the ends tucked.

WHIP ROLL = СКАЛО – Whip Roll or Whiproll:- it sets above the warp beam and guides the warp ends as they come up from the warp beam on their way to the lease rods and heddles. This guide roller is in the same flat plane with the breast beam and selvage edges. The arrangement makes weaving possible. / Качающееся Скало ткацкого станка.

WHIPSAW = ПРОЛЁТ (или ПОДРЕЗАНИЕ) – A Whipsaw occurs when a buy or sell signal is reversed in a short time. Volatile markets and sensitive indicators can cause whipsaws. For example, a whipsaw would occur if a position trader initiates a long position on a bullish MACD crossover and has to close it the next day because of a bearish moving average crossover. The signal was reversed and the trader had to exit quickly. A quick exit after entering the market. Normally due to a tight stop-loss order in a trading range environment. Can also explain a trader being caught in a bull or bear trap. Whipsaw is a condition where a security's price heads in one direction, but then is followed quickly by a movement in the opposite direction. The origins of term is derived from the push and pull action used by lumberjacks to cut wood with a type of saw with the same name. There are two types of whipsaw patterns. The first involves an upward movement in the share price, which is then followed by a drastic downward move, which causes the share's price to fall relative to its original position. The second type involves the share price to drop for a little while, and then suddenly, the price abruptly surges towards positive gains relative to the stock's original position. Is when the market rapidly reverses its direction several times in succession. Whipsaw describes the movement of a security when, at a certain time, the security's price is moving in one direction but then quickly pivots to move in the opposite direction. There are two types of whipsaw patterns. The first involves an upward movement in a share price, which is then followed by a drastic downward move causing the share's price to fall relative to its original position. The second type occurs when a share price drops in value for a short time and then suddenly surges upward to a positive gain relative to the stock's original position. The origins of the term Whipsaw are derived from the push and pull action of lumberjacks when cutting wood with a saw of the same name. A trader is considered to be 'whipsawed' when the price of a security he has just invested in abruptly moves in the opposite and unexpected direction. Whipsaw patterns most notably occur in a volatile market in which price fluctuations are unpredictable. Day traders or other short-term investors are accustomed to being whipsawed. Those who have a long-term, buy-and-hold approach to investing can often ride the volatility of the market and emerge with positive gains. Two Examples of a Whipsaw:- (1) One example of a whipsaw is also the most common. When an investor goes long on a stock, the expectation is that the price will increase in value over time. However, there are many occasions when an investor purchases shares of a company at the top of a market rally. For example, an investor may purchase a stock at its peak assuming that it will continue to post significant gains. Almost immediately after purchasing the stock, the company releases a quarterly report that shakes investor confidence and causes the stock to decline in value by more than 10%, never to recover. The investor is holding the stock at a loss, with no option to sell the stock, effectively whipsawed. (2) Conversely, some investors, specifically those who short-sell, can face a whipsaw at the bottom of a market. For example, an investor may anticipate a downturn in the economy and purchase put options on the S&P 500. The investor profits if the market continues to decline. However, almost immediately after purchasing the put options, the market unexpectedly rallies and the investor's options quickly become 'out of the money', or worthless. In this case, the whipsaw occurs during a recovery phase, and the investor loses his investment. Whipsaw:- to buy and have the price collapse, and then sell short and watch the market rally. A Whipsaw is a volatile price action in which a security swings back and forth in a chaotic pattern that crisscrosses obvious support and resistance levels. This occurs often in modern markets, robbing profits and lowering confidence levels. While it can be confusing, traders and market timers can manage whipsaws by looking at price structure before the pattern develops. Whipsaws tend to fall into one of two categories. In the first type, the security breaks new ground and then reverses, triggering a failed breakout or breakdown. There are risk management rules that help with profit production in this case, which has become increasingly common in our predatory algorithmic markets. The second type requires more attention, with contrary action often persisting for weeks or months before a trend emerges and price leaves the contested territory. While this whipsaw may start as a well-organized trading range, it quickly evolves into a nightmare of higher highs, lower lows, gaps and sudden reversals. Two technical studies will reveal what's needed to manage these whipsaws into the most advantageous outcomes:- (i) What price action preceded the whipsaw? (ii) What happened at similar price levels in the past? Examine The Prior Trend:- Look at the trend preceding the whipsaw and the territory it covers. Does the security break out to a new high or low prior to the period of conflict, or does it print within a broader trading range? Whipsaws that are well-contained within prior ranges provide base periods in which sharp conflict between buyers and sellers triggers a series of tests and reversals. These can occur when a security lifts off a low in an uptrend or pulls back from a high in a downtrend, leaving behind a reversal pattern that fails to draw in adequate sponsorship. In the simplest terms, longs buy a new base or shorts sell a new top, but weak volume fails to alter the technical characteristics, exposing the reversal to rounds of conflict despite textbook patterns. Measure the trend using a Fibonacci grid when whipsaws occur at new highs or lows. You'll often find the pattern is contained within the top 38% retracement. Add a second grid at a smaller harmonic, by locating the next higher low in an uptrend or lower high in a downtrend. This additional layer extracts order from the chaos, intersecting at price levels that predict key turning points within the choppy pattern. Adobe Systems (ADBE) rallied from 49 to 61 and dropped into a whipsaw that lasted nearly two months. Lower lows and higher highs indicate stop running and other predatory actions that are common in these chaotic patterns. A Fibonacci grid contains the whipsaw within the 38% rally retracement while a second grid over the November to December

rally confines the lows within 38% and 50% retracement levels, indicating harmonic support between 57 and 58 that yielded a February breakout. Examine Past Action At Similar Levels:- Look at prior action at similar price levels when examining whipsaws within long or short term trading ranges. This is a fractal process, with short-term traders concentrating on levels crossed hours or days ago while market timers zoom back and examine levels hit months or years ago. Locate gaps, especially unfilled ones, as well as swing highs or lows that may come into play in the current whipsaw. Look for possible volume that signals strong emotions and a conflict between buyers and sellers. Consider the possibility that similar action will unfold this time around. This 'Trend Mirror' analysis can uncover the primary theme at play in the current whipsaw, allowing a readjustment of strategies if positioned and a more defensive posture if sidelined. It also identifies support and resistance zones that may be masked by the chaotic pattern. In turn, this highlights new entry prices where the whipsaw may come to an end, encouraging a trend-following strategy. A 2012 Amazon (AMZN) high volume breakout triggered a 4-month whipsaw. The vertical rally filled the last piece of the 2012 gap between 200 and 225 (blue lines), printing an equally large gap that set off a chaotic reversal. A Fibonacci grid laid across the prior downtrend organized the volatile action, with the rally ending at the 78.6% sell-off retracement while support developed at the 50% retracement. Bottom Line:- Look at past action to organize a whipsaw's volatile characteristics, identifying harmonic levels that may offer low risk entry prices. / бычий МЭКДИ (MACD) . Фибоначчи (Fibonacci). WHIPSAWED = ПРОЛЕТЕВШИЙ (или ПОДРЕЗАН) – Whipsawed:- subjected to a double market loss through trying inopportunely to recoup a loss by a subsequent short sale of the same security. The United States has been Whipsawed by the revolutionary upheaval in Egypt (2011). A trader is said to be Whipsawed when the price of a security suddenly moves in the opposite direction of a trade that he just placed. For instance, if a trader buys shares of Apple at USD250/share, and over the course of the day the price drops to USD230, the trader has been whipsawed. This usually occurs in a volatile market when traders are subjected to high risk. Short-term traders can be whipsawed often, but long term traders are likely to see better results over a longer time horizon. Whipsawed:- buying stocks just before prices fall and selling stocks just before prices rise in a volatile market, often as the result of misleading signals. Whipsawed:- subjected to a double loss, as when an investor has bought a stock at a high price soon before it declines and then, in order to make good the loss, sells it short before it advances. / Эпл (Apple). Пролетевший – потерпеть двойной убыток на операции с ценными бумагами. Потерпеть значительный убыток с обеих сторон сделки с ценными бумагами. Буквально Разрезанный Надвое:- ситуация, когда обе стороны сделки понесли значительные убытки. Попасть в период лихорадочных колебаний котировок и совершать убыточные сделки по мере роста и спада цен. Говорят, что торговец понёс значительные убытки по обеим сторонам сделки, если он совершает покупку как раз перед падением цен и продажу перед подъёмом цен. Этот термин используется в техническом анализе по отношению к вводящим в заблуждение сигналам на графике тенденций рынков или определённых ценных бумаг.

WHISKERING = БАХРОМЧАТОСТЬ (или ХХ) – Whiskering:- (also Whisker Wash) parallel horizontal distress marks on the upper thigh on the front of denim jeans; replicates the natural wear of jeans from sitting down after long periods of wear and use; actual whiskering originates from cowboys/ranchers that would sit on their horses for long periods of time, and through wearing and weathering creases on the upper thigh cause a lighter line or 'whisker' to appear; name comes from parallel appearance that has resemblance to animal whiskers.

WHISKERS = УСЫ – Whiskers are the fine fibrils or crystals from polymers, metals, etc.

WHISKERS™ = УСЫ™ (или ВИСКОЗ™) – Whiskers™ is a trademarked method for inserting DNA (genes) into plants cells, so that those plant cells will then incorporate that new DNA and express the protein(s) coded-for by that DNA. / Вискоз™ (Whiskers™).

WHISKEY = ВИСКИ – Whiskey (pronunciation:- WISS-kee) or W is international nautical signal flag meaning:- I require medical assistance.

WHISPER NUMBER OR FORECAST = НАШЕПЧЕННЫЕ ЧИСЛО ИЛИ ПРОГНОЗ – Whisper Number Or Forecast:- an unofficial earnings estimate of a company given to clients by a security analyst if there is more optimism or pessimism about earnings than shown in the published number. These are often found on the Internet.

WHISPER STOCK = НАШЁПТАННАЯ (или ТАЙНАЯ, или ПОДСЛУШАННАЯ) ДОЛЯ – Whisper Stock is a stock that is rumore to be a takeover target. Speculators, arbitrageurs, and other investors may buy shares in the company hoping that the 'whispers' they have heard are true, allowing them to reap huge profits when the takeover is officially announced. Whisper stocks may trade in heavier-than-usual volume once the rumors about the takeover spread widely. Investing in whisper stocks is risky, however, because the takeover rumors may prove to be inaccurate. Whisper Stock is a stock rumored to be the target of a takeover bid, drawing speculators who hope to make a profit after the takeover is completed. / Акция Шёпота (Whisper Stock):- акции, о которых распространились слухи, что их будут скупать при поглощении компании-эмитента. Спекулянты, арбитражеры и другие инвесторы могут покупать акции компании в надежде, что то, что о них шепчется, соответствует истине, и рассчитывать на получение высокой прибыли, когда о поглощении будет объявлено официально. Как только слухи о поглощении распространятся достаточно широко, акции шепота могут начать продаваться по цене выше обычной. Однако, инвестировать в такие акции – довольно рискованно, поскольку слухи о поглощении могут оказаться неверными.

WHISTLE BLOWER = ДОНОСЧИК (или СТУКАЧ, или СВИСТУН, или 'ДОБРОЖЕЛАТЕЛЬ') – Whistle Blower is an employee or other person with inside knowledge of wrongdoing inside a company or government agency. The employee is supposed to be protected from retribution by the employer by several federal laws protecting whistle blowers, though whistle blowers frequently are punished for revealing wrongdoing by their employer. Several employees who disclosed illegal billing practices by defense contractors were demoted or fired, for example. In securities, under the US Insider Trading and Securities Fraud Enforcement Act of 1988, whistle blowers who provide the Securities and Exchange Commission (SEC) with information about illegal insider trading or other illegal activity that leads to a conviction may qualify for bounties. Whistle Blower is a person who has knowledge of fraudulent activities inside a firm or government agency, who is protected from the employer's retribution by federal law. / Буквально Свистун (whistle blower) – работник компании или другое лицо, имеющее доступ к конфиденциальной информации внутри фирмы или правительственного учреждения и использующее свои знания во вред своему учреждению. Считается, что работник должен быть защищён от возмездия со стороны работодателя по нескольким федеральным законам, защищающим свистунов, хотя часто работодатели карают свистуна, обнаружив нанесённый ущерб. Некоторые работники, раскрывавшие незаконные злоупотребления, осведомляли противоположную сторону о нарушениях при составлении или исполнении договоров, были, например, понижены в должности или уволены. В области ценных бумаг, согласно Акту о Пресечении Незаконных Операций с Ценными Бумагами на Основе Внутренней Информации и Мошенничества с Ценными Бумагами от 1988 (Insider Trading and Securities Fraud Enforcement Act of 1988), те, кто сообщит в Комиссию по Ценным Бумагам и Биржам (КЦББ (SEC)) сведения о

незаконных операциях с использованием конфиденциальной информации или о другого рода незаконной деятельности, которая может привести к ущербу, могут получить вознаграждение.

WHISTLE BLOWING = ДОНОСИТЕЛЬСТВО (или 'ДОБРОЖЕЛАТЕЛЬСТВО', или ХХ) – Whistle Blowing:- the exposure and reporting of fraud by a member of the public or within an insurer by a director of the board, a manager or a member of staff. Whistle-Blower is a a person who informs on another or makes public disclosure of corruption or wrongdoing. Whistleblowing is the disclosure by a person, usually an employee in a government agency or private enterprise, to the public or to those inauthority, of mismanagement, corruption, illegality, or some other wrongdoing. Since the 1960s, the public value of whistle-blowing has been increasingly recognized. For example, federal and state statutes and regulations have been enacted to protect whistleblowers from various forms of retaliation. Even without a statute, numerous decisions encourage and protect whistleblowing on grounds of public policy. In addition, the federal False Claims Act (31 USCA § 3729) will reward a whistleblower who brings a lawsuit against a company that makes a false claim or commits Fraud against the government. Persons who act as whistleblowers are often the subject of retaliation by their employers. Typically the employer will discharge the whistleblower, who is often an at-will employee. An At-Will Employee is a person without a specific term of employment. The employee may quit at any time and the employer has the right to fire the employee without having to cite a reason. However, courts and legislatures have created exceptions for whistleblowers who are at-will employees. Whistleblowing statutes protect from discharge or discrimination an employee who has initiated an investigation of an employer's activities or who has otherwise cooperated with a regulatory agency in carrying out an inquiry or the enforcement of regulations. Federal whistle-blower legislation includes a statute protecting all government employees, 5 USCA §§2302(b)(8), 2302(b)(9). In the federal civil service, the government is prohibited from taking, or threatening to take, any personnel action against an employee because the employee disclosed information that he or she reasonably believed showed a violation of law, gross mismanagement, gross waste of funds, abuse of authority, or a substantial and specific danger to public safety or health. In order to prevail on a claim, a federal employee must show that a protected disclosure was made, that the accused official knew of the disclosure, that retaliation resulted, and that there was a genuine connection between the retaliation and the employee's action. Many states have enacted whistleblower statutes, but these statutes vary widely in coverage. Some statutes apply only to public employees, some apply to both public and private employees, and others apply to public employees and employees of public contractors. Some statutes cover a broad array of circumstances, such as those that apply to federal employees that prohibit employers from dismissing workers in Reprisal for disclosing information about, or seeking a remedy for, a violation of law, gross mismanagement, gross waste of funds, abuse of authority, or a specific danger to public safety and health. Other statutes are narrow in scope, such as one that limits the protection of public and private employees to retaliation for reporting possible violations of local, state, or federal environmental statutes. A whistleblower statute may also limit protection to discussions of agency operations with members of the legislature or to disclosure of information to legislative committees or courts. In whistleblower cases, states follow their general rules for determining whether a public policy Cause of Action exists in favor of the employee. Therefore, in states in which Wrongful Discharge actions must have a statutory (legal) basis, the case will be dismissed if the employer did not violate a statutorily enacted public policy. In many cases, the courts have refused to recognize a whistleblower's claim because no clearly mandated statutory policy has been identified. In addition, employees who blow the whistle on matters that affect only private interests (e.g., complaints about internal corporate policies) will generally be unsuccessful in maintaining a cause of action for discharge in violation of public policy. Under the federal False Claims Act, any person with knowledge of false claims or fraud against the government may bring a lawsuit in his own name and in the name of the United States. As long as the information is not publicly disclosed and the government has not already sued the defendant for the fraud, the whistle-blower, who is called a Relator in this action, may bring a False Claims Act case. The relator files the case in federal court under seal (in secret), and gives a copy to the government. The government then has 60 days to review the case and decide whether it has merit. If the government decides to join the case, the case is unsealed, a copy is served on the defendant, and the government and the relator work together in the case as co-plaintiffs. If the government declines to join the suit, the relator may proceed alone. In a successful False Claims Act case the relator will receive at least 15 percent but not more than 25 percent of the proceeds of the action or settlement of the claim, depending upon the extent to which the person substantially contributed to the prosecution of the action. In the early 1990s, commentators were claiming that men were more likely than women to blow the whistle on improper conduct. Some analysts suggested the reason for this perception was that men seem to seek financial gain for whistleblowing. During the early 2000s, however, a number of women became involved in high profile acts of whistleblowing – for reasons other than fame and fortune. In 2001, Sherron Watkins, a vice president at Enron Corporation, informed the company's board that Enron's accounting practices were improper. Enron later suffered a major collapse – largely as a result of its accounting practices – that led to the company's Bankruptcy and to the indictment of the company's auditor and chief financial officer. The following year, Cynthia Cooper, an auditor with WorldCom, told the company's board that WorldCom had covered up major losses of USD3.8 billion through false bookkeeping. Like Enron, the accounting failures led to WorldCom's bankruptcy. During the same year, Coleen Rowley, an FBI staff attorney for more than 20 years, sent a letter to FBI director Robert Mueller, indicating that the FBI's national headquarters had mishandled an investigation of Zacarias Moussaoui, who was later believed to be a co-conspirator in the September 11, 2001, terrorist attacks. Rowley later spoke before the intelligence committees of the House of Representatives and the Senate about her accusations. Time magazine dubbed 2002 the 'Year of the Whistleblower', and named Watkins, Cooper, and Rowley as its 'Persons of the Year'. Their stories fueled the observation that women are more likely to become whistleblowers not for the potential for fame and financial gain, but out of a sense of duty. Although Watkins, Cooper, and Rowley were each subjected to rather harsh treatment by their respective employers following their disclosures, they became national celebrities by 'speaking up when no one else would'. / Шерэн Воткинз (Sherron Watkins), Энрон Корпорэйшэн (Enron Corporation). WHITE = БЕЛОЕ – White:- the achromatic object color of greatest lightness characteristically perceived to belong to objects that reflect diffusely nearly all incident energy throughout the visible spectrum.

WHITE BELLY = БЕЛОЕ БРЮШКО – White Belly is a chalky white spot in the lateral part of the endosperm.

WHITE BIOTECHNOLOGY = БЕЛАЯ БИОТЕХНОЛОГИЯ – White Biotechnology is a term utilized in some countries to refer to industrial applications of genetic engineering. One example would be production of laccase in genetically engineered organisms.

WHITE BLOOD CELL = БЕЛАЯ КРОВЯНАЯ КЛЕТКА – White Blood Cells (WBCs), also called Leukocytes or Leucocytes, are the cells of the immune system that are involved in protecting the body against both infectious disease and foreign invaders. All white blood cells are produced and derived from multipotent cells in the bone marrow known as Hematopoietic Stem Cells. See also Leukocytes. / Белая Кровяная Клетка:- .

WHITE CANDLE = БЕЛАЯ СВЕЧА – A White Candle represents the open, high, low and closing points on a candlestick chart for a time period where the closing price is above the opening price. At the top and bottom of the candle are Wicks which are also

sometimes called Shadows. A white candle is the same as a Green Candle. Some candlestick charts show the up candles as green candles and the down candles as red candles. / На графиках технического анализа биржевого рынка под Белой Свечой понимается .

WHITE CAP = БЕЛАЯ ШАПКА (или БЕЛЯК) – White Cap is the white froth on the crests of waves.

WHITE CENTER = БЕЛЫЙ ЦЕНТР – White Center is the chalky area in the center of the endosperm of the milled nonglutinous Rice.

WHITE COLLAR CRIME = ПРЕСТУПЛЕНИЕ БЕЛЫХ ВОРОТНИЧКОВ – White Collar Crime is a number of miscellaneous nonviolent crimes lumped together as white collar crimes. There is no fixed definition of white collar crime, although it usually includes bribery, embezzlement, fraud, forgery, and violations of trust committed by corporations or individuals engaged in commerce. Historically, in the United States many white collar crimes have received lenient punishment from a criminal justice system that considered white collar crimes to be less serious than more violent crimes. Today, the trend is for stricter punishment of white collar crimes in recognition of the financial damage they inflict on society.

WHITE COLLAR WORKER = РАБОТНИК С БЕЛЫМ ВОРОТНИЧКОМ – White Collar Worker is an office worker in professional, managerial, or administrative position. Such workers typically wear shirts with white collars. Those working in factories or doing manual labor typically wear blue collars, and are therefore called Blue-Collar Workers. White-Collar Workers:- office, clerical, administrative, sales, professional, and technical employees, as distinguished from production and maintenance employees who are usually referred to as Blue-Collar Workers. A White Collar Worker is a person who does non-routine work in an administrative or professional position, and does not perform manual labor. A higher level of training is typically demanded for a white collar position; a college degree is a common requirement. This group of workers tends to earn a higher wage than manual laborers, and is more likely to be paid a salary than an hourly wage. The dress code associated with a white collar position may be somewhat higher than for other positions. Examples of white collar jobs are:- accountants; attorneys; bankers; consultants; doctors; engineers; information technology positions; managers; and scientists. Those performing routine support work, such as clerks, nurses, and laboratory technicians, are not considered to be white collar workers. White collar workers may have improved working conditions and benefits packages, so this type of labor is considered quite desirable. However, the stress level can also be quite high, and there is downward pressure on white collar pay levels as more of these positions face competition from lower-wage countries. The term originates from an early requirement that people in these positions wear white shirts while on the job. / Работник С Белым Воротничком – любой конторский служащий (работник), не занятый физическим трудом, включая церковнослужителей, административных, управленческих и профессиональных работников. Работник С Белым Воротничком – служащий – специалист конторы, руководитель или административный работник. Такие работники обычно носят рубашки с белым воротничком. Производственные рабочие, занятые ручным трудом, обычно носят голубые (синие) воротнички и поэтому называются Работниками С Голубым (Синим) Воротничком (Blue-Collar Workers).

WHITE CORN = БЕЛОЗЁРНАЯ КУКУРУЗА (или БЕЛАЯ КУКУРУЗА) – White Corn is a Corn that is white-kerneled and contains not more than two percent of Corn of other colors. White kernels of Corn with a slight tinge of light straw or pink color are considered white Corn. See also Corn Classes. / Белозерная Кукуруза – Кукуруза с белым цветом зерна, которая содержит не более 2.0% Кукурузы другого цвета. Белые зёрна Кукурузы с незначительным светло-соломенным или розовым оттенком относятся к белозёрной Кукурузе. Смотрите также Классы Кукурузы (Corn Classes). Белозёрная Кукуруза является уникальным средством, действие которого направлено на снижение уровня сахара в крови больного человека. При переработке и создании, таким образом, крупы, в кочанах происходит повышение уровня амилозы. Поэтому каша при сахарном диабете является очень полезным продуктом. Кукуруза обладает очень низким гликемическим индексом, поэтому при попадании её в кровяной поток, происходит замедление процесса направления глюкозы. Употребление варёной Кукурузы при сахарном диабете 2 типа приводит в тонус весь организм. Благодаря большому количеству полезных компонентов, содержащихся в Кукурузе, организм наполняется витаминами, вследствие чего у человека на протяжении долгого времени отсутствует аппетит.

WHITE CORPUSCLE = БЕЛОЕ ТЕЛЬЦЕ (или БЕЛАЯ ЧАСТИЦА) – White Corpuscle:- blood cells that engulf and digest bacteria and fungi; an important part of the body's defense system. Synonyms:- Leucocyte, Leukocyte, White Blood Cell (WBC), White Blood Corpuscle, and White Cell. See also Leukocytes. / Белая Частица:- .

WHITE CREASES = БЕЛЫЕ ЗАСЕЧКИ (или БЕЛЫЕ ЗАЛОМЫ, или БЕЛЫЕ СГИБЫ, или БЕЛЫЕ НАЖИМЫ ВАЛЬЯНОМ) – White Creases:- shining due to mechanical friction on the fabric, it known as White Creases. It is visible as a long line. Dyeing defect. / Порок или дефект крашения. Под Заломом понимается местный порок в виде неустранимых следов складок. Размер порока – по всему куску.

WHITE ELEPHANT = БЕЛЫЙ СЛОН – White Elephant is a business or investment that is unprofitable and is likely to remain unprofitable. In the case of a business, a business usually becomes known as a White Elephant if it is unable to turn a profit because it is so expensive to operate and maintain. Very few people are interested in owning or purchasing something considered to be a white elephant. The term is derived from a traditional Asian practice of a monarch owning a white elephant; the elephant was considered sacred, but it was very costly and impractical to own. / Белый Слон:- собственность, которую настолько накладно содержать, что практически невозможно её использовать и получать доход; также собственность, в отношении которой убыток несомненен.

WHITE FLOWER = БЕЛЫЙ ЦВЕТОК – White Flower:- A Cotton flower with white petals which occurs on the day of anthesis (pollination). On the day prior to anthesis, the unopened flower is referred to as a candle and on the day following anthesis, the flower petals turn pink then red.

WHITEFLY = БЕЛОКРЫЛКА – Whitefly is any sap-sucking member of the Insect Family Aleyrodidae (Order Homoptera). The nymphs, resembling scale insects, are flat, oval, and usually covered with a cottony substance; the adults, 2–3 mm (0.08–0.12 inch) long, are covered with a white opaque powder and resemble tiny moths. The four wings develop within the insect and evert during the last molt. These pests are abundant in warm climates and are found on houseplants and in greenhouses. The Citrus Whitefly (Dialeurodes Citri) is economically important, sucking sap from orange and date trees and producing honeydew, a sweet by-product of digestion, upon which a sooty fungus grows that ruins the fruit. Control is by oil or parathion sprays. The Citrus Blackfly (Aleurocanthus Woglumi) is well-established in Mexico and the West Indies. A sooty Fungus that grows on the honeydew excreted by the Citrus Blackfly reduces the host plant's ability to photosynthesize. The Greenhouse Whitefly (Trialeurodes Vaporariorum) is one of the most abundant and destructive members of the Family. It damages plants by reducing vigour and causing them to wilt, turn yellow, and die. Sprays that kill both adult and larval stages are necessary to control this Pest. Whitefly is a small, white-winged insect with piercing-sucking mouthparts; damages Cotton both directly via its sap-feeding and indirectly via voiding honeydew, resulting in 'Sticky Cotton', a ginning and milling problem. Like Aphids, Whiteflies are members of the Homopteran Order. And like their cousins, are widely distributed Pests. With several Species being problematic in greenhouse crops. Whiteflies attack a huge assortment of vegetable, herb and floral crops, causing, perhaps, millions in damage every year across the United States. Fortunately, they are one of the easiest

Pests to detect and identify-at least in the cursory sense. Further identification is rather important if you're planning to prevent Whiteflies (highly recommended) or deal with them while still in small numbers. How They Become A Problem:- as things begin to warm up in the spring – or much earlier in greenhouses – Whiteflies can show up. Normally, to observant growers, a flitting white insect or two may be seen in or around the crop. If this is your situation, you should act immediately, especially if you haven't already initiated your control program. If your initiative is biological-based, you'll need to know the identification of your Whitefly, at least at the Genus level. There are a small handful of Whiteflies which infest greenhouse crops, of which are three Species from two Genera which are usually the troublemakers (more on this in a bit). If you're just starting out and this is your first time dealing with whiteflies, or if you don't have historical records or experience to rely upon, you'll either need to get some help or to spend a little more money so that all your bases are covered. Since the three Species can be a problem just about anywhere in the country, one of the best ways you can at least get an edge on which Species are most prevalent in your locality is through your university's cooperative extension. They should be able to clue you in-at least to give your odds better than 50/50. Once you've determined your area's typical whitefly species, this is the species you'll usually have in the future-unless you start bringing in plant material from new sources. Often Whiteflies come in on purchased plant material. When that's not the case, though, they usually come in from outdoors or from their winter hiding places. The female Whitefly, upon entering the facility, will typically lay her eggs on a desirable plant located very close to the opening in which she came. This might be, as an example, in close proximity to fans, vents, etc. She'll lay a circular pattern of eggs on the underside of newer leaves located in the upper portions of the plants. The eggs are white, but darken as they get closer to hatching. When the eggs hatch, the subsequent larvae move a short distance then set up shop, feeding and growing in size as they edge closer to maturity. Like thrips, Whiteflies undergo a somewhat mixed metamorphosis-somewhere between complete and incomplete. Their larval and pupal stages are very similar in appearance – they all look like little scales. From the pupae, new whitefly adults emerge to mate and repeat the cycle spreading the problem throughout the crop. As this process continues, the stages or instars seem to be found lower on the plants. The Whitefly immatures do not move, but the plants continue to put forth new growth thus putting these pests on a sort of time-line. Top of plants:- eggs and adults. Middle sections:- larvae. Bottom sections of plants:- pupae and new adults (which fly outward and upward seeking a mate and new place to lay eggs). This information can help you in determining the age of the infestation, the seriousness of the problem, and where to look for the pupae for identification purposes. A Seriuos Pest:- the Whitefly pupal stage is the easiest stage in which one can most accurately identify Whiteflies. Identification is very important. Here's why:- one of the parasitoids available for control, Encarsia Formosa, prefers greenhouse Whitefly, Trialeurodes Vaporariorum, and it may take several generations before acclimating to a different Genus. Another popular parasitoid, Eretmocerus Eremicus, prefers the B-Whitefly Species; 'B' for the Bemisia Spp. Bemisia Argentifolii, or the Silverleaf Whitefly is one, and B. Tabaci, or the Sweet Potato Whitefly is the other. Like Encarsia Formosa, Encarsia Eremicus may take several generations before acclimating to a different Genus. This is why knowing which Genus of Whitefly you have is so important. Choosing wrong can cost you valuable time. And all are found in greenhouses so there are no clues there. If your plan is to prevent Whiteflies before they show up, you'll need to know which type you'll likely encounter. Otherwise you'll end up releasing both parasitoids as insurance, and that can be cost prohibitive. Greenhouse Whitefly pupae are off-white and coin-like. There is a distinct vertical surface, as viewed from the side, along the pupa's side. The uppermost half will normally be fringed with long, Einstein-like waxy 'hairs'. The Bemisia Spp., on the other hand, lack that vertical surface and will be more dome-like. Moreover, they too have 'hairs' but their's are shorter and more sparse. In both cases, the pupal casings remain after the adult's emergence and can also be used for cursory identification purposes. The larval forms share these characteristic but are less defined. The adults, too, are distinguishable for identification purposes, by the way they hold their wings and other vague factors, but are not as unique as the pupae and tend to be a less reliable source of information. The adults from both Genera, as their name suggests, are white and fly. The whiteness, though, is actually a powdery, waxy bloom or coating. Underneath, these flies are actually yellow to orange. This may be detectable when the Whiteflies are caught in sticky traps as the goop on the traps breaks down their waxy coating. Now with all this apparent whiteness, what with all the adult and immature stages, they may in some cases, not even be Whiteflies. Aphid castings or old molted aphid skins are sometimes figured for whiteflies when in fact they are not. Flight is the difference. If there are fliers, they are probably Whiteflies. Some Advice:- Whiteflies, if not defeated early in the game, before damaged parts can be auto-corrected and outgrown by the continued development of the plants, can cause considerable economical damage to an otherwise salable crop. They feed by sucking plant sap or juices. This feeding activity will normally cause leaf spotting and yellowing or interveinal chlorosis. Moreover, it can aid the transmission of various plant diseases. Both of which can affect the plant's appearance and value and may even, if left unchecked, kill the plant. Other problems associated with their presence may be the build up of sticky honeydew which can spur the development of an ugly black-sooty mold and may, if in great quantity, negatively affect the growth of the plants. The stickiness of the honeydew can attract dirt and debris and lower the overall value of the crop. The honeydew, or Whitefly feces, may also attract ants. This can be a real problem as ants often protect Whitefly immatures from predators and parasitoids. A Whitefly infestation, though, should never get to the point where copious amounts of honeydew can accumulate and cause these problems. These Pests are easy to detect and growers should never be surprised by them. For The Scout:- if you're not in a position to prevent Whiteflies from calling your facility home by preventing them with prophylactic releases of the appropriate parasitoid Species, do detect them when their numbers are still low. This is done by scouting. Yellow sticky traps are useful for this purpose. But be careful once you begin making releases of parasitoids; remove or limit your use of these traps as they tend to lure these biocontrol agents to their capture. Black and yellow Encarsia Formosa may be seen, but Encarsia Eremicus are all yellow and tend to disappear on the yellow traps. Simple plant inspections and looking out for flying adults is probably safer. Using indicator plants, eggplant being one example, can really give you a place to focus as Whiteflies will normally visit them first. This, of course depends upon what your cash crop is – which can be even more alluring. The indicator plants can also be a place to release parasitoids if also using them as a trap-crop. Some Solutions:- if numbers begin to climb, using a vacuum cleaner to suck up the adults which fly when plants are disturbed can be a sound strategy. Moreover, other biocontrols, better suited than the parasitoids for taking down larger numbers, may be used in concert with the wasps. One example is Delphastus Pusillus, a little, black whitefly-predatory Beetle. But prevention and scouting is the key. Screening can be used to prevent Whiteflies from establishing, too. Especially if you don't know which Species you'll have. Whiteflies are small, winged Insects that feed exclusively on leaves, and are especially destructive to Cotton, citrus, and greenhouse plants. Whiteflies are closely related to Aphids, Mealybugs and Scale, all of which feed by sucking sap from plants. Whiteflies can be found on the undersides of leaves and are active during the daytime when the temperature is warm. When a heavily infested plant is disturbed, white clouds of winged adults fly into the air. Some Species of Whiteflies can become serious Pests of certain vegetable crops, greenhouse plants or ornamental plants. Two of the most important Species are the greenhouse Whitefly, Trialeurodes Vaporariorum, and the Sweet Potato Whitefly, Bemisia Tabaci. In colder climates, Whiteflies die outdoors, but in warmer climates, as well as indoors and in greenhouses, they can reproduce throughout the year with several overlapping generations. Biology:- adult whiteflies are about 1/10 to 1/16 inch long and look like tiny moths. They have four broad, delicate wings that are held rooflike over the body and covered with a white powdery wax. Adult females usually lay between 200 and 400 eggs. Sometimes the eggs are deposited in a circular pattern in groups of 30 to 40 because the female will often keep her mouthparts in the plant to feed while moving her abdomen in a circle. Within about a week, the eggs hatch into flattened nymphs, called Crawlers, that wander about the plant. Soon, they insert their mouthparts into the plant and begin to feed. After their first molt, the nymphs lose their legs and antennae. They attach

themselves to the undersides of leaves with several waxlike rods coming from their bodies, giving them the appearance of small white oval scale. The nymphs remain fixed to the plant and feed for about four weeks. After a pupa stage, the adults emerge and live for about one month. Within a population, all life stages are present, and generations often overlap. Damage:- Whiteflies damage plants by sucking out plant juices. Because large amounts of sap can be removed, primarily by the developing nymphs, heavily infested plants can be seriously weakened and grow poorly. Leaves often turn yellow, appear dry and drop prematurely. Also, Whiteflies suck out more plant juice than they can digest, and they excrete the excess as a sweet, sticky substance called Honeydew. The honeydew covers leaf surfaces and acts as a growth medium for a black, sooty mold. Both the removal of plant juices and the presence of the black, sooty mold growing on the honeydew can interfere with photosynthesis. In some parts of the country, some species of whitefly can transmit several plant viruses. Control:- (i) Cultural Control:- ornamental plants in or around the home and plants in greenhouses or gardens often become infested with whiteflies through the introduction of infested plants. A slight infestation from one plant can quickly spread to other plants. Inspect all new plants thoroughly, and isolate them for a few days before placing them among established plants. During this isolation period, inspect the plants and treat those infested. Inspect plants regularly, and remove by hand older leaves that are heavily infested with whiteflies in the nonmobile nymphal and pupal stages. (ii) Biological Control:- Whiteflies have many natural enemies in the garden setting, such as spiders, lady beetles and lacewings. However, frequent or widespread use of insecticides to control other garden pests prevents these predators from effectively controlling whitefly populations. The tiny parasitoid Encarsia Formosa has been used successfully in managing whitefly populations in greenhouses and conservatories for many years. However, in an outdoor setting where favorable temperature and light conditions cannot be maintained, use of Encarsia Formosa is limited. Encarsia Formosa is available from commercial suppliers. (iii) Mechanical Control:- the use of traps can be very helpful in controlling light infestations of whiteflies in greenhouses. You can make a trap from a 12-by-6-inch strip of cardboard or strong poster board. Paint both sides bright yellow and coat with a sticky substance, such as Tanglefoot, petroleum jelly, petroleum jelly/mineral oil mix, mineral oil or a heavy-grade motor oil (SAE 90). Hang the trap vertically or support it on stakes just above the plants. The adults are attracted to the yellow color and become trapped on the sticky substance. Whitefly traps are available commercially also. The use of yellow traps outside may have limited value because of the large number of traps required. One trap for every two large vegetable plants is recommended. Clean the traps periodically to remove insects and other debris, and apply fresh adhesive to the yellow surface. To avoid trapping too many of the Whitefly's natural enemies, use traps when Whiteflies first start to appear, but remove them when the whitefly population seems to be decreasing. Another mechanical technique that can help control Whiteflies is to vacuum them with a small, hand-held vacuum cleaner. Vacuum the adult whiteflies in the early morning when the temperature is cool and they are slow-moving. Put the vacuum bag containing the Insects (not the vacuum cleaner itself) inside a large plastic bag and freeze for 24 hours to kill the insects. Vacuuming adults is most helpful and effective when an infestation is just starting and when the adults have not laid many eggs. (iv) Chemical Control:- in many cases, controlling Whiteflies with insecticides has been difficult because they have developed resistance to some chemicals. Because of this resistance, a certain product may work well in one area but not in another. Resistance may be delayed by alternating the types of chemicals used. In addition, the eggs and nonfeeding pupae are generally not as susceptible to insecticides as are the nymphs and adults. Consequently, eradication of a Whitefly population usually requires four to five applications of a registered insecticide at five- to seven-day intervals. Be sure the applications are made to the lower leaf surface. Apply the insecticide as soon as whiteflies are detected; do not wait until populations become severe. Over-the-counter insecticides commonly used for whitefly control include neem oil, insecticidal soap, horticultural oil, pyrethrins, permethrin, imidacloprid and malathion. Before you use any insecticide for Whitefly control, make sure that both the site and the target plant are listed on the label. Follow label directions carefully. Whitefly is any of several plant-sucking, homopterous Insects of the Family Aleyrodidae, having the body and wings dusted with a white, powdery wax, and being widely distributed chiefly in tropical regions where they are often serious crop Pests, as Dialeurodes Citri (Citrus Whitefly) commonly occurring on citrus trees, and Trialeurodes Vaporariorum (Greenhouse Whitefly) inhabiting greenhouses. Whitefilies (Aleurothrix) are sucking Insects, related to Aphids and Scales, that feed on plant sap. The adults are small (approximately 1/16 inch (1.5 mm long), with a fine white powdery wax over their four white wings and body. Both the adults and immature whiteflies are found on the undersides of leaves. In sufficient numbers, whiteflies will weaken and eventually kill this host plant. Whiteflies can reproduce rapidly in the enclosed area of a greenhouse and make c cloud of white when disturbed. Life Cycle:- female whiteflies lay eggs on the undersides of a plant's upper leaves. Following an incubation period of four to 12 days, those eggs hatch out into crawling nymphs. The nymphs commence feeding by piercing the leaf cells and sucking the plant's sap. Within approximately six weeks, depending on temperature, the nymphs grow, molt and reach their four-winged adult stage. The adults live for one to two months. Symptoms:- among the many possible causes of an orchid's failure to thrive, whitefly is a significant consideration. Although they are quite small and not necessarily immediately obvious, they can eventually kill a plant if left unchecked. Signs of whitefly on orchids include weakened plants, damaged or unhealthy new growth, yellow mottled leaves that eventually drop, the presence of sooty mold or ants and, most especially, a cloud of tiny white insects arising from an affected plant when it is moved or disturbed. Because the whitefly larvae feed on the plants' sap, plant vigor is severely impacted. The honeydew (a sugary liquid) excreted by the larvae encourages growth of sooty mold, is unsightly and reduces the light available to the plant for photosynthesis, thus further weakening it. Ants are also attracted to this honeydew and will farm whitefly in much the same manner as they farm aphids. Control:- a clean greenhouse or growing area will help to minimize potential insect pest problem. A minimum of two weeks' quarantining any new plant or cutting that enters the growing area can also help curtail the introduction of new pests and diseases. According to the University of Connecticut's Integrated Pest Management department, certain nonorchid plants make excellent host plants for whitefly. Among these are astilbe, chenille plant, columbine, chrysanthemum, dicentra, flowering maple, gerbera daisy, glory bower, hibiscus, lavender, lantana, malva, monarda, mints, Martha Washington geranium, primula, salvia, scaevola, tomato, rosemary (and many other herbs), verbena and zinnia. To eliminate a Whitefly problem, it may be necessary to remove these other favored hosts from the growing area. For the overall health of an orchid collection, it is a good idea to check each plant (for smaller collections) or spot-check plants or groups of plants (in a larger collection) and the growing area at least once a week for signs of anything unusual – Pests, disease, environmental damage, etc. In this way, an invading insect can be detected and treated before it becomes an infestation. For Whiteflies and some other flying Insect Pests, yellow sticky cards are a useful part of that monitoring program. The insects are drawn to the color of the card and become adhered to its sticky coating. The cards can be placed among plants, and, in a greenhouse, should also be placed near doors and vents. Whether purchased or homemade, these simple insect traps can provide early warning of new Pests in the growing area. Treatment Options:- several natural enemies including predators, parasitoids and Insect pathogens are commercially available for use in controlling whitefly populations. Many greenhouse supply companies sell helpful Insects (insect predators and parasitize Pest Insects. Those that are useful for treating whitefly include ladybugs, praying mantids, assassin bugs and parasitic wasps. They are not usually a cure for the infestation, but instead reduce the whitefly population to the point where it is no longer a significant threat to your plants. These helpful Insects are best used in a greenhouse or enclosed structure. Encarsia Formosa and Eremocerus Sp. are small parasitic wasps that attack Whiteflies. The adult wasp lays its eggs in whitefly nymph. The parasitized larvae then die. Caution must be exercised when using parasitic wasps, as they may be sensitive to pesticide residues on plants or in the greenhouse, and the adult wasps may be attracted to yellow sticky cards. Plan in advance so that insecticides with a long residual effect are not used before the wasps are released. Insecticidal soaps, horticultural oils and many insect growth regulators

are more compatible with the use of parasitic wasps than other stronger insecticides. A common fungus can also be employed as a control for Whitefly. Beauvaria Bassiania is available commercially as Naturalis O and Botanigard from garden and greenhouse supply firms. The fungal spores penetrate the Insect's cuticle. Toxins produced by the Fungus as it grows within the Insect weaken the Whitefly's immune system, eventually killing it. Spray the growing area thoroughly when using this pathogen, as it must actually contact the Insect to work. Do not use any fungicides concurrently in the growing area, or even use a sprayer that has been used previously for fungicides, as this can severely reduce the effectiveness of the treatment. Like Aphids, whiteflies excrete honeydew that attracts Ants, and as with Aphids, ants will 'farm' Whitefly to obtain this food. If ants are present, it is necessary to eliminate their population as well to eradicate the Whiteflies. One method of ant control is to mix syrup of boric acid powder, sugar and water, and place small containers of it throughout the growing area. The sugar draws the Ants just like honeydew. They will eat the poison and take it back to the queen. This should remove the ant colony within a few days. Another option is Orange Guard, a 100 percent biodegradable and water-soluble insecticide made from oranges that is considered safe for use around humans, pets and food, and is effective against ants. Systemic insecticides (those that enter the plant cells and affect insects that consume any part of that plant) registered for use on orchids and deemed effective against whitefly include Diazinon, Malathion and Pyrethins. Some of the topical remedies labeled for use against whitefly and safe for orchids are Spectracide Houseplant and Garden Insect Spray 1 and Safer Insecticidal Soap. Enstar II Insect Growth Regulator may also be used against whitefly. It employs excess juvenile-growth hormones to cause sterile eggs in adult whiteflies and incomplete development of immature-growth stages. An added benefit in using Enstar is that insects do not develop a resistance to this treatment. It is also considered safe around humans and pets. As always, use of any insecticide should be in strict compliance with the manufacturer's recommended dosages and safety precautions. In the spring, be especially observant for whiteflies that can injure the health of your orchids. / Под Белокрылковыми или Алейродидовыми понимается Подотряд Насекомых Отряда Равнокрылых. Длиной обычно 1–2 миллиметра (мм). Свыше 200 видов, преимущественно в тропиках. В бывшем Союзе Советских Социалистических Республик (СССР) насчитывалось около 25 Видов. Особенно вредны личинки Тепличной, Цитрусовой и Земляничной Белокрылок. Белокрылки или Алейродиды (Aleyrodinea) Подотряд Насекомых Отряда Равнокрылых. Размеры мелкие (длина 1.3–1.8 мм), взрослые особи напоминают крошечных молей. К наиболее распространённым в бывшем СССР вредным Белокрылкам относились Тепличная, Цитрусовая и Земляничная. Тепличная или Оранжерейная Белокрылка (Trialeyrodes Vaporariorum) встречается в теплицах и оранжереях, повреждает Томат (особенно сильно), Огурец, некоторые цветочные растения – Бегонию, Фуксию и другие. Вредят личинки, питающиеся соками листьев и выделяющие липкие сахаристые вещества, на которых поселяются сажистые грибы ('чернь'). Листья буреют, засыхают, плоды опадают. Белокрылки способны быстро размножаться, давая через каждые 25–40 минут новые поколения. Меры борьбы:- повторные (2–3-кратные) с 3–5 дневными промежутками опрыскивания метилэтилтиофосом или окуривание сернистым газом для послеуборочного обеззараживания теплиц; исключение совместного выращивания в теплицах цветочных и овощных растений. Цитрусовая Белокрылка (Dialeyrodes Citri) – карантинный вредитель Лимонов и Апельсинов. Распространена в Индии, Китае, Северной и Южной Америке и в Японии. В бывшем СССР впервые обнаружена в 1957 в районе Батуми. Развивается в 3–4 поколениях. Расселяется при помощи ветра, может быть перенесена с посадочным материалом. Меры борьбы:- опрыскивание растений (до начала вегетации и перед окрашиванием плодов) эмульсией минерального масла с тиофосом или метилэтилтиофосом; биологический метод – эффективен Наездник из Рода Encarsia. Земляничная Белокрылка (Aleyrodes Fragariae) встречается в открытом грунте на садовой и лесной Землянике, а также на некоторых дикорастущих растениях Семейства Розовых, например, Малине. В условиях центральной части Нечернозёмной Зоны развивается в 3–4 поколениях. Меры борьбы:- опрыскивание заражённых участков тиофосом. Алейродиды (Aleyrodinea) или Белокрылки, Подотряд Насекомых Отряда Равнокрылых (Homoptefa). Обычно мелкие (1–2 миллиметра (мм)) Насекомые с жёлтым или красноватым телом, часто с тёмными пятнами. Две пары почти одинаковых крыльев покрыты белым пылевидным налётом, в покое складываются кровлеобразно. Алейродиды сосут соки растений; держатся обычно на нижней поверхности листьев. Здесь же откладывают яйца. Личинки первого возраста подвижны, последующих – неподвижны. Более 200 Видов. Большинство Алейродидов – обитатели тропиков. В бывшем СССР – около 30 Видов. Особенно вредны личинки Тепличной, Цитрусовой и Земляничной Белокрылки. Тепличная, или Оранжерейная, Белокрылка (Trialeurodes Vaporariorum) распространена в теплицах и оранжереях. Повреждает Томаты (особенно сильно), Огурцы и некоторые цветочные растения. Через каждые 25–40 дней даёт новое поколение. Обильно заселяет листья верхних ярусов растений, высасывая из них соки. Листья буреют и засыхают, плоды опадают. Цитрусовая Белокрылка (Dialeurodes Citri) распространена в Японии, Индии, Китае, Северной и Южной Америке; в бывшем СССР – на Черноморском побережье Кавказа. Карантинный вредитель Цитрусовых. Развивается в 3–4 поколениях, расселяется с ветром, посадочным материалом. Земляничная Белокрылка (Aleurodes Fragariae) встречается в Европе. Повреждает садовую и лесную Землянику. Развивается в 3–4 поколениях. Меры борьбы с Белокрылками:- опрыскивание растений инсектицидами; обеззараживание теплиц и оранжерей; против Цитрусовой Белокрылки использование паразитов – Гриба Aschersonia и Наездника Encarsia Formosa.

WHITE GLUTINOUS RICE = БЕЛЫЙ ГЛЮТИНОЗНЫЙ РИС – White Glutinous Rice means Rice that is obtained by removing bran from cargo glutinous Rice. See also White Rice. Thai White Glutinous Rice or White Sweet Rice is a kind of Rice that's planted in Asia. The Rice has sticky characteristic so it is called Sticky Rice by local people. Glutinous Rice is widely consumed in Thai Northern and North Eastern region and also in many other countries near Thailand. The product from Glutinous Rice such as sweet Rice flour is widely used an ingredient in many recipes in the food industries. / Клейкий (Глютинозный) Рис (Oryza Sativa L) в отличие от обычного Риса разваривается в клейкую массу в связи с высоким содержанием амилопектина и применяется в лечебном, диетическом и детском питании. Благодаря особым качествам и полезным свойствам популярность глютинозного Риса растёт во всём мире. Несмотря на то, что в странах Азии глютинозный Рис возделывается уже давно, в Казахстане селекция глютинозных сортов до недавнего времени не проводилась, также на Казахстанском рынке полностью отсутствуют глютинозные сорта Риса. Для продовольственной безопасности страны необходимо создание собственных глютинозных сортов Риса адаптированных к местным условиям возделывания. Поэтому получение исходных форм и линий для создания отечественного глютинозного сорта Риса является своевременной и актуальной проблемой. В настоящее время в селекции Риса широко используют биотехнологические методы, позволяющие повысить результативность селекционного процесса. Одним из них является метод культуры изолированных пыльников и микроспор, которая позволяет получить стабильное растение за одно поколение.

WHITE GOLD = БЕЛОЕ ЗОЛОТО – White Gold is a gold alloy containing whitening agents such as silver, palladium or nickel as well as other base metals. Often used as a setting for diamond jewellery. White Gold is a popular alternative to yellow gold, silver or platinum. Some people prefer the silver color of white gold to the yellow color of normal gold, yet may find silver to be too soft or too easily tarnished or the cost of platinum to be prohibitive. While white gold contains varying amounts of gold, which is always yellow, it also contains one or more white metals to lighten its color and add strength and durability. The most common white metals that form the white gold alloy are nickel, palladium, platinum and manganese. Sometimes copper, zinc or silver are added. The purity of white gold is expressed in karats, the same as with yellow gold. The Color of White Gold:- the properties of white gold, including its color,

depend on its composition. Although most people think white gold is a shiny white metal, that color is actually from the rhodium metal plating that is applied to all white gold jewelry. Without the rhodium coating, white gold might be gray, dull brown, or even pale pink. Allergies to White Gold:- white gold jewelry typically is made from a gold-palladium-silver alloy or gold-nickel-copper-zinc alloy. However, about one in eight people experiences a reaction to the nickel-containing alloy, usually in the form of a skin rash. Most European jewelry manufacturers and some American jewelry manufacturers avoid nickel white gold, since alloys made without nickel are less allergenic. The nickel alloy is most often encountered in older white gold jewelry and in some rings and pins, where the nickel produces a white gold that is strong enough to stand up to the wear and tear these pieces of jewelry experience. What is the usual karat value of white gold? It varies, but 14k and 10k white gold are common. You can find 18k too. If it's less than 10k, it can't be labeled as gold. Is white gold durable? Can you bath, wash, or wok wearing it? Yes, stay away from nitric acid. / Белое Золото – это такой же золотой сплав, только лигатура в нём особая. Это либо палладий, либо никель. Это и придаёт сплаву белый оттенок. Если лигатура с палладием, то сплав имеет бело-стальной оттенок, если с никелем, то чуть, чуть, едва уловимо желтоватый, а если это родиевое покрытие, то изделие отдаёт холодной голубизной.

WHITE GOODS = БЕЛЫЕ ТОВАРЫ – (1) White Goods:- heavy consumer durables such as air conditioners, refrigerators, stoves, etc, which used to be painted only in white enamel finish. Despite their availability in varied colors now, they are still called White Goods. See also Brown Goods. / Белые Товары – класс потребительских товаров длительного пользования, объединяющий стиральные и посудомоечные машины, холодильники, сушилки, морозильные камеры, плиты и печи для приготовления пищи. Название Белые эти товары получили в связи с тем, что они обычно покрыты белой эмалью, хотя в настоящее время, для того чтобы сделать их более незаметными в современной кухонной обстановке, их красят в коричневый и другие цвета. Сравните с Коричневыми Товарами (Brown Goods).

(2) White Goods is a very broad term which implies any goods bleached and finished in the white condition. Some of the cotton white goods are muslin, cambric, dimity, lawn, longcloth, organdy, voile, etc.

WHITEHEAD = БЕЛАЯ МЕТЁЛКА (или ОФИОБОЛЁЗ) – Whitehead:- white, empty panicles resulting from the attack of stem borers that cut the lower portion of the stem. Whitehead can also be caused by drought, dry wind, or desiccation.

WHITE KNIGHT = БЕЛЫЙ РЫЦАРЬ – A White Knight is a bidder who makes an agreed takeover bid as an alternative to a hostile takeover bid that is already in progress. There are a number of reasons why the directors of the target company may prefer the white knight. It may be that the white knight offers a better deal for shareholders. It may also be that the white knight offers a better deal to the directors. While directors have a legal duty to make recommendations on the basis of shareholder's interests, there are often clear conflicts of interest when takeovers occur. See also Hostile Takeover Bid. White Knight is friendly acquirer sought by the target of an unfriendly Takeover. White Knight is a friendly potential acquirer sought out by a target firm that is threatened by a less welcome suitor. White Knight is an entity that comes to the rescue of a corporation that is being taken over. White Knight is a friendly bidder who rides tp rescue a firm from a hostile bid. See also Raider. / Белый Рыцарь:- лицо или фирма, которые делают компании желательное предложение о поглощении (takeover bid) на более выгодных условиях вместо неприемлемого и нежелательного предложения, поступившего от так называемого Чёрного Рыцаря (Black Knight). Если компания стала целью поглощения какой-либо нежелательной фирмой или же её не удовлетворяют условия сделанного предложения о поглощении, она часто пытается найти более подходящего владельца – так называемого Белого Рыцаря – в надежде получить от него более привлекательное предложение. Сравните с Серым Рыцарем (Grey Knight). Белый Рыцарь:- иное предложение на более выгодных условиях, которое появляется с целью стимулировать успешное поглощение компании другой компанией. Смотрите также Белый Сквайр (White Squire), и Серый Рыцарь (Gray Knight). Белый Рыцарь – дружественная компания-покупатель. Дружественная компания-покупатель, которую стремится привлечь компания, являющаяся мишенью поглощения враждебно настроенной компанией.

WHITE LIST = БЕЛЫЙ СПИСОК – In a card-based system, White List is a database containing the list of all authorized card numbers. / В системе на основе карт Белый Список – база данных, содержащая перечень всех авторизованных номеров карт.

WHITEMAIL = БЕЛАЯ КОЛЬЧУГА (или БЕЛАЯ ПОЧТА) – Whitemail:- sale of a large amount of stock by a company that is the target of a takeover bid to a friendly party at below-market prices, so that the raider is forced to buy more of highly priced shares to accomplish the takeover. Whitemail is a strategy that a takeover target uses to try and thwart an undesired takeover attempt. The target firm issues a large amount of shares at below-market prices, which the acquiring company will then have to purchase if it wishes to complete the takeover. If the whitemail strategy is successful in discouraging the takeover, then the company can either buy back the issued shares or leave them outstanding. Whitemail is the anti-takeover device whereby a vulnerable company sells a large amount of stock to a friendly party at below-market prices. This puts a potential raider in a position where it must buy a sizable amount of stock at inflated prices to get control and thus helps perpetuate existing management. Whitemail is an anti-greenmail provision whereby a publicly-traded company sells a significant portion of its stock to a friendly company, usually at a discount to its market value. Greenmail is a practice in which a corporate raider buys stock directly from shareholders with no intention to actually take over the company, but instead wishes to force the company to buy back its own shares at a significant premium. When the target company engages in whitemail, it sells its shares to the friendly company in the belief or assurance that the friendly company will sell to the corporate raider only at a significant premium. Whitemail makes the greenmail more expensive for the corporate raider, who may then be forced to abandon the attempt. / Буквально Белая Кольчуга (whitemail) – механизм, разработанный против поглощений (takeover), при котором уязвимая компания продаёт большое число своих акций дружественной компании по цене ниже рыночной. Это ставит потенциального рэйдера в положение, когда он должен будет купить примерно такое же число акций, но по вздутой цене, чтобы захватить контроль над компанией. Этот метод помогает нынешнему руководству компании сохранять своё положение.

WHITE MEAT = БЕЛОЕ МЯСО – White Meat:- generally, poultry and seafood. These meats are much paler in color than red meats. However, pork and veal are more white than red, and often are classified as whitemeats. See also Red Meat.

WHITE MOLD DISEASE = ЗАБОЛЕВАНИЕ БЕЛАЯ ПЛЕСЕНЬ – White Mold Disease:- the common name that is used to refer to a plant disease which is caused under certain conditions (e.g., moist, humid, etc) by the Sclerotinia Sclerotiorum. / Заболевание Белая Плесень – заболевание растений, вызываемое Грибом Sclerotinia Sclerotiorum.

WHITENESS = БЕЛИЗНА – (1) Whiteness:- attribute of color perception by which an object color is judged to approach the preferred white.

(2) Whiteness of Rice:- measured with a Kett Whiteness Meter Model C-3 (Malaysia; IRRI (short for the International Rice Research Institute headquartered in Los Baños, Philippines))), C-300 (Thailand), or C-100 (Indonesia) using light reflected by the surface of the Rice grain. Use pure white MgO powder as basis (100%) or barium oxide standard (87%). Whiteness is also measured with a Minolta Chromameter Model CR-110 on L*a*b* mode, where L* is a measure of whiteness; a*, a measure or redness; and b*, a measure of

yellowness (IRRI). Visual score (Bangladesh). Whiteness is a combination of varietal physical characteristics and the degree of milling. In milling, the whitening and polishing greatly affect the whiteness of the grain. During whitening, the silver skin and the bran layer of the brown Rice is removed. Polishing after whitening is carried out to improve the appearance of the white Rice. During polishing some of the bran particles stick to the surface of the Rice which polishes and gives a shinier appearance.

WHITENESS INDEX = ИНДЕКС ПО БЕЛИЗНЕ (или ПОКАЗАТЕЛЬ БЕЛИЗНЫ) – Whiteness Index is a number, computed by a given procedure from colorimetric data that indicates the degree of departure of an object color from a preferred white.

WHITE NOISE = БЕЛЫЙ ШУМ – In signal processing, White Noise is a random signal with a constant power spectral density. The term is used, with this or similar meanings, in many scientific and technical disciplines, including physics, acoustic engineering, telecommunications, statistical forecasting, and many more. White Noise refers to a statistical model for signals and signal sources, rather than to any specific signal. In discrete time, white noise is a discrete signal whose samples are regarded as a sequence of serially uncorrelated random variables with zero mean and finite variance; a single realization of white noise is a random shock. Depending on the context, one may also require that the samples be independent and have the same probability distribution (in other words independent and identically distributed (i.i.d.) is a simplest representative of the white noise). In particular, if each sample has a normal distribution with zero mean, the signal is said to be Gaussian White Noise. The samples of a white noise signal may be sequential in time, or arranged along one or more spatial dimensions. In digital image processing, the pixels of a White Noise Image are typically arranged in a rectangular grid, and are assumed to be independent random variables with uniform probability distribution over some interval. The concept can be defined also for signals spread over more complicated domains, such as a sphere or a torus. An infinite-bandwidth white noise signal is a purely theoretical construction. The bandwidth of white noise is limited in practice by the mechanism of noise generation, by the transmission medium and by finite observation capabilities. Thus, a random signal is considered White Noise if it is observed to have a flat spectrum over the range of frequencies that is relevant to the context. For an audio signal, for example, the relevant range is the band of audible sound frequencies, between 20 and 20 000 Hz. Such a signal is heard as a hissing sound, resembling the /sh/ sound in 'ash'. In music and acoustics, the term White Noise may be used for any signal that has a similar hissing sound. White noise draws its name from white light, although light that appears white generally does not have a flat spectral power density over the visible band. The term White Noise is sometimes used in the context of phylogenetically based statistical methods to refer to a lack of phylogenetic pattern in comparative data. It is sometimes used in non technical contexts, in the metaphoric sense of 'random talk without meaningful contents'. White Noise:- the audio equivalent of Brownian motion. Sounds that are unrelated and sound like a hiss. The video equivalent of white noise is 'snow' in television reception. White Noise is created by a continuum of frequencies equally distributed over the whole hearing range. In healthcare applications, white noise is used to treat hyperacusis, an increased sensitivity to normal environmental sounds, or to camouflage the annoyance caused by tinnitus, a ringing in the ear occurring without any stimulus. White noise is also used to mask background noises in the office, or to aid in sleep. Pink Noise and Brown Noise variations:- although all frequencies are produced in equal intensity, white noise sounds much brighter than what we would expect from a spectrally flat noise. This is due to the nature of our hearing, which doesn't sense all frequencies equally. Therefore, people often prefer to listen to Pink Noise, a noise that boosts the lower frequency range to compensate for the unnatural brightness of white noise, or Brown Noise, a noise that puts even more emphasis on the lower frequencies. When one exactly compensates for the particular sensitive curve of the human hearing, White Noise turns Grey. White Noise:- in music, the effect of the complete range of audible sound-wave frequencies heard simultaneously, analogous to white light, which contains all the frequencies of the light spectrum. The sound of cymbals and snare drums has white-noise characteristics. Electronically synthesized white noise can be filtered so as to produce combinations of frequencies not obtainable on traditional musical instruments; or the white noise itself may be used as an element of music. White noise is aperiodic sound (that is, its wave pattern is not uniform). Its constituent frequencies are of random amplitude and occur at random intervals. / Белый Шум – стационарный шум, спектральные составляющие которого равномерно распределены по всему диапазону задействованных частот. Примерами белого шума являются шум близкого водопада (отдалённый шум водопада – Розовый Шум, так как высокочастотные составляющие звука затухают в воздухе сильнее низкочастотных), или Дробовой Шум на клеммах большого сопротивления, или шум стабилитрона, через который протекает очень малый ток. Название получил от белого света, содержащего электромагнитные волны частот всего видимого диапазона электромагнитного излучения, а также существует много цветов. В природе и технике 'чисто' белый шум (то есть белый шум, имеющий одинаковую спектральную мощность на всех частотах) не встречается (ввиду того, что такой сигнал имел бы бесконечную мощность), однако под категорию белых шумов попадают любые шумы, спектральная плотность которых одинакова (или слабо отличается) в рассматриваемом диапазоне частот.

WHITE–ON–WHITE = БЕЛОЕ–НА–БЕЛОМ – White-On-White:- a fabric in any fiber mixture or blend that has a white woven-in design on a white background. Usually, it is a fabric with a white dobby or Jacquard design on a white ground, common in madras, broadcloth, or nylon. See also Madras. White-On-White:- some fabrics, such as men's shirtings or broadcloth, poplin, madras, etc, are made on a dobby or Jacquard loom so the white motifs will appear on a white background. / Жакяр (Jacquard). Найлан[T3] (Nylon[TM]).

WHITE PAPER = БЕЛАЯ БУМАГА – A White Paper is an authoritative report or guide helping readers to understand an issue, solve a problem, or make a decision. White papers are used in two main spheres:- government and B2B marketing. White papers originated in governments, and many point to the Churchill White Paper of 1922 as the earliest well-known example. White Papers are a '... tool of participatory democracy ... not (an) unalterable policy commitment'. 'White Papers have tried to perform the dual role of presenting firm government policies while at the same time inviting opinions upon them'. In Canada, a white paper 'is considered to be a policy document, approved by Cabinet, tabled in the House of Commons and made available to the general public'. The 'provision of policy information through the use of white and green papers can help to create an awareness of policy issues among parliamentarians and the public and to encourage an exchange of information and analysis. They can also serve as educational techniques'. 'White Papers are used as a means of presenting government policy preferences prior to the introduction of legislation'; as such, the 'publication of a White Paper serves to test the climate of public opinion regarding a controversial policy issue and enables the government to gauge its probable impact'. By contrast, green papers, which are issued much more frequently, are more open ended. Also known as Consultation Documents, green papers may merely propose a strategy to be implemented in the details of other legislation or they may set out proposals on which the government wishes to obtain public views and opinion. White papers published by the European Commission are documents containing proposals for European Union action in a specific area. They sometimes follow a green paper released to launch a public consultation process. Examples of governmental white papers include White Paper on Full Employment, White Paper of 1939, and the 1966 Defence White Paper. Since the early 1990s, the term white paper has been applied to documents used as B2B marketing or sales tools. Far more commercial white papers are now produced for B2B vendors than political white papers for governments. Many B2B white papers argue that one particular technology, product or method is superior for solving a specific business problem. They may also present research findings, list a set of questions or tips about a certain business issue, or highlight a particular product or service from a vendor. B2B white papers are marketing communications documents designed to

promote the products or services from a specific company. As a marketing tool, these papers use selected facts and logical arguments to build a case favorable to the company sponsoring the document. B2B white papers are often used to generate sales leads, establish thought leadership, make a business case, or inform and persuade prospective customers, channel partners, journalists, analysts, or investors. While some list dozens of different types of B2B white papers, there are essentially three main types:- (i) Backgrounder:- describes the technical and/or business benefits of a certain offering from a vendor, either a product, service, or methodology. This type of white paper is best used to supplement a product launch, argue a business case, or support a technical evaluation at the bottom of the sales funnel. (ii) Numbered List:- presents a set of tips, questions, or points about a certain business issue. This type is best used to get attention with new or provocative views, or cast aspersions on competitors, especially by using fear, uncertainty and doubt (FUD). (iii) Problem/Solution:- recommends a new, improved solution to a nagging business problem. This type is best used to generate leads at the top of the sales funnel, build thought leadership, or inform and persuade stakeholders. A numbered list may be combined with either other type, but it is not workable to combine the detailed product information of a backgrounder with the industry-wide perspective of a problem/solution white paper. White Paper is:- (1) in a technological industry, is an informational brief offering an overview of a technology, product, issue, standard, policy, or solution - its importance, use and implementation, and business benefits. White Papers have emerged as the standard way of communicating more in-depth information to business decision-makers in terms of problems solved and markets addressed. (2) A White Paper can be an official government report of an investigation into a public event that received a great deal of publicity and notoriety; it indicates the official government position on a particular public issue. White Papers:- this list contains all White Papers published since 1993 – and some from before then. Белая Бумага была опубликована в 1985 как программа ЕС Завершение Формирования Внутреннего Рынка. В ней были перечислены свыше 300 законодательных предложений и график их принятия. Одобрена главами государств и правительств. Цель заключалась в том, чтобы объединить 12 самостоятельных экономик стран в единый рынок – единую Европу – к 1992. Программа была одобрена главами государств и правительств ЕС; получила конституционное обоснование в Едином Европейском Акте от 1986. К середине 1988 был достигнут прогресс в направлении следующих целей:- отмена пограничного контроля товаров; свобода перемещения и жительства для людей; открытие рынков государственных закупок; разнообразные услуги, включая финансовые и транспортные; либерализация движения капиталов; создание надлежащих условий для промышленной кооперации; упразднение фискальных границ, оказывающих влияние на торговлю внутри ЕС и вне его. Другие области включают второй этап либерализации движения капиталов; государственные закупки; страхование имущества; три мероприятия в сфере прямых налогов с целью улучшить финансовые условия для приграничной торговли; взаимное признание дипломов; телевидение без границ; наземный транспорт; строительные материалы; законы о продовольствии; крупные пакеты акций; вторая банковская директива; сближение косвенных налогов.

WHITE PATCHES = БЕЛЫЕ ЛЯПКИ (или БЕЛЫЕ ПЯТНА) – White Patches on denim fabric. Possible Cause:- localized over bleaching. Chemical spillage could be a cause. This is a major defect. It has left clear visible white patches on the article which can not be made less apparent by any means. Finishing defect.

WHITE RICE = БЕЛЫЙ РИС – White Rice means Rice that is obtained by removing bran from cargo non-glutinous Rice. White Rice, it is also known as Polished Rice, and Total Milled Rice or Fully Milled Rice because most of the outher layer – the husk and the bran layer – are removed from the kernel, through the milling process. See also Brown Rice, and White Glutinous Rice. / Белый Рис, известен также как Полированный Рис или Шлифованный Рис (Polished Rice), и Полностью Обрушеный Рис (Total Milled Rice или Fully Milled Rice). Смотрите также Бурый Рис (Brown Rice). Белый Рис – это Рис, прошедший все стадии шлифовки. Зерна такого Риса имеют гладкую и ровную поверхность, характерный белоснежный цвет и полупрозрачность, однако отдельные

зёрна или их части могут быть непрозрачными, потому что они содержат мельчайшие пузырьки воздуха. Он наиболее распространён и легко узнаваем. Белый Рис может быть длиннозёрным, среднезёрным или круглозёрным. По содержанию витаминов и минералов белый Рис проигрывает коричневому или пропаренному Рису, однако именно он является основным типом Риса, потребляемым во всём мире. Время приготовления такого Риса минимально – 10–15 минут, а готовые блюда из белого Риса обладают превосходными вкусом и внешним видом.

WHITE ROT = БЕЛАЯ (ВОЛОКНИСТАЯ) ГНИЛЬ – Decay attacking both the cellulose and the lignin, producing a generally whitish residue that may be spongy or stringy. White Rot is a decay characterized by degradation of all wood components:- cellulose, hemicelluloses, and lignin. The wood is usually normal color or bleached and retains some fibrous structure. White Rot is fibrous because some cellulose remains intact till very late stages. It is typically less fibrous in hardwoods than in softwoods because of the shorter fibers in hardwoods. It usually turns whitish because of bleaching by oxidation and loss of lignin, which is slightly brown. Color and texture vary among white rots caused by different fungi:- (i) stringy white rot; (ii) spongy white rot; (iii) laminated white rot (separation of annual rings); (iv) mottled white rot; (v) white pocket rot; and (vi) zone lines sometimes present. In some white rots, there is a phenomenon called Selective Delignification. All components are removed, but the relative rate varies. Lignin and hemicelluloses are selectively removed in early stages. This leaves enriched cellulose. This is what happens in the white regions of a mottled rot and in the pockets of a white pocket rot. There is a tremendous amount of interest in using these fungi in industry, because many uses of wood involve removing lignin, e.g., biopulping. In selectively delignified wood there are often pockets of clear, gelatinous remnants of the wood. Armillaria species in particular often cause these gelatinous pockets. This may become colonized by yeast and may contain alcohol. We don't know what role this may play in the legend, but one noted forest pathologist who was trying to have kids ate some Armillaria jelly while on a trip and his wife became pregnant soon after. Incidentally, the delignified wood is quite useful as fodder for ungulates. It can be readily broken down with the aid of microorganisms in their gut. Even in Alaska, I have seen evidence that moose have fed on logs decayed by Ganoderma Applanatum. / (iv) крапчатая белая гниль (mottled white rot). виды (species). Под Белой Гнилью или Белой Волокнистой Гнилью понимается гниение или загнивание. трухлявая, твёрдая, мягкая гниль. Гниль, характеризующаяся пониженной твёрдостью и светло-жёлтым или почти белым цветом и волокнистой структурой. Поражённая древесина часто приобретает пёструю окраску, напоминающую рисунок мрамора, в которой светлые участки бывают отграничены от более тёмных тонкими чёрными извилистыми линиями. При сильном разрушении древесина становится мягкой, легко расщепляется на волокна и крошится. Встречается на лиственных породах. В простонародье именуется Белой Мраморной Гнилью. Синева Древесины – порок древесины в виде местной ненормальной сине-серой или сине-зелёной окраски заболони (наружных молодых слоёв древесины). Синева портит внешний вид древесины и снижает её сопротивляемость ударным нагрузкам. Рак Древесины – порок древесины в виде углубления или вздутия, возникающий на поверхности ствола растущего дерева при поражении его паразитными грибами или бактериями.

WHITES = БЕЛЫЕ ОДЕЖДЫ – Whites:- white clothing.

WHITE SHEETS = БЕЛЫЕ ЛИСТКИ – White Sheets:- a list of prices published by the National Quotation Bureau for market makers in over-the-counter stocks traded in Chicago, Los Angeles, and San Francisco. Metro Data Company's 'White Sheets' reflect markets for securities of lesser-known issuers. These markets are generally characterized by low levels of trading activity and dealer competition. Information concerning these issuers often is not readily available to the marketplace, and few analysts regularly follow their securities. / Белые Листки:- публикуемые Национальным Бюро Котировок (National Quotation Bureau) для маркет-мэйкеров котировки акций внеучётного рынка, обращающихся в Чикаго, Лос Анджелесе и Сан Франциско. Белые Листки:- ежедневный курсовой бюллетень, издаваемый Национальным Бюро Котировок для создателей рынка и информирующий о ценах акций на внеучётном рынке в Чикаго, Лос Анджелесе и Сан Франциско. Сравните с Жёлтыми Листками (Yellow Sheets); и Розовыми Листками (Pink Sheets).

WHITE–SHOE FIRM = ФИРМА В БЕЛОЙ ОБУВИ – White-Shoe Firm is the anachronistic characterization of certain broker-dealers as venerable, 'upper-crust' and 'above' such practices as participating in hostile takeovers. Derives from the 1950s culture of Ivy League colleges, where white buck shoes were de rigueur in elite fraternities and clubs. White-Shoe Firm:- broker-dealer firms that disdain practices such as hostile takeovers. White-Shoe Firm:- the most prestigious firms in professions such as law, investment banking and management consulting. White-shoe firms typically have a blue-chip clientele, acquired over the several decades that they have been in existence. The term is believed to have been derived from the 'white buck' suede oxford shoes that were popular among certain sections of the student population at Yale and other Ivy League colleges during the 1950s. Although the term initially referred to leading US firms such as JP Morgan or Goldman Sachs (banking), Cravath, Swaine & Moore (law) and McKinsey (management consulting), its usage has expanded to denote top-tier firms in most countries. Although white-shoe US firms in relatively stable businesses such as law and management consulting have managed to thrive over the decades, those in the investment banking business have struggled to retain their independence in the face of sweeping change and challenges in recent years. Over the year, a number of white-shoe investment banking firms in the US have been acquired by bigger rivals – thereby becoming victims of their own success – while a few others have gone out of business. / такие как Дьжей.Пи. Моргэн (JP Morgan) или Голдмэн Сэкс (Goldman Sachs) (банковская деятельность), Кровас (Cravath), Свэйн Энд Моо (Swaine & Moore) (право) и МэкКинзи (McKinsey). дё ригёр или строгими или неукоснительными или необходимыми или обязательными или суровыми или точными (de rigueur). Фирма Белые Ботинки:- характеристика определённых брокеров-дилеров, которые считаются аристократией и сливками в таких операциях, как участие во враждебных поглощениях. Выражение возникло из истории колледжей высшей лиги – аристократических (лучших) колледжей (culture of Ivy League college) 1950-х, где белые лайковые ботинки были знаком принадлежности (de rigueur) к членам элитных обществ и клубов.

WHITE SPECKS = БЕЛЫЕ МУШКИ (или БЕЛЫЕ КРАПИНКИ) – White Specks:- Fabric:- printed cotton dress goods; Construction:- (i) Count:- 68 x 72; (ii) Warp:- 23/1 carded cotton; (iii) Filling:- 21/1 carded cotton; Finish:- navy-ground blotch print. Defect:- numerous white specks throughout the printed areas. Analysis:- careful inspection disclosed the fact that the white specks were places that the print color had not penetrated. Upon further examination, it was found that the fabric contained an excessive amount of small neps of cotton which were readily dislodged from their original position but, in many cases, still adhered to the cloth surface. Microscopic examination showed that these cotton neps were composed of dead or immature fibers. Apparently the printing was commercially satisfactory, but in the normal soaping as part of the finishing process, the neps were loosened or moved sufficiently to expose the uncolored areas under them. While extra preparation of the gray goods might have minimized the presence of these small bunches of immature cotton fibers, it was concluded that the defect was due to the use of an extremely poor quality of cotton, which was not suitable for printing. White Specks are undyed spots on dyed fabric, and are commonly caused by neps. According to the American Society for Testing and Materials (ASTM D123-96, 1996), a nep is 'a tightly tangled knot-like mass of unorganized fibers'. Due to low cellulose content of the neps, clumps of these fibers do not accept dye. Therefore, when a fabric is dyed, the mechanical and biological neps formed by fine or immature fibers create undyed spots in the finished fabric. See also Neps. White Specks:- Fabric:- gabardine suiting; Construction:- (i) Count:- 107 x 58; (ii) Warp:- 36/2 combed cotton; (iii) Filling:- 24/2 combed cotton; Finish:- plain dyed light

blue. Defect:- numerous white specks in filling only. Analysis:- examination showed that the spots were confined to the filling yarns except in a few instances, in which there appeared to have been some transfer to the warp yarns. Tensile-strength tests made on a number of the filling yarns in those places showed them to be considerably weaker than similar yarns in other parts of the same piece, the breaks always occurring at the white specks. Chemical tests revealed the presence of traces of iron around the edges of the spots. It was concluded that the defect was due to contamination of the filling yarn by spots of oil which contained small amounts of iron originating from a bearing and carried by the lubricating oil onto the yarn. In subsequent bleaching of the goods prior to dyeing, the iron acted as a catalytic agent in producing overbleaching. The resultant oxycellulose which was formed is low in tensile strength and is also more resistant to dyeing than are the normal, undamaged fibers. White Specks:- Fabric:- spun-rayon sheer dress goods; Construction:- (i) Count:- 42 x 42; (ii) Warp:- 14/1 85% 1%-in. 1%-den. bright viscose rayon 15% viscose-rayon nubby stock; (iii) Filling:- 14/1 75% 1%-in. 1%-den. bright viscose rayon 25% viscose-rayon nubby stock; Finish:- plain dyed navy. Defect:- white specks throughout piece. Analysis:- the white specks, which were found to be present in both warp and filling yarns, consisted of bits of undyed real-silk thread. Since the nubby stock was prepared from garnetted yarn waste, it was concluded that the small pieces of silk were present in that stock as it was delivered to the mill. It was possible to use this fabric by redyeing it, adding a dyestuff to make the silk the same shade as the rayon. / пятна. Уточина:- 21/1 кардная хлопковая. , комки этих волокон не воспринимают краситель. Белые Мушки это непрокрашенные пятна на гладкокрашенной ткани, как правило вызванные наличием узелков (neps) в пряже. Согласно стандарту ASTM D123-96, 1996 Американского Общества по Испытаниям и Материалам (АОИМ; American Society for Testing and Materials (ASTM)) к узелкам относятся ‘прочно спутанные массы неорганизованных волокон, похожие на узел’. Из-за низкого содержания целлюлозы в узелках, скопление этих волокон не прокрашивается. В этой связи при гладкокрашении ткани, механические и биологические узелки, сформированные тонкими или незрелыми волокнами, оставляют на готовой ткани непрокрашенные пятна. WHITE SPIRIT = ВАЙТ СПИРИТ (или УАЙТ СПИРИТ) – White Spirit is refined distillate intermediates with a distillation in the naphtha/kerosene range. White Spirit is one of industrial spirits with a flash point above 30 °C. The distillation range of white spirit is 135 °C to 200 °C. Also known as Special Naphtha. White Spirit is a highly refined distillate with a boiling point range of about 150 degrees to 200 degrees Centigrade. It is used as a paint solvent and for dry-cleaning purposes. / Под Уайт Спиритом, от Английских слов White, означающее Белый, и Spirit, означающее Бензин или Спирт, понимается смесь жидких углеводородов, выкипающая в пределах 165–200 °C. Получают прямой перегонкой нефти. Используется в качестве растворителя, главным образом в лакокрасочной промышленности. Уайт Спирит – фракция бензина, получаемого прямой перегонкой нефти. Выкипает в интервале 165–200 °C. Растворитель лаков и красок, называемый также бензином-растворителем для лакокрасочной промышленности.

WHITE SPIRIT AND SBP = УАЙТ СПИРИТ И ОТК – White Spirit And SBP (short for the Special Boiling Point) are refined distillate intermediates with a distillation in the naphtha/kerosene range. They are subdivided as:- (i) Industrial Spirit (SBP):- light oils distilling between 30 and 200 °C. There are 7 or 8 grades of industrial spirit, depending on the position of the cut in the distillation range. The grades are defined according to the temperature difference between the 5% volume and 90% volume distillation points (which is not more than 60 °C); and (ii) White Spirit:- industrial spirit with a flash point above 30 °C. The distillation range of white spirit is 135 to 200 °C. / с определённой температурой кипения (ОТК).

WHITE SPOT = БЕЛОЕ ПЯТНО (или БЕЛОЕ ПЯТНЫШКО) – White Spot:- if the gray fabric is made of cotton and in the cotton, polyester or other synthetic fibers is mixed to a negligible amount, after dyeing the polyester fiber remain white, showing white spot in the fabric.

WHITE SPOTS AND HOLES = БЕЛЫЕ ПЯТНА И ДЫРЫ (или БЕЛЫЕ ПЯТНЫШКИ И ПРОБОИНЫ) – White Spots And Holes:- Garment:- man’s tan spurt shirt; Fabric Construction:- (i) Count:- 120 x 54; (ii) Warp:- 120/40 dull acetate rayon; (iii) Filling:- IS 1 50$ 2-in. 3-den. dull acetate rayon 50$ 2-in. 3-den. bright viscose rayon. Complaint:- very small white spots and holes were found in scattered areas throughout the shirt. Analysis:- inspection of the garment submitted showed the presence of numerous small white specks on both sides of the fabric and a few small holes in the spotted places. Some of these specks were found on the shirt fabric under the pocket, which indicate! 1 that the damage was not produced after the shirt had been made up. Microscopic examination revealed what appeared to be small white deposits on the fabric, but ordinary laboratory soap scouring and dry cleaning did not remove them. Tensile-strength tests indicated that the yarns were tender wherever the specks were present. Although the foreign substance could not be identified, it was concluded that the defect was dtie to the spattering of some solvent which attacked the acetate rayon in the fabric. While this type of damage would be more likely to take place in a finishing-plant operation than in the cutter’s factory, it was difficult to understand why the garment manufacturer had not noticed the defect during the laying out of the pieces, prior to cutting. / Уточина:- .

WHITE SQUIRE = БЕЛЫЙ СКВАЙР (или БЕЛЫЙ ЗЕМЛЕВЛАДЕЛЕЦ, или БЕЛЫЙ ПОМЕЩИК) – White Squire is very similar to a ‘White Knight’, but instead of purchasing a majority interest, the squire purchases a lesser interest in the target firm. A white squire is still considered to be a friendly acquirer, they just don’t require controlling interest like a ‘white knight’ does. The term White Squire arose in the 1980s as an alternative to White Knight. The white knight is a company or individual that helps defend a company from an unwelcome bidder by buying the target itself. The problem for a target company in an M&A (short for the mergers and acquisitions) bid which enlists the assistance of a ‘white knight’ is that the target gives up its independence, albeit to a preferred bidder (the white knight) instead of the initial bidder which the target did not like. So, in order to stop an unwelcome bidder whilst at the same time remaining independent, the concept of a white squire defence was developed. White Squire is a white knight who buys less than a majority interest. A White Squire is an investor who buys stakes in a company in the best interest of that company, usually with the intent to prevent a hostile takeover of that company. White squires only acquire a partial share of the company which does not give them complete controlling power. However, this partial interest is enough for said company to avoid a hostile takeover. In some cases, it may also give the company some time to rethink its strategy. White squires give confidence to the company to face any unfavorable takeovers and, in this sense, act as a savior. White squires are similar to white knights in that both are allies to the company and they are both involved in defeating a hostile takeover. However, a major difference between the two is that white knights acquire a major share while white squires acquire a minor share. The idea behind the role of white squires is to prevent the advances of black knights. The objective of black knights is to take control over a company against the wishes of the current owners or management by using legal means. To avoid this advancement, a white squire takes a substantial block of shares and allies with the current owners as the majority shareholders in order to reduce the amount of shares available for purchase thereby blocking the black knight from taking controlling power. Despite the benefits that come from having a white squire, there are also some risks. Over time, the white squire may get unhappy with the current management and can switch allegiances. They can team with black knights, thereby increasing the chance of a successful hostile takeover. For this reason, current owners evaluate carefully before choosing a white squire for their company and they prefer to pick individuals or institutions that are steadfast in their approach. However, this careful evaluation does not rule out the risk, but simply mitigates it. / Белый Сквайр – белый рыцарь (white knight), который покупает меньше акций, чем

мажоритарная доля. Белый Сквайр:- рискованная тактика противодействия поглощению, призывающая фирму – цель поглощения разместить большой пакет собственных акций у выбранного инвестора для своей изоляции от нежелательной атаки. Сравните с Белым Рыцарем (White Knight).

WHITE'S RATING = ВАЙТС РЭЙТИНЬ (или РЭЙТИНЬГ ОТ ВАЙТА) – White's Ratings are the ratings service that investigates tax exempt bonds. It rates a bond on a scale of one to 100 according to its liquidity, that is, the ease with which it can be bought and sold. Importantly, unlike other rating services, White's Ratings does not account for the issuer's creditworthiness. White's Rating is the White's Tax-Exempt Bond Rating Service's classification of municipal securities, which is based on market factors rather than credit considerations and which attempts to determine appropriate yields. See also Municipal Bond. White's Ratings are tax-exempt bond rating service's classification of municipal securities. It measures the marketability of a bond, rather than its credit risk. It considers macroeconomic factors and trends rather than the issuer's credit. For example, an issuer may have good credit, but if there has been an excessive number of foreclosures in that municipality, then it may not be able to collect enough in property taxes in order to pay off the bond. White's ratings attempt to account for these situations. White's Rating is a rating of municipal securities, that uses market factors rather than credit considerations to find appropriate yields. White's Ratings is a rating service for tax-exempt bond issues in which a relative market value index is constructed from bond trading patterns rather than from credit analysis. A bond's yield is scaled on an index of 1 to 100. / Рэйтиньг От Вайта:- рэйтиньг фирмы Вайт по категориям муниципальных ценных бумаг службой рэйтиньга облигаций, доход от которых освобождён от налогообложения. WHITE STAINS = БЕЛЫЕ РАЗВОДЫ (или БЕЛЫЕ ПОТЁКИ) – White Stains:- Fabric:- combination-yarn dress goods; Construction:- (i) Count:- 52 x 52; (ii) Warp:- 100/40/50 bright viscose rayon, plied with 150/40 dull acetate rayon arranged 1 S and 1 Z; (iii) Filling:- 150/40/20 dull acetate rayon; Finish:- plain dyed black. Defect:- white stains. Analysis:- inspection of the sample submitted showed the stains to be irregular in size and shape and to be scattered throughout the piece. Microscopic examination disclosed the fact that, in the stained areas, the acetate portion of the warp combination yarns and the acetate filling yarns were partially dissolved. Since there was no possibility of the gray mill's having any chemicals in the plant which might produce such a solvent action, it was concluded that this defect was caused by some careless contamination in the finishing plant. / Уточина:- 150/40/20 .

WHITE STEM BORER = БЕЛЫЙ СТЕБЛЕВОЙ ТОЧИЛЬЩИК – White Stem Borer lays its eggs in batches of about 100 which are covered with silky grayish hairs. Incubation period is about 8 days. The larva is similar to yellow borer larva, except that it is white and reaches full growth in about 30 days. Pupation is completed in about 8 days. The adult lives for about 7 days. It is white and slender. It resembles the yellow rice borer, but does not have a black spot on the forewing. The abdominal tip of the female is pink. The life cycle of the white stem borer is completed in about 53 days. Scientific name:- Scirpophaga Innotata.

WHITE TIP = БЕЛАЯ ВЕРХУШКА – White Tip is a disease of Rice caused by the nematode Aphelencoides Besseyi, with symptoms consisting of chlorosis of the leaf tips which become brownish and tattered. The infected plants are stunted and produce a few, small spikelets/panicles.

WHITE WHEAT = БЕЛОЗЁРНАЯ ПШЕНИЦА (или БЕЛАЯ ПШЕНИЦА) – White Wheat (Triticum Aestivum) is a common Wheat, or Triticum compactum, a club Wheat; fall or spring seeded, soft or hard, low-protein Wheat used principally for pastry flours and shredded and puffed breakfast foods. It accounts for most of the US club Wheat acreage. White Wheat is a a Wheat with white or pale yellow kernels that are usually soft and suitable for pastry flour. Compare Soft Wheat.

WHO = WORLD HEALTH ORGANIZATION

WHOIS = ХУИЗ (или КТОЕСТЬ) – WHOIS (pronounced 'who is'; not an acronym) is an Internet protocol (IP) that is used to query databases to obtain information about the registration of a domain name (or IP address). The WHOIS protocol was originally specified in RFC 954, published in 1985. The current specification is documented in RFC 3912. (The Internet Corporation for Assigned Names and Numbers) ICANN's gTLD agreements require registries and registrars to offer an interactive web page and a port 43 WHOIS service providing free public access to data on registered names. Such data is commonly referred to as 'WHOIS Data', and includes elements such as the domain registration creation and expiration dates, nameservers, and contact information for the registrant and designated administrative and technical contacts. WHOIS services are typically used to identify domain holders for business purposes and to identify parties who are able to correct technical problems associated with the registered domain. / WHOIS (произносится как 'ху из' ('who is') и не является аббревиатурой) – протокол Интернета, который используется для запросов к базам данных с целью получения информации о регистрации доменного имени (или IP-адреса). Первоначально параметры протокола WHOIS были описаны в документе RFC 954, опубликованном в 1985. Документом действующей спецификации является RFC 3912. Соглашения Корпорации Интернета по Распределению Имён и Номеров (КИРИН) с рДВУ требуют, чтобы реестры и регистраторы предлагали интерактивную веб-страницу и услугу WHOIS через порт 43 с бесплатным открытым доступом к сведениям о зарегистрированных именах. Эти сведения обычно называются 'данными WHOIS' и включают такие элементы, как дата создания регистрационной записи домена и сроке её действия, серверы имён, реквизиты для связи с владельцами регистраций, а также контактные данные лиц, назначенных для связи по административным и техническим вопросам. Службы WHOIS в основном используются для определения держателей доменов в деловых целях и для определения сторон, способных исправить техническую неполадку, связанную с зарегистрированным доменом.

WHOLE ACCOUNT = ЦЕЛЫЙ СЧЁТ (или ХХ) – Whole Account:- an excess of loss treaty arranged to cover all or some of the types of Accident, Fire, marine or Aviation business written by a ceding company (either from one branch of business, or more than one).

WHOLE AND LARGE BROKEN KERNELS = ЦЕЛИКОВАЯ И КРУПНАЯ БИТАЯ ЗЕРНОВКА (или ЦЕЛЫЕ И КРУПНЫЕ БИТЫЕ ЯДРА) – In the Rice industry of the United States, Whole And Large Broken Kernels are the Rice (including seeds) that (i) passes over a 6 plate (for southern production), or (ii) remains on top of a 6 sieve (for western production). Whole or broken kernels of Rice (Oryza Sativa L.) from which the hulls and at least the outer bran layers have been removed and which contain not more than 10.0 percent of seeds, paddy kernels, or foreign material, either singly or combined. / Посевной Рис (Oryza Sativa) .

WHOLE–CELL PATCH–CLAMP RECORDING = ЦЕЛЬНАЯ КЛЕТКА ХХ – Whole-cell Patch-clamp Recording developed by Bert Sakmann and Erwin Neher in 1976, this is a method for measuring the current/potential of a single ion channel. Although the initial 1976 technique was slow and laborious (i.e. to 'hook up' the cell to electrodes, to measure electrical potential), several companies have since developed easier/faster methodologies to measure the electrical potential across a cell's ion channel(s) as that cell is exposed to one or more pharmaceutical candidate compounds. / Берт Закман (Bert Sakmann; 1942–) и Эвин Нихя (Erwin Neher; 1944–).

WHOLE COTTONSEED = ЦЕЛОЕ СЕМЯ ХЛОПЧАТНИКА (или ЛЕТУЧКА) – Whole Cottonseed is high in protein, fat, fiber and energy. This combination of nutrients in one feedstuff is unusual. Whole cottonseed with the lint still attached is white and fuzzy in appearance. It sometimes is called Fuzzy Seed, and has the analysis shown below. Whole cottonseed from which the lint has been removed is called Delinted Seed, is black and smooth in appearance, and tends to be slightly higher in protein and fat than the fuzzy seed. / Отдельное семя Хлопчатника, покрытое волокнами.

WHOLE EGGS = ЦЕЛЫЕ ЯЙЦА – Whole Eggs are the eggs that contain both the yolk (yellow portion) and albumen (white or clear portion).

WHOLE–FARM INSURANCE = СТРАХОВАНИЕ ЦЕЛОЙ ФЕРМЫ – Whole-Farm Insurance:- an approach to insurance in which the guarantee would be based on the revenue from the producer's entire operation or a subset of designated commodities so as to provide a more comprehensive approach to managing whole-farm risk than the current crop-by-crop approach. See also Adjusted Gross Revenue (AGR).

WHOLE–FARM PLANNING = ПЛАНИРОВАНИЕ ЦЕЛОЙ ФЕРМЫ – Whole-Farm Planning:- a conservation, family-oriented approach to farm management with the goal of allowing producers to manage biologically complex farming systems in a profitable manner. Using management system theories used by other businesses, it encourages producers to set explicit goals for their operation; carefully examine and assess all the resources (cultural, financial, and natural) available for meeting their goals; develop short- and long-term plans to meet their goals; make decisions on a daily basis that support their goals; and monitor their progress toward meeting goals. / сохранение (conservation).

WHOLE FARM UNIT = ЦЕЛАЯ ФЕРМЕРСКАЯ ЕДИНИЦА – Whole Farm Unit:- for crop insurance purposes, the unit must be composed of two or more crops planted in the county. All crops must be included and no one crop can constitute more than 75 percent of the total liability in the whole farm unit. All crops in the unit must be insured under the same plan or insurance and with the same insurance provider. See also Basic Unit, Enterprise Unit, Insurance Unit, Optional Unit, and Whole-Farm Insurance.

WHOLE–GENOME AMPLIFICATION = ПОЛНЫЙ ШОТГАН СИКВЕНС ГЕНОМА – A term Whole-Genome Amplification (WGA) refers to a methodology that is required for sequencing an entire genome (i.e. the entire DNA of an organism); that of first amplifying (i.e. making copies of) every sequence within the selected organism's DNA.

WHOLE–GENOME ASSOCIATION = АССОЦИАЦИЯ ПОЛНОГО ГЕНОМА – A term Whole-Genome Association refers to the use of gene expression analysis across tissue (e.g., blood) samples taken from a very large number of organisms (e.g., people), in order to find out which genes(SNPs) are associated with a given disease or with a given phenomenon (e.g., short term memory).

WHOLE–GENOME SHOTGUN SEQUENCING = ПОЛНЫЙ ШОТГАН СИКВЕНС ГЕНОМА – A term Whole-Genome Shotgun Sequencing is sometimes used for Shotgun Sequencing. The first genome sequenced by shotgun sequencing was that of Cauliflower Mosaic Virus, published in 1981. However, whole genome shotgun sequencing for small (4000- to 7000-base-pair) genomes had been suggested already in 1979. Whole-genome shotgun sequencing would not result in a single unbroken sequence for entire chromosomes. Even using recombination and restriction-deficient Escherichia Coli strains, a small portion of the genome would likely be resistant to cloning or would not yield stable clones. Sequences from long arrays of tandem repeats such as centromeric satellite DNA, rDNA repeats, and some minisatellites would not be able to be assembled perfectly. Note, however, that these limitations apply to both whole-genome shotgun and clone-by-clone sequencing approaches. The feasibility of whole-genome shotgun sequencing was also supported by the recent success achieved by Venter and colleagues in sequencing three bacterial genomes with sizes ranging from 0.6 to 1.8 Mb. Neither raw sequence generation, sequence assembly, nor sequence finishing was an impediment to the shotgun sequencing of the bacterial chromosomes. Distances between human STSs are much smaller than the sizes of the bacterial genomes. Advantages of Whole-Genome Shotgun Sequencing:- Whole-genome shotgun sequencing of human genomic DNA holds a number of important advantages compared to conventional clone-by-clone sequencing. Foremost among these advantages are detection of large numbers of DNA polymorphisms, more complete and less artifactual coverage of the genome, and improved speed and cost. A significant fraction of all common human DNA polymorphisms can be detected through shotgun sequencing. Polymorphisms are important because they are used to map genes through linkage analysis, to presymptomatically predict disease status, to detect submicroscopic chromosomal rearrangements, to identify individuals in, for example, paternity and forensic testing, and to study a wide range of biological phenomena such as evolution, population biology, and recombination. Polymorphisms within coding and regulatory elements are also the source of relative risk for many common diseases. Common variants of the apolipoprotein E gene on chromosome 19, for example, strongly influence an individual's risk of developing late onset Alzheimer's disease. Many highly informative human DNA polymorphisms based on short tandem repeats have already been identified, but the vast majority of the much more frequent biallelic base substitution and short insertion/deletion polymorphisms remain unknown. Although allele frequencies vary widely, most human DNA polymorphisms are common to all populations. DNA polymorphisms would not usually be detected through clone-by-clone sequencing because only one variant for each genomic region would be sampled. If the genome is sequenced through the clone-by-clone approach, then much additional funding would be required to identify the polymorphisms at a later date and many years would be lost. Calculation of the exact fraction of polymorphisms that would be identified through whole-genome shotgun sequencing requires a distribution of polymorphisms as a function of informativeness, which is not yet known. However by generating 6 billion nucleotides of raw sequence from each of five unrelated individuals, it can be calculated that ~65% of all 20% heterozygosity biallelic polymorphisms and >99% of all 80% multiallelic polymorphisms would, for example, be detected. To optimize polymorphism detection, DNA should ideally be sequenced from donors with widely differing geographic ancestry. Sequencing errors would likely be encountered much more frequently in whole-genome shotgun sequencing than true polymorphisms. Sequencing error rates would likely be at least 1%, whereas the rate of polymorphisms would likely be on the order of 0.1%. Although confirmation may be necessary in many cases, several factors would allow many of the polymorphisms to be identified despite the background of sequencing errors. True polymorphisms would often have multiple sequence reads per allele, true polymorphisms would usually have high-quality values attached to each allele, and true polymorphisms do not occur randomly thoughout the genome. Specific sequence features will spotlight polymorphisms. For example, it has been known for many years that CpG dinucleotides are more commonly polymorphic than other dinucleotides. Rearrangements in the large insert contig clones and biases in the coverage of these clones will, to a large degree, be eliminated by whole-genome shotgun sequencing. Many of the cosmid clones projected for use in sequencing have been developed from hybrid tissue culture cell lines which, themselves, have been propagated for many cell generations. Rearrangements and artifacts have undoubtedly been introduced into the cloned material during this process. Although BACs/PACs (P1-derived artificialchromosomes) appear to be more stable than cosmids, artifacts such as chimeras and deletions still occur at a significant frequency. By starting with total human genomic DNA, many of these artifacts will be eliminated. The cosmid or BAC/PAC assemblies will also likely exclude at least some long arrays of tandem repeats. The genome will be more equally represented with shotgun sequencing using small inserts. In addition, overlaps between large insert clones will lead to largely unproductive duplicative sequencing or to the expenditure of resources to avoid this duplication. Whole-genome shotgun sequencing would also be less

expensive and therefore faster than the clone-by-clone approach. The steps of preparation, mapping, storage, and tracking of tens of thousands of sequence-ready large-insert clones; parallel generation, storage and tracking of subclones for each of the large insert clones; and avoidance of large-insert clone overlap would be entirely eliminated with shotgun sequencing. The processes of sequence assembly and sequence finishing could be carried out much more efficiently in central facilities. Reducing the process of DNA sequencing to the core task of raw sequence generation would also allow efforts to be focused on driving down the costs of a few relatively straightforward procedures in large factory-like operations. With shotgun sequencing there would be no need to wait for expensive, sequence-ready large-insert clone assemblies to be generated and no need to sequence one chromosome or one chromosomal segment at a time. To date, no one has generated overlapping cosmid or BAC/PAC assemblies that span even significant portions of human chromosomes without many gaps. Perhaps this can be accomplished eventually but only through great effort, time, and cost. The assertion that collection of large-insert templates for sequencing is trivial is simply wrong. Although initiation of genome-wide sequence assembly would probably not be worthwhile until ~2.5-fold sequence coverage was obtained, completion of partial cDNA sequences, identification of regulatory regions, definition of intron/exon boundaries, and identification of polymorphisms are all tasks that could be undertaken continuously from the start of shotgun sequence generation. The large number of laboratories worldwide undertaking position cloning projects, for example, could utilize the shotgun sequences from the outset. Estimating the actual costs of human genomic sequencing is certainly hazardous. Nevertheless, our best effort is summarized in Table 5. Assuming optimistically that clone-by-clone sequencing of human DNA can be completed for USD0.30 per finished base, and assuming that sequencing is completed by the end of the year 2003, an average cost per year of USD130 million is calculated. Assuming conservatively a cost of USD0.01 for generation of a single base of raw sequence, spending of USD130 million per year would give 10-fold coverage by about the end of the millennium with USD90 million remaining for software development and computer assembly. Filling gaps and resolving uncertainties would add additional costs to whole-genome shotgun sequencing in the next century. See also Shotgun Sequencing. / Полный Шотган Сиквенс Генома:- .

WHOLE–HERD BUYOUT PROGRAM = ПРОГРАММА ВЫКУПА ЦЕЛОГО СТАДА – The Whole-Herd Buyout Program:- a month ago (in April 1986), cattle prices plunged after the government announced details of a program to reduce the number of dairy cattle by 1.55 million, from a total of about 16 million dairy cows and heifers, over the next 18 months. The 'whole-herd buyout program' is supposed to reduce milk production by 12.3 billion pounds and save the government some USD2 billion to USD3 billion in costs of buying and storing surplus milk. The government is paying 14 000 dairy farmers to send their cattle to slaughter and stay out of the business for at least five years, and presumably for good. The prospect of all those cows, calves, and heifers coming onto the meat market sent cattle prices plummeting – more than 20 percent in some places. In the last week, however, the tide has turned for cattlemen. On Tuesday and Wednesday, traders bid up cattle prices up the maximum allowed in a day. In part, that was caused by the fire at the nuclear power plant in the Ukraine. In 1984, the Ukraine produced 22 percent of the Soviet Union's meat and 23 percent of its milk. Traders speculated that the Soviets may have to import meat. Cattlemen also won a case in the courts. On Wednesday, a federal judge in Lubbock, Texas, ordered a preliminary injunction on the marketing of dairy cows under the whole-herd buyout program. He told the US Department of Agriculture (USDA) to come up with an orderly marketing plan by June 01. 'It was the lack of such a plan that drove prices down', says Darrell Wilkes, spokesman for the National Cattlemen's Association, which filed the suit. The Cattlemen's Association says many dairy farmers brought their herds to market as soon as the program would permit, which was in April. The cattlemen wanted a plan that would smooth out the flow of dairy cattle into the meat market. See also Milk Production Termination Program. Xxxxx. Taking milk cows out of production as a way to control milk prices is a controversial approach. The federal government tried that in the 1980s through the whole herd buyout program, and while the policy worked for a time, milk production eventually bounced back and farmers were once again grappling with low milk prices. The buyout also sent beef prices crashing, as slaughtered cows entered the meat supply. Economists say the problem for the dairy industry is that when milk supplies fall, and prices climb, farmers generally push their cows to produce more to cash in. Then milk prices tumble again. This time, falling milk prices come as the economy is in a tailspin and farmers have a harder time finding credit to buy equipment, expand their farms or otherwise improve their businesses. California, the nation's top milk producer, has been hit especially hard because its farms are producing more milk than the state's plants can process, Mr. Peterson (Rep. Collin C. Peterson, D-Minn., chairman of the House Agriculture Committee) said Wednesday (2009-January-14). 'We've got a problem', said Mr. Peterson, who had approached the National Milk Producers Federation about ways to reduce herds. California is somewhat separated from the rest of the nation's dairy industry and has its own marketing order system that sets minimum prices. But milk prices across the country, including in the north country, are not totally immune from such a big milk-producing region's effects. The National Milk Producers Federation (NMPF), representing bargaining cooperatives for dairy farmers, already has a herd retirement program that is not publicly funded. The so-called Cooperatives Working Together program has paid farmers since 2003 to retire cows. In 2007, the program helped take 52 783 cows out of production. Mr. Peterson said he asked the NMPF if it could use stimulus money to speed up the Cooperatives® Working Together (CWT) program. The program also coordinates sales of dairy products to foreign countries, in an effort to reduce domestic supplies. A study last year indicated that the program raised milk prices paid to farmers by an average of 55 cents per 100 pounds since 2004. But some farm groups object to the practice. The National Family Farm Coalition (NFFC) generally opposes herd reductions to manage milk supplies and has pushed against using the stimulus for that purpose, said Kathy Ozer, the group's executive director. By some measures, the United States already has a milk deficit, not a surplus, the NFFC has said. Instead of slaughtering cows, the NFFC has said, Congress should implement more generous price protections and crack down on anti-competitive behavior by cooperatives and milk processors that holds down milk prices. / Дэрэл Вилкс (Darrell Wilkes). WHOLE–HOUSE COOLING FAN = ОХЛАЖДАЮЩИЙ ВЕНТИЛЯТОР НА ВЕСЬ ДОМ – Whole-House Cooling Fan is a mechanical/electrical device used to pull air out of an interior space; usually located in the highest location of a building, in the ceiling, and venting to the attic or directly to the outside.

WHOLE HOUSE FAN = ВЕНТИЛЯТОР НА ВЕСЬ ДОМ – Whole House Fan is a system capable of cooling a house by exhausting a large volume of warm air when the outside air is cool.

WHOLE KERNEL = ЦЕЛЬНАЯ ЗЕРНОВКА (или ЦЕЛЬНОЕ ЯДРО) – Whole Kernel is a grain with one-quarter or less of the kernel removed. Whole Kernel (white Rice) is the unbroken kernel of Rice that has been milled.

WHOLE KERNELS = ЦЕЛИКОВАЯ ЗЕРНОВКА (или ЦЕЛЫЕ ЯДРА) – Whole Kernels mean Rice kernel that are in whole condition without any broken part, including kernels which have at least nine parts. Unbroken kernels of Rice and broken kernels of Rice which are at least three-fourths of an unbroken kernel. Whole Kernels mean Rice kernels that are in whole condition without any broken part, including the kernels that have length as from 9 parts onward.

WHOLE–LIFE CONTRACTS = ПОЖИЗНЕННЫЕ ДОГОВОРЫ (или ПОЖИЗНЕННЫЕ КОНТРАКТЫ) – Whole Life Insurance Policy is a life insurance contract with level premiums that has both an insurance and an investment component. The insurance

component pays a stated amount upon death of the insured. The investment component accumulates a cash value that the policyholder can withdraw or borrow against. As the most basic form of cash-value life insurance, whole life insurance is a way to accumulate wealth as regular premiums pay insurance costs and contribute to equity growth in a savings account where dividends or interest is allowed to build-up tax-deferred. / Пожизненные Договоры – договоры пожизненного страхования.

WHOLE–LIFE COST = ПОЛНЫЙ РАСХОД ЗА ЖИЗНЬ (или ПОЖИЗНЕННЫЙ РАСХОД) – Whole-Life Cost is the total cost of owning an aset over its entire life. Whole life cast includes all costs such as design and building costs, operating costs, associated financing costs, depreciation, and disposal costs. Whole-life cost also takes certain costs that are usually overlooked into account, such as environmental impact and social costs. Also known as a Life-Cycle Cost. When comparing investment decisions, an analyst must look at all potential future costs, not just acquisition expenses. While most costs can be readily measured or estimated, costs such as environmental or social impact cannot be easily quantified. Nevertheless, whole-life costing may provide a more accurate picture of the true cost of an asset than most other methods. / Полный Расход За Жизнь – затраты в течение срока службы.

WHOLE LIFE INSURANCE = ПОЛНОЕ СТРАХОВАНИЕ ЖИЗНИ (или СТРАХОВАНИЕ ВСЕЙ ЖИЗНИ, или ПОЖИЗНЕННОЕ СТРАХОВАНИЕ) – Whole Life Insurance is a form of life insurance policy that offers protection in case the insured dies and also builds up cash value. The policy stays in force for the lifetime of the insured, unless the policy is canceled or lapses. The policyholder usually pays a level premium for whole life, which does not rise as the person grows older (as in the case of term insurance). The earnings on the cash value in the policy accumulate tax-deferred, and can be borrowed against in the form of a policy loan. The death benefit is reduced by the amount of the loan, plus interest, if the loan is not repaid. Traditionally, life insurance companies invest insurance premiums conservatively in bonds, stocks, and real estate in order to generate increases in cash value for policyholders. Policyholders have no input into the investment decision-making process in a whole life insurance policy. Other forms of cash value policies, such as universal life insurance and variable life insurance give policyholders more options, such as stock, bond, and money market accounts, to choose from in investing their premiums. Whole life insurance is also known as Ordinary Life Insurance, Permanent Life Insurance, or Straight Life Insurance. Whole Life Insurance:- a contract with both insurance and investment components:- (1) it pays off a stated amount upon the death of the insured, and (2) it accumulates a cash value that the policyholder can redeem or borrow against. / Страхование Всей Жизни или Полное Страхование Жизни вплоть до смерти владельца полиса. Форма страхования жизни, предлагающая защиту в случае смерти страхователя, которая позволяет накапливать наличные средства. Полис остаётся в силе в течение всей жизни страхователя, если полис не отменён или не истекает. Владелец полиса полного страхования жизни обычно выплачивает установленный ежегодный страховой взнос или премию (premium), размер которой не увеличивается с возрастом (как в случае со срочным страхованием (term insurance)). Доходы от прироста наличной стоимости полиса накапливаются и не облагаются налогом, под них может быть получена ссуда в форме займа (под залог полиса (policy loan). Сумма страховой выплаты в случае смерти страхователя сокращается на сумму ссуды, если страхователь не успевает погасить ссуду, поскольку полисы полного страхования жизни традиционно предлагали более низкий доход по вложениям, поэтому многие владельцы полисов перешли в 1970-х к новым, приносящим более высокий доход формам полного страхования жизни, например к универсальному страхованию жизни (universal life insurance) и страхованию жизни с плавающей суммой (variable life insurance). Полное страхование жизни также известно как обычное (ordinary), постоянное (permanent) или прямое (straight) страхование жизни.

WHOLE LOAN = ЦЕЛИКОВЫЙ ЗАЁМ (или ЦЕЛИКОВАЯ ССУДА) – Whole Loan is the secondary mortgage market term that distinguishes an investment representing an original residential mortgage loan (whole loan) from a loan representing a participation with one or more lenders or a pass-through security representing a pool of mortgages. Whole Loan is a mortgage loan, generally one that is not part of a pass-through security. Whole Loan is a mortgage loan sold to an investor in a secondary market. The investor purchasing the loan assumes full responsibility of the loan and all the contractual terms and rights associated with the funds. The original lender no longer has any rights to the loan after it has agreed to sale the loan to another party. Whole Loan is a term that distinguishes an investment representing an original mortgage loan from a loan representing a participation with one or more lenders. / Полный Заём или Целая Ссуда – термин рынка вторичных закладных, который отличает инвестиции, представляющие жилищный заём под закладную (полный заём), от заёма, представляющего участие с одним или более займодавцами или передающеё доход ценной бумаги, представляющей пул закладных. Целая Ссуда:- разновидность инвестиций на вторичных рынках закладных. Её особенность заключается в приобретении первичной закладной, представляющей полную первоначальную ссуду под жилищное строительство, от ссуды, представляющей участие нескольких кредиторов, или ценной бумаги, представляющей пул закладных.

WHOLE LOAN SALE = ПРОДАЖА ЦЕЛИКОВОЙ ССУДЫ (или ПРОДАЖА ТОЛЬКО КРЕДИТА) – Whole Loan Sale:- selling whole loans for cash. Selling whole loans to Fannie Mae can help your company achieve its business goals. Whether you are pursuing more loan originations, more profitable loan operations, or the ability to better meet the needs of your community, whole loan sales are the simplest and most straightforward type of secondary market transaction. Whole loan sales provide important benefits such as risk reduction and immediate liquidity. / Продажа Только Кредита – продажа кредита без дополнительных условий (в том числе без обязательства обратного выкупа на случай дифолта), не предусматривающая создание нового финансового инструмента. WHOLE OF GOVERNMENT HARMONISED STANDARD = ГАРМОНИЗИРОВАННЫЙ СТАНДАРТ ВСЕГО ПРАВИТЕЛЬСТВА – Whole of Government Harmonised Standard:- the term refers to the harmonization of Generally Accepted Accounting Principles (GAAP) and Government Finance Statistics. The Australian Accounting Standards Board (AASB) has issued a new standard, applicable from 01 July 2007, 'AASB 1049, Whole of Government and General Government Sector Financial Reporting'. The objective of the standard is to produce a single set of Government reports which are auditable, comparable between jurisdictions, and in which the outcome statements are directly comparable with the relevant budget statements. The standard requires governments to report according to accounting standards, choosing options that are consistent with GFS (short for the Government Finance Statistics) accounting where available, and present according to the GFS principles.

WHOLE–OF–LIFE POLICY = ПОЛИС НА ВСЮ ЖИЗНЬ (или ПОЖИЗНЕННЫЙ ПОЛИС) – Whole-Of-Life Policy:- whole-of-life policies payout a lump sum when you die, whenever that is. The size of the payout depends on your policy. With some policies, you can stop paying once you reach a certain age, but with others you have to make monthly or annual payments right up until you die. If you set up your policy in a trust, payment will be made to the trustees to distribute to the beneficiaries of that trust. When might a whole-of-life policy be for you? A whole-of-life policy may be for you if:- (i) you want the chance to earn a higher payout for your dependents by linking life assurance with investing; (ii) you understand that payouts depend on your investment's performance; and (iii) you understand that charges will reduce your policy's value. Some whole life insurance policies only give you life assurance, while others are linked to an investment. If you're looking for investment growth to increase how much is paid out when you die, make sure

the policy is investment-linked. How they work:- (i) you buy a whole-of-life plan using monthly or annual payments or a one-off sum; (ii) for unit-linked whole of life policies your money will be split – some is used to buy the life assurance to pay the sum assured. The rest will be invested in an investment fund. (iii) For unit-linked/flexible whole of life policies the insurance company will have regular review dates, where they'll compare the value of your policy with the cost of the life assurance it needs to provide. If they find the investment fund isn't performing well enough to cover the cost of benefits, your provider may suggest increasing your regular contribution or else reducing the sum assured. (iv) Some policies give you the choice of adding insurance against certain illnesses or against becoming disabled. How your money is invested? When you buy whole-of-life insurance some of your money may be used to pay the life insurance premiums and some put into investment funds. The two main options are:- (i) unit-linked funds – you may have choice between different funds; and (ii) with-profits funds. Risk and return:- (i) your estate will get a lump sum when you die, so long as you are still paying the premiums (or paid the premiums up to the age stated in the policy); (ii) usually a minimum payment on death is specified. For unit-linked/flexible whole of life policies anything over and above this depends on the value of the unitised funds you are invested in, or the bonus payments received by your with profits policy. (iii) You might end up getting back less than you invested. Access to your money:- a whole-of-life policy is designed to pay out on death whenever that is. If you decide to surrender the policy you will receive the value of the fund less any penalties/charges applied, which may be considerably smaller than the amount paid in premiums. Ending your policy early:- (i) You can end a whole-of-life policy early, but there can be high charges to do so and you may get back less than you invested. (ii) If you end a policy early, it might be difficult to open a new one later. Whole-of-life policies get more expensive as you get older, and you may have developed a health problem that makes it more difficult to obtain life assurance cover. If you have a whole-of-life policy and are thinking about taking your money out, learn about your options with our guide on Ending your with-profits policy early. Charges:- (i) the provider will charge for their services, so make sure that you understand what the charges will be and the impact they might have on your investment returns; and (ii) if you end your with-profits policy early, you'll end up paying high charges and penalties. Before you buy a policy make sure you understand the impact charges can have on your investment. Safe and secure? If the insurance company goes bust another insurer may take over the company's business. Otherwise you may be able to claim compensation. You cannot claim compensation simply because the value of your investment falls. Where to get a whole-of-life policy? You can buy a whole-of-life policy from a financial adviser or directly from an insurer. Friendly Societies (member-run mutual benefit organisations) are another option. Their whole-of-life policies may offer some additional tax advantages although the amounts of money that can be paid into them is very limited. Keep in mind that these are complex financial products. If you don't understand what a policy is offering – or if you're unsure whether these policies are a good fit for your needs – speak to a financial adviser before you buy. Tax:- with some planning, your dependants may be able to receive the lump sum tax-free. Find out more at our guide on Life insurance and Inheritance Tax. Xxxxx. Whole-Of-Life Polices are designed to provide a sum of money (the 'sum assured') to a consumer's family or estate when the consumer dies. The consumer pays either a lump sum at the outset or a premium every month. As the name suggests, whole-of-life policies are intended to remain in place for the rest of the consumer's life. However, some policies do not require the consumer to keep paying premiums once they have reached a certain age. Whole-of-life policies sometimes provide other benefits to the consumer – for example, cover for specified illnesses or disabilities. The main types of policy we come across are:- (i) Non-Reviewable:- the consumer chooses the sum assured. The financial business then tells the consumer how much they need to pay to provide that sum. This is either a one-off lump sum payment or regular premiums for the rest of the consumer's life. Regardless of what happens in the future, the business will not request any further payment or any increase in regular premiums. These policies may or may not contain an investment element. (ii) Limited Payment Term:- the consumer chooses a sum assured when they take out the policy. They then pay a regular premium to the business. However, the premiums are only paid for a set term – usually to a set age, such as 65. After this point, the consumer pays no more premiums, but the policy stays in place until their death. The sum assured is fixed when the last premium is paid and cannot usually be altered later. (iii) Reviewable:- this is the most common type of policy. The consumer chooses a sum assured when they take out the policy and pays either a lump sum, or more often, regular monthly premiums to the business. Part of the premium is used to build up an investment fund. The amount that the consumer is required to pay – and the sum assured – is set on the basis of certain assumptions about what will happen in the future. These assumptions include the cost of providing life cover and how well the investment fund will perform in the future. These policies no rmally have 'review dates' when – if things have not gone as well as expected – the business may ask for the contributions to be increased, or may suggest that the sum assured is reduced. They also usually accrue a value as time goes by. This means the consumer can cash in the policy. Because of this, businesses sometimes recommend whole-of-life policies for savings purposes – or where the consumer wanted savings and life assurance together. Many types of reviewable policy offer a choice about how much of the premium pays for life assurance and how much is paid into the fund. They are often marketed as 'minimum', 'standard' and 'maximum' options. The differences will usually be reflected in the sum assured. For example, taking the 'maximum' option will usually mean that a high level of life cover is provided, with only a relatively small amount left to be invested in the fund. / Полис На Всю Жизнь:- полис страхования жизни, по которому в случае смерти его владельца выплачивается определённая сумма. По другим причинам страховые суммы не выплачиваются, а сам полис действует до момента смерти его владельца при условии, что регулярно – либо в течение всей жизни, либо до определённого времени – вносятся страховые премии. Такие полисы могут быть Полисами С Прибылями (With-Profits Policies) или Полисами, Связанными С Паевыми Трестами (Unit-Linked Policies).

WHOLESALE = ОПТОВАЯ ПРОДАЖА – (1) Wholesale:- wholesale establishments, on the other hand, are primarily engaged in selling or arranging the purchase or sale of:- (a) goods for resale, (b) capital or durable nonconsumer goods, and (c) raw and intermediate materials and supplies used in production. Wholesalers normally operate from a warehouse or office and are characterized by having little or no display of merchandise. In addition, neither the design nor the location of the premises is intended to solicit walk-in traffic. Wholesalers also do not normally use advertising directed to the general public. See also Wholesaling. Чем старше корова, тем темнее её мясо – телячье мясо имеет розоватый оттенок, а мясо коровы – тёмно-красный. Тот же принцип касается и жира:- жир телёнка белый, со слегка желтоватым оттенком, а у взрослой коровы – тёмно-жёлтый. Мясо животных постарше более твёрдое и крепкое, чем у молодых животных. Поэтому для приготовления пищи больше подходит мясо молодых коров. В разных странах мясо разделывают по-разному. Существуют Итальянская схема разделки говядины, Немецкая, Голанская, Датская и Австралийская схемы. Наиболее распространённая схема это Южно-Американская так как в ней вся туша поделена на 19 номеров. WHOLESALE FUNDS TRANSFER SYSTEM = СИСТЕМА ПЕРЕВОДА ФОНДОВ ОПТОВОЙ ТОРГОВЛИ – Wholesale Funds Transfer System:- xxxxx. See also Large-Value Funds Transfer System. Wholesale Funds Transfers:- the movement of funds through the banking system; excludes all transactions governed by the Electronic Funds Transfer Act. The typical wholesale wire transfer involves sophisticated parties who seek great speed in transferring large sums of money. The Dollar value of commercial or wholesale wire transfers over the two major transfer systems – Fedwire and Clearing House Interbank Payments System (CHIPS) – is almost USD4 trillion per business day. Funds Transfer is a series of transactions, beginning with the originator's payment order, made for the purpose of making payment to the beneficiary of the order. The term includes any payment order issued by the originator's bank or an intermediary bank intended to carry out the originator's payment order. A funds transfer is completed by acceptance by the beneficiary's bank of a payment order for the benefit of the beneficiary of the originator's payment order. / Система Перевода Денежных Средств Оптом:- система перевода денежных средств, через которую осуществляются переводы денежных средств крупной суммы и высокоприоритетные переводы денежных средств между участниками системы за их собственный счёт или от имени их клиентов. WHOLESALE INVENTORIES = ЗАПАСЫ ТОВАРОВ В ОПТОВОЙ ТОРГОВЛЕ – Wholesale Inventories:- amount of unsold inventory still in the possession of the wholesaler. If wholesale inventories start to become elevated, that typically means that retailers are purchasing less because demand for the products has decreased. Analysts look to wholesale inventory figures to see how the consumer market is performing. Wholesale Inventories is a monthly report issued by the US Census Bureau that tracks changes in wholesale sales and inventory levels. Of the two numbers, the wholesale inventory number is the more significant because high inventory levels can reflect slowing demand and translate into decreased manufacturing production, which in turn can affect Gross Domestic Product (GDP). The significance of the report is reduced, however, because it covers a reporting period two months prior. The data are released around the 10th day of each month and is available at a variety of financial information Web sites. / Запасы Товаров В Оптовой Торговле или Товарные Запасы На Сладах Оптовой Торговли (Wholesale Inventories):- индекс

характеризует отношения между оптовиками и розничной торговлей. Оказывает ограниченное влияние на рынок, однако даёт представление о тенденциях в этих секторах экономики, которые могут проецироваться на экономику в целом. Рост значения индекса оказывает негативное влияние на курс Доллара. Его значение публикуется около 10-го числа каждого месяца в 10:00 EST (Eastern Standard Time; UTC –5) (Нью Йорк).

WHOLESALE MONEY = ОПТОВЫЕ ДЕНЬГИ – Wholesale Money:- funds borrowed by corporations, in high amounts, through financial institutions. Wholesale money is a way for large institutions to obtain capital without having to issue shares or bonds. These loans will usually be issued by large financial institutions and banks to long-standing, financially secure companies and have a lower-than-average interest rate. The advantages of this type of loan are the quick availability and immediate use of the funds. For example, these funds may be used by a company to quickly act on an opportunity which might otherwise be missed. Wholesale money is obtained as a loan and therefore requires periodic payments, much like a bond, but requires less time and effort than a bond or new-stock issue. / Оптовые Деньги – суммы, заимствованные в крупных количествах у банков, крупных фирм и финансовых учреждений.

WHOLESALE MARKET = ОПТОВЫЙ РЫНОК – Wholesale Market is an interbank money market, where banks and other financial institutions deal with each other. Wholesale Market is the market for the sale of securities to institutional investors rather than individuals. Wholesale Market is the market for the sale of goods to a retailer. That is, a wholesaler receives large quantities of goods from a manufacturer and distributes them to stores, where they are sold to consumers. A wholesaler is generally able to extract a better price from the manufacturer because it buys so many good relative to an individual retailer. In theory, this enables the retailer to sell the good at a better price for the consumer. See also Economies Of Scale. / Оптовый Рынок:- рынок продажи ценных бумаг институциональным инвесторам, а не индивидуалам. Синоним термина Внутренний Рынок (Inside Market). Оптовый Рынок, или Рынок Предприятий, – это рынок лиц или организаций, приобретающих товары либо услуги для их дальнейшего использования в процессе производства, перепродаж или перераспределения. В соответствии с этим определением можно говорить о том, что оптовый рынок представлен:- (1) предприятиями, закупающими товары для их последующей переработки; (2) организациями-посредниками, приобретающими товары для их перепродажи с целью получения прибыли; (3) государственными учреждениями, осуществляющими закупки с целью обеспечения выполнения своих функций. Имея в виду, что закупки на оптовом рынке производятся от имени организаций отдельными людьми, можно вкратце остановиться на особенностях этого рынка. (1) У предприятий, действующих на рынке товаров промышленного назначения, закупками занимаются агенты по снабжению, отделы материально-технического обеспечения и тому подобные, но в любом случае этим занимаются профессионалы. Кроме того, данный рынок характеризуется крупными, но немногочисленными покупателями; их сравнительной географической концентрацией, неэластичностью, изменчивостью и зависимостью спроса на товары промышленного назначения от спроса на товары широкого потребления. Если фирма имеет дело с предприятиями, действующими на этом рынке, прежде всего необходимо выяснить:- какие конкретно лица и на какие принимаемые решения оказывают влияние, степень этого влияния, а также какими критериями при принятии решений они пользуются. Помимо этого следует изучить характер влияния на поведение лиц, принимающих решения о закупках, факторов окружающей среды, особенностей организации, межличностных отношений и индивидуальных особенностей личности. Процесс принятия решения о закупках имеет свои особенности и включает:- осознание потребности; её обобщённое описание; функционально-стоимостный анализ; поиск поставщиков; запрос предложений; выбор поставщика; выдача окончательного заказа; оценка работы поставщика. (2) К организациям, перепродающим ранее приобретённые товары, относятся главным образом предприятия оптовой торговли. В целом на принятие решения о закупках здесь оказывают влияние те же факторы, что и на рынке товаров промышленного назначения. Однако при взаимодействии с организациями-посредниками следует принимать в расчёт их особенности, связанные со спецификой стоящих перед ними задач. (3) На государственные учреждения, осуществляющие закупки товаров для обеспечения выполнения своих функций, связанных с решением различных социальных, политических и других вопросов, приходится значительная доля оптового рынка. Особенность рынка государственных учреждений состоит в том, что закупки производятся за счёт средств государственного и местного бюджетов, а значительная доля всех приобретений приходится на правительство. Диапазон закупок от имени государственных учреждений чрезвычайно широк и включает приобретение продукции, начиная от товаров народного потребления и сельскохозяйственной продукции и кончая различными видами вооружения. Ещё одной отличительной чертой данного рынка, которую необходимо принимать во внимание при взаимодействии с государственными учреждениями, является повышенное внимание и контроль над этой сферой деятельности со стороны общественности. Итак, оптовый рынок – более ёмкий по сравнению с розничным и характеризуется сравнительно небольшим числом субъектов, действующих на нём, преобладанием крупных закупок и значительной ориентацией на потребительский рынок. И, пожалуй, наиболее существенной особенностью, которую стоит учитывать при выходе на рынок предприятий, является тот факт, что от имени организации выступает конкретный человек, на принятие решений которым оказывает влияние множество факторов – объектов изучения маркетинга. Таким образом, с анализа рыночных возможностей начинается сам процесс маркетинговой деятельности. Этот этап очень важен с точки зрения определения перспектив деятельности фирмы и наиболее привлекательных направлений вложения капитала. Анализ рыночных возможностей предусматривает:- проведение комплекса маркетинговых исследований, результатом которых должны быть возможные рекомендаций, вырабатываемые на основе анализа всего массива деловой информации; анализ среды маркетинга, позволяющий выявить контролируемые и неконтролируемые факторы среды, влияющие на деятельность компании, и выработать мероприятия для минимизации воздействия неконтролируемых факторов; изучение розничного и оптового рынков, дающее представление о покупательском поведении индивидуальных потребителей и лиц, выступающих от имени организаций, что позволяет точнее определить рыночные возможности фирмы. На основе сопоставления целого набора выявленных рыночных возможностей с целями и ресурсами фирмы выделяются подходящие возможности, именуемые маркетинговыми. Оптовый Рынок – это территория, на которой организуется купля-продажа продовольственных и непродовольственных товаров, оснащённая торговыми местами, которые сдаются в долгосрочную или краткосрочную аренду продавцам. Все оптовые рынки снабжены складскими помещениями, обеспечены транспортной инфраструктурой и являются важным элементом инфраструктуры определённого региона и даже страны. Оптовый Рынок – это рынок, который обеспечивает взаимодействие нескольких лиц или организаций с целью приобретения услуг или продукции. Приобретённые на оптовом рынке товары могут быть использованы в производственном процессе или направлены для перепродажи. Оптовый рынок часто называют Рынком Предприятий, в настоящее время оба термина описывают одну экономическую структуру.

WHOLESALE MORTGAGE BANKING = ОПТОВОЕ БАНКОВСКОЕ ОБСЛУЖИВАНИЕ ЗАКЛАДНЫХ – Wholesale Mortgage Banking:- the purchasing of loans originated by others, for the acquisition of the servicing rights. / приобретение займов, выданных другими структурами, для .

WHOLESALE POWER MARKET = ОПТОВЫЙ РЫНОК ЭНЕРГИИ – Wholesale Power Market:- the purchase and sale of electricity from generators to resellers (who sell to retail customers), along with the ancillary services needed to maintain reliability and power quality at the transmission level.

WHOLESALE PRICE = ОПТОВАЯ ЦЕНА – Wholesale is a generic term for sales of goods to retailers for eventual sale to the consumer. Specific wholesale petroleum product prices include:- contract price, rack price and spot price. Although there are a variety of wholesale prices, the most often quoted wholesale price is rack price, since it is publicly quoted, and easily available through several market price reporting services. Rack and spot prices serve as useful indicators of trends in other types of wholesale pricing activity. Also known as Wholesale Markets. Wholesale Price is a cost for goods before retail markup. Wholesale Price:- the rack sales price charged for No. 2 heating oil; that is, the price charged customers who purchase No. 2 heating oil free-on-board at a supplier's terminal and provide their own transportation for the product. / Оптовая Цена – цена товаров до розничной наценки. Под Оптовой Ценой понимается цена, по которой предприятие или сбытовая организация реализует свою продукцию. Она используется между изготовителями товаров и оптовыми торговцами, а также оптовыми и розничными торговцами.

WHOLESALE PRICE INDEX = ИНДЕКС ПО ОПТОВЫМ ЦЕНАМ – Wholesale Price Index is a measure of changes in the prices charged by manufacturers and wholesalers. Wholesale price indexes measure the changes in commodity prices at a selected stage or stages before goods reach the retail level; the prices may be those charged by manufacturers to wholesalers or by wholesalers to retailers or by some combination of these and other distributors. In the United States, the index measures the price movements of all commodities flowing into primary markets of the United States – whether domestically produced or imported. Primary markets are those in which a good in a given stage of fabrication is first sold in substantial quantities. Because primary markets include goods of all degrees of fabrication, the same commodity is often priced at several stages of processing. Cotton, for example, is priced in the form of raw cotton, cotton yarn, cotton gray goods, cotton piece goods, and cotton clothing. One of the earliest wholesale price indexes was produced for Great Britain in 1886, covering the period after 1846. The official wholesale price index in the United Kingdom, produced by the Board of Trade, goes back to 1871. In the United States, the first major effort to summarize wholesale price changes through index numbers was published in a report of the US Senate in 1893. The present wholesale price index of the United States, maintained by the Bureau of Labor Statistics, has been computed for the period since 1890. In both the United Kingdom and the United States, economic historians have attempted to reconstruct wholesale price indexes for the XIX century that are superior to the early efforts. The number and character of the commodities included in wholesale price indexes vary widely from country to country. In large industrial countries like the United Kingdom, the United States, and Germany, the commodities that are included usually number in the thousands; but for most countries it is much smaller, often only 100 or 200. The smaller numbers of products will serve well enough if only a general all-commodities index (or a few subindexes at most) is wanted. Greater numbers are required when many subindexes are desired. The United States, for example, publishes indexes for commodities classified according to stage of processing (crude materials, intermediate materials, and finished goods), according to the durability or nondurability of the products, and according to the economic sector for which goods are intended (consumers, producers, etc). The commodities are also grouped into 15 categories and nearly 100 subgroups (fresh fruits, grains, etc) and a large number of product classes (apples, bananas, barley, corn, etc), for each of which monthly price indexes are published. In addition, there are a number of indexes for special commodity groups such as various categories of pharmaceutical preparations. The number of commodities included in the US index has expanded from 250 when the index was started in 1902 to about 2 400 in the late XX century. The new commodities have tended to be more highly fabricated and to have more stable prices, and they have therefore dampened the fluctuations in the index. One reason for the inclusion of more commodities was a gradual shift in the conception of the function of the index. Originally it was regarded as a measure of movements in the general price level, but as other indexes became available, such as the consumer price index, less reliance was placed on the wholesale price index for this purpose. At the same time, there was a growing demand for subindexes pertaining to particular classes of products for various business and analytical purposes. Countries in which industrial production is not highly variegated usually have smaller numbers of product classifications; these serve to distinguish between price movements of domestic goods and price movements of imports and between those of food or agricultural products and those of industrial products. Raw materials and standardized products in early processing stages that are easy to price tend to be well represented in the wholesale price indexes of all countries; whereas more complex types of producers' goods, such as heavy electrical equipment, tend to be underrepresented or omitted even in the indexes of the advanced industrial countries. This is a source of upward bias in the general wholesale indexes since there is reason to believe that technological change has been particularly important in bringing about improvements in complex goods. Price data used to construct the indexes are usually gathered from business firms by mail, less frequently from trade journals and trade associations, and also from government purchasing agents. Weights are generally based on relative sales volume. Data from censuses of production (manufacturing, mining, agriculture, etc) are used for weights when they are available. Wholesale Price Index is the measure of average changes in prices of commodities sold in primary US markets. 'Wholesale' refers to sales in large quantities by producers, not to prices received by wholesalers, jobbers, or distributors. In agriculture, it is the average price received by producers for their farm commodities at the first point of sale after the commodity leaves the farm. A Wholesale Price Index (WPI) is the price of a representative basket of wholesale goods. Some countries use WPI changes as a baseline measure of inflation. However, most countries now report a Producer Price Index (PPI) instead. Calculation of Wholesale Price Index:- The WPI consists of over 2 400 commodities. The indicator tracks the price movement of each commodity individually. Based on this individual movement, the index is determined through an average calculation. Below are the various methods used to calculated the WPI:- Laspeyres Formula (also know as the Relative Method):- This is the weighted arithmetic mean based on the fixed value-based weights for the base period. Ten-Day Price Index:- This calculation takes 'sample prices' with high intra-month fluctuations and selects them to be surveyed every ten days through phone. Using the data retrieved by this procedure and with the assumption that other non-surveyed 'sample prices' remain unchanged, a 'ten-day price index' is compiled and released. Calculation Method:- Monthly price indexes are compiled by calculating the simple arithmetic mean of three ten-day 'sample prices' in the month. Wholesale Prices Index is a measure that reflects changes in the prices paid for goods at various stages of distribution up to the point of retail. It can include prices of raw materials for intermediate and final consumption, prices of intermediate or unfinished goods, and prices of finished goods. The goods are usually valued at purchasers' prices. For some countries the name Producer price index replaced the name Wholesale price index in the 1970s or 1980s after a change in methodology. For some countries, the name Wholesale price index is used for historical reasons and in fact refers to a price index following the same methodology as for a Producer price index. The Wholesale Price Index (WPI) is the price of a representative basket of wholesale goods. Some countries (like India and The Philippines) use WPI changes as a central measure of inflation. However, United States now report a producer price index instead. The Wholesale Price Index or WPI is the price of a representative basket of wholesale goods. Some countries use the changes in this index to measure inflation in their economies, in particular India – The Indian WPI figure was earlier released weekly on every Thursday and influenced stock and fixed price markets. The Indian WPI is now updated on a monthly basis. The Wholesale Price Index focuses on the price of goods traded between corporations, rather than goods bought by consumers, which is measured by the Consumer Price Index. The purpose of the WPI is to monitor price movements that reflect supply and demand in industry, manufacturing and construction. This helps in analyzing both

macroeconomic and microeconomic conditions. The wholesale price index (WPI) is based on the wholesale price of a few relevant commodities of over 240 commodities available. The commodities chosen for the calculation are based on their importance in the region and the point of time the WPI is employed. For example in India about 435 items were used for calculating the WPI in base year 1993–94 while the advanced base year 2004–05 uses 676 items. The indicator tracks the price movement of each commodity individually. Based on this individual movement, the WPI is determined through the averaging principle. The following methods are used to compute the WPI:- (i) Laspeyres Formula (Étienne Laspeyres – German economist and statistician):- it is the weighted arithmetic mean based on the fixed value-based weights for the base period; and (ii) Ten-Day Price Index:- under this method, 'sample prices' with high intra-month fluctuations are selected and surveyed every ten days through phone. Utilizing the data retrieved by this procedure and with the assumption that other non-surveyed 'sample prices' remain unchanged, a 'ten-day price index' is compiled and released. Calculation Method Monthly price indexes are compiled by calculating the simple arithmetic mean of three ten-day 'sample prices' in the month. Monthly price indexes are compiled by calculating the simple arithmetic mean of three ten-day 'sample prices' in the month. Wholesale Price Index measures changes in prices in the manufacturing and distribution sector of the economy and tends to lead the consumer price index by 60 to 90 days. The index is often quoted separately for food and industrial products. See also Producer Price Index. / Формула Ляпэра (Laspeyres Formula) (Немецкий экономист и статистик Эрнст Люи Этьен Ляпэр (Ernst Louis Étienne Laspeyres); 1834–1913). Индекс по Оптовым Ценам измеряет изменения цен в производственном и сбытовом секторе экономики и оказывает влияние на индекс по потребительским ценам через 60–90 дней. Данный индекс часто подразделяется на две группы продуктов:- продовольственные и промышленные товары. Индекс по Оптовым Ценам – относительный показатель, рекомендуемый Международным Валютным Фондом (МВФ) (International Monetary Fund (IMF)) для выявления изменения уровня цен на первой важнейшей стадии коммерческих операций – оптовой торговле. Этот индикатор международной финансовой статистики отражает изменение цен набора товаров на разной стадии их производства. Является средней взвешенной индексов по ценам отдельных групп товаров – минерального сырья, изделий обрабатывающей промышленности, производства электроэнергии и так далее. Для его исчисления используются материалы выборочных наблюдений за уровнем цен набора товаров, представляющих важнейшие товарные группы на первой стадии коммерческих операций с ними. В качестве весов используются сведения об объёме валовой и чистой выручки оптовой торговли в базисном периоде. Базовые веса рекомендуется пересматривать каждые пять лет, по мере обработки материалов очередных сплошных наблюдений (переписей). Агрегатная форма построения (index-number applies to international comparison) индекса по оптовым ценам даёт возможность выявить изменение уровня цен как всей промышленности в целом, так и её отдельных отраслей. При выявлении конъюнктуры рынка оптовой торговли, включающей вывозные (или экспортные) поставки и привозные (или импортные) закупки, масштаб инфляции измеряется также с помощью широко распространённого в мировой статистической практике показателя – индекса по ценам производителей (producer price index). Этот индекс в обобщённом виде характеризует изменение цен на сырьё, топливо, электроэнергию, материалы, полуфабрикаты и готовую продукцию без учёта торговой наценки и налога с оборота.

WHOLESALER = ОПТОВЫЙ ПРОДАВЕЦ (или ОПТОВИК) – (1) Wholesaler is a person who buys goods in bulk from a producer and then sells them in smaller quantities to retailers or other wholesalers, earning a profit either by charging a commission to the retailer or by adding to the manufacturer's price. An intermediary between manufacturers and retailers in various activities such as promotion, warehousing, and the arranging of transport and/or distribution. In general, Wholesaler is a middleman or distributor who sells mainly to retailers, jobbers, other merchants, and industrial, commercial, and institutional users as distinguished from consumers. See also Vendor. Wholesaler is an intermediary between manufacturers and retailers in various activities such as promotion, warehousing, and the arranging of transport and or distribution. / Посредник между производителями и розничными торговцами в различных сферах деятельности, таких как, обеспечение, складирование и обеспечение транспортом и/или распределение. Оптовый Продавец или Оптовик в общем значении:- посредник или оптовый торговец (distributor), продающий ценные бумаги, главным образом, розничным торговцам, мелкооптовым распространителям (jobbers), другим торговцам, а также промышленным, коммерческим пользователям и организациям, но не потребителям. Смотрите также Vendor. Оптовый Торговец – дистрибьютор, который продаёт товары большими партиями, как правило, другим дистрибьюторам. Обычно оптовый торговец покупает и хранит большие партии товаров, производимых несколькими производителями, и затем дробит их на более мелкие партии и формирует поставки по количеству и ассортименту в соответствии с заказами розничных торговцев (retailers).

(2) In securities trading, a Wholesaler is:- (1) an investment banker acting as an underwriter in a new issue or as a distributor in a secondary offering of securities. See also Secondary Distribution. (2) A broker-dealer who trades with other broker-dealers, rather than with the retail investor, and receives discounts and selling commissions. (3) A sponsor of a mutual fund. Wholesaler is an underwriter or a broker-dealer who trades with other broker-dealers, rather than with the retail investor. / Оптовый Торговец или Оптовик:- (1) в отношении ценных бумаг, инвестиционный банк, выступающий в качестве гаранта размещения новой эмиссии (андеррайтера) или оптовика при вторичном предложении ценных бумаг. (2) При инвестировании, спонсор взаимного фонда. (3) При инвестировании, брокер-дилер, который совершает сделки с другими брокерами-дилерами вместо сделок с розничным инвестором, получая скидки и комиссионные сборы за продажу. В торговле ценными бумагами:- (1) инвестиционный банкир (investment banker), действующий в качестве андеррайтера (underwriter) нового выпуска ценных бумаг (new issue) или гаранта при вторичном предложении ценных бумаг. Смотрите также Secondary Distritution. (2) Брокер-дилер, ведущий операции с иными брокерами-дилерами, а не с розничными инвесторами и получающий скидки и комиссионные за продажу. (3) Спонсор (sponsor) во взаимном фонде (mutual fund).

WHOLESALE SALES = ОПТОВЫЕ ПРОДАЖИ – Wholesale Sales:- energy supplied to other electric utilities, cooperatives, municipals, and Federal and State electric agencies for resale to ultimate consumers. / Под Оптовой Торговлей понимается часть внутренней торговли, охватывающая продажу крупных партий товаров предприятиями-производителями предприятиям розничной торговли или, в части средств производства, предприятиям – потребителям этой продукции.

WHOLESALE TRADE = ОПТОВАЯ ТОРГОВЛЯ – (1) Wholesale Trade is defined in the International Standard Industrial Classification (ISIC) as the resale (sale without transformation) of new and used goods to retailers; to industrial, commercial, institutional or professional users; to other wholesalers; or acting as agents in buying merchandise for, or selling merchandise to, such persons or companies. Wholesale trade is defined in ISIC Rev. 3 as comprising the following Groups in Division 51):- (i) wholesale on a fee or contract basis; (ii) wholesale of agricultural raw materials, live animals, food, beverages and tobacco; (iii) wholesale of household goods; (iv) Wholesale of non-agricultural intermediate products, waste and scrap; (v) wholesale of machinery, equipment and supplies; and (vi) other wholesale. See also Wholesaling. Wholesale Trade is a form of trade in which goods are purchased and stored in large quantities and sold, in batches of a designated quantity, to resellers, professional users or groups, but not to final consumers. This corresponds to the NACE (Nomenclature of Economic Activities) Rev. 1 Division wholesale trade and commission trade, except of motor vehicles and motorcycles. It includes the following Groups:- (i) wholesale on a fee or contract basis; (ii) wholesale of agricultural

raw materials and live animals; (iii) wholesale of food, beverages and tobacco; (iv) wholesale of household goods; (v) wholesale of non-agricultural intermediate products, waste and scrap; (vi) wholesale of machinery, equipment and supplies; and (vii) other wholesale.

(2) Wholesale Trade:- during the second week of the month the United States Bureau of Census at the United States Department of Commerce release the Wholesale Trade figures. These figures lag the release month by 2 meaning that January figures are published in March. The Wholesale Trade sector consists of establishments engaged in wholesaling merchandise (without transformation – generally) and rendering services incidental to the sale of merchandise. The wholesaling process is an intermediate step in the distribution of merchandise. Wholesalers sell or arrange the purchase or sale of:- (i) goods for resale (i.e. goods sold to other wholesalers or retailers); (ii) capital or durable non-consumer goods; and (iii) raw and intermediate materials and supplies used in production.

WHOLESALE TRANSMISSION SERVICES = УСЛУГИ ОПТОВОЙ ПЕРЕДАЧИ (или ХХ) – Wholesale Transmission Services:- the transmission of electric energy sold, or to be sold, in the wholesale electric power market. Wholesale Transmission Services:- the transmission of electric energy sold, or to be sold, at wholesale in interstate commerce (from EPAct (short for the US Energy Policy Act)).

WHOLESALE WHEELING = ОПТОВАЯ ПЕРЕКАЧКА (или ПЕРЕКАЧКА ПО ОПТОВОЙ ПРОДАЖЕ) – Wholesale Wheeling is an arrangement in which electricity is transmitted from a generator to a utility through the transmission facilities of an intervening system. Wholesale Wheeling is the transmission of gas or electricity to bulk distributors.

WHOLESALING = ОПТОВАЯ ПРОДАЖА – Wholesaling is the selling of merchandise to anyone other than a retail customer. The merchandise may be sold to a retailer, a wholesaler, or to an enterprise that will use it for business, rather than individual, purposes. Wholesaling usually, but not necessarily, involves sales in quantity and at a cost that is significantly lower than the average retail price. Wholesaling became particularly advantageous after the introduction of mass production and mass marketing techniques in the XIX century. Without wholesale organizations, large manufacturers would have to market their products directly to a great many retailers and/or consumers at high unit costs, and retailers or consumers would have to deal with a large number of manufacturers at great inconvenience. There are three main categories of wholesalers:- (i) merchant wholesalers, (ii) manufacturers' sales branches, and (iii) merchandise agents and brokers. The most important are the merchant wholesalers. These independent businesses buy merchandise in large quantities from manufacturers, process and store that merchandise, and redistribute it to retailers and others. Manufacturers' sales branches are businesses established by manufacturers to sell directly to retailers. They tend to be established by large companies which modify their products frequently and to whom rapid, accurate information on sales and suggestions for improvement are especially valuable. Merchandise agents and brokers sell complementary products of several manufacturers. Unlike merchant wholesalers and manufacturers' sales branches they ordinarily do not take title to the merchandise they handle. Rather, they simply arrange for shelf space and the display of merchandise of the manufacturers they represent. See also Marketing, Wholesale, and Wholesale Trade.

WHOLESOME MEAT ACT OF 1967 = АКТ О ЗДОРОВОМ МЯСЕ ОТ 1967 – Wholesome Meat Act of 1967 (PL 90-201) (21 USC §§ 601 et seq.):- signed into law December 15, 1967. The Act amended the Federal Meat Inspection Act of 1906 by requiring inspection, by either the states or the federal government, of slaughter plants operating in intrastate commerce. See also Federal Meat Inspection Act Of 1906, and Processed Products Inspection Improvement Act Of 1986. The Wholesome Meat Act (also called 'Equal To' Law) is a United States federal law enacted in 1967 that regulates the Federal meat inspection. It requires that states have inspection programs 'equal to' that of the federal government which are Administered by the Food Safety and Inspection Service (FSIS) of the United States Department of Agriculture (USDA).

WHOLE–TREE HARVESTING = УБОРКА ЦЕЛЫМ ДЕРЕВОМ – Whole-Tree Harvesting (WTH) can be defined as the removal of most branches and needles from a harvesting site in addition to the stem wood that is removed in conventional harvesting. The stump is left in situ. Traditionally, WTH has been little used in British forestry, but, in the last decade (1990'), the interest in this type of harvesting has increased for a number of reasons. These include:- (a) when using cable crane, the reduced cost and greater safety of WTH on steep ground. The whole tree is extracted to the roadside where de-limbing can occur on level ground using modern timber processing machinery; (b) the limited amount of brash present after clearfelling with WTH so that subsequent restocking is perceived to be easier, quicker and cheaper; (c) the possibility of removing the woody residues from the site for marketing as fuel, fibre or as a mulch; (d) the ability to respond to changes in timber product specification resulting in improved margins and reduced timber stocks at roadside; (e) better use of the forest road system; (f) improved visual appearance of harvested sites. Two systems of WTH are currently employed in British forestry: one-stage working where the whole tree is removed from the site in a single operation; and two-stage working involving the conventional harvesting (CH) of stem wood followed by a subsequent operation to harvest residues. Cable crane and skidder working are one-stage systems. Cable cranes are ropeway systems where timber is extracted by means of moving cables, powered by a stationary winch. The trees are normally carried partially or wholly clear of the ground. Because of the relatively high cost of extraction, the use of cable cranes is normally confined to the most difficult sites, in particular to forests on steep ground in northern and western Britain. Skidders are tractors which extract the tree from the felling site by lifting the butt end up from the ground and pulling the tree with the crown dragging along the ground. At the present time, clambunk skidders are the machines most often employed in this type of WTH. Two-stage systems involve forwarder working on CH sites and are therefore without the attendant benefits described in (a), (d) and (e) above. We estimate that some 10 per cent of current clearfelling programmes in Forest Enterprise are being achieved through WTH, of which 60% is by cable crane working and 40% is by skidder working. So far, very little WTH is carried out by forwarder working. Harvesting systems should aim to minimise damage, a policy advocated in the Helsinki Guidelines (Ministry of Agriculture and Forestry, Finland 1993) and reinforced by the recent Government statement on Sustainable Forestry (UK Government, 1994). The environmental standards for harvesting practice are covered by existing guidelines (e.g., Forests and Water Guidelines (1993), Forest Landscape Design Guidelines (1994) & Forest and Soil Conservation Guidelines (FC, in prep)). The use of WTH poses particular hazards to sensitive sites of which the forest manager should be aware, because serious damage can be caused to the forest environment which is not compatible with sustainable forest management. Whole-Tree Harvesting is a harvesting method in which the whole tree above the stump is removed.

WHOLLY OWNED SUBSIDIARY = ПОЛНОСТЬЮ ВЛАДЕЕМОЕ ДОЧЕРНЕЕ ПРЕДПРИЯТИЕ – Wholly Owned Subsidiary is a subsidiary whose common stock is virtually 100%-owned by the parent company. Wholly Owned Subsidiary is an entity whose parent owns virtually 100% of its common stock. A Wholly Owned Subsidiary is an entity whose stock is entirely owned by another entity. The owning entity is called the Parent. A subsidiary may become wholly owned as the result of an acquisition, or because the parent spun off certain assets and liabilities into a separate entity. There are a number of reasons why a parent company would want to have a wholly owned subsidiary, including the following:- (i) to maintain valuable contracts with customers that would otherwise terminate if the subsidiary were to be liquidated; (ii) to manage operations in a foreign country; (iii) to separate a certain risk profile from the assets of the parent entity; (iv) to recognize or offload taxable income, depending on the tax rates where the subsidiary is located; and (v) to

separate the operations of the subsidiary from those of the rest of the company. A parent entity may have a large number of wholly owned subsidiaries, depending upon the extent to which it is managing its operations based on the preceding factors. When a subsidiary is not wholly owned, third parties also have an ownership interest in the subsidiary. This situation may arise when it was not possible for the owning entity to purchase all existing shares in the subsidiary, or when the owning entity chooses to limit the total amount of its investment in the subsidiary. Wholly Owned Subsidiary is a subsidiary whose parent company owns virtually 100% of its common stock. See also Subsidiary. / Полностью Владеемое Дочернее Предприятие – дочернее предприятие, капитал которого в виде обыкновенных акций фактически на все 100% принадлежит материнской компании.

WHOOPS = ВУПС (или ОП!) – WHOOPS is a nickname for the Washington Public Power Supply System. In the late 1970's and early 1980's, WHOOPS raised billions of Dollars through municipal bond offerings to finance construction of five nuclear plants in the State of Washington. Because of cost overruns, bad management, and numerous delays, two of the plants were canceled, and it was doubtful that two others would ever be completed. WHOOPS defaulted on the payments to bondholders on the two canceled plants after the Washington Supreme Court ruled that the take-or-pay contracts with the many utilities in the Northwest that had backed the bonds were invalid. This was the largest municipal bond default in history. Whoops:- a nickname for the Washington Public Power Supply System (WPPSS), which in the 1970s raised billions of Dollars through municipal bond offerings, the projects that never materialized. WPPSS defaulted on the payments to bondholders. Whoops:- in the United States, the large-scale municipal bond default that occurred when the underlying contractual arrangements, and hence bond security, were declared invalid (Ultra Vires). / ВУПС – прозвище Системы Общественного Энергоснабжения Вашингтона (Washington Public Power Supply System (WHOOPS)). В конце 1970-х – начале 1980-х WHOOPS привлекла миллионы Долларов путём предложения муниципальных облигаций (municipal bond) для профинансирования постройки пяти атомных электростанций в Штате Вашингтон. Вследствие превышения сметы, плохого управления и многочисленных проволочек постройка двух из пяти электростанций была отложена. Возникли сомнения в том, что ещё две электростанции вообще будут когда-либо завершены. ВУПС не произвела выплат владельцам облигаций на две непостроенные электростанции после того, как Верховный Суд Штата Вашингтон (Washington Supreme Court) постановил, что контракты о покупке или оплате неустойки (take-or-pay contracts), которые были заключены со многими предприятиями коммунального хозяйства на Северо-Востоке страны под залог облигаций, считаются недействительными. Это было крупнейшим в истории непогашением муниципальных облигаций.

WHORL = МУТОВКА – Whorl is:- (i) a ring of similar organs arising from a node; and (ii) the arrangement of leaves in a circle. Whorl is the arrangement of three or more like organs in a circle around the axis. / Мутовка:- (i) круг аналогичных органов, . Мутовка:- три или более органа, таких, как листья, расположенных вкруг на одной оси.

WHORL = РОЛИК (ВЕРЕТЕНА) – Whorl:- small round grooved bits, on flyer or bobbin to take drive band. The term is also with weaving for the pulley in a draw loom. Whorl are what helps keep the spindle spinning. Whorls shapes can take many forms – disks, spheres, half spheres, etc. The whorl can also be a set of cross arms as in the case of the Turkish Spindle. Whorls can be made of almost any material – wood, ceramics, glass, polyclay, a CD, or stone to name a few.

WHORLED = МУТОВЧАТОЕ – Whorled:- of leaves or other parts, not alternate or opposite but placed in a circle around the stem. See also Leaf. Whorled (leaves):- with three or more leaves positioned on the stem at the same level; three or more leaves occurring at each node. Compare with Alternate and Opposite. Whorled:- several leaves disposed at the same level around the stem. Leaves may be arranged on the stem in a variety of ways. The place on the stem from where the leaves grow is called a Node and the part between the nodes is the Internode. If only one leaf arises at a node the leaves are said to be Alternate, if there are two leaves they are Opposite and if there are more than two they are Whorled. / Мутовчатое:- о расположении листьев или других органов, и не очередное или супротивное, а расположенное в окружности вокруг стебля. Смотрите также Лист (Leaf). Листорасположение – расположение листьев на стебле. По мере роста стебля, листья располагаются на нём в определённом порядке, который обусловливает оптимальный доступ к свету. В сущности, листья появляются на стебле по спирали, по либо против часовой стрелки, под определённым углом расхождения. Мутовчатым называется расположение листьев, где от каждого узла стебля отходит по три листа. Это очень редкий вид расположения листьев, чаще всего можно встретить на комнатных растениях, например, у такого растения как Олеандр. Мутовчатое – листья располагаются по три и более на каждом узле стебля. В отличие от супротивных листьев, у мутовчатых каждый последующий завиток может находиться под углом в 90° от предыдущего, а может и не находиться, вращаясь на половину угла между листьями в завитке. Следует однако учесть, что супротивные листья могут показаться мутовчатыми на конце стебля.

WHORL MAGGOT = МУТОВЧАТАЯ ЛИЧИНКА – Rice Whorl Maggot:- Hydrellia Philippina Ferino. What it does:- the feeding damage of whorl maggots causes yellow spots, white or transparent patches, and pinholes. The larva uses its hardened mouth hooks to rasp the tissues of unopened leaves or the growing points of the developing leaves. The damage becomes visible when the leaves grow old. Mature larva prefers to feed on the developing leaves of the new developing tillers at the base of the Rice plant. Why and where it occurs:- standing water in paddies during the vegetative stage, presence of host plants year-round, and transplanting of young seedlings favor the development of Rice Whorl Maggot. The Rice Whorl Maggot is semi-aquatic. It is common in irrigated fields and feeds on the central whorl leaf of the vegetative stage of the Rice plant. It does not occur in upland Rice. It also prefers ponds, streams and lakes or places with abundant calm water and lush vegetation. The insect does not prefer direct-seeded fields and seedbeds. The adult is active during the day and rests on Rice leaves near the water. It floats on the water or perches on floating vegetation. At midday, it is sedentary or it clings on upright vegetation. It prefers thick vegetation and is attracted to open standing water around seedbeds. Neonate maggots feed on the unopened central leaves where larval development is completed in 10–12 days. The full-grown maggots pupate outside the feeding stalk. How to identify:- check the plant for the following symptoms:- (i) white or transparent patches; (ii) pinholes; (iii) damaged leaves easily break from the wind; (iv) somewhat distorted leaves; (v) clear or yellow spots on inner margins of emerging leaves; (vi) stunting; and (vii) few tillers. Check for the presence of insects:- (i) elongate, white eggs glued on leaves; (ii) transparent to light cream legless young larvae rasping the tissues of unopened leaves; and (iii) yellow mature larva feeding on developing leaves of the new developing tillers at the base of the Rice plant. Why is it important:- the Rice Whorl Maggot begins to infest the Rice plant at transplanting. It locates Rice fields by reflected sunlight from the water surface. Using insecticides is not recommended for the Rice Whorl Maggot control because the Rice plant can compensate for the damage. How to manage:- there is no cultural control for Rice Whorl Maggot. Small wasps parasitized the eggs and the maggots. Dolicopodid flies prey on the eggs and ephydrid flies and spiders feed on the adults. The Rice plant can compensate for the damage caused by the Rice Whorl Maggot. Usually, the symptoms disappear during the maximum tillering stage of the crop. Whorl Maggot is a Hydrellia Philippina, the larva of which feeds on leaves in the whorl. The Rice Whorl Maggot is semi-aquatic. It is common in irrigated fields and feeds on the central whorl leaf of the vegetative stage of the Rice plant. It does not occur in upland Rice. The Insect does not prefer direct-seeded fields and seedbeds. The adult is active during the day and rests on Rice leaves near the water. It floats on the water or perches on floating vegetation. It prefers thick vegetation and is attracted to open standing water around seedbeds. Neonate maggots feed on the unopened central leaves where larval development is completed in 10–12 days. The full-grown maggots pupate outside the feeding

stalk. Rice Whorl Maggot:- Hydrellia philippina Ferino (Diptera:- Ephydridae). Kannada Name:- Whorl Maggot. Vernacular Name:- Adult Whorl Maggot. Period of Occurrence:- central whorl leaf of the vegetative stage of the Rice Plant. Alternate Hosts:- its alternate hosts include grasses such as Brachiaria Sp., Cynodon Sp., Echinochloa Sp., Leersia Sp., Leptochloa Sp., Panicum Sp., and wild Rice. Damaging Stage of The Insect:- maggot. Factors Favouring Insect Damage:- (i) standing water in paddies during the vegetative stage; (ii) host plants; (iii) transplanted young seedlings; and (iv) standing water and thick vegetation near fields. Damage:- feeding damage causes yellow spots, white or transparent patches and pinholes. Life Cycle:- (i) Eggs:- the egg is whitish and elongate. It is banana-shaped with a hard shell covering. (ii) Maggot:- small, white or yellowish legless maggots are approximately five to seven mm in length. (iii) Pupa:- pupae are elongate, tapered at both ends and brown colored. (iv) Adult:- adults are small gray to dark gray colored flies of about two to three mm in length. Symptoms of Damage:- (i) white or transparent patches; (ii) pinholes; (iii) damaged leaves easily break from the wind; (iv) somewhat distorted leaves; (v) clear or yellow spots on inner margins of emerging leaves; and (vi) stunting. Control Measures:- there is no cultural control for rice whorl maggot. Biological Control:- small wasps parasitized the eggs and the maggots. Dolicopodid flies prey on the eggs and ephydrid flies and spiders feed on the adults. Nature of Damage of Whorl Maggot:- (i) yellow spots, transparent streaks and pin holes are the other symptoms found on leaves; and neonate maggots feed on the unopened central leaves; and (ii) under severe infestation many broken or bent leaves willappear resulting in poor growth and reduced tillering. Management of Whorl Maggot:- (i) application of carbofuron granules in the nursery 5–7 days before pulling of seedlings will protect the crop until 20DAT; (ii) if severe infestation is observed after 25 DAT spray monocrotophos 36 WSC @ 850 ml ha-1 or chlorpyriphos 20 EC @ 1 500 ml ha-1; and (iii) high volume or low volume sprayers can be used to apply the insecticides.

WICK = ФИТИЛЬ – Wick:- thread, strip, or bundle of fibers that, by capillary action, draws up the oil of a lamp or the melted wax in a candle to be burned. By 1000 BC, wicks of vegetable fibers were used in saucer-type vessels containing olive oil or nut oil in order to provide light, and by 500–400 BC these wicks were in general domestic use. See also Lamp. / Фитиль .

WICKABILITY = КАПИЛЛЯРНОСТЬ (или ФИТИЛЬНОСТЬ, или ВОЗМОЖНОСТЬ ФИТИЛЯ) – Wickability is the ability of a fiber or a fabric to disperse moisture and allow it to pass through to the surface of the fabric, so that evaporation can take place. Wickability is the ability to draw moisture through the fiber. Wickability is the property of a fiber that allows moisture to move rapidly along the fiber surface and pass quickly through the fabric.

WICKET = ВОРОТА ШЛЮЗА (или ЗАСЛОНКА) – Wicket is a rectangular heavily constructed slab of wood and steel hinged in a counterbalanced way so as to be lying flat on the riverbed when down, and held upright by the pressure of the water when raised. Wickets are placed in a parallel line across the river. When all are in raised position, they form a wall or dam, thus backing up the water and raising it to the pool level. / Ворота Шлюза:- гидротехнические затворы для закрывания камеры шлюза со стороны верхнего и нижнего бьефов и обеспечения пропуска судов при выравнивании уровней смежных бьефов. Шлюзные Ворота:- для закрывания шлюзов, как морских, так и устраиваемых в каналах и реках, служат преимущественно ворота. Шлюзные ворота устраиваются большей частью двустворчатые, причём плотно сходятся под некоторым углом и, таким образом, упираются не только в порог шлюза, но и друг в друга. Давление воды передаётся через полотна, следовательно, и боковым стенам шлюза. Недостаток двустворчатых ворот заключается в затруднительности достигнуть одновременного плотного смыкания обеих створок между собой и с порогом шлюза. При небольшой неточности размеров или лёгкой деформации ворот между створами или между воротами и порогами остаются просветы, через которые теряется вода. Распределение напряжений в частях ворот при таком неправильном смыкании оказывается совершенно другое, чем нормальное, соответствующее плотному смыканию; отсюда дальнейшие деформации и повреждения. Существенный недостаток одностворчатых ворот заключается в том, что они требуют больше места для поворота и тем уменьшают полезную длину камеры шлюза. Кроме того, при одном полотне свободная длина горизонтальных частей, входящих в состав ворот, увеличивается значительно, откуда необходимость делать их толстыми. По этим причинам одностворчатые ворота долго употреблялись только при малых пролётах шлюзов (около 5 м), преимущественно в Англии и Швеции. Но в последнее время их начали делать и для больших отверстий. Так, в канале из Гавра в Танкарвилль употреблены одностворчатые металлические ворота длиной в 18.75 м.

WICKING = ФИТИЛЬ (или ПЛЕТЕНИЕ, или ФИТИЛЬНОЕ ПИТАНИЕ) – Wicking:- cord, loosely woven or braided tape, or tubing to be cut into wicks.

WICKING = ФИТИЛЬНОЕ ПИТАНИЕ (или ФИТИЛЬНЫЙ МАТЕРИАЛ) – Wicking is the vertical absorption of a liquid into a porous material by capillary forces. Wicking is a dispersing or spreading of moisture or liquid through a given area, vertically or horizontally, by capillary action in a material.

WIC PROGRAM = WOMEN, INFANTS, AND CHILDREN PROGRAM

WID = WOMEN IN DEVELOPMENT

WIDE AREA NETWORK = ШИРОКООХВАТНАЯ РАБОЧАЯ СЕТЬ – Wide Area Network (WAN) is a computer network that connects computers over large distances by means of high-speed communications links or satellites. / Глобальная Рабочая Сеть (Wide Area Network (WAN)):- коммуникационная сеть, передающая информацию сквозь обширную территорию, например,

между заводами, городами и странами. Глобальная сеть предоставляет интерактивный доступ к прикладным программам через удалённые терминалы. Несколько локальных сетей могут быть превращены в глобальную сеть.

WIDEBAND = ШИРОКОПОЛОСНОЕ – Wideband:- frequency band for data transfer via the power cable. The frequencies used for wide band range from 140 kHz to 400 kHz. / полоса частот для передачи данных по силовому кабелю. .

WIDE BERTH = ШИРОКАЯ ЯКОРНАЯ СТОЯНКА (или ШИРОКОЕ ПРОСТРАНСТВО, или ДОСТАТОЧНОЕ РАССТОЯНИЕ, или СВОБОДНОЕ ПРОСТРАНСТВО) – Wide Berth:- at a considerable distance. Wide Berth is the adequate distance from sea vessels or other objects to ensure safety and maneuverability. Steer to port and give the rocks a wide berth.

WIDE BODY = ШИРОКИЙ ФЮЗЕЛЯЖ (или ШИРОКИЙ КОРПУС) – Wide Body:- an aircraft with two aisles, such as a Boeing 747 or Airbus A340. Wide-Body Aircraft is a commercial aircraft with two aisles for the movement of passengers. / Боинь (Boeing) или Эрбюс (Airbus).

WIDE CROSS = ШИРОКИЙ КРОСС (или ШИРОКАЯ ПОМЕСЬ, или ШИРОКОЕ СКРЕЩИВАНИЕ) – A term Wide Cross refers to the plant breeding technologies/techniques that are utilized to cross two plant Species that would not normally cross in nature. Wide Cross is a cross between two distantly related Species. / Широкое Скрещивание – техника скрещивания между растениями разного вида.

WIDE HYBRIDIZATION = ШИРОКАЯ ГИБРИДИЗАЦИЯ – Wide Hybridization is a hybridization between plants belonging to different Species or Genera. It is also referred to as Interspecific, Intergeneric, Remote or Distant Hybridization. Wide Hybridization is interspecific and intergeneric hybridization which is a first step to introduce alien variation and to transfer desirable genes and traits from wild Species into cultivated Species.

WIDELY HELD FIXED INVESTMENT TRUSTS = ШИРОКО РАСПРОСТРАНЁННЫЕ ТРАСТЫ ФИКСИРОВАННЫХ ИНВЕСТИЦИЙ – In the United States, Widely Held Fixed Investment Trusts (WHFITs):- despite the name, a WHFIT need not be widely held. Rather, a WHFIT is any fixed investment trust that is taxable as a grantor trust if any interest in the trust is held by a middleman (including virtually any type of custodian or nominee). A WHFIT is further limited to trusts that are domestic trusts under the Code. Virtually all domestic trusts issuing pass-through certificates would be WHFITs. Investors in trusts holding mortgages need additional information to compute income because of special substantive rules relating to prepayments. To accommodate these rules, the reproposed regulations require additional information for WHFITs that are widely held mortgage trusts (WHMTs). A WHMT is a WHFIT, substantially all the assets of which, measured by value, are mortgages, amounts received on mortgages, and reasonably required reserve funds. Under the reproposed regulations, a trustee would no longer be required to file Form 1041 (with an attached statement) for a WHFIT. Instead, the following somewhat elaborate reporting scheme would apply:- (i) The trustee for a WHFIT must file Form 1099s annually with the Service reporting tax information with respect to a certificate holder, but only where pass-through certificates are held directly by US individuals, or other US persons that are not exempt recipients. (ii) Where payments are made by a trust through one or more middlemen, the last person in the chain making payment to a person who is not an exempt recipient is responsible for filing a Form 1099 reporting on such payment. (iii) Any person (trustee or middleman) filing a Form 1099 with respect to a certificate holder must provide an annual statement to the holder that is consistent with but more detailed than the Form 1099. (iv) Middlemen, and exempt recipients or non-calendar-year certificate holders holding certificates directly (not through a middleman), may request tax information for any reporting period from the trustee for the WHFIT. (v) Exempt recipients or non-calendar-year certificate holders holding certificates through a middleman may request tax information for any reporting period from that middleman. (vi) Payments by a WHFIT to a foreign person are subject to the normal withholding and reporting rules for such payments. The tax information that must be provided on Form 1099s is less extensive than the information reported in taxpayer statements or on request (described below). A Form 1099 for a calendar year must include information identifying the WHFIT and certificate holder, and the following amounts for the trust attributable to the certificate holder for the year:- gross income, sales proceeds (including scheduled and unscheduled principal payments received), the gross proceeds paid to the holder in redemption of certificates (with an exception for a pro rata redemption in kind which leaves the holder owning directly the same assets as it owned indirectly through the trust), gross proceeds paid to the holder for the sale of certificates on a secondary market established for the WHFIT, and any other information required by the form. A trustee or middleman who is required to file a Form 1099 with respect to a holder must provide to the holder an annual information statement including information identifying the WHFIT and certificate holder, and the following amounts attributable to the certificate holder for the year:- (i) each item of income (including OID (short for the Original Issue Discount)), deduction and credit (with separate identification of any item that if taken into account separately would change the holder's income tax liability); (ii) in the case of a sale or exchange of trust assets during the year (1) if the trust meets a de minimis sales test, the holder's share of the trust sale proceeds (apparently aggregating all sales), or (2) if the trust fails the de minimis test, the following information with respect to each sale or disposition of a trust asset:- the date of the sale or disposition, information regarding the trust sale proceeds, information that would enable the holder to allocate with reasonable accuracy a portion of its basis in its interest to the sale or disposition and a portion of the holder's market discount or amortizable bond premium (if any) with respect to the sale or disposition; (iii) gross proceeds paid on redemption or sale of certificates; (iv) in the case of a WHMT, information regarding market discount and premium and information regarding principal payments, scheduled and unscheduled, received by the trust; and (v) any other information necessary for the certificate holder to report with reasonable accuracy its items of income, deduction, or credit under the grantor trust rules. The statements provided to certificate holders must (not surprisingly) be consistent with Form 1099s and the information provided on request by the trustee. If the trustee uses certain safe harbor rules (discussed below) in reporting income to requesting parties, then the statements provided to certificate holders must be computed in a consistent manner (under rules set out in the reproposed regulations). The safe harbors use factors for reporting items of income or expense, and simplified information for reporting sales of assets, and redemptions and sales of certificates.

WIDELY HELD MORTGAGE TRUST = ШИРОКО РАСПРОСТРАНЁННЫЙ ТРАСТ ЗАКЛАДНЫХ – In the United States, Widely Held Mortgage Trust (WHMT) is a trust, which is a Widely Held Fixed Investment Trust (WHFIT) substantially all the value of the assets of which are mortgages, amounts received on mortgages, and reasonably required reserve funds. If you held an interest in a unit investment trust, mortgage backed security, royalty trust, HOLDR trust, or commodities trust, we are required to report certain details regarding transactions for these securities on the US IRS (Internal Revenue Service) Form 1099 because these products are considered widely held fixed investment trusts (WHFITs). WHFITs whose assets are mortgages, amounts received on mortgages, and reasonably required reserve funds as measured by value are considered widely held mortgage trusts (WHMTs). A WHFIT is also considered a WHMT if substantially all of its assets include trust interests in one or more WHMTs and regular interests in one or more real estate mortgage investment conduits (REMICs). IRS rules governing reporting for WHMTs require us to provide detailed and comprehensive information on Forms 1099. Information (such as income that you received and any proceeds from the sale of assets held by a WHMT) is displayed on Forms 1099-B issued by UBS for tax year 2010. Forms 1099-DIV, 1099-INT, and 1099-OID also display items of gross income and expense as required for WHMTs. We are also required to provide you with detailed information

regarding items of gross income and expenses for WHMTs by no later than March 15, 2011. This information is presented in the 'Supplemental Information for Widely Held Mortgage Trusts' section of your statement. You need this additional information to complete your tax return. The information is provided only to you, and not to the IRS. It sets forth detailed information regarding income and expenses for WHMTs. Below is an explanation of information reflected on your Form 1099 and in the Supplemental Information section for WHMTs:- Principal Paid or Proceeds:- represents the principal distributed to record date holders or the proceeds of a sale net of accrued interest. This amount includes redemption and sales proceeds and redemption and sales asset proceeds. It also includes principal payments that completely retire a debt instrument (other than a final scheduled principal payment) and pro rata partial principal prepayments. The amount should be reported on Form 1040 Schedule D. Cost/Purchase Price:- represents the original amount paid for the units including broker's commissions or the fair market value of such units on the date they were distributed) net of accrued interest. This amount should be entered on IRS Form 1040, Schedule D. Interest:- represents the gross amount of interest distributed to you and received as accrued interest on sales or paid as accrued interest on purchases. Expenses:- this amount represents your share of investment expenses paid by the trust. You may be able to deduct these expenses on IRS Form 1040, Schedule A, line 14, but the deduction is limited to net investment income. Income Adjustment:- you must increase or decrease your taxable income by the amount of this premium or discount on purchases for your account. Market Discount Fraction:- is the ratio used to compute your market discount income or premium amortization for the year. Amortization of bond premiums is deductible on Form 1040, Schedule A, line 28. If you are claiming a deduction for amortization of premiums for bonds acquired after October 22, 1986, but before January 01, 1988, the deduction is treated as interest expense and is subject to the investment interest limitations. Use Form 4952, Investment Interest Expense Deduction, to compute the allowable deduction. For taxable bonds acquired after 1987, you can elect to amortize the bond premium over the life of the bond. See IRS Publication 550 for more information. Redemption Proceeds:- represents the total amount paid to a redeeming trust interest holder and should be reported on IRS Form 1040 Schedule D. For purposes of your statement, this amount also includes redemption asset proceeds (i.e. redemption proceeds less the cash held for distribution with respect to the redeemed trust interest) and trust sales proceeds (i.e. the total amount paid to a selling trust interest holder for the sale of a trust interest). The trust sales proceeds presented includes principal payments that completely retire a debt instrument (other than a final scheduled principal payment) and pro rata partial principal prepayments. It does not include pro rata sales by NMWHFITs (Non Mortgage Widely Held Fixed Investment Trusts) to affect redemption or assets received in any corporate reorganization.

WIDE MARKET = ШИРОКИЙ РЫНОК – Wide Market is a market with substantial or wide profit margins or spread. Opposite of Close Market or Thin Market. WIDE–RANGING DAY = ШИРОКОДИАПАЗОННЫЙ ДЕНЬ – Wide-Ranging Day:- in visual analysis, a spike up that was followed by subsequent up bars would simply be a wide-range bar (also called Large-Range Bars), which is a bar with a significantly larger range than preceding bars. How many bars, and how much bigger a bar must be to qualify as a wide-range bar can be defined mathematically, for example, two or three times the average bar of the last n days, but for now we're just talking about the basic principle. Conversely, you could argue that a wide-range bar followed by a number of bars in the opposite direction becomes a spike. / В техническом анализе биржевых рынков, день, в который лихорадочность рынка значительно превосходит среднюю лихорадочность последних торговых дней. В широкодиапазонный день коэффициент лихорадочности больше k (например, k = 2.0). Широкодиапазонные дни могут иметь особое значение, например широкодиапазонный день с высоким закрытием, который случился после продолжительного снижения цен, часто является сигналом разворота тенденции к росту. Аналогичным образом широкодиапазонный день с низким закрытием, появившийся после продолжительного роста цен, часто может сигнализировать о развороте тенденции к падению.

WIDE REEF = ШИРОКАЯ ОТМЕЛЬ (или ШИРОКИЙ РИФ) – Wide Reef is an illusion caused by the wind blowing upstream against the current. There is generally a deep trench under the ripples caused by the wind.

WIDER–RANGE SECURITIES = ЦЕННЫЕ БУМАГИ С БОЛЕЕ ШИРОКИМ ДИАПАЗОНОМ – Wider-Range Securities:- the proportion of a trust's pool of liquidity that is invested in higher risk securities such as stocks or junk bonds. A trust generally invests in both wider-range securities and narrow-range securities, which carry less risk. It adjusts the proportion according to how risk averse the trust's managers are. WIDOW = ВДОВА – Widow is a woman who was married but whose husband has died.

WIDOW–AND–ORPHAN STOCK = ВДОВЬЯ–И–СИРОТСКАЯ ДОЛЯ (или ВДОВЬЯ–И–СИРОТСКАЯ АКЦИЯ) – Widow-And-Orphan Stock is a stock that pays high dividends and is very safe. It usually has a low Beta coefficient and is involved in a noncyclical business. For years American Telephone and Telegraph (AT&T) was considered a widow-and-orphan stock, but it lost that status after the breakup of the Bell System in 1984. High-quality electric utility stocks are still considered widow-and-orphan stocks by and large. A Widow-and-Orphan Stock is a relatively low-risk stock from a well-known firm that pays high dividends. Widow-and-Orphan stocks are popular during bear markets because they are generally able to continue their dividend payments during a down turn in the market even if it is for a protracted period. During bull markets these stocks are often ignored. The term comes from the fact that widows and orphans need a steady income to house and feed them and for that reason the best investments for them are ones that provide a reliable and steady dividend stream. Characteristics of a Widow-and-Orphan stock:- strong financial position, non-cyclical industry, consistent dividend amount, consistent dividend payment, and consistent dividend growth. The main difference between a blue chip stock and a Widow-and-Orphan stock is that a blue chip stock is not required to pay a dividend to be a blue chip stock. Widow-And-Orphan Stock:- stock that pays high dividends and is very safe, e.g., AT&T, eye beam, etc. Widow-And-Orphan Stock is a stock that pays high dividends and is generally considered to carry low risk. Widow-and-orphan stocks would most likely be in non-cyclical industries that are less likely to be negatively impacted during economic downturns. Prior to being broken up in 1984, AT&T was considered to be a widow-and-orphan stock, and was widely held by all classes of investors. Some utilities are deemed to be safer than the broader market. Investors seeking higher returns may shy away from widow-and-orphan stocks because they provide low returns, regardless of the company size. Widow-And-Orphan Stock is a stock paying high dividends with a low beta and noncyclical business, that is an extremely safe investment. In stock markets, a Widow-And-Orphan Stock is one that reliably provides a regular dividend while also yielding a slow but steady rise in market value over the long term. As such, this type of stock has traditionally been an attractive investment for retirees – in some cases actually widows – as well as for professional investors managing trust funds for orphans. The term serves to denote mostly passive small investors in contrast to wealthy individuals and professional investors who tend to play a more active role and seek greater returns. / Жаргонный термин. Некоторые снабжающие предприятия (utilities). Доля Вдов И Сирот:- акции, по которым выплачиваются высокие дивиденды и которые вследствие этого считаются безопасными. Они обычно имеют низкий коэффициент Бета и связаны с нециклическим производством. В течение многих лет акции Американской Телефонной и Телеграфной компании (AT&T) считались основными акциями такого типа, но их статус был изменён после решения суда о ликвидации активов местных действующих отделений компаний в середине 1980-х. Вдовья-И-Сиротская Акция:- высокодоходные, не зависящие от цикла акции с обеспечением, которые являются в иных случаях 'невознаграждающими', например, с медленным обращением на рынке.

WIDOWED MOTHER'S ALLOWANCE = ПОСОБИЕ ОВДОВЕВШЕЙ МАТЕРИ – Widowed Mother's Allowance:- a pension you receive from the Department of Social Security following the death of your husband provided you are aged between 45 and 60 and you have children or are pregnant.

WIDOW'S BEREAVEMENT ALLOWANCE = ПОСОБИЕ ДЛЯ ВДОВ ПРИ ПОТЕРЕ СУПРУГА – Widow's Bereavement Allowance is the extra allowance a widow receives in the tax year of her husband's death, and the following tax year.

WIDOW'S EXEMPTION = ВДОВЬЕ ОСВОБОЖДЕНИЕ (или ОСВОБОЖДЕНИЕ ВДОВЫ) – In general terms, a Widow's Exemption refers to the amount that can be deducted from taxable income by a widow, thereby reducing her tax burden. In the United States, it usually refers to the amount exempt from state inheritance taxes on a widow's share of her husband's estate. Since it is claimed as a deduction by the widow, it has the effect of reducing her inheritance taxes. Less frequently, the term may also apply to the amount of the property tax exemption offered to widows in certain states, such as Florida. A widow would not be eligible for this exemption if she remarries. A similar exemption is also offered to widowers in some other states. / льготы для вдов должников.

WIDOW'S PENSION = ПЕНСИЯ ВДОВЫ – Widow's Pension is a pension you receive from the Department of Social Security following the death of your husband, provided you were aged between 45 and 65 when your husband died or when you ceased to be entitled to a widowed mother's allowance. It is reduced if you were then under the age of 55. If your husband was employed, you might also be entitled to a widow's pension from his former employer.

WIDTH = ШИРИНА – (1) Width is a horizontal measurement of a material. In woven fabric, it is the distance from selvage to selvage, and in knitted fabric, the distance from edge to edge.

WIENER BÖRSE AG = ВИНА БЁРЗЭ А.ГЕ. (или ВЕНСКАЯ БИРЖА АО) – In Austria organized trading for the cash and the derivatives market takes place at the Vienna Stock Exchange (Wiener Börse AG). The Vienna Stock Exchange was founded in 1771 by Empress Maria Theresa, making it one of the oldest in the world. In December 1997 the former Vienna Stock Exchange and ÖTOB AG (Österreichische Termin und Optionenbörse AG, the Austrian Futures and Options Exchange) were merged to form Wiener Börse AG. Since the amendment of the Stock Exchange Act (Börsegesetz) in 1998, Wiener Börse AG has been an exchangeoperating company organized under private law. It was granted a license to operate and manage the Vienna exchange by way of an official notice of 1998-April-03. In June 1999 the Republic of Austria sold its 50% stake in Wiener Börse AG to 30 listed companies. The new ownership structure now includes major Austrian banks and listed companies. The Vienna Stock Exchange is Austria's only stock exchange. The creation of the new Vienna Stock Exchange was a major step forward in establishing Vienna as an independent market for Austrian, central and eastern European securities and their corresponding derivative instruments. Compared with other international stock exchanges, the Vienna Stock Exchange is relatively small. However, the introduction of international capital market standards, a wide range of listed companies and a link-up with the German Xetra® (exchange electronic trading) system have made Vienna more attractive to potential international investors. As a stock, futures and options exchange, the Vienna Stock Exchange intends to function as a center of expertise for Austria and central and eastern Europe. Following the trend of growing co-operation between exchanges, Wiener Börse AG established a strategic partnership with Deutsche Börse AG, which led to the introduction of the Xetra® system. Wiener Boerse AG (Austrian Stock Exchange):- established in 1771, the major securities market of Austria. Wiener Börse AG is the regional exchange of Austria, trading equities, derivatives, and indices. As part of its information service to investors, the exchange develops, calculates, and disseminates in real time more than 40 indices of Austrian as well as Central and East European stocks and bonds. Equity trading includes stocks, bonds, investment fund certificates and index certificates, participation certificates, profit-sharing certificates, and subscription rights. Futures and options are traded on Austrian stocks, the Austrian Trade Index (ATX), and the Central European Clearinghouses & Exchanges (CECE) indices. A separate warrants market has been established. The ATX represents the continuously traded stocks on the prime market with the highest liquidity and market capitalization. The Wiener Börse Index (WBI) represents the performance of all Austrian stocks admitted to listing on the official market. The Vienna Dynamic Index (ViDX) tracks price trends of the growth of technology stocks listed on the Wiener Börse. The ATX Prime contains all the stocks listed on the prime market segment and serves as a benchmark for institutional investors. The CECE indices track the most attractive companies listed on Central and East European stock exchanges to make these markets measurable and tradable through futures and options. Trading is conducted Monday through Friday. See also Vienna Stock Exchange. / Вина Бёрзэ А.Ге. (Wiener Börse AG). Ё.Тэ.О.Бэ. А.Ге. (ÖTOB AG) Ёстэрайхишэ Тэмин унд Опционэнбёрзэ А.Ге. WIENER PHILHARMONIKER = ВЕНСКИЙ ФИЛАРМОНИСТ – Austrian Philharmonikers are produced by the Austrian Mint in Vienna, who have a rich history of producing some of the worlds most beautiful coins for over eight centuries. They receive their name from the Vienna Philharmonic Orchestra, which is commemorated in both the obverse and reverse designs of the coin. These coins are known to collectors and gold bullion coin investors as Austrian Philharmonica's or Philharmonikers. The Vienna Philharmonic Orchestra is considered to be one of the finest performing orchestras on earth and the Austrian government chose to honor this organization by immortalizing it in the purest of gold. The Austrian Philharmoniker is thus minted in one full ounce of 24 carat gold, meaning it has 99.99% purity. The obverse design of the Austrian Philharmonikers represents the great organ of the Golden Hall at Musikverein in Vienna. This organ is at the heart of the Vienna Philharmonic Orchestra's performance center and is an internationally recognized symbol of the group. The reverse side of the Austrian Philharmonikers design features several of the instruments that are integral to the performance of orchestral music. This design incorporates musical instruments from the wood, wind, brass and stringed instrument groups along with the Wiener Philharmoniker, which translates to Vienna Philharmonic. The Austrian Philharmonikers are currently minted in four sizes, ranging from one tenth of an ounce to one full ounce. Their face value ranges from 25 Euros to 2 000 Schillings. In addition to the four regular denominations of Austrian Philharmonikers issued each year, the Vienna Mint also creates commemorative coins on an average of ten per year. In the years, 1992, 1995 and 1996, the Austrian Philharmoniker was declared the best selling gold bullion coin by the World Gold Council. Since February of 2008, the Austrian Mint has also produced a version of the Austrian Philharmoniker in silver, which is identical to the gold Austrian Philharmonikers with the exception of it's face value being 1.50 Euros. The silver Austrian Philharmonikers is intended for purchase as an investment coin and there are a limited number produced each year according to the current demand. These coins are crafted of one ounce of 99.9% pure silver, even finer than the .925 Sterling silver used in the production of high end jewelry items. At the time of this writing, these coins could be purchased from the mint for less than USD20 per coin. In 2004, the Austrian Mint released a commemorative Austrian Philharmoniker coin with a 100 000 Euro face value that weighed in at 31.103 kilograms. The total production of these coins was fifteen. At the time of this writing, with a current gold spot price of USD1 246.00 per Troy ounce, one of these coins would have a bullion value of USD1 246 000, a full USD1 118 830 above the face value of the coin. While the commemorative Austrian Philharmonikers coins are legal tender in Austria, they cannot be used to make purchases outside of the country. The majority of these coins are intended for collector value because their actual gold content

exceeds their face value. Wiener Philharmoniker is the Austrian gold coin of 999.9 fineness, first issued in 1989. Actual Gold Content:- 1.0 Troy ounce (31.103 grams). Diameter:- 37 mm. Face value:- 2 000 Schillings or 100 Euro. Also minted in 1/2, 1/4, 1/10 ounce sizes. The Austrian, or Vienna, Philharmonic is the best-selling gold coin in Europe. Attesting to its international popularity as one of the 'pure gold coins' the Philharmonic led sales worldwide in 1992, 1995 and 1996, according to the World Gold Council. In 2008, at the height of the worldwide credit-financial crisis, more one-ounce Philharmonics were sold on a global basis than US Eagles or Krugerrands. Like its competitors, the Philharmonic tracks the gold price and is internationally liquid. As already mentioned, the Philharmonic is struck in pure, 24-karat gold. The obverse of the coin depicts the great organ in Vienna's concert hall, home of the famed Vienna Philharmonic Orchestra. The obverse shows a harmonious medley of musical instruments – a string base, cellos, violins, a bassoon, harp and Viennese horn. The Philharmonic is minted in one-ounce (Troy), half-ounce, quarter-ounce and one-tenth ounce sizes with successive face values of 100, 50, 25 and 10 Euros respectively. Earlier mintages before the creation of the Euro were denominated in Schillings. In 2004, the Austrian Mint issued a 1 000-ounce gold Philharmonic to mark the 15th anniversary of the popular bullion coin. It has a face value of 100 000 Euros. Fifteen coins were struck and they sold out within two weeks of offer. The relief on the coin was sculpted by computer and finished by hand. Each coin took 130 hours to mint. Not to be mistaken for pocket change, the 1 000-ounce Philharmonic is listed in the Guinness Book of World Records as the world's largest gold coin. The Vienna Philharmonic coin is struck in pure gold, 999.9 fine (24 karats). It is issued every year, in four different face values, sizes and weights. It is used as an investment product (bullion coin), although it inevitably ends up in private collections. According to the World Gold Council, it was the best-selling gold coin worldwide in 1992, 1995 and 1996. A design of musical instruments representing the Vienna Philharmonic Orchestra, as well as the text Wiener Philharmoniker ('Vienna Philharmonic'), can be seen on the reverse of the coin. The subject of the obverse is the great organ in the Golden Hall in Vienna's Musikverein, the concert hall of the Vienna Philharmonic Orchestra. The face value in Euros, the weight, alloy purity and year of issue are also inscribed on this side of the coin. Since 2008-February-01, the coin has also been minted in silver. The design of the silver coin is identical to that of the gold coin, except for its face value of 1.50 Euro. The Austrian Mint first began producing the Vienna Philharmonic in 1989. This coin was the best selling gold bullion coin in the world in 1992, 1995, and 1996 according to the World Gold Council. Design:- the obverse (front) depicts a collection of orchestral instruments:- a cello, four violins, a Vienna horn, bassoon, and harp. These instruments are arranged beneath the German name of the orchestra:- 'WIENER PHILHARMONIKER'. The reverse (back) features the great organ in the Vienna's Golden Concert Hall (Musikverein), which houses the Philharmonic Orchestra. Beneath the organ are the weight, fineness, date of issue, and face value in Euros (Prior to 2002, Philharmonics carried face values denominated in Schilling:- 2 000 Schilling (1-oz), 1 000 Schilling (1/2-oz), 500 Schilling (1/4-oz), and 200 Schilling (1/10-oz)). Above the organ is the official name of the country, 'REPUBLIK ÖSTERREICH'. Minted in 1-oz (face value 100 Euro), 1/2-oz (face value 50 Euro), 1/4-oz (face value 25 Euro), and 1/10-oz (face value 10 Euro) sizes, all Vienna Philharmonics are minted from 99.99% pure gold. No alloyed metals are added. All coins are minted at the Austrian Mint AG, now a subsidiary of the Austrian National Bank. The Austrian Mint guarantees the Philharmonic's weight and purity and backs its monetary face value, which was the highest of any gold bullion coin when it was denominated in Schilling, prior to the creation and acceptance of the Euro. / 'ВИНА ФИЛАРМОНИКА' ('WIENER PHILHARMONIKER'). 'РЭПУБЛИК ЁСТЭРАЙХ' ('REPUBLIK ÖSTERREICH').

WIFE'S EARNED INCOME RELIEF = НАЛОГОВАЯ СКИДКА НА ЗАРАБОТАННЫЙ ДОХОД ЖЕНЫ – Wife's Earned Income Relief (WEIR):- if you are a married person or in a civil partnership, this deduction is given against the married woman's earned income or the earned income of civil partner 'B'. The maximum deduction is £4 500. This means that if the wife's or partner's income is less than this sum after employment expenses (e.g., employer pension contributions) the relief is restricted to this amount. For example, salary is £6 000 but a one off payment of £5 000 has been made into a pension scheme. The wife's earned income relief would therefore only be £1 000. Earned income includes:- (i) employment income; (ii) self-employment income; (iii) casual earnings; (iv) pension income in persons own right; and (v) invalid care allowance paid by social security. It does not include:- (i) income from any unearned sources (e.g., bank accounts and investments); and (ii) income from shareholder taxation. See also Unearned Income. When this was first introduced in 1920, it was equal to the difference between the married man's allowance (MMA) and two single person allowances. In 1942 the WEIR was increased to the level of the single person's allowance, putting working couples at a distinct advantage. This allowance would be added to their husband's MMA when calculating the total earnings a couple could receive tax-free:- in 1989/90 this was £7 160. By comparison, if a couple were not married, their total allowances would be £5 570. As its name suggests, the WEIR did not cover savings income. As a result, the tax system strongly penalised those married couples in which the wife had had to give up work to have, and look after, children, yet contributed to the household finances with savings of her own. However, the system encouraged marriage, being more generous to working married couples than to unmarried couples. The position for these three types of family situation is summarised below, using figures for 1989–90:- combined value of personal allowances:- (i) single person – £2 785; (ii) two unmarried people – £5 570; (iii) couple in which husband only works – £4 375; and (iv) couple where at least wife works – £7 160. / Налоговая Скидка На Заработанный Доход Жены:- персональная налоговая льгота, действовавшая до Апреля 1990 и распространявшаяся на мужчин, чьи жёны работали. В соответствии с льготой из налогооблагаемого дохода разрешалось вычитать заработанный женой доход, либо – если это было целесообразно – применялась налоговая льгота одиноким людям. Налоговая скидка на заработки жены была отменена с введением Раздельного Налогообложения Заработков Жены (Separate Taxation Of Wife's Earnings). WI–FI = ВАЙ–ФАЙ – Wi-Fi is a set of standards for technology allowing computers and other devices to communicate using radio connections instead of cables. It was originally intended to allow the replacement of the cables which commonly connect computer networks on a single site with more convenient radio links. It has proved to be useful well beyond this limited role. Wi-Fi is also known as WLAN, because it is a wireless type of local area network (LAN). One particularly important application is the use of wi-fi for mobile internet access. Its main competitor in this role are 3G mobile phone networks. In comparison to them:- (i) mobile networks provide extensive coverage, covering whole countries. Wi-Fi provides coverage in 'hot spots' and even city wide coverage is only now becoming common. (ii) Wi-Fi requires much cheaper infrastructure. It is so cheap that some cities are building free wi-fi networks and cafés and airports offer free hotspots. Even some private individuals provide free internet access through a single hotspot. (iii) Wi-Fi uses unregulated spectrum (radio frequencies) so the barriers to entry are much lower. (iv) Mobile networks can provide uninterrupted

connections to moving equipment. Because of its low cost and the increasingly wide availability of equipment (such as laptop computers) that can use Wi-Fi, it is a serious threat to mobile phone networks' data revenues. / Вай-Фай (Беспроводная Точность) Wi-Fi (Wireless Fidelity) – стандарт широкополосной беспроводной связи для организации беспроводных локальных компьютерных сетей, а также для создания точек высокоскоростного доступа в Интернет (так называемых Hot-Spot – Хот-Спот) для пользователей ноутбуков в аэропортах, деловых центрах, гостиницах и прочих местах скопления посетителей.

WIG = ПАРИК – Wig is a manufactured covering of natural or synthetic hair for the head. Wig:- manufactured head covering of real or artificial hair worn in the theatre, as personal adornment, disguise, or symbol of office, or for religious reasons. The wearing of wigs dates from the earliest recorded times; it is known, for example, that the ancient Egyptians shaved their heads and wore wigs to protect themselves from the sun and that the Assyrians, Phoenicians, Greeks, and Romans also used artificial hairpieces at times. It was not until the XVI century, however, that the wig again became a generally acceptable form of adornment or corrective for nature's defects, as in the case of Queen Elizabeth I. Men's perukes, or periwigs, for the first time since ancient Egypt, came into widespread use in the XVII century, after Louis XIII began wearing one in 1624. By 1665 the wig industry was established in France by the formation of a wigmakers guild. The wig became a distinctive class symbol for more than a century. In the XVII century it attained its maximum development, covering the back and shoulders and flowing down the chest. During the same century, women also wore wigs, though less often than did men. Certain professions established specific wigs as part of their official costume; the practice is retained today only in some legal systems, notably that of the United Kingdom. Men's wigs in various forms were worn throughout the West in the XVIII century, until the French and American revolutions swept away these and other symbols of social status. From the XVIII century, women wore wigs and hairpieces, but only surreptitiously. The popularity of women's naturally styled wigs in the XX century, and candour about wearing them, increased substantially, especially after the development of wigs made from inexpensive synthetic hairs. In the Orient, wigs have been used rarely except in the traditional theatre of China and Japan.

WIGAN = ВИГЭНСКАЯ (или ЛОЩЁНКА, или ЖЁСТКАЯ ПАРУСИНОВАЯ ПРОКЛАДКА) – Wigan is a converted cotton cloth, dyed black, brown or gray, and given a firm starched, plain calender finish, and used for interlinings in men's and boys's clothing to give body to the garment. WIL = WEB INTERFACE LAYER

WILD CARD = ШАЛЬНАЯ КАРТА – (1) Wild Card:- infrastructure systems face a number of pressing challenges relating to demographics, environment, finance and governance pressures. Furthermore, infrastructure mediates the way in which everyday lives are conducted; their form and function creating a persistence of unsustainable practice and behaviour that cannot be changed even if change is desired. There is a need to find means by which this obduracy can be broken so that new, more sustainable futures can be planned. This paper develops a methodology, taking concepts from both engineering and social science. Wild Cards, or Physical Disruptions, are used to 'destructively test' complex infrastructure systems and the multi-level perspective is used as a framework for analysing the resulting data. This methodology was used to examine a number of case studies, and with focus groups consisting of a range of different infrastructure providers and managers, to gain a better understanding of systems' socio-technical characteristics and behaviours. A number of impactful 'intervention points' emerged that offered the opportunity to promote radical changes towards configurations of infrastructure systems that provide for 'less' physical infrastructure. This paper also examines the utility of wild cards as enablers of transition to these 'less' configurations and demonstrates how a 'wild card scenario' can be used to co-design infrastructure adaptation from with both infrastructure providers and users. / Дикая Карта:- инвестиционный инструмент, в особенности депозитный сертификат или сберегательный сертификат, которому законным образом разрешено иметь самую высокую процентную ставку или иногда не иметь ограничений по ставке дохода.

(2) Wildcard:- in the State's (Florida) Project Aspire, used to search for items for which the end-user has only partial information. The percent sign (%) is the wildcard symbol in Aspire. For example, when searching for a vendor, enters BOB% to return all vendors whose names start with Bob. / Эспайэ (Aspire).

WILD CARD OPTION = ОПЦИОН НА ШАЛЬНУЮ КАРТУ – Wild Card Option is the right of the seller of a Treasury bond futures contract to give notice of intent to deliver at or before 08:00 pm Chicago (GMT –6 hours) time after the closing of the exchange (03:15 pm Chicago time) when the futures settlement price has been fixed. Related:- Timing Option. Refers to a provision of any physical delivery Treasury Bond or Treasury Notes futures contract that permits shorts to wait until as late as 08:00 pm on any notice day to announce their intention to deliver at invoice price that are fixed at 03:15 pm (or at 02:00 pm), the close of futures trading, on that day. Wild Card Option is an option associated with treasury bond or treasury note futures contracts that permits the short position to delay the delivery of the underlying. This provision allows the short futures contract holder to announce his or her intention to deliver the underlying securities on any notice day before a specified time, which is later than the regular trading hours, in which invoice prices are normally fixed. The security that is delivered is usually the cheapest to deliver on that specific day. Wild Card is a slang:- an unpredictable or unforeseeable factor:- a surprise witness proved to be the wild card at the trial; or the weather was a wild card. Another type of embedded delivery option is the wildcard option. A wildcard option arises when the settlement price of a futures or option contract is established before the final exercise opportunity and when exercise closes the underlying asset position. The Treasury bond (T-bond) futures contract traded at the Chicago Board of Trade, for example, contains two wildcard options. An end-of-day wildcard option arises because the settlement price of the T-bond futures contract is set at 02:00 pm central standard time (CST), and the short futures can wait until 08:00 pm to declare an intention to deliver. An end-of-month wildcard option arises because the

settlement price of the T-bond futures contract is set seven business days before the end of the contract month, and the short futures can wait until the end of the month to deliver. / в Чикагской Палате Торговли (Чикагском Табло Торговли, если быть более точными). Термин Опцион На Дикую Карту относится к положению о любой фактической поставке по фьючерсным контрактам на Казначейские Облигации или Казначейские Ноты, которое разрешает продавцам дожидаться вплоть до 20:00 часов в любой день уведомления для объявления о своём желании поставить по цене счёта-фактуры, которая была зафиксирована по времени в 15:15 часов, то есть по закрытии торговой сессии по этим фьючерсам, в тот же день.

WILDCAT = ДИКАЯ КОШКА – (1) Wildcat is a sprocket wheel on the windlass for taking links of the chain cable.

(2) Wildcat is a slang term in energy industries. A 'Wildcat' is a well that is not drilled in a proven field. / Поисковая Скважина (Wildcat) – скважина, бурящаяся с целью поисков новых месторождений полезных ископаемых и отстоящая на значительном расстоянии от уже известных месторождений.

WILDCAT ACRES = АКРЫ ПОД ДИКОЙ КОШКОЙ – Wildcat Acres:- in the Unuted State, this term refers to cropland used in the production of a covered commodity over the 1998 to 2001 period that was not receiving PFC payments provided for in the 1996 Farm Bill. This is land that has not been 'in the program' from 1996 to 2002. If a producer chooses to update base acres then this land can be added during signup:- (i) Will have to prove acres; (ii) Program yields for the purposes of calculating direct payments will be assigned to these acres:- (a) Law states that yields for similar farms in the area will be used; and (b) The County Committee will assign a yield based on yields for 3 similar farms in the count; and (iii) Program yield used for calculating the CCP can be 'updated' using proven yields over the 1998 to 2001 period and choices discussed earlier. WILDCAT BANK = БАНК ДИКАЯ КОШКА – Wildcat Bank is the unsound bank chartered under state law during the period of uncontrolled state banking (1816–63) in the United States. Such banks distributed nearly worthless currency backed by questionable security (e.g., mortgages, bonds) and were located in inaccessible areas to discourage note redemption. Note circulation by state banks ended after the passage of the National Bank Act of 1863, which provided for the incorporation of national banks under federal law and the issue of bank notes on the security of government bonds. The term Wildcat Bank was subsequently applied to any unstable bank. Wildcat Bank:- in the United States, a bank that issued notes without adequate security in the period before the establishment of the national banking system in 1864. Wildcat Bank:- in the United States, an unsound bank chartered under state law during the period of state banking control (1816–63). Such banks distributed currency backed by questionable securities (e.g., mortgages, bonds) and were located in inaccessible areas to discourage note redemption. Note circulation by state banks ended with the passage of the National Bank Act of 1863, which provided for the incorporation of national banks and the issue of banknotes on the security of government bonds. The term Wildcat Bank was later applied to any unstable bank. / Банк Дикая Кошка:- так в 1830–60 называли банки, зарегистрированные в штатах. Эти банки печатали свои собственные бумажные деньги (wildcat currency), не обладая необходимым капиталом для их обеспечения. Начало их существованию было положено в 1836 фактическим упразднением Президентом Эндрю Дьжексэном (Andrew Jackson) Второго Банка Соединённых Штатов (Second Bank of the United States); в 1837 во время финансовой паники многие из них обанкротились, а в 1863 по Акту О Национальном Банке (National Bank Act of 1863) большинство из них перешли под федеральный контроль.

WILDCAT DRILLING = БУРЕНИЕ ПО МЕТОДЕ ДИКОЙ КОШКИ (или БУРЕНИЕ ДИКОЙ КОШКИ) – Wildcat Drilling is the process of drilling for oil or natural gas in an unproven area, that has no concrete historic production records and has been unexplored as a site for potential oil and gas output. The most successful energy companies are the ones with a very high rate of drilling success, irrespective of whether the wells are drilled in known areas of production. Wildcat drilling is also known as Exploratory Drilling. The term 'Wildcat Drilling' probably has its origins in the fact that drilling activity in the first half of the XX century was often undertaken in remote geographical areas. Because of their remoteness and distance from populated areas, some of these locations may have been, or appeared to be, infested with wildcats and other untamed creatures. Presently, with global energy companies having scoured much of the earth's surface, including oceans, for oil and gas, few areas remain unexplored for their energy potential. Wildcat drilling amounts to a small proportion of the drilling activity of large energy companies. For small energy companies, wildcat drilling can be a 'make-or-break' proposition. Investors in such companies can reap significant rewards if such drilling results in locating large energy reservoirs. Conversely, wildcat drilling that repeatedly results in dry holes can lead to adverse performance for a small-cap energy stock. See also Wildcat Well. Wildcat Drilling is an exploring for oil and gas in an unproven area. A wildcat oil and gas limited partnership is structured so that investors take high risks but can reap substantial rewards if oil or gas is found in commercial quantities. / Бурение Дикой Кошки:- экспериментальная разработка месторождений. WILDCAT STRIKE = СХОДКА ДИКАЯ КОШКА – Wildcat Strike:- spontaneous or unannounced illegal industrial action by a section of employees, without following the proper procedure for striking such as majority approval through a union ballot. In such situations, the employer usually has the legal right to fire the offending workers and to sue the union for damages. Also called Outlaw Strike or Quickie Strike. See also Strike. Wildcat Strike is a strike called in violation of an existing contract between labor and management. Wildcat strike is an employee work stoppage that is not authorized by the Labor Union to which the employees belong. When employees join a union, they give the union the right to collectively bargain with their employers concerning the terms and conditions of work. Since the passage in 1932 of the Norris-LaGuardia Act (29 USCA § 101 et seq.), employees have had the right to strike for the purpose of demanding concessions from their employers. When employees go on strike without union authorization, however, their action is called a Wildcat Strike. Federal courts have held that wildcat strikes are illegal under the Wagner Act (National Labor Relations Act of 1935 (29 USCA § 151 et seq.)), and employees may be discharged by their employers for participating in wildcat strikes. A wildcat strike brings into conflict sections 7 and 9(a) of the Wagner Act. Section 7 protects employees who bargain collectively and engage in other concerted activities for the purpose of Collective Bargaining. Section 9(a) states that representatives chosen for the purpose of collective bargaining shall be the exclusive representatives of all the employees in that bargaining unit. Because wildcat strikers engage in concerted activity without the authorization of their union, they appear to be both protected because of section 7 and unprotected because of section 9(a). The critical issue is whether the wildcat strikers should be protected to the same

extent as strikers authorized by the union, or whether their activity is unprotected because of the exclusivity principle behind section 9(a). The Supreme Court ruled in Emporium Capwell Co. v. Western Addition Community Organization, 420 US 50, 95 S. Ct.977, 43 L. Ed. 2d 12 (1975) that when wildcat strikers bargain separately, they are not protected by the Wagner Act. Mostlower courts have applied Emporium Capwell broadly, holding that all wildcat strikers are unprotected. Therefore, even when wildcat strikers have not attempted to bargain separately, the majority rule is that the strike is unprotected activity. Ordinarily a wildcat strike constitutes a violation of an existing collective bargaining contract, so the strikes are not protected unless the whole union joins them and ratifies the protest. The union may, however, discipline its members for participating in a wildcat strike and impose fines. Wildcat Strike (Americanism) is a labor strike that has not been called or sanctioned by the officials of the union. A Wildcat Strike is a work stoppage that occurs during the term of a collective bargaining agreement without approval of union leadership and in violation of a no-strike clause. Such strikes generally occur because:- (i) labor has specific problems or concerns that have not been satisfactorily addressed by employers; or (ii) workers feel that union leaders are not acting in the best interest of the union members. It is also referred to as an 'Outlaw Strike'. Despite its statutory recognition of the right to strike, the federal Taft-Hartley Act prohibits some types of concerted pressure. Individuals who participate in wildcat strikes are engaged in unprotected activity and may be subject to employer discipline. Discipline imposed against wildcat strikers must be nondiscriminatory. The employer may, however, single out instigators for harsher discipline than is imposed against other participants. Union stewards and officers may not be given harsher discipline than other wildcat strikers, unless:- (i) the contract gives the union specific affirmative obligations to attempt to prevent or end wildcats; (ii) the union authorized or ratified the wildcat; or (iii) the officer or steward instigated the strike. An employer may seek an injunction against a wildcat strike, but an injunction will be issued only if the employer is willing to arbitrate the underlying dispute. / Акт Нориса-ЛаГодиа (Norris-LaGuardia Act). WILDCAT WELL = СКВАЖИНА ДИКАЯ КОШКА (или ОБОСОБЛЕННАЯ СКВАЖИНА, или ОПОРНАЯ СКВАЖИНА, или ПРЕДВАРИТЕЛЬНАЯ ПОИСКОВАЯ СКВАЖИНА, или НАБЛЮДАТЕЛЬНАЯ СКВАЖИНА) – Slang in energy industries. A 'Wildcat' is a well that is not drilled in a proven field. A well drilled in a previously unexplored or unproved area. See also Exploratory Well. Wildcat Well is an exploration well. The significance of this type of well to the drilling crew and well planners is that by definition, little if anything about the subsurface geology is known with certainty, especially the pressure regime. This higher degree of uncertainty necessitates that the drilling crews be appropriately skilled, experienced and aware of what various well parameters are telling them about the formations they drill. The crews must operate top-quality equipment, especially the blowout preventers, since a kick could occur at virtually any time. If a wildcat is especially far from another wellbore, it may be described as a 'rank wildcat'. Проходка скважины осуществляется буровыми установками. Элементы скважины:- забой – дно; ствол или стенки – боковая поверхность; устье – выход на поверхность скважины. Под Наблюдательной Скважиной понимается специальная скважина, используемая для контроля и наблюдения внутрипластовых процессов (изменения температуры при вытеснении нефти теплоносителями, пластового давления, степени насыщенности пор пласта флюидами). Наблюдательная скважина не входит в состав фонда добывающих скважин. Разведочное Бурение – проведение разведочных скважин для составления по кернам геологических разрезов (картировочное разведочное бурение), построения структурных карт тектонического рельефа (структурное разведочное бурение), исследования геологического разреза новой территории (опорное разведочное бурение), доразведки и оконтуривания залежи (промышленное разведочное бурение). Буровая Скважина – цилиндрическая горная выработка, имеющая относительно малое поперечное сечение (обычно 75–350 миллиметров). Различают горнотехнические, исследовательские, строительные и эксплуатационные скважины.

WILD CROP = ДИКИЙ УРОЖАЙ (или ДИКАЯ КУЛЬТУРА) – Wild Crop is any plant or portion of a plant that is collected or harvested from a site that is not maintained under cultivation or other agricultural management.

WILD FILLING = ШАЛЬНАЯ УТОЧИНА – Defect Name:- Wild Filling. Defect Type:- weft lines, horizontal lines. Fabric Type:- Shirting and Dress Goods – Chambray. Description:- Wild Filling:- This is the result of loose or stray yarn having been pulled into the loom shed along with a regular pick of filling. Severity:- Major.

WILDFIRE CONTROL = КОНТРОЛЬ НАД ЛЕСНЫМИ ПОЖАРАМИ – Wildfire Control:- actions taken to contain and suppress uncontrolled fires.

WILDFIRES = ЛЕСНЫЕ ПОЖАРЫ (или ШАЛЬНЫЕ ПОЖАРЫ) – Wildfires:- uncontrolled fires occurring in forestland, brushland, and grassland. Wildfire is a fire in a wild area (such as a forest) that is not controlled and that can burn a large area very quickly.

WILD FISH = ДИКАЯ РЫБА – Wild Fish is a naturally born or hatchery-raised fish and shellfish harvested in the wild. Wild Fish is a naturally-born or hatchery-raised fish and shellfish harvested in the wild, including fillets, steaks, nuggets, and any other flesh from a wild fish or shellfish, but not including netpen or other farm-raised fish.

WILD FREE–ROAMING HORSE AND BURRO ACT = АКТ О ДИКОМ СВОБОДНОМ КОЧЕВНИЧЕСТВЕ ЛОШАДЕЙ И ОСЛОВ – Wild Free-Roaming Horse and Burro Act (WH&B) (PL 92–195):- signed into law December 15, 1971. The Act requires the protection, management, and control of wild, free-roaming horses and burros on public lands at population levels that assure a thriving natural ecological balance and multiple-use relationship. Bureau of Land Management management of wild horses and burros is conducted at the minimum feasible level to treat the animals as a wild species and not as livestock. Management focuses on monitoring, removal of excess animals, preparing animals for adoption, adoption, and compliance. The Wild and Free-Roaming Horses and Burros Act of 1971 (WFRHBA), is an Act of Congress (Pub.L. 92–195), signed into law by President Richard M. Nixon on December 18, 1971. The Act made it a crime for anyone to harass or kill feral horses or feral burros on federal land, required the departments of the Interior and Agriculture to protect the animals, required studies of the animals' habits and habitats, and permitted public land to be set aside for their use. In addition, the act required that Mustangs be protected as 'living symbols of the historic and pioneer spirit of the West', and that management plans must 'maintain a thriving natural ecological balance among wild horse populations, wildlife, livestock, and vegetation and to protect the range from the deterioration associated with overpopulation'. Although feral horse ranges were principally for the protection of the horses, the land was required to be maintained for multiple use. / Ричод Эм. Никсэн (Richard M. Nixon).

WILDLAND = ДИКАЯ ЗЕМЛЯ – Wildland:- non-urban lands having natural cover not intensively managed and manipulated.

WILDLAND FIRE = ТАЁЖНЫЙ ПОЖАР (или РАСТИТЕЛЬНЫЙ ПОЖАР) – Wildland Fire:- uncontrolled fire in a forest, grassland, brushland, or land sown to crops. Fire danger in a wildland setting varies with weather conditions:- drought, heat, and wind participate in drying out the timber or other fuel, making it easier to ignite. Once a fire is burning, drought, heat, and wind all increase its intensity. Topography also affects wildland fire, which spreads quickly uphill and slowly downhill. Dried grass, leaves, and light branches are considered flash fuels; they ignite readily, and fire spreads quickly in them, often generating enough heat to ignite heavier fuels such as tree stumps, heavy limbs, and the matted duff of the forest floor. Such fuels, ordinarily slow to kindle, are difficult to extinguish. Green fuels – growing vegetation – are not considered flammable, but an intense fire can dry out leaves and needles quickly enough to allow ready ignition. Green fuels sometimes carry a special danger:- evergreens, such as pine, cedar, fir, and spruce, contain flammable oils that burst into flames when heated sufficiently by the searing drafts of a forest fire. Tools for fighting wildland fires range from the standard equipment of urban fire departments to portable pumps, tank trucks, and earth-moving equipment. Firefighting forces specially trained to deal with wildland fires are maintained by public and private owners of forestlands. Such a force may attack a fire directly by spraying water, beating out flames, and removing vegetation at the edge of the fire to contain it behind a fire line. When the very edge is too hot to approach, a fire line is built at a safe distance, sometimes using strip burning or backfire to eliminate fuel in the path of the uncontrolled fire or to change the fire's direction or slow its progress. Backfiring is used only as a last resort. Aircraft were first used in fighting wildland fires in California in 1919. Airplanes and helicopters are primarily used for dumping water, for observation, and occasionally for assisting in communication and transporting personnel, supplies, and equipment. / Лесные Пожары (Forest Fires):- (i) низовые (наиболее часты), при которых горят лесная подстилка, травяно-кустарничковый покров, подрост и подлесок; (ii) верховые – также кроны деревьев; и (iii) подземные – торфяной слой и корни растений.

WILDLAND–URBAN INTERFACE = ВЗАИМОДЕЙСТВИЕ ПРИРОДНОГО И ГОРОДСКОГО ЛАНДШАФТА – Wildland-Urban Interface:- the geographic area where urban structures, primarily dwelling places, are built in the immediate proximity to naturally occurring flammable fuels, thus enhancing the risk associated with wildfires and forest fires.

WILDLIFE CONSERVATION = ОХРАНА ДИКОЙ ЖИЗНИ (или СОХРАНЕНИЕ ДИКОЙ ЖИЗНИ) – Wildlife Conservation:- the regulation of wild animals and plants in such a way as to provide for their continuance as a natural resource. The term stands for the husbandry and use of natural resources by the present and succeeding generations. Aesthetic, sporting, economic, and ethical use of landscapes, game, minerals, animals, plants, soils, and water is thus implied in the concept. The term wildlife conservation has been used to include an ever-widening group of animals – mammals, birds, fish, reptiles, amphibians, arthropods (such as the lobster), and mollusks (such as the oyster) – and includes plants as well. Certain aesthetically and economically important groups of animals have tended to dominate the list; but it is expanding as values broaden, interest in science grows, and increasingly subtle but important relationships among animals and plants are reported. Animal-conservation problems vary widely depending on the type of animal (whether, for example, it is exploited primarily for commercial or recreational reasons, whether or not it is free to range over national boundaries) and on the social and economic conditions of various countries. In many countries, game animals are widely hunted by sportsmen, over both private and public lands; thus an outstanding factor in wildlife conservation in such regions is the licensing and supervision of hunters. Game birds and mammals whose migrations take them across national boundaries require an international conservation effort. Marine mammals and fish also present the need for international agreement and legislation because they live in waters that know no national boundaries and are exploited commercially by fishermen from many countries. Small mammals that are trapped for their furs must be protected by domestic laws, but seals are the subject of international agreement. Saltwater fish, exploited mainly for commercial reasons, are protected by international agreement; but the exploiters of freshwater fish, chiefly anglers who fish for recreation (except in such large inland water areas as the Great Lakes), are licensed and controlled domestically. Ethical considerations appear to occupy a central position in wildlife-conservation thinking, but their development has been delayed by the fact that people for so many generations had to fight against nature. Although primitive people had a far more immediate stake in wildlife than modern people do, it is virtually certain that early humans had little concept of conserving game. The disappearance of the moa and the mammoth taught no lessons; the disappearance of the passenger pigeon did. Convinced of the enormous destructive power of humankind, pioneer conservationists of the early XX century emphasized the ethical responsibility of their own generation to conserve natural resources for posterity. Modern ecologists perceive that nature is a series of complex biotic communities of which the human species is an interdependent part; a spokesman for conservationists, Aldo Leopold, has argued that the Golden Rule applies to the land and to its animals as well as to people. Thus we find ourselves responsible for the fate of many products of nature, guided by a conservation tradition and code of conduct less than a century old. The Problem:- during the past 2 000 years the world has lost, through extinction, well over 100 Species or Subspecies of Mammals. Approximately two-thirds of these losses have occurred since the mid-XIX century, most since the beginning of the XX. In addition to those mammals already extinct, many others are vanishing or threatened. The primary factor in the depletion of the world's fauna has been modern human society, operating either directly through excessive commercial hunting or, more disastrously, indirectly through invading or destroying natural habitats, placing firearms in the hands of peoples who previously were without them, or introducing to the native fauna of certain areas (Australia and various islands) more aggressive exotic (nonnative) mammals. Except in the West Indies, comparatively few species seem to have died out within the past 2 000 years from such natural causes as evolutionary senility, disease, or climatic change. Persons interested in the conservation of wildlife recognize that much more is required than the mere protection of individual animals from destruction by shooting and other forms of direct action. Animal protection must begin with the conservation of the habitat – the area where animals feed, rest, and breed. This naturally involves the preservation of much besides the animal population itself, including conservation of vegetation cover and soil. The comparatively new science of ecology focuses on the association of living things in natural communities and their mutual interdependence and on the possibility of preserving the conditions under which the variety and abundance of natural living forms may continue to exist. But the immense growth of the world's human population and its expanding economic needs, fostering the consequent extension and intensification of industry and agriculture, have encroached upon remaining natural habitats throughout the world. This has been accompanied by the introduction of new types of cultivation, by the drainage of marshes, by the general lowering of the water table, by pollution of rivers and lakes, by destruction of woodlands, and by indiscriminate use of insecticides and herbicides. In many parts of the world there has also been widespread destruction of forests and other great belts of natural vegetation. Attitudes toward wild animals liable to be killed for food, oil, skins, feathers, or sport are undergoing considerable change in many countries of the world. An example of earlier attitudes is well illustrated by Great Britain, which passed through two centuries of so-called Game Protection, the original purpose of which was to create artificially high populations of grouse, partridge, pheasant, mallard, and other sporting species and, at the same time, to reduce the populations of such predators as the stoat, weasel, otter, wildcat, and badger, as well as birds of prey including owls. This alteration of the natural equilibrium had many other consequences, particularly in agriculture and forestry. The rabbit and wood pigeon population increased rapidly and caused widespread damage. In some places in Great Britain the landscape was changed by the planting of woods and the creation of other new areas, including artificial lakes for wildfowl – all with the purpose of creating larger populations of certain species for sport. Sport was the privilege of the affluent. There were strictly kept dates for the shooting of game species, and, most significant, there was very strict etiquette in shooting. Poaching was punished by heavy penalties and was kept under control. As a result, the game species did exceptionally well while the total

wildlife resources experienced varied fortunes. The modern view is different:- total wildlife conservation is rapidly replacing game protection. Techniques:- wildlife-conservation techniques have counterparts in forestry and in soil, water, and landscape conservation. They include prohibitions, and controls, restoration, subsidy, sanctuary, and public ownership. The oldest forms of prohibitions and controls are those that regulate hunting, fishing, and trapping. Although, as already stated, many early regulations resulted in misguided efforts aimed solely at increasing game populations, other early controls did play an important role in protecting wildlife. Especially useful were those limitations on hunting that protected animals during the breeding season. Bag limits – i.e. limits on the number of animals that can be taken by an individual hunter, fisher, or trapper – are also important conservation tools. Although modern limitations on hunting, fishing, and trapping have successfully adjusted available game supplies to mounting human populations in much of North America and Western Europe, they have been less successful in countries where the rural population is poverty-stricken and poorly fed. Moreover, the exploitation of migratory waterfowl has been successfully regulated only in North America, where, because few countries are involved, international treaties are easier to work out than they are elsewhere. Among the most important modern legal tools in wildlife conservation are those laws that protect threatened and endangered species. In the United States, for example, the Endangered Species Act makes it illegal to hunt, trap, or collect endangered animals and plants. The act also tightly restricts the use of federal funds in projects that are likely to adversely affect endangered species, and it prohibits the importation of endangered species or products made from endangered species. Perhaps equally important are those laws that mandate pollution controls; the resultant improvements in air and water quality enhance the prospects for wildlife (not to mention human) survival. The amelioration of habitats that have been damaged by pollutants is often a lengthy process, however, and in many cases the implementation of anti-pollution laws has been hampered by litigation and by lax enforcement. Artificial methods of offsetting resource depletion include programs of population restocking and habitat restoration. Game farms and fish hatcheries, which provide stocks of popular game species, are long-established tools of wildlife management. Of more recent development are those programs designed to restock wild populations of endangered species with individuals raised in captivity. Captive rearing and release is part of the effort being made to save the endangered whooping crane of North America. A similar program has been undertaken in behalf of the California condor, another endangered North American bird. Such efforts depend not only on the successful rearing of the endangered species in captivity but also on the ability of the released individuals to made the transition to life in the wild. An even more ambitious approach is the restoration of degraded habitats. Habitat restoration has frequently proved to be expensive, but its results are dramatic in the restoration of marshes, as is now evidenced in many of the national wildlife refuges in the United States. The oldest types of subsidies are bounties on predators and crop-destroying species, which were offered at least as early as the Middle Ages in England. Some surviving bounties are deplored by ecologists but sponsored by politicians as a form of unofficial rural relief. In the United States, federal subsidies are intended to encourage municipalities to construct sewage works and farmers to retire land in the soil-bank program. Sanctuaries – also called Preserves, Reserves, and Refuges – have been prominent in wildlife conservation since the mid-XIX century. With the large national parks, they have provided the protection and space critically needed in America and Africa by the larger predators and grassland-dwelling big game and the freedom from human interference needed by nesting birds during the breeding season; in the United States they also give migratory waterfowl at least partial relief from hunting pressure. In the United States, public ownership, which usually accompanies the establishment of sanctuaries, facilitates the management of wildlife food and cover resources to an extent seldom possible on privately owned lands. Public ownership finds its soundest manifestations in the development of sanctuaries and in the preservation of wildlife in national parks, though government ownership of forests in Canada and the United States also helps maintain various species of wildlife. / привоз (importation).

WILDLIFE CORRIDORS = КОРИДОРЫ ДИКОЙ ЖИЗНИ (или КОРИДОРЫ ДИКИХ ЖИВОТНЫХ, или КОРИДОРЫ ДИКОЙ ПРИРОДЫ, или КОРИДОРЫ ДИЧИ) – Wildlife Corridors:- habitat linkages that connect suitable wildlife habitat areas in a region otherwise fragmented by rugged terrain, changes in vegetation, or human disturbance so as to provide access to mates, food, and water; allow the dispersal of individuals away from high population density areas; and facilitate the exchange of genetic traits between populations. See also Habitat.

WILDLIFE HABITAT INCENTIVES PROGRAM = ПРОГРАММА ПО МЕРАМ ПООЩРЕНИЯ МЕСТ ОБИТАНИЯ ДИКИХ ЗВЕРЕЙ И ПТИЦ – Wildlife Habitat Incentives Program (WHIP):- established under the Federal Agriculture Improvement and Reform Act of 1996 (Sec. 387) and amended by the Farm Security and Rural Investment Act of 2002 (Sec. 2502). The USDA cost-sharing program administered by the Natural Resources Conservation Service to encourage the development of habitat for upland and wetland wildlife, threatened species and endangered species, fish, and other types of wildlife. WHIP is a voluntary, two-year program with the USDA providing cost-share assistance totaling 75 percent of the contract cost. Under the Farm Security and Rural Investment Act of 2002, the USDA may use up to 15 percent of WHIP funds in any fiscal year to augment the regular cost-share funds on lands enrolled for at least 15 years. / Служба Сохранения Природных Ресурсов.

WILDLIFE REFUGE = ПРИРОДНЫЙ ЗАПОВЕДНИК (или ЗАПОВЕДНИК ДИКОЙ ЖИЗНИ) – A Wildlife Refuge is an area designated for the protection of wild animals, within which hunting and fishing are either prohibited or strictly regulated. A Wildlife Refuge, also called a Wildlife Sanctuary, is a naturally occurring sanctuary, such as an island, that provides protection for species from hunting, predation or competition, it is a protected area, a geographic territory within which wildlife is protected. Such wildlife refuges are generally officially designated territories. They are created by government legislation, publicly or privately owned (the Chernobyl nuclear accident site has accidentally become a wildlife refuge). Refuges can preserve animals that are endangered.

WILDLIFE SERVICES = СЛУЖБЫ ДИКОЙ ЖИЗНИ – In the United States, Wildlife Services (WS):- the Animal and Plant Health Inspection Service unit, formerly known as Animal Damage Control, that reduces wildlife damage due to agriculture, aquaculture, and natural resources; minimizes potential wildlife threats to human health and safety; and protects threatened species and endangered species. WS cooperates with foreign governments, international organizations, and other government and private organizations with respect to animal, reptile, and bird damage, and nuisance control.

WILD OAT = ОВСЮГ (или ПУСТОЙ ОВЁС, или ДИКИЙ ОВЁС) – Wild Oats (Avena Fatua):- (i) Provincial Noxious Weed; (ii) annual grass with hollow erect stems from 0.3 to 1 meter tall; leaves of seedlings twist counter-clockwise when viewed from above; yellow to black seeds with a a bent, twisted bristle (awn); seeds with a circular scar (sucker mouth) at the base; (iii) seeds can remain viable in soil for over 10 years; and (iv) cultivated Oats lack the circular scar on the seed and either lack an awn or the awn is straight. Heavily bearded flowers. Awns are twisted and bent at right angles when mature. Base of leaf blades are slightly hairy. Wild Oats is a fibrous-rooted grass with hollow, upright stems and long flat leaf blades. Flowers are simple drooping spikelets with two to three florets inside. Seeds are yellow to black with a bent, twisted bristle and a circular scar at the base (cultivated oats lack the bristle or it is straight and has no scar). Mature grass grows 0.6–1.5 m tall. Damage:- Wild Oats causes loss in crop productivity through competition and lowered grain quality. Long bristles on the seed can injure livestock. Wild Oats is an alternative host for virus diseases of cereals and alfalfa. It is not a problem on undisturbed lands. It can invade disturbed sites, where its rapid growth and development make it competitive. Chemicals from the roots inhibit the growth of other species. Habitat:- In British Columbia (Canada), Wild Oats occurs in fields and disturbed areas. It is present in all agriculture regions but occurs rarely in the Peace River region. Spread:- most seeds are

shed around the parent plants. Seeds are moved during harvesting when the plant is mixed with cultivated crops. Wild Oat (Avena Fatua) is an annual grassy Weed. It reduces crop yield, increases dockage and cleaning costs, lowers the grade, and is costly to control. Seeds of Wild Oats vary in color from white to black. They are normally more slender than domestic Oats and have a slanting, circular, depressed scar, sometimes called a Sucker Mouth, at their base, and a bent twisted awn. Wild Oat (Avena Sativa) is a member of the grass Family native to Scotland. There are approximately 25 Varieties of the Oat Plants, and Oat is now grown throughout the world. Avena Sativa is the Species that is used in herbal remedies. The mature seed of the Oat Plant is used as a cereal grain. However, much of the Plant is used to maintain good health and to remedy disease conditions. Before maturity Oat seeds are in a liquid phase, and they are collected for use in tonics that treat nervous conditions. Wild Oat is usually in this stage for two weeks during August. The seeds mature in the late summer and early fall. If harvested then, the seeds are rolled or ground into oatmeal. If the seeds aren't harvested at that time, they are referred to as Groats. Once the seeds are harvested, the straw from the plant can be cut up and brewed as oatstraw tea. And the husks surrounding the seeds are used as oat bran. The only part of this grain that is not used in alternative medicine is the root. Wild Oat is also known as Oat, Groats, Oatstraw, and Straw. General use:- Avena Sativa is Latin for Wild Oat, a name that does not provide the complete picture of this grain's use in alternative and conventional medicine. The old saying 'sowing your Wild Oats' is based on the observation that stallions given wild oat experienced greater sex drives. Wild Oat was thought to have the same effect on men, although that has never been scientifically proven. Nevertheless, dietary supplements containing wild oats are still advertised and sold as boosting the male sex drive. Wild Oat may not be an aphrodisiac or a means of promoting fertility, but the grain has numerous other health benefits. In the past, people recovering from illnesses ate oatmeal because it was easily digested. Doctors advised overworked people to drink a beverage consisting of wine and Oats. The drink was said to restore nervous energy. Oatmeal also served as a treatment for skin conditions. In contemporary times, oatmeal is acknowledged as a rich source of bran and fiber. The grain is associated with treating high cholesterol. Whole Oat products with at least 0.02 oz (0.75 g) of soluble fiber in each serving can reduce the risk of heart disease. The US Food and Drug Administration allowed manufacturers to make that statement, and add that the fiber product must be part of a diet that is low in cholesterol and saturated fat. A study published in the summer of 2002 reported that oat cereal is superior to wheat cereal in lowering LDL (short for the low density lipoprotein) cholesterol levels in adult males. A new use for the beta-glucans (complex carbohydrates) contained in oats is in the manufacture of functional foods for the management of Type 2 (adult-onset) diabetes. Functional foods are a relatively recent category of foods. They are not currently defined by any government regulatory body, but are commonly understood to be any potentially healthful food or food ingredient that may provide health benefits beyond the traditional nutrients it contains. Functional foods are sometimes called Nutraceuticals. Oat fiber is also used as a substrate, or growing medium, for Lactobacillus and other bacteria that are introduced into the digestive tract of patients suffering from severe infections of the pancreas. The 'good' bacteria in the intestines help the body to fight off infections elsewhere in the digestive system. The Oat fiber provides the bacteria with nourishment without causing any side effects to the patient. Furthermore, pregnant women can benefit from the calcium and other trace nutrients found in oat straw. Wild Oat is recognized as a natural antidepressant and a mild sedative. It acts like a tonic to the nervous system, providing both nourishment and balance. Oat tea or an Oat Bach flower remedy is used as a nervine (preparation given to calm the nerves). In these capacities, Wild Oat can be used to treat conditions including headaches, depression, tension, insomnia, anxiety, and feelings of sadness. Wild Oat is also a remedy for nerve painand chronic fatigue. Oatstraw can be used to ease emotional anxieties and to treat skin conditions such as rashes, psoriasis, burns, eczema, warts, and insect bites. An oatmeal pack may be used to treat skin conditions. The oatmeal facial is a popular treatment for promoting smoother skin because the textured oat sloughs off dead skin when used as a mask or scrub. An oatstraw bath can provide more relief for skin conditions and neuralgia. Wild Oat is also believed to help with nicotine withdrawal, a remedy recommended by German doctors. The Wild Oat extract is said to be effective when used for this purpose, and Oat cereal is also said to be helpful. Preparations:- Wild Oat is available in various forms and is used in various alternative medicine traditions such as homeopathy. Commercial preparations include oatstraw tea, tincture, and the Wild Oat Bach flower remedy (a liquid concentrate called a Stock). The packaged oatmeal sold in the grocery store can also be used for treatments. Wild Oat tea, which is also known as an Infusion, is made by pouring 1 c (240 ml) of boiling water over 1–3 tsp (1.5–3 g) of the dried straw. The mixture is steeped for 10–15 minutes and then strained. Wild Oat tea should be drunk three times a day. When wild oat tincture is used, the dosage is 1 oz (1 ml) taken three times a day. Wild Oat can be combined with skullcap and mugwort to provide relief from depression and to improve sleep. A flower remedy:- flower remedies are liquid concentrates made by soaking flowers in spring water. Also known as Flower Essences, 38 remedies were developed by homeopathic physician Edward Bach during the 1930s. Bach's wild oat remedy is taken to resolve conditions such as career anxiety and uneasiness about a lack of direction or commitment. The daily dosage of the Bach wild oat flower remedy is 2–4 drops (1/8–1/4 ml) taken four times each day. The drops can be placed under the tongue or added to a glass of water. Another remedy is to add some stock to the bath water. Oat baths:- an oatstraw bath can provide relief for irritated skin and neuralgia. A bath is prepared by boiling 1 lb (500 g) of shredded oatstraw in 2 qt (0.95 l) of water. After boiling for 20 minutes, this mixture is strained and used in the bath. Another option is to place cooked rolled oats in a bag and the bag is put in the bath. Precautions:- Wild Oat has not been associated with any health risks when taken in proper dosages, according to Physician's Desk Reference for Herbal Medicines, the 1998 book based on the findings of Germany's Commission E. The commission is the German counterpart of the US Food and Drug Administration (FDA). The European group's findings about herbal remedies were published in a 1997 monograph. However, people diagnosed with gluten sensitivity (celiac disease) should consult with a doctor or health practitioner to determine if they can safely take wild oat internally. Side effects:- there are no known side effects associated with designated dosages of Wild Oat. Interactions:- there are no known interactions associated with the use of Wild Oat and other medications or herbs. Wild Oat is any of several tufted annual grasses of the Genus Avena (Family Poaceae), native to Eurasia. Wild oats are sometimes cut for hay, and young plants provide forage for grazing animals. The best-known Species is Avena Fatua, which has become a common field and roadside weed in temperate Australia, North America, and Southern Africa. It grows in small tufts about 0.9 to 1.2 m (3 to 4 feet) tall. Mature spikelets are bell-shaped, with bent, bristlelike projections. / Под Овсюгом или Пустым Овсом понимается Однолетнее Растение Семейства Злаков. Произрастает в Евразии и Северной Африке, как заносное Растение – в Северной Америке и Южном полушарии. В бывшем Союзе Советских Социалистических Республик (СССР) Овсюг встречался повсеместно как трудноискоренимый Сорняк преимущественно яровых культур (Овса, Пшеницы, Ячменя). Овсюгом называют и другие Виды Овса – также злостные Сорняки. Под Овсюгом или Пустым Овсом (Avena Fatua) понимается один из Видов Овса, злостный однолетний Сорняк яровых зерновых культур (Овса, Пшеницы, Ячменя). Распространён в Европе, Азии, Северной Африке, занесён в Северную и Южную Америку, Австралию, Южную Африку. В бывшем Союзе Советских Социалистических Республик (СССР) засорял посевы преимущественно в зоне выращивания яровой Пшеницы. Размножается только семенами (каждое растение даёт до 600 зерновок). Образуя 1 000 и более всходов на 1 метр^2, Овсюг сильно иссушает почву и снижает её плодородие, заглушает посевы культурных Растений, резко снижает урожайность. Овсюг легко скрещивается с Посевным Овсом, ухудшая его сортовые качества. Меры борьбы:- очистка семенного материала; содержание почвы под чистым паром на сильно заовсюженных полях; зяблевая обработка с предварительным лущением; посевы поздних яровых культур (Гречиха, Кукуруза, Просо), в которых Овсюг уничтожают послойными предпосевными обработками; скашивание на сено ранних яровых культур

во время вымётывания Овсюга и дальнейшая обработка почвы по типу пара; применение гербицидов – карбина, триаллата, далапона, пропазина и других; уничтожение Овсюга на необрабатываемых землях. Скармливать скоту зерно, засорённое Овсюгом, можно только в запаренном или размолотом виде; навоз с семенами Овсюга нельзя использовать для приготовления компостов. Овсюгом называют и некоторые Виды Овса:- Волосистолистный Овёс (Avena Trichophylla), Южный Овёс (Avena Meridionalis), Сходный Овёс (Avena Cultiformis) и другие; все они злостные сорняки зерновых культур, главным образом Овса. Овсюг Обыкновенный или Овсюг Пустой (Avena fatua L.) – однолетнее злаковое растение семейства Злаки. Вредоносность:- (i) ЭПВ Овсюга – 10–25 шт/м^2 (в зависимости от состояния посевов); (ii) сильно иссушает и истощает почву; (iii) на образование 1 кг зерна и соломы Овсюга требуется 600–700 литров воды, тогда как Пшенице требуется 460–510 литров; (iv) на формирование 10 ц зерна Овсюг выносит из почвы Азота – 45–51 кг; Фосфора – 10–15 кг; Калия – 30–32 кг, а на формирование 10 ц товарного зерна Пшенице необходимо Азота – 30–35 кг; Фосфора – 10–12 кг; Калия – 20–25 кг; (v) Овсюг является косвенной причиной распространения корневых гнилей; (vi) Овсюг является резерватом для размножения Шведской Мухи; (vii) Если плотность овсюга на 1 м^2 составляет 10 растений – то с 1 га можно собрать 6 центнеров семян Овсюга; (viii) При наличии 1 растения Овсюга на 1 м^2 урожайность яровой Пшеницы снижается на 10 кг с 1 га; и (ix) При наличии 15 растений Овсюга на 1 м^2 с 1 га Овсюгом потребляется воды равной 100 мм осадков. Распространение в Казахстане:- распространён повсеместно, но массовое распространение получил в Акмолинской, Костанайской, Северо-Казахстанской областях. Площадь посевов засорённых Овсюгом в этих областях составляет порядка 4–4.5 миллионов гектаров. Злостный сегетальный сорняк (сорняк, произрастающий в посевах культурных растений) в посевах яровой Пшеницы, Ячменя, Овса и других яровых, пропашных культур. Сильно иссушает почву, является резерватом болезней и вредителей растений (Шведской Мухи, нематоды, головни). Благоприятные условия для прорастания:- (i) минимальная температура для прорастания всходов из зерновок 3–5 °C; (ii) оптимальная температура 15–20 °C; наиболее жизнеспособные всходы получаются из семян, находящихся на глубине не менее 10 см; (iii) семена могут прорастать с глубины 20–30 см при наличии влаги и оптимальной температуры, жизнеспособность зерновок сохраняется до 5 лет; (iv) массовые всходы Овсюга появляются при температуре 8–10 °C на глубине их залегания (через 4–5 дней после того, как на Берёзах распускаются почки). Согласно ГОСТ 10467-67 (пункт 1.7):- в семенах питомника размножения, суперэлиты и элиты не допускается наличие семян Овсюга. Морфология:- корневая система мочковатая, хорошо развитая. Стебель высотой 60–120 см, прямой, голый. Листья линейные, до 30 см длиной, широкие, с влагалищем у основания, по краю реснитчатые, имеют язычок, но без ушек; слегка скручены против часовой стрелки. Соцветие – длинная, раскидистая или сжатая метёлка. Плод – плёнчатая веретёнообразная зерновка. Масса 1 000 зерновок – 15–25 граммов. Размножение:- размножается Овсюг только семенами. Одно растение образует до 500 семян. Резко выражена гетерокарпия. В пределах одной метёлки, в нижней её части образуются более крупные зерновки (70% от общего числа), которые удерживаются в метёлке более 30 дней. Они попадают в бункер и засоряют зерно. В верхней части метелки образуются мелкие зерновки (30% от общего числа), которые сразу после созревания осыпаются в почву. Созревание семян в метёлке растянуто и проходит сверху вниз. Семена из верхней части имеют на основании зерновки углублённое сочленение (подковку), легко отделяются от растения и, осыпаясь, засоряют почву. Семена же из нижней части засоряют семенной материал, где их трудно отделить от семян зерновых. В каждом колоске метёлки Овсюга образуются 2–3 зерна, сильно отличающихся друг от друга по внешнему виду и биологическим особенностям. Нижние крупные зерновки засоряют зерно, средние – осыпаются и служат для ежегодного возобновления всходов Овсюга, верхние, мелкие – лежат в почве, сохраняя жизнеспособность до пяти лет. Сильно скрученная ость помогает зёрнам Овсюга ‘ввинчиваться’ в почву. Меры борьбы:- применение гербицидов, парование сильно засорённых полей, использование кондиционного семенного материала, и уничтожение Овсюга в ранние фазы, до осыпания семян. Эффективность гербицидов:- для борьбы с Овсюгом в посевах Пшеницы рекомендуется использовать Горизон, Аксиал, Топик Супер. В посевах Ячменя рекомендуется Аксиал. Горизон 080 к.э. – новый, высокоэффективный препарат, который контролирует не только Овсюг, но Просо и Щетинники. Норма расхода Горизон 080 к.э. для борьбы с Овсюгом 0.3–0.5 л/га, в зависимости от степени засорённости посевов. Препарат Аксиал 045 к.э. можно применять для борьбы с Овсюгом и другими однолетними злаковыми сорняками как в посевах Пшеницы, так и в посевах Ячменя. Аксиал содержит новое действующее вещество пиноксаден, который является отличным инструментом в антирезистентной программе. Топик Супер 240 к.э. – это известный препарат Топик, который стал более концентрированным, с улучшенной формуляцией. Норма расхода Топик Супер – 0.1–0.15 л/га.

WILD RICE = ДИКИЙ РИС – Wild Rice is the grain of an aquatic grass native to North America; not a true Rice. It is dark brown and has a nutty flavor. Wild Rice:- Species of Oryza that are not cultivated. Wild Rice is a tall aquatic North American perennial grass (Zizania aquatica) that yields an edible grain. Wild Rice is a kind of grain that is produced by a tall North American plant that grows in water. Wild Rice:- also called Indian Rice, Water Rice, or Water Oats (species Zizania Aquatica), coarse annual grass of the family Poaceae whose grain, now often considered a delicacy, has long been an important food of North American Indians. Despite its name, the plant is not related to Rice (Oryza Sativa). Wild Rice grows in shallow water in marshes and along the shores of streams and lakes in north-central North America. Natural stands of wild Rice formerly provided a staple food of many Indians of the Midwest. Cultivated varieties of wild Rice are now grown in man-made paddies in Minnesota and California, where the plants are planted and harvested on a large scale by mechanical means. Natural and cultivated stands also provide food and shelter for waterfowl and other birds. The Wild Rice plant is about 1 to 3 m (3 to 10 feet) tall and is topped with a large, open flower cluster. The ripened grains, dark brown to purplish black, are slender rods 1 to 2 cm (0.4 to 0.8 inch) long. A closely related perennial, Zizania Caducifolia (or Zizania Latifolia), is cultivated as a vegetable in eastern Asia. Wild Rice:- the black grains of a North American grass that are eaten, often with Rice. / Дикий Рис:- виды Ориза (Oryza), которые не культивируются.

WILD RYE = ДИКАЯ РОЖЬ (или ПЫРЕЙНИК, или ЭЛИМУС, или КОЛОСНЯК, или ОСТРЕЦ, или ВОСТРЕЦ, или ВОЛОСНЕЦ) – Wild Rye:- also called Lyme Grass (Genus Elymus) any of a group of about 50 species of perennial forage grasses in the Family Poaceae that are native to temperate and cool parts of the Northern Hemisphere. Giant Wild Rye (Elymus Cinereus), Virginia Wild Rye (Elymus Virginicus), and Canada Wild Rye (Elymus Canadensis) are the most widespread North American species. Sea Lyme, or Dune, Grass (Elymus Arenarius) is a Eurasian species 0.6 to 2.5 m (2 to 8 feet) tall, with creeping rootstocks and flowers borne in dense terminal spikes resembling those of rye. It is used as a sand binder on coastal dunes. / Элимус, Пырейник (Elymus), Род Многолетних Дерновинных Трав Семейства Злаков. Соцветие – линейный колос. Около 100 видов, почти во всех внетропических областях и в горах тропиков. В бывшем Союзе Советских Социалистических Республик (СССР) около 35 Видов. Многие виды Элимуса – ценные кормовые травы. Элимус Якутский (Elymus Jacutensis) растёт в Восточной Сибири и на Севере Дальнего Востока, большей частью на пойменных лугах; Элимус Шренка (Elymus Schrenkianus) – в Средней Азии по каменистым склонам. Элимус Новоанглийский (Elymus Novae-Angliae), или Бескорневищный Пырей (Elymus Trachycaulus Subsp.), культивируют как кормовое растение. Кормовое значение имеют и другие виды Элимуса, включаемые часто в Род Волоснец (Leymus). Виды Элимуса прежде объединяли с Родом Регнерия. Острец (или Волоснец или Вострец) – виды многолетних Злаков, преимущественно из Рода Колосняк. Острец Ветвистый (злостный Сорняк) и другие Виды используются на корм скоту. Острец или Вострец или Волоснец, несколько Видов многолетних Злаков, преимущественно из Рода Колосняк.

Острец Ветвистый (Leymus Ramosus) по внешнему виду и биологическим особенностям сходен с Пыреем Ползучим; в бывшем Союзе Советских Социалистических Республик (СССР) произрастает в Южных районах Европейской части, в Предкавказье, Казахстане и некоторых районах Сибири; размножается преимущественно корневищами. Острец Ветвистый – злостный Сорняк хлебных посевов; меры борьбы с ним примерно те же, что с Пыреем Ползучим, однако в связи с более глубоким залеганием корневищ борьба с Острецом труднее, чем с Пыреем; вместе с тем Острец Ветвистый – ценное кормовое Растение, дающее первоклассное сено. На Алтае, в Красноярском Крае, в Иркутской Области, в Бурятской и Тувинской АССР, в Читинской Области и Монголии произрастает Острец Ложнопырейный, или Китайский (Leymus Chinensis), – одна из лучших кормовых трав; нередко образует обширные острецовые степи. Волоснец, название некоторых Видов Злаков из Родов Колосняк (Leymus) и Элимус (Elymus). Колосняк (Leymus), Род Растений Семейства Злаков. Многолетние травы, большей частью с ползучими корневищами и жёсткими листьями. Колоски сидят на колосьях группами по 2–6, реже по 1. Около 30 видов, в Евразии и Северной Америке. В бывшем Союзе Советских Социалистических Республик (СССР) около 15 видов, преимущественно в Южных областях. Солевыносливые и засухоустойчивые Растения. Некоторые Колосняки имеют кормовое значение. Многие Виды – хорошие закрепители песков. Колосняк Ветвистый (Leymus Ramosus), называется также Волоснец, или Острец, – трудно истребимый Сорняк. Часто Колосняком называют также Виды Рода Элимус (Elymus).

WILD SILK = ДИКИЙ ШЁЛК – Wild Silk is the Silk from uncultivated silkworms that eat leaves other than mulberry leaves. Wild Silk is coarser and is more uneven than cultivated Silk. The resulting fabric is usually duller in finish and rougher in texture than other types of silk. Tussah is a silk fabric made from wild Silk. / Шёлк диких шёлкопрядов.

WILD TYPE = ДИКИЙ ТИП – Wild Type is the traditional/historical form of an organism as it is ordinarily encountered in nature, in contrast to domesticated strains, natural mutant, or laboratory mutant individuals (organisms). One example of a measurable difference between the two types is that wild strains of animals respond to the presence of EMF (short for the electromagnetic fields) fields (e.g., weak magnetic fields such as those generated near power transmission cables), but laboratory strains of the same animals do not. / Дикий Тип – традиционный тип организма, встречающийся в дикой природе.

WILL = ЗАВЕЩАНИЕ – Will is a legal document drawn up by a person, usually under the advice of a solicitor, giving instructions as to how the person's estate is to be distributed after his or her death. The signature on a will has to be witnessed by two people, neither of whom is a beneficiary but can be an executor. Will is the written instrument by which a person makes disposition of his/her property, to take effect upon his/her death. Will is a document in which a person specifies the method to be applied in the management and distribution of his estate after his death. A will is the legal instrument that permits a person, the testator, to make decisions on how his estate will be managed and distributed after his death. At Common Law, an instrument disposing of Personal Property was called a Testament, whereas a will disposed of real property. Over time the distinction has disappeared so that a will, sometimes called a Lastwill And Testament, disposes of both real and personal property. If a person does not leave a will, or the will is declared invalid, the person will have died intestate, resulting in the distribution of the estate according to the laws of Descent and Distribution of the state in which the person resided. Because of the importance of a will, the law requires it to have certain elements to be valid. Apart from these elements, a will may be ruled invalid if the testator made the will as the result of Undue Influence, Fraud, or mistake. A will serves a variety of important purposes. It enables a person to select his heirs rather than allowing the state laws of descent and distribution to choose the heirs, who, although blood relatives, might be people the testator dislikes or with whom he is unacquainted. A will allows a person to decide which individual could best serve as the executor of his estate, distributing the property fairly to the beneficiaries while protecting their interests, rather than allowing a court to appoint a stranger to serve as administrator. A will safeguards a person's right to select an individual to serve as guardian to raise his young children in the event of his death. Will is a document, also called Testament, that, when signed and witnessed, gives legal effect to the wishes of a person, called a Testator, with respect to disposal of property upon death. Will:- also called Testament legal means by which an owner of property disposes of his assets in the event of his death. The term is also used for the written instrument in which the testator's dispositions are expressed. There is also an Oral Will, called a Nuncupative Will, valid only in certain jurisdictions, but otherwise often upheld if it is considered a death-bed bequest. A will is valid if it meets the formalities of the law, which usually, but not always, requires that it be witnessed. The advantage of having a will drawn by an attorney arises from his knowledge of what the law requires. A holograph will, for example, which is usually unwitnessed, is an instrument wholly written in the handwriting of the signer, and it may be accepted as legally binding upon the law to carry out its dispositions, barring the findings of anything that could render it invalid. A will may be considered invalid if, among other instances, the testator was mentally incapable of disposing of his property; if the will imposed unreasonable or cruel demands as a condition of inheritance; or if the testator did not have clear title to the bequeathed assets. Business partners often draw up 'mutual wills' involving transfer of business assets upon the death of one partner. See also Probate. / , подписан и засвидетельствован, предоставляет легальный эффект . Инструмент в письменной форме, посредством которого лицо производит распоряжение своим имуществом, вступающее в силу после его/её смерти. Под Завещанием понимается распоряжение гражданина относительно своего имущества на случай смерти, сделанное в установленной законом форме (нотариальной или приравненной к ней). Завещатель может лишить права наследования одного, нескольких или всех наследников по закону, за исключением лиц, имеющих право на обязательную долю. Завещание – документ, в котором содержатся указания по поводу распоряжения имуществом какого-либо лица после его смерти. Завещание не имеет юридической силы до момента смерти завещателя (testator) и по желанию завещателя может быть неоднократно изменено. Чтобы быть действительным, завещание должно быть оформлено в соответствии с некоторыми установленными законом формальностями, а именно:- составлено в письменной форме, подписано наследователем либо по его указанию и в его присутствии. При рассмотрении завещания не должно возникать сомнений в том, что подпись была поставлена с целью придать завещанию законную силу (обычно завещание подписывается в конце текста сразу после последних слов относительно имущества). Завещание должно быть обязательно засвидетельствовано двумя лицами, которые также ставят на нём свои подписи. Свидетели завещания не могут быть бенефициарами по завещанию. Завещание – документ, также называющийся Testament. Надлежащим образом составленный, подписанный и заверенный документ даёт лицу, называемому Testator (Завещатель) официальную гарантию того, что после его смерти имущество будет распределено так, как он того пожелал.

WILLEMITE = ВИЛЛЕМИТ – Willemite:- white or greenish-yellow silicate mineral, zinc silicate, Zn_2SiO_4, that is found as crystals, grains, or fibers with other zinc ores in many deposits. Included are various localities in Sussex County, State of New Jersey, the United States, where it occurs in crystalline limestone and constitutes an important zinc ore; it was worked at Nutley for more than 100 years before the reserve was exhausted in 1954. Occurrences outside the United States include Belgium, Algeria, South West Africa/Namibia, and Greenland. Its brilliant green fluorescence led to its use in early television tubes. For detailed physical properties, see Silicate Mineral (table). / Виллемит – минерал подкласса островных силикатов, $Zn_2(SiO_4)$. Примеси Mn, Fe, Ca, Mg. Агрегаты игольчатых кристаллов, сплошные, зернистые массы. Твёрдость 5.5; плотность около 4.2 г/см^3. Контактово-метасоматический гидротермальный; часто гипергенный. В больших скоплениях – руда Zn. Прозрачные жёлтые виллемиты – драгоценные камни. Синтетические виллемиты – люминофоры.

WILLIAM F. GOODLING CHILD NUTRITION REAUTHORIZATION ACT OF 1998 = АКТ ВИЛЪЙЭМА ЭФ. ГУДЛИНГА О ПОВТОРНОЙ АВТОРИЗАЦИИ ДЕТСКОГО ПИТАНИЯ ОТ 1998 – William F. Goodling Child Nutrition Reauthorization Act of 1998 (PL105-336):- signed into law October 31, 1998. The Act made changes to all the child nutrition programs, made a number of improvements to the Commodity Distribution Program, and reauthorized the program through September 30, 2003. William Franklin 'Bill' Goodling (born on 1927-December-05 in Loganville, PA) was a Congressman from Pennsylvania, 1975–2001. The term 'William F. Goodling Child Nutrition Reauthorization Act of 1998' as it applies to the area of agriculture can be defined as:- This law (enacted as PL 105-336; October 31, 1998) extended expiring authorizations for child nutrition and commodity assistance programs, and the Women, Infants, and Children (WIC) program, through FY2003. It also made modest revisions to child nutrition and WIC program rules. Most prominently, it significantly expanded the availability of federal subsidies (through the school lunch program and the Child and Adult Care Food Program (CACFP)) for snacks served in after-school programs, authorized demonstration projects providing free breakfasts for elementary schoolchildren without regard to family income, and added a number of provisions to child nutrition law to protect the integrity of the WIC program and the CACFP.

WILLIAMS %R = %C ВИЛЪЙЭМЗА (или ПРОЦЕНТ СОПРОТИВЛЕНИЯ ВИЛЪЙЭМЗА) – Developed by Larry Williams, Williams %R (percent of resistance) is a momentum indicator much like the Stochastic Oscillator and is especially popular for measuring overbought and oversold levels. The scale ranges from 0 to 100 with readings from 0 to 20 considered overbought, and readings from 80 to 100 considered oversold. Typically, Williams %R is calculated using 14 periods and can be used on intraday, daily, weekly, or monthly data. Williams %R is similar to Stochastic %K, except that Williams %R is plotted using negative values. Williams %R is a momentum indicator that measures overbought and oversold (bullish) levels. When the indicator reaches the levels of 80–100 it suggests the security is oversold. Conversely, readings in the 0–20 range signal overbought (bearish) conditions. / В техническом анализе биржевых рынков, . WILLIAMS ACT = АКТ ВИЛЪЙЭМЗА – The US Williams Act (WA) is the federal legislation enacted in 1968 that imposes requirements with respect to public tender offers. It was inspired by a wave of unannounced takeovers in the 1960s, which caught managers unawares and confronted stockholders with decisions they were ill prepared to make, The Williams Act and amendments now comprise Sections 13(d) and 14(d) of the Secutiries Exchange Act of 1934. The law requires the bidder opening a tender to file with both the Securities and Exchange Commission and the target company a statement detailing the terms of the offer, the bidder's background, the cash source, and his or her plans for the company if there is a takeover. The same information is required within 10 days from any person or company acquiring 5% or more of another company. The law mandates a minimum offering period of 20 days and gives tendering shareholders 15 days to change their minds. If only a limited number of shares are accepted, they must be prorated among the tendering stockholders. Williams Act is the federal legislation enacted in 1968 (and now constituting Rules 13d and 14d of the Security Exchange Act of 1934) that imposes requirements with respect to public tender offers. / Акт Вилъйэмза (AB) – федеральный закон от 1968, требующий, чтобы предложение о приобретении фирмы делалось для всех владельцев ценных бумаг по одинаковой цене. Смотрите также Специально В Субботу Вечером (Saturday Night Special); и Тактика Бланкового Чека (Blank-Check Tactic). Акт Вилъйэмза – федеральный закон, принятый в 1968, который устанавливает требования, касающиеся открытых тендерных предложений (tender offers). Принятие этого акта было вызвано волной внезапных поглощений компаний (takeovers) в 1960-х, которые застали управляющих врасплох и поставили акционеров перед необходимостью принимать решения, к которым они не были готовы. Акт Вилъйэмза и поправки к нему в настоящее время составляют разделы 13(d) и 14(d) Акта О Бирже Ценных Бумаг от 1934 (Securities Exchange Act of 1934). Закон требует, чтобы сторона, делающая открытое тендерное предложение, представила заявление как в Комиссию по Ценным Бумагам и Биржам (Securities And Exchange Commission), так и в компанию, являющуюся мишенью поглощения (target company). В этом заявлении должны быть детально изложены условия тендерного предложения, приведено описание стороны, делающей тендерное предложение, указаны источник наличных средств, а также планы в отношении компании в случае совершения поглощения. Ту же информацию в течение 10 дней должны предоставить любые лица или компании, приобретающие более 5% акций любой компании. Закон устанавливает минимальный период для рассмотрения предложений – 20 дней и позволяет акционерам предприятия, относительно которого было сделано тендерное предложение, в течение 15 дней изменить своё решение. Если принимается только ограниченное число акций, то они должны быть соответствующим образом пропорционально распределены между акционерами предприятия, относительно которого было сделано тендерное предложение.

WILLIAMS UNIT = ЕДИНИЦА ВИЛЪЙЭМЗА – Williams Unit is a wet-processing unit for open-width processing of fabric. The fabric passes up and down over rollers in the liquor. The unit is widely used for dyeing, washing, pretreating, and aftertreating.

WILLINGNESS TO ACCEPT = ГОТОВНОСТЬ ПРИНЯТЬ – Willingness To Accept:- the stated price that an individual would accept in compensation for the loss or the diminution of an environmental service. / Готовность Принимать – готовность принять компенсацию за негативные изменения в окружающей среде в результате экономической деятельности.

WILLINGNESS TO PAY = ГОТОВНОСТЬ ОПЛАТИТЬ – Willingness To Pay:- the stated price that an individual would accept to pay for avoiding the loss or the diminution of an environmental service. / Готовность Платить – готовность платить за то, чтобы сохранить благоприятную окружающую среду и не проводить определённую экономическую деятельность, которая может привести к негативным экологическим изменениям.

WILLOW = ИВА – Willow:- shrubs and trees of the Genus Salix, Family Salicaceae, mostly native to North temperate areas, valued for ornament, shade, erosion control, and timber. Salicin, source of salicylic acid used in pain relievers, is derived from certain Willows. All species have alternate, usually narrow leaves and catkins, male and female on separate trees; the seeds have long, silky hairs. Three of the largest Willows are Black (Salix Nigra), Crack, or Brittle (Salix Fragilis), and White (Salix Alba), all reaching 20 meters (m) (65 feet (ft)) or more; the first named is North American, the other two Eurasian but naturalized widely. All are common in lowland situations. Widespread from Mexico to Chile, the Chilean Willow (Salix Chilensis) reaches 18 m; the Columnar Xochimilco Willow (Salix Chilensis Fastigiata) is a variety especially common at Xochimilco near Mexico City. The shrubby common, or silky, osier (Salix Viminalis) supplies twigs used for basketmaking in Europe. Woolly Willow (Salix Lanata), of Northern Eurasia, to over 1 m, has woolly white leaf buds. Several species and hybrids with drooping habit are called Weeping Willows, especially Salix Babylonica and its varieties from East Asia. From Northern Asia, Salix Matsudana has sharply toothed leaves, whitish beneath. One Variety, Salix Matsudana Tortuosa, is called Corkscrew Willow for its twisted branches. Pussy Willows, the male form of several shrubby species, have woolly catkins that are considered a harbinger of spring. The catkins are formed before the leaves appear. The North American Salix Discolor is slightly smaller than the Eurasian species, which attain a maximum 7.5 m. There are numerous shrubby Willows common along watercourses (e.g., Salix Purpurea and Salix Sericea) and several range to the tundra, where they grow as small matted woody plants (e.g., Salix Arctica and Salix Glacialis). / Ива:- (1) Род Деревьев, Кустарников и Кустарничков Семейства

Ивовых. Около 300 видов, в умеренном поясе Евразии и Северной Америки; в бывшем СССР свыше 140 видов. Многие виды декоративны, служат также для закрепления песков, оврагов. Древесина идёт на поделки, ветви – для плетения корзин и прочего. Кора богата дубящими веществами. (2) Род Трав или Кустарников Семейства Сложноцветных. 4 Вида в Северной Америке. Иногда включают в Род Циклахена. Ива (Salix), Род Растений Семейства Ивовых. Деревья, кустарники или кустарнички со спирально расположенными, большей частью короткочерешковыми, листьями. Цветки однополые двудомные, без околоцветника; они сидят в пазухах кроющих чешуек и собраны в кисти, называемые Серёжками. В мужских цветках большей частью 1–8 (до 12) тычинок, в женских – 1 пестик с одногнёздной завязью и двумя нередко расщеплёнными рыльцами. Плод – коробочка, содержащая много семян с длинноволосистой летучкой. Опыление при помощи насекомых (главным образом Пчёл). Около 300 видов, преимущественно в умеренном поясе Евразии и Северной Америки. В бывшем СССР около 120 видов; часто встречаются их межвидовые гибриды. Различные Ивы называются:- Верба, Ветла, Лоза, Лозняк (кустарниковые виды), Ракита (крупные деревья и кустарники, главным образом в Западных областях Европейской части СССР), Тал, Тальник (большей частью кустарниковые виды, в Восточных областях Европейской части, в Сибири и Средней Азии) и Шелюга. Полярные и высокогорные Ивы – низкорослые стелющиеся кустарнички – до нескольких сантиметров (см) над землёй (Ива Полярная – Salix Polaris, Ива Травянистая – Salix Herbacea и другие). Однако есть Ивы высотой 30–40 м и диаметром более 0.5 м. Большинство Ив – небольшие деревья (10–15 м) или кустарники. Благодаря способности давать придаточные корни Ивы легко размножаются черенками и даже кольями (за исключением Бредины, или Ивы Козьей – Salix Caprea). Семена теряют всхожесть в течение нескольких дней; лишь у Ивы Пятитычинковой (Salix Pentandra) семена сохраняют всхожесть до следующей весны. Древесина Ив очень легка и мягка, быстро загнивает. Идёт на многие поделки. В безлесных районах Ивы используют как строительный материал. Прутья некоторых кустарниковых Ив – Прутьевидной, Пурпурной (Желтолозник), Трёхтычинковой и других – используют для плетения корзин, изготовления мебели и прочего. Облиственные ветви Ив идут на корм животным (особенно Козам и Овцам). Кору многих Ив (например, Серой, Козьей, Белой) употребляют для дубления кож. Кора некоторых видов содержит гликозид салицин, имеющий лекарственное значение. Многие виды декоративны (Ива Конопляная – Salix Viminalis). Ивы применяют для укрепления песков (Шелюга, Ива Каспийская), берегов каналов, канав, откосов плотин (Ива Белая, Ива Ломкая), в противоэрозионных насаждениях в лесостепных и степных районах (Белая, Ломкая, Прутьевидная), для полезащитных и придорожных лесных полос на более влажных почвах. Разные виды Ив (на рисунке):- Ива Козья:- 1а – ветка с листьями; 1б – ветка с мужскими серёжками; 1в – женская серёжка; 1г – мужской цветок; 1д – женский цветок; 1е – серёжка с раскрывшимися плодами; 1ж – раскрывшаяся коробочка; 1з – семя. Ива Пятитычинковая:- 2а – ветка с листьями и мужскими серёжками; 2б – ветка с листьями и женскими серёжками; 2в – мужской цветок. Ива Прутьевидная:- 3а – ветка с листьями. 4 – Ива Травянистая. Ива (Iva), Род Растений Семейства Сложноцветных; то же, что Циклахена. Циклахена, Ива (Cyclachaena, Iva), Род Растений Семейства Сложноцветных. Травы или кустарники. Цветки однополые в мелких корзинках, образующих метельчатое или иного рода общие соцветия. Около 15 видов, в Америке (4 Североамериканских вида часто выделяют в особый Род под названием Ива). Со 2-й половины XIX века в Россию занесена Циклахена, или Ива Дурнишниколистная (Iva Xanthifolia, Cyclachaena Xanthifolia), – однолетник высотой до 2 метров (м), с крупными черешчатыми яйцевидными листьями и с крупным метельчатым общим соцветием. Встречается как сорное растение в Южной половине Европейской части бывшего СССР, реже в других районах. Примесь к сену вредна для скота, а пыльца вызывает заболевание – сенную лихорадку. Сравнительно легко искоренима, но некоторые другие виды Рода Iva относятся к трудно уничтожаемым сорнякам.

WILSHIRE 5000 TOTAL MARKET INDEX = ИНДЕКС ПО 5000 АКЦИЯМ КОМПАНИЙ СО ВСЕГО РЫНКА ОТ ВИЛШИР – The Wilshire 5000 Total Market Index:- perhaps the broadest barometer of US stocks is the Wilshire 5000 Total Market Index. This index is made up of over 6 500 companies from the AMEX®, NASDAQ®, and NYSE®. The total market value of the index exceeded USD14 trillion at the end of 2000. The index is weighted according to market capitalization and consists only of companies headquartered in the United States. Whereas the AMEX®, NASDAQ®, and NYSE® composite indices include preferred shares, ADRs and foreign issues, the Wilshire 5000 is a pure domestic index of common stocks. The broadest index, the Wilshire 5000 tracks all stock traded on the over-the-counter (OTC) and the exchanges (including the S&P 500). The Wilshire 5000 Total Market Index represents the broadest index for the US equity market, measuring the performance of all US equity securities with readily available price data. No other index comes close to offering its comprehensiveness. When the index was created in 1974 Wilshire's founder took advantage of then-new technologies that made it possible to collect stock prices and calculate returns for a volume of issues never before brought together. The index was named after the nearly 5 000 stocks it contained when it was originally created, but it has grown to include over 5 000 issues, reflecting the growth in US equity issues as a whole. In 1983 the Wilshire 4500 Index was created by removing the 500 stocks in the S&P 500 from the Wilshire 5000. Medium and small capitalization managers use the Wilshire 4500 as a performance benchmark. Barron's was the first to publish the Wilshire 5000 Index on 1975-January-13. Now the Wilshire 5000 is published daily in a variety of outlets, including print, television, and online media. As the broadest measure of the US equity market, it is watched by all major institutions, including the Federal Reserve Board. Wilshire Associates Incorporated, a leading global independent investment consulting and services firm, provides consulting services, analytics solutions and customized investment products to plan sponsors, investment managers and financial intermediaries. Its business units include, Wilshire Analytics, Wilshire Consulting, Wilshire Funds Management and Wilshire Private Markets. With ten offices on four continents, Wilshire Associates and its affiliates are dedicated to providing clients with the highest quality counsel, solutions and services. Wilshire Associates was started in 1972 when the founder and current Chief Executive Officer applied then-new computing technology to investment concepts and helped revolutionize the industry. Wilshire Associates Incorporated headquartered in Santa Monica, State of California (CA), the United States. The Wilshire 5000 Total Market Index, or more simply the Wilshire 5000, is a market-capitalization-weighted index of the market value of all stocks actively traded in the United States. As of September 30, 2014 the index contained only 3 698 components. The index is intended to measure the performance of most publicly traded companies headquartered in the United States, with readily available price data, (Bulletin Board/penny stocks and stocks of extremely small companies are excluded). Hence, the index includes a majority of the common stocks and REITs traded primarily through New York Stock Exchange, NASDAQ®, or the American Stock Exchange. Limited partnerships and ADRs are not included. It can be tracked by following the ticker W5000. The Wilshire 5000 Total Market Index was established by the Wilshire Associates in 1974, naming it for the approximate number of issues it included at the time. It was renamed the 'Dow Jones Wilshire 5000' in April 2004, after Dow Jones & Company assumed responsibility for its calculation and maintenance. On March 31, 2009 the partnership with Dow Jones was terminated and the index returned to Wilshire Associates. The base value for the index was 1404.60 points on base date December 31, 1980, when it had a total market capitalization of USD1 404.596 billion. On that date, each one-index-point change in the index was equal to USD1 billion. However, index divisor adjustments due to corporate actions and index composition changes have changed the relationship over time, so that by 2005 each index point reflected a change of about USD1.2 billion in the index's total market capitalization. The index increased tenfold in less than twenty years from its base date, peaking at a XX-century closing record high of 14 751.64 points on March 24, 2000, a level that would not be surpassed until February 20, 2007. A hypothetical investment in the Wilshire 5000, made at the 2000 peak and with subsequent dividends reinvested, did not become profitable on a closing basis until October 03, 2006. On April 20, 2007, the index closed above 15 000 for the first time.

On that day, the S&P 500 was still several percentage points below its March 2000 high, because small cap issues absent from the S&P 500 and included in the Wilshire 5000 outperformed the large cap issues that dominate the S&P 500 during the cyclical bull market. The index reached an all-time high on October 09, 2007 at the 15 806.69 point level, right before the onset of the late-2000s recession and the related late-2000s financial crisis. Since late 2007, the expansion of subprime lending difficulties into a wider Financial Crisis, plunged the United States into a renewed bear market that accelerated beginning on September 15, 2008. On October 08, the Wilshire 5000 closed below 10 000 for the first time since 2003. The index continued trading downward towards a 13-year low, reaching a bottom of 6 858.43 points, on March 09, 2009, representing a loss of about USD10.9 trillion in market capitalization from its highs in 2007. The Wilshire 5000 gained approximately USD2.5 trillion in market value during the first 11 months of 2009 while the index rose 2 105 points. Therefore, as of November 2009, each index point represented about USD1.2 billion in market value. The index achieved a new highest yearly close on December 31, 2012, a few percent above those of 1999 and 2007, but failed to do so above the 15 000 level (after achieving it intraday) by fewer than 5 points, closing with 14 995.11 points. However, it continued to rise in the short term such that, on February 08, 2013, the index surpassed the 16 000 level for the first time. It would be the first of four 1 000-point milestones that the index reached in 2013, as the index closed above 17 000 for the first time on May 03, 18 000 for the first time on August 01, and 19 000 for the first time on November 14. The Wilshire 5000 would close out 2013 on a record high, finishing the December 31, 2013 trading session at 19 706.03 points. On February 28, 2014, the Wilshire 5000 had its first intraday high over 20 000 points. On March 04, the index closed above this milestone for the first time. On July 01, 2014, the index closed above the 21 000 level for the first time. There are five versions of the index:- (i) Full capitalization total return; (ii) Full capitalization price; (iii) Float-adjusted total return; (iv) Float-adjusted price; and (v) Equal weight. The difference between the total return and price versions of the index is that the total return versions accounts for reinvestment of dividends. The difference between the full capitalization, float-adjusted, and equal weight versions is in how the index components are weighted. The full cap index uses the total shares outstanding for each company. The float-adjusted index uses shares adjusted for free float. The equal-weighted index assigns each security in the index the same weight. Wilshire 5000 Total Market Index – TMWX is a market capitalization-weighted index composed of more than 6 700 publicly-traded companies that meet the following criteria:- (i) The companies are headquartered in the United States; (ii) The stocks are actively traded on an American stock exchange; and (iii) The stocks have pricing information that is widely available to the public. The Wilshire 5000 was originally comprised of 5 000 stocks, but today it is made up of more than 6 700. As with all market capitalization-weighted indices, the Wilshire overweights companies with a higher firm value and underweights those with a lower firm value. This is one of the broadest indexes and is designed to track the overall performance of the American stock markets. Its ticker symbol is TMWX. / Дау Дьжонз (Dow Jones). сводные индексы. WILSHIRE INDICES = ИНДЕКСЫ ОТ ВИЛШИР – Wilshire Indices performance measurement indices created by Wilshire Associates, Inc. of Santa Monica, State of California (CA), the United States. The Wilshire 5000 Equity Index is the most widely followed index; it is published in national daily newspapers and is carried by the Associated Press. It measures the performance of all US-headquartered equity secutities with readily available price data; more than 7 000 capitalization-weighted security returns are used to adjust the index. The Wilshire 5000 base is its December 31, 1980 capitalization of USD1 404.596; its capitaliazation is approximately 81% New York Stock Exchange (NYSE®), 2% American Stock Exchange (AMEX®), and 17% National Association of Dealers Automated Quotations (NASDAQ®). Equity issues include common stocks, REITs, and master limited partnerships. Additions to the index are made monthly, after the month-end close. Initial public offerings (IPOs) are generally added at the end of the month. The Wilshire 4500 Equity Index is the Wilshire 5000 less the Standard & Poor's 500 Composite Index; current capitalization is about 60% NYSE®, 3% AMEX®, and 37% NASDAQ®. The Wilshire Small Cap Index consists of 250 companies with an average market capitalization of USD933 million, and is designed to meet the need for derivative trading instruments reflecting the true character of the small cap market. Wilshire Small Cap Index options are traded on the Pacific Exchange (PCX), which helped develop the index. Four Wilshire asset managemet indices are derived from the Wilshire 5000; six individual style indices (such as growth and value) and three real estate securities indices. WILT = ВИЛТ (или УВЯДАНИЕ) – Wilt is a characteristic of the plant indicated by drooping, folding, rolling, or collapsing leaves due to an unfavorable water balance. Wilt is a fungus disease ... that attacks Cotton and many other plants ... Affected plants are stunted, the leaves turn yellow and shed and often eventually die. The only effective control measure is the planting of wilt-resistant varieties that have been developed. Wilt is any of several diseases that cause plants to wilt and die. Wilt:- the drying out, drooping, and withering of the leaves of a plant due to inadequate water supply, excessive transpiration, or vascular disease. Wilt is a disease so characterized, as Fusarium Wilt. Wilt is a virus disease of various caterpillars, characterized by the liquefaction of body tissues. Wilt is a any plant disease characterized by drooping and shriveling; usually caused by parasites attacking the roots. Wilt is a common symptom of plant disease resulting from a water loss in leaves and stems. Affected parts lose their turgidity and droop. Specific wilt diseases – caused by a variety of fungi, bacteria, and viruses – are easily confused with root and crown rots, stem cankers, insect injuries, drought or excess water, soil compaction, and other noninfectious problems. Verticillium wilt is a very destructive fungal disease in cool climates. It affects several hundred Species of trees, shrubs, vines, flowers, house plants, vegetables, fruits, field crops, and weeds. The causal agent is the soil-inhabiting Fungus Verticillium albo-atrum (Verticillium Dahliae). In hot weather, the leaves on one or more branches turn dull green to yellow, wilt, and wither, often from the base upward. Annuals and young trees are often stunted and usually die; perennials may die branch by branch over a period of from several weeks to years or apparently recover. The sapwood (just beneath the bark) of wilted branches, when cut lengthwise, usually shows dark streaks. Infections occur through roots and wounds. Control can be obtained by growing disease-free and resistant or immune plants, rotating with highly resistant or immune plants for five years or longer, destroying infected plants and susceptible weeds, fertilizing and watering to encourage vigour, removing wilted branches on trees and shrubs (sterilizing tools between cuts), and avoiding the wounding of roots or stems when planting or cultivating. Soil known to harbor Verticillium can be fumigated or heat-treated to kill the disease organisms. Oak wilt, caused by the fungus Ceratocystis fagacearum, is a serious disease in the eastern half of the United States. All oaks (Quercus) are susceptible, as are Chinese, European, and American

chestnuts, tan oak (Lithocarpus densiflorus), and bush chinquapin. Trees in the red- and black-oak group usually die within several weeks during late spring and summer. Their leaves turn pale or dull green, look water-soaked, curl upward, and often become yellowed or bronzed from the margins inward; the upper branches are usually affected first. White and bur oaks commonly die back slowly over several years. Their leaves usually wilt, turn light brown, curl, and cling to their stems. The disease is spread from tree to tree by natural underground root grafts, sap- and fungus-feeding insects, and possibly by squirrels. Control measures include prompt removal of diseased trees, injecting Vapam (sodium methyldithiocarbamate) into the soil midway between healthy and recently infected trees, avoidance of injuring or pruning of trees from budbreak to midsummer, and painting wounds promptly with tree-wound dressing. Bacterial wilt, caused by numerous species of the genera Corynebacterium, Erwinia, Pseudomonas, and Xanthomonas, induces stunting, wilting, and withering, starting usually with younger leaves. Stems, which often shrivel and wither, show discolored water-conducting tissue. A bacterial ooze is often evident when infected stems are cut and squeezed. Rapidly expanding, dark green, water-soaked areas or streaks may develop first in leaves. Bacterial wilt may be managed by growing resistant varieties; planting disease-free materials in well-drained, fertile soil that is clean or sterilized; observing stringent sanitation including weed- and insect-control measures; and rotating susceptible crops. Spotted wilt, caused by a virus, is transmitted by the larvae of several species of insect called Thrips. Plants commonly are stunted and bunchy. Brown, purplish, pale green, red, yellow, or white rings (often zoned) and spots form in leaves, flowers, and fruit; long streaks may develop in petioles and stems. Leaves are distorted, sometimes mottled, and may turn yellow or bronze. Tops may wilt and wither; fruit is often rough and distorted. Control includes growing resistant varieties and disease-free stock, spraying or dusting during thrips infestations, promptly destroying infected plants and crop debris after harvest, and observing stringent weed control. See also Dutch Elm Disease; Fusarium Wilt; and Panama Disease. / Под Вилтом, от Английского слова Wilt, означающее Вянуть, понимается болезнь растений, вызываемая паразитическими грибами. Наиболее вредоносен вилт Хлопчатника. Поражается сосудистая система, растения увядают и, как правило, погибают. Под Вилтом понимается увядание растений, вызываемое разнообразными причинами. Чаще вилтом называют трахеомикозную болезнь, вызываемую несовершенными Грибами Verticillium Dahliae (Verticillium Albo-Atrum) – Вертициллиозный Вилт и Fusarium Oxysporum – Фузариозный Вилт. Первый поражает около 350 Видов Двудольных Растений. Наиболее сильно вилт поражает Хлопчатник, несколько меньше Лён, Томат, Картофель, Дыню, Арбуз, Персик, Абрикос и другие. Возбудитель развивается в почве, через корни проникает в растение и распространяется в водопроводящей системе ксилемы, вызывая увядание надземных органов. Чаще погибает всё растение, реже – отдельные его части. Болезнь передаётся через почву, с растительными остатками, посадочным материалом, поливной водой (Фузариозный Вилт) и с семенами. Поражённые растения или не дают урожая, или качество его резко снижается. Меры борьбы:- подбор устойчивых к вилту сортов; очищение почвы от возбудителей вилта путём введения рациональных севооборотов и обработки земли, внесение органических удобрений, активизирующих развитие сапрофитных микробов и Грибов-антагонистов возбудителя вилта; на сильно заражённых вилтом участках Хлопчатника внесение в почву под зяблевую вспашку фунгицидов.

WILT = ВЯНУТЬ – Wilt:- to droop, usually due to loss of turgor pressure; to become limp and drooping, as a fading flower. / тургорного давления.

WILTING = ЗАВЯДАНИЕ (или УВЯДАНИЕ) – Wilting is the loss of turgidity in plant tissue where the intake of water is insufficient to replace that lost by transpiration or other means, causing a deflation of the plant cells. / Под Завяданием растений понимается утрата растениями тургора вследствие нарушения водного баланса (транспирация воды листьями превышает поступление её в ткани). Проявляется в повисании листьев и стеблей; может быть временным и длительным. Временное завядание растения наступает, когда поступающая из почвы вода не успевает компенсировать её расход растением, но при ослаблении транспирации водный баланс и нормальное состояние растения восстанавливаются. Длительное завядание растения наступает, когда в почве остаётся слишком мало (или не остаётся вообще) доступной растению воды и водный дефицит не восполняется даже в ночные часы. При завядании растения приостанавливается рост, нарушаются фотосинтез, дыхание и другие жизненно важные процессы, клетки отмирают и (при длительном завядании растения) наступает гибель растения. Завядание растения предотвращают применением орошения, улучшением минерального питания растений, предпосевным закаливанием семян и рассады, применением засухоустойчивых сортов сельскохозяйственных культур.

WILTING COEFFICIENT = КОЭФФИЦИЕНТ ЗАВЯДАНИЯ – Wilting Coefficient is the percentage of water necessary for a plant that has begun to wilt to recover, if that water is supplied. Wilting Coefficient is the level of soil moisture at which water becomes unavailable to plants and permanent wilting ensues.

WILTING POINT = ТОЧКА ЗАВЯДАНИЯ (или ВЛАЖНОСТЬ ЗАВЯДАНИЯ) – Wilting Point (WP) is reached when the soil cannot supply enough water to balance the plant's losses by transpiration.

WILTON CARPET = ВИЛТОНСКИЙ КОВЁР (или БАРХАТНЫЙ КОВЁР С РАЗРЕЗНЫМ ВОРСОМ) – Wilton Carpet is a woven carpet in which the pile yarns are woven in as an integral part of the carpet, being held in place by the filling, usually made on a loom with a Jacquard head. The pile may be formed by wires and hooks or by weaving between two backings, in which case, the pile ends are cut to form two separate carpets. Wilton carpets are made in two types:- (i) cut pile, e.g., tournia, Wilton moquette, plush, and velvet; and (ii) loop pile, e.g., Brussels. Located in lower Fairfield County (State of Connecticut, the United States), Wilton is a town of sophistication, wealth, and people who are better than you are. / уточина. Жакяр (Jacquard).

WIM = WEIGH–IN–MOTION

WIM CARD = КАРТА МИБ – Wireless Application Protocol (WAP) Identity Module (WIM) implemented on a smart card. / Модуль Идентификации Протокола Беспроводных (МИБ) Приложений (ПБП), встроенный в смарт карту.

WIMPLE = ПЛАТ (или АПОСТОЛЬНИК) – Wimple is a cloth covering worn over the head and around the neck and chin especially by women in the late medieval period and by some nuns. Wimple is headdress worn by women over the head and around the neck, cheeks, and chin. From the late XII until the beginning of the XIV century, it was worn extensively throughout medieval Europe, and it survived until recently as a head covering for women in religious orders. The wimple originally was adopted as a chin veil by Western women after the crusaders brought back from the Near East such fashions as the veil of the Muslim woman. The wimple, usually made of fine white linen or silk, framed the face and covered the neck and sometimes part of the bosom.

WIN = WASTE INFORMATION NEEDS

WINCH = БАРКА – Winch or Beck is a vessel for dyeing fabric in rope form, consisting primarily of a tank and a reel to advance the fabric. For example, washing winches. Winch Beck:- the common element in all winch beck machines is the winch mechanism used to move the fabric. The winch draws the fabric via a guide roller out of the bath and returns it in folds into the bath. In the conventional winch beck, the bath stands still, while the fabric is kept in circulation by a reel positioned in the upper part of the machine. In modern

winches both the bath and the fabric are kept in circulation, which improves homogenisation and exchange of the liquor with the fabric. Greige goods are loaded into the winch either in rope form or in open width, which means that the winches must be 5–6 meters in width. The ends of the fabric piece to be dyed are sewn together to form endless loops over the rotating boom (winch). Winch becks are primarily machines for dyeing, but for practical reasons both preparation and dyeing are normally carried out in the same machine. These machines are essentially operated at atmospheric pressure although the development of synthetic fibres has led to the production of pressurised machines (HT machines may reach 130–140 °C). Winch beck is a very versatile machine and it can be used for all types of fabric. It is a very common technique for dyeing carpets (they are usually dyed in full width). Typical bath ratios vary from 1:15 to 1:40 (typically 1:30 in the carpet sector), which makes this technique fairly expensive due to high water and energy consumption. However, recent technological developments have been made to improve its environmental performance. See also Beck. Winch Dyeing Machines:- Winch Dyeing:- a dyeing machine consisting essentially of a dye vessel fitted with a driven winch (usually above the liquor level) which rotates and draws a length of fabric, normally joined end to end, through the liquor. Winch dyeing machines are a low cost design that is simple to operate and maintain, yet versatile in application proving invaluable for preparation, washing or after treatments as well as the dyeing stage itself. In all winch dyeing machines a series of fabric ropes of equal length are immersed in the dye bath but part of each rope is taken over two reels or the winch itself. The rope of fabric is circulated through the dye bath being hauled up and over the winch throughout the course of the dyeing operation. Dyestuff and auxiliaries may be dosed manually or automatically in accordance with the recipe method. Description and Dyeing Method on Winch Dyeing Machine:- the basic principle of all winch dyeing machines is to have a number of loops or ropes of the fabric in the dye bath, these ropes are of equal length, which are mostly immersed in the liquor in the bath. The upper part of each rope runs over two reels which are mounted over dyebath. At the front of the machine, above the top of the dye liquor, is a smaller reel, which is called Jockey or Fly Roller. The fly roller remain free wheeling along with fabric rope. At the back of winch tank is the winch wheel, which pulls the fabric rope from the dye bath over the jockey reel for dropping in the dye bath for immersion. From the dropped location, the fabric rope travels back to be lifted and fed to winch wheel. The dyeing process on winch dyeing machines is based on higher M:L as compared with other dyeing machines. The process is conducted with very little tension. The total dyeing time is lengthier as compared to other machines. Advantages of Winch Dyeing:- (a) construction and operation of winch are very simple; (b) the winch dyeing machines are suitable for types of wet processing operations from desizing to softening; (c) the winch dyeing machine is suitable for practically all types of fabrics, which can withstand creasing in rope form processing; (d) the tension exerted on winch is less than jigger, the material thus dyed is with fuller hand; and (e) the appearance of the dyed goods is clean and smooth on winch dyeing machines. Limitations Of Winch Dyeing:- (a) batch dyeing operations needs trimming, sewing, opening out the rope, loading and unloading for individual lots separately; (b) since several lengths of fabric are run over the winch reel into the liquor and sewn end to end, Continuous length processing is not possible in a single batch; (c) fabric is processed in rope form which may lead to crease marks, particularly in heavy, woven, thin and light synthetics; and (d) most of the machine work under atmospheric conditions. / Красильная Барка:- для крашения ткани жгутом или в расправку в длинной ванне. WINCH = ЛЕБЁДКА (или ВОРОТ, или ПОДЪЁМНИК) – Winch is an engine for handling drafts of cargo secured on deck and fitted with drums on a horizontal axle. Winch is a machine that has a rope or chain and that is used for pulling or lifting heavy things. Winch is any of various machines or instruments for hauling or pulling; especially:- a powerful machine with one or more drums on which to coil a rope, cable, or chain for hauling or hoisting. Winch is the stationary motor-driven or hand-powered machine used for hoisting or hauling, having a drum around which is wound a rope or chain attached to the load being moved.

WINCHESTER BUSHEL = ВИНЧЕСТЕРСКИЙ БУШЕЛЬ – The Winchester Bushel, established by the 13 W. III. c. 5, A. D. 1701, was made the standard of grain; a cylindrical vessel, eighteen and a half inches in diameter, and eight inches deep inside, contains a bushel; the capacity is 2 145.42 cubic inches. By law or usage it is established in most of the United States. The exceptions, as far as known, are Connecticut, where the bushel holds 2 198 cubic inches, Kentucky 2 150 2/3; Indiana, Ohio, Mississippi and Missouri, where it contains 2 150.4 cubic inches. Winchester Bushel is measure of dry and liquid volume equal to 35.24 liters used in US and Canada. Originating in England and one of the units of Winchester measure. Abbreviated bu. Winchester Bushel is a cylinder with a diameter of 18.5 inches and a height of eight inches. The official unit of the United States defined as 2 150.42 cubic inches or 77.627 01 pounds of water. See also Level Bushel, and Struck Bushel. / В США применяют так называемый старый Винчестерский Бушель, применявшийся до 1826 и в Великобритании главным образом при объёмном измерении зерновых грузов. 1 bu (US) = 1 pc (US) = 8 gal = 32 qt dry = 64 pt dry = 3.523 93$\cdot 10^{-2}$ м^3 = 35.239 3 л. В США существует большое различие в значении одной и той же меры веса сыпучих тел, например, 1 бушель Пшеницы соответствует 60 фунтам, 1 бушель Риса соответствует 45 фунтам, а 1 бушель Овса – 32 фунтам. Происходит это вследствие того, что бушель, вообще говоря, – мера вместимости. В США 1 бушель = 2 150.42 кубических дюймов (так называемый Винчестерский бушель), а в Англии 1 бушель = 2 219.36 кубических дюймов (так называемый Имперский бушель). Как мера веса бушель равен весу материала, занимающему указанный объём.

WINCH RIG = ПОДЪЁМНОЕ ТРАНСПОРТНОЕ СРЕДСТВО (или ТЯГАЧ С ЛЕБЁДКОЙ) – Winch Rig is a straight truck or tractor with a hoist.

WIND = ВЕТЕР – Wind:- in climatology, the movement of air relative to the surface of the Earth. Winds play a significant role in determining and controlling climate and weather. Wind occurs because of horizontal and vertical differences (gradients) in atmospheric pressure. Accordingly, the distribution of winds is closely related to that of pressure. Near the Earth's surface, winds generally flow around regions of relatively low and high pressure – cyclones and anticyclones, respectively. They rotate counterclockwise around lows in the Northern Hemisphere and clockwise around those in the Southern Hemisphere. Similarly, wind systems rotate around the centers of highs in the opposite direction. In the middle and upper troposphere, the pressure systems are organized in a sequence of high-pressure ridges and low-pressure troughs, rather than in the closed, roughly circular systems nearer the surface of the Earth. They have a wavelike motion and interact to form a rather complex series of ridges and troughs. The largest of the wave patterns are the so-called Standing Waves that have three or four ridges and a corresponding number of troughs in a broad band in middle latitudes of the Northern Hemisphere. The westerlies of the Southern Hemisphere are much less strongly affected by standing disturbances. Associated with these long standing waves are the short waves (several hundred kilometers in wavelength) called Traveling Waves. Such traveling waves form the upper parts of near-surface cyclones and anticyclones to which they are linked, thus guiding their movement and development. At high latitudes the winds are generally easterly near the ground. In low, tropical, and equatorial latitudes, the northeasterly trade winds north of the intertropical convergence zone (ICZ), or thermal equator, and the southeasterly trade winds south of the ICZ move toward the ICZ, which migrates north and south with the seasonal position of the Sun. Vertically, winds then rise and create towering cumulonimbus clouds and heavy rain on either side of the ICZ, which marks a narrow belt of near calms known as the Doldrums. The winds then move poleward near the top of the troposphere before sinking again in the subtropical belts in each hemisphere. From here, winds again move toward the Equator as trade winds. These gigantic cells with overturning air in each of the hemispheres in low latitudes are known as the Hadley Cells. In the mid-latitudes, oppositely rotating wind systems called

Ferrel Cells carry surface air poleward and upper tropospheric air toward the Hadley cells. The three-dimensional pattern of winds over the Earth, known as General Circulation, is responsible for the fundamental latitudinal structure of pressure and air movement and, hence, of climates. On a smaller scale are the local winds, systems that are associated with specific geographic locations and reflect the influence of topographic features. The most common of these local wind systems are the sea and land breezes, mountain and valley breezes, Foehn Winds (also called Chinook, or Santa Ana, Winds), and katabatic winds. Local winds exert a pronounced influence on local climate and are themselves affected by local weather conditions. Wind speeds and gustiness are generally strongest by day when the heating of the ground by the Sun causes overturning of the air, the descending currents conserving the angular momentum of high-altitude winds. By night, the gustiness dies down and winds are generally lighter. / Хэдли Сэлз (Hadley Cells). Ферэл Сэлз (Ferrel Cells). Ветры Фён (Foehn Winds; называются также Ветры Шынок (Chinook Winds) или Ветры Санта Ана (Santa Ana Winds)). Ветер – движение воздуха относительно земной поверхности, вызванное неравномерным распределением атмосферного давления и направленное от высокого давления к низкому. Ветер характеризуется скоростью и направлением. Скорость выражается в метрах в секунду (м/с), километрах в час (км/ч), в узлах или приближённо в баллах по Шкале Бофорта.

WIND ANGLE = УГОЛ НАМОТКИ – Wind Angle is the angular measure in degrees between the direction parallel to the filaments and an established reference.

WIND–BELL = ВЕТРЯНОЙ КОЛОКОЛЬЧИК – Wind-Bell:- also called Wind Chime, a bell or a cluster of resonating pieces that are moved and sounded by the wind. The wind-bell has three basic forms:- (i) a cluster of small pieces of metal, glass, pottery, bamboo, seashell, or wood that tinkle when blown by the wind; (ii) a cluster of chimes that are rung by a central clapper, to which is attached a flat plate to catch the wind; and (iii) a bell whose clapper is attached to a flat plate to catch the wind. Although the wind-bell has existed from prehistoric times in many cultures, it received its most elegant and prolific development in east and south Asia, from Bali to Tibet and Japan, where it was often elaborately decorated, cast, or carved and was hung from the eaves of sacred structures. Buddhists especially made use of wind-bells, attaching them profusely by the hundreds or even thousands to the eaves of temples, shrines, and pagodas, causing during breezy moments an almost overwhelming volume of tintinnabulation. In Asia – and also in the ancient Mediterranean – wind-bells served to attract beneficent spirits. In China and Japan (where they are known as Feng-Ling and Fūrin, respectively – literally 'Wind-Bell'), they became a decorative art on private homes as well as on sacred structures, and in the XIX and XX centuries their popular use spread more widely among Western countries. / В Китае и Японии (где они известны соответственно как Фанг-Линь (Feng-Ling) и Фюринь (Fūrin) –) они стали декоративным искусством .

WINDBILL = ВЕТРЯНОЙ ВЕКСЕЛЬ (или ДУТЫЙ ВЕКСЕЛЬ) – Windbill or Windmill is an informal name for Accomodation Bill. / Смотрите также Дружеский Вексель (Accomodation Bill).

WINDBOX = ДУТЬЕВОЙ КОРОБ (или ВОЗДУШНАЯ КОРОБКА) – Windbox is a chamber below the grate or surrounding a burner, through which air under pressure is supplied for combustion of the fuel. Windbox is a plenum chamber that supplies air for combustion to a stoker, gas burner, or oil burner.

WINDBOX PRESSURE = ДАВЛЕНИЕ В ДУТЬЕВОМ КОРОБЕ (или ДАВЛЕНИЕ В ВОЗДУШНОЙ КОРОБКЕ) – Windbox Pressure is the static pressure in the windbox of a burner or stoker.

WINDBREAK = ВЕТРОЗАЩИТНОЕ ОГРАЖДЕНИЕ (или ВЕТРОЗАЩИТНАЯ ПОЛОСА) – Windbreak is a shelter, either natural (e.g., a line of trees or a thick hedge) or artificial (a screen), which breaks or interrupts the force of the wind. Windbreak is a planting of trees, shrubs, or other vegetation, usually perpendicular or nearly so, to the principal wind direction, to protect soil, crops, homesteads, roads, etc, against the effects of winds, such as wind erosion and the drifting of soil and snow. Windbreaks are linear plantings of trees and shrubs designed to enhance crop production, protect people and livestock, and benefit soil and water conservation. There are several types of windbreaks. Field windbreaks protect a variety of wind-sensitive crops, control wind erosion, and increase bee pollination and pesticide effectiveness. Livestock windbreaks help reduce animal stress and mortality, reduce feed consumption, and help reduce visual impacts and odors. Living snowfences keep roads clean of drifting snow and increase driving safety. They can also spread snow evenly across a field, increasing spring soil moisture. See also Farmstead Windbreak, Field Windbreak, and Livestock Windbreak. / насаждение из деревьев, кустов, или . сохранение (conservation).

WINDBREAKER = ВЕТРОВКА (или ШТОРМОВКА) – Windbreaker is a jacket made of a closely woven fabric or a fabric treated with a finish designed to prevent the passage of air. The fabric used in windbreakers offen has a degree of water repellency because of its tight construction. Windbreaker is an outer jacket made of wind-resistant material.

WIND–BURN = ЗАПАЛ (или ЗАХВАТ) – Wind-Burn:- young seedlings may be killed by exposure to strong, hot, dry winds. Plants become completely dessicated with leaves remaining attached to the plant and the plant leaning in the direction the wind was blowing. In less severe conditions one side of the seedling stem, between the soil surface and the cotyledonary node, becomes blackened and seedlings die or further growth is inhibited. The blackened lesion occurs on the same side of every seedling in the affected area. Symptoms are more likely to develop if the wind is blowing along rows rather than across rows. / При внезапном и сильном напряжении всех метеорологических факторов растение может быстро погибнуть в результате высыхания (захват) или высоких температур (запал). Засухоустойчивость различных органов растений неодинакова. Так, молодые растущие листья за счёт притока ассимилятов дольше сохраняют способность к синтезу, относительно более устойчивы, чем листья, закончившие рост, или старые, которые при засухе подвядают в первую очередь. В условиях затянувшейся засухи отток воды и веществ в молодые листья может происходить и из генеративных органов. Засуха в ранние периоды развития приводит к гибели цветочных зачатков, их стерильности (белоколосица), а в более поздние – к образованию щуплого зерна (захват). При этом захват будет более вероятен при хорошо развитой к началу засухи листовой поверхности. Поэтому при сочетании влажной весны и начала лета с очень сухой второй половиной (или даже отдельных сильных суховеев) опасность снижения урожая наиболее вероятна.

WIND DAMAGE = ПОВРЕЖДЕНИЕ ВЕТРОМ – Wind Damage:- excessive wind can result in sandblasting. Leaves and bark are damaged on the windward side of the plant only. Excessive dry winds may completely desiccate and kill plants. Leaves rubbing across opening bolls can become scratched on the under surface resulting in burn-like spots on the upper surface. / протирание или притирка (rubbing). Повреждение – одно из понятий теории надёжности; событие, заключающееся в нарушении исправности изделия. Повреждение может быть существенным и являться причиной нарушения работоспособности (отказа) и несущественным, при котором работоспособность изделия сохраняется.

WIND ENERGY = ВЕТРОВАЯ ЭНЕРГИЯ (или ВЕТРЯНАЯ ЭНЕРГИЯ, или ЭНЕРГИЯ ВЕТРА) – Wind Energy is a kinetic energy present in wind motion that can be converted to mechanical energy for driving pumps, mills, and electric power generators. Wind Energy is the kinetic energy of wind exploited for electricity generation in wind turbines. Wind Energy is the kinetic energy of wind converted into mechanical energy by wind turbines (i.e. blades rotating from a hub) that drive generators to produce electricity for distribution.

WIND ENERGY CONVERSION SYSTEM OR DEVICE = СИСТЕМА ИЛИ УСТРОЙСТВО КОНВЕРСИИ (или ПРЕОБРАЗОВАНИЯ) ВЕТРОВОЙ ЭНЕРГИИ – Wind Energy Conversion System (WECS) or Device is an apparatus for converting the energy available in the wind to mechanical energy that can be used to power machinery (grain mills, water pumps) and to operate an electrical generator.

WIND EROSION = ВЕТРОВАЯ ЭРОЗИЯ – Wind Erosion is a serious environmental problem attracting the attention of many across the globe. It is a common phenomenon occurring mostly in flat, bare areas; dry, sandy soils; or anywhere the soil is loose, dry, and finely granulated. Wind erosion damages land and natural vegetation by removing soil from one place and depositing it in another. It causes soil loss, dryness and deterioration of soil structure, nutrient and productivity losses and air pollution. Suspended dust and dirt is inevitably deposited over everything. It blows on and inside homes, covers roads and highways, and smothers crops. Sediment transport and deposition are significant factors in the geological changes which occur on the land around us and over long periods of time are important in the soil formation process. Soil movement is initiated as a result of wind forces exerted against the surface of the ground. For each specific soil type and surface condition there is a minimum velocity required to move soil particles. This is called the Threshold Velocity. Once this velocity is reached, the quantity of soil moved is dependent upon the particle size, the cloddiness of particles, and wind velocity itself. See also Erosion. / Под Ветровой Эрозией или Дефляцией понимается процесс разрушения, развевания ветром горных пород и почв. Развивается на рельефе любого типа. При сильной ветровой эрозии почвы (пыльные бури) ветер поднимает в воздух верхние горизонты почвы, иногда вместе с посевами, и переносит почвенные массы на большие расстояния. Ветровая Эрозия – одно из наиболее значимых факторов, отрицательно влияющих на качество полей. Самыми незащищёнными в этом плане являются гладкие, рыхлые с мелкими гранулами почвы. Ветер, дующий на высоте 30 см со скоростью 6 м/час, заставляет почву двигаться. Любые меры, направленные на снижение скорости ветра над поверхностью почвы, позитивно скажутся на её состоянии. Пожнивные Остатки – самый простой и надёжный способ снижения ветровой эрозии. Растительный материал улавливает движущиеся частицы почвы и ограничивает их лавинообразный эффект. Минимальная технология обработки почвы, при которой на поверхности остаются пожнивные остатки, снижает ветровую эрозию и предотвращает измельчение почвы до пылеобразного состояния. Стоячие растительные остатки более эффективные при замедлении скорости ветра по сравнению с лежащими. Определяющий фактор – почвы и полевые условия:- почвы с грубой структурой нуждаются в большем количестве растительных остатков, чем с тонкой структурой. В грубых структурах содержится много кальция м карбоната, но мало ила, глины и органического вещества. Все это приводит к образованию склонных к эрозии фракций и хрупких комков. Устойчивые комки помогают снизить эрозию. При обработке почвы следует стремиться к формированию больших комков. Неровная почва, полученная в результате обработки, является весьма эффективной для снижения ветровой эрозии. Гребни и впадины поглощают и меняют направление воздействия части ветровой энергии, а также улавливают летающие частицы почвы. Гребни высотой 10, 16–20, 32 см наиболее эффективны для защиты почвы. При сберегающем земледелии для минимизации ветровой эрозии на почве должно находиться адекватное количество растительных остатков. Такие проблемы чаще всего создаются при засухе или выращивании культуры, после которой на поверхности имеется мало остатков. Чтобы приостановить развитие ветровой эрозии, защитить почву и растущие культурные растения при засухе или незначительном количестве растительных остатков, используйте обработку поля для создания гребней, комков на поверхности, не дожидаясь дождя. Для эффективного противостояния эрозии она должна проводиться да начала её развития, когда земля ещё влажная. Если же выдувание почвы уже началось, срочно обработайте её на том конце участка, откуда дует ветер. В таком случае главная цель – создать как можно больше комков на гребнях перпендикулярно направлению ветра. Оборудование, больше всего подходящее для борьбы с ветровой эрозией, зависит от текстуры почвы, её влажности и плотности. На земле со средним гранулометрическим составом двухотвальная борона или большие рыхлительные лапы формируют гребни и выбрасывают комки на поверхность. Неровности необходимо создавать как можно быстрее. При меньшей скорости движения агрегата получится больше комков. А при высокой – больше гребней. Недавно посеянные пропашные или только что давшие всходы культуры более всего подвержены воздействию ветровой эрозии. Их можно обезопасить, обработав почву боронами, прикреплёнными на сеялки сзади по рядам движения. В таком случае разрыхляется выровненная поверхность. После сева для разрушения образовавшейся корки и для формирования комков можно использовать ротационную мотыгу или культиватор. Какое время выбирать? Самое эффективное время для создания комков – после дождя, когда верхний 5-сантиметровый слой будет влажным. Это первый агроприём. Второй способ срочной защиты почвы от ветровой эрозии – растительные остатки, навоз, оставшийся от крупного рогатого скота, а также орошение для повышения влажности земли, облегчения её обработки и создания искусственных преград для ветра. Что зависит от уборки? Уборка урожая фундаментально влияет на всю систему сберегающего земледелия. Плохо проведённая уборка может разрушить гребни, уплотнить почву или оставить пожнивные остатки в валках, усложняя последующие полевые работы. Проведение уборки с использованием современных методов делает борьбу с эрозией максимально эффективной и минимизирует потребность обработки пашни перед посевом последующей сельхозкультуры. Ровное распределение пожнивных остатков за комбайном – первостепенная задача сберегающего земледелия.

WIND EROSION EQUATION = ВЫРАВНИВАНИЕ ПРИ ВЕТРОВОЙ ЭРОЗИИ – Wind Erosion Equation (WEQ) is an equation used to predict wind erosion, based on climate, soil erodibility, unsheltered field distance, and vegetative cover.

WINDFALL PROFIT/GAIN = НЕПРЕДВИДЕННАЯ ВЫГОДА/ПРИБЫЛЬ – Windfall Profit/Gain is profit that occurs suddenly as a result of an event not controlled by the company or person realizing the gain from the event. For example, a hurricane may bring extraordinary revenue to a roofing contractor as a result of the natural disaster.

WINDFALL PROFITS = НЕПРЕДВИДЕННЫЕ ПРИБЫЛИ – Windfall Profits are the huge profits that occur unexpectedly due to fortuitous circumstances. Such profits are generally well above historical norms and may occur due to several factors – such as a price spike or supply shortage – that are either temporary in nature or may be longer lasting. Windfall profits are generally reaped by an entire industry sector, but can also be reaped by an individual company. In recent years, surging prices for crude oil have led to record profits for many energy companies, leading to demands from politicians to deem them as windfall profits and tax them accordingly. Needless to say, most companies that have made windfall profits strongly resist attempts to pay additional taxes on them. Arguments made by such companies are that record profits lead to record taxes payable by them in any case, as well as the fact that windfall profits are likely to be only temporary in nature. Windfall Profits are profits accruing to a company as a result of a general change in the market sitution rather than the company's own efforts. If, for instance, the price of a commodity soars due to political or economic developments, the energy-producing company earns windfall profits without any rise in production costs. Windfall Profits are any type of additional income over expenses that is completely unexpected. In many countries, there are laws that specifically define windfall profit for the purpose of establishing the tax schedule that applies to the unanticipated additional revenue. For this reason, it is important for individuals and businesses to be clear on what is windfall profit and what constitutes a different class of revenue according to local tax laws. Part of understanding what constitutes a windfall profit situation is to consider some of the ways in which a sudden windfall may come about. When real estate holdings owned by an individual suddenly appreciate in value, the owner can sell the holdings at a substantial and unanticipated level of profit. An unexpected increase in sales that drains products that have been

setting in warehouses for some time can also be interpreted as windfall profits. The key factor in any windfall situation is that there is no advance indicators that demand or value is likely to increase dramatically in a short period of time. Because the sudden appearance of a windfall can result in a substantial infusion of revenue, many countries pass windfall profit tax laws that make it possible to tax the unexpected profit separately rather than bundling it into other taxable income. One example would be windfall profit taxes enacted and applied to oil companies during the 1970's and 1980's. While some countries eventually repealed those laws, others remain in effect for many years and continue to be in place today. When an individual or company experiences a sudden influx of windfall profits, it is important to track the extra income closely. Verifying current tax laws and reviewing relevant reporting procedures will make it possible to comply with any tax regulations that are in place, and prevent the business from paying penalties at a later date. It is not unusual for the accounting of these unanticipated profits to involve the creation of a special line item, making the process of keeping track of the amount of extra profits generated a little easier. While the general concept of windfall profits is similar around the world, the guidelines used to identify what constitutes this type of income does vary from one country to another. This can make the process of tabulating and reporting windfall profits somewhat more difficult for corporations that maintain facilities in several different nations. Depending on how and where the windfall originated, prevailing laws in the country where the company is headquartered may apply, or laws governing taxes in the nation where the windfall took place may determine the qualification and proper taxation of any windfall profits. Windfall Profit is a sudden unexpected profit uncontrolled by the profiting party. / Сверхприбыль или Непредвиденная Прибыль – прибыль, полученная неожиданно, в результате события, не зависящего от лица или компании, получивших прибыль. Например, нефтяные компании получили прибыль в 1970-х в результате взлёта цен на нефть, вызванного введением нефтяного эмбарго, и увеличения цен, которого потребовала Организация Стран, Вывозящих Нефть (или Организация Стран Экспортёров Нефти; Organization of Petroleum Exporting Countries). WINDFALL PROFITS TAX = НАЛОГ НА НЕПРЕДВИДЕННЫЕ ПРИБЫЛИ – Windfall Profits Tax is an ad valorem tax or flat tax imposed on inordinate and sudden increase in the income or profit of a firm or industry. In 1980, the United States enacted the Crude Oil Windfall Profit Tax Act (PL 96-223) as part of a compromise between the Carter Administration and the Congress over the decontrol of crude oil prices. The Act was intended to recoup the revenue earned by oil producers as a result of the sharp increase in oil prices brought about by the OPEC oil embargo. According to the Congressional Research Service, the Act's title was a misnomer. 'Despite its name, the crude oil windfall profit tax ... was not a tax on profits. It was an excise tax ... imposed on the difference between the market price of oil, which was technically referred to as the Removal Price, and a statutory 1979 base price that was adjusted quarterly for inflation and state severance taxes'. Windfall Profits Tax is a tax levied on an unforeseen or unexpectedly large profit, especially one regarded to be excessive or unfairly obtained. Windfall Tax is a tax levied by governments against certain industries when economic conditions allow those industries to experience above-average profits. Windfall taxes are primarily levied on the companies in the targeted industry that have benefited the most from the economic windfall, most often commodity-based businesses. As with all tax initiatives instituted by governments, there is always a divide between those who are for and those who are against the tax. The benefits of a windfall tax include proceeds being directly used by governments to bolster funding for social programs. However, those against windfall taxes claim that they reduce companies' initiatives to seek out profits. They also believe that profits should be reinvested to promote innovation that will in turn benefit society as a whole. Windfall taxes will always be a contentious issue debated between the shareholders of profitable companies and the rest of society. This issue came to a head in 2005, when oil and gas companies, such as Exxon Mobil who reported profits of USD36 billion for the year, experienced unusually large profits due to rising energy prices. / ЭКСАН (Эксан Мобл Корпорэйшэн; EXXON (Exxon Mobil Corporation)). Налог На Непредвиденную Прибыль или Незаработанные Доходы – налог на прибыль, полученную в результате неожиданного кризиса в некоторой компании или отрасли. В 1980 был принят федеральный закон, согласно которому подобный налог был обращён на прибыли нефтяных компаний, полученных ими в результате резкого роста цен на нефть в 1970-х. Налог На Непредвиденную Прибыль (ННП; Windfall Profits Tax (WPT)):- (1) Дополнительный подоходный налог, взимаемый в случае резкого увеличения доходов предпринимателя, например, в результате повышения цен. WIND FARM = ВЕТРЯНАЯ ФЕРМА (или ОБЪЕДИНЁННАЯ СИСТЕМА ВЕТРОЭЛЕКТРИЧЕСКИХ СТАНЦИЙ) – Slang in energy industries. A Wind Farm is a group of wind turbines used to generate electricity. See also Wind Power Plant.

WIND INDICATOR = ВЕТРОВОЙ ИНДИКАТОР (или УКАЗАТЕЛЬ НАПРАВЛЕНИЯ ВЕТРА, или ФЛЮГЕР) – Wind Indicator is a visual device used to provide wind information.

WINDING = НАМАТЫВАНИЕ (или НАМОТКА, или ПЕРЕМАТЫВАНИЕ) – Winding is the process of transferring yarn or thread from one type of package to another to facilitate subsequent processing. The rehandling of yarn is an integral part of the fiber and textile industries. Not only must the package and the yarn itself be suitable for processing on the next machine in the production process, but also other factors such as packing cases, pressure due to winding tension, etc, must be considered. Basically, there are two types of winding machines:- precision winders and drum winders. Precision widers, used primarily for filament yarn, have a traverse driven by a cam that is synchronized with the spindle and produce packages with a diamond-patterned wind. Drum winders are used principally for spun yarns; the package is driven by frictional contact between the surface of the package and the drum. Winding:- this spinning term refers to winding the finished yarn onto a bobbin and secured to prevent unraveling. Winding is the process of transferring yarn or thread from one type of package to another. / филаментная (комплексная) пряжа (filament yarn). Перематывание Пряжи:- Технологическая Схема Процесса:- на шпуледержателе установлен прядильный початок. Сматываемая с початка нить проходит направляющий пруток, натяжной прибор, контрольно-очистительный прибор, нитеводитель и наматывается на мотальную паковку. Для перематывания пряжи с мотка его натягивают на специальный держатель. Функцию натяжного устройства выполняет груз, который с помощью хомутика надет на ступицу мотовила. В процессе перематывания пряжи моток вращается вместе с мотовилом. Нить с мотка огибает пруток, проходит контрольно-очистительный прибор, нитеводитель и наматывается на мотальную паковку. Пруток является баллоноограничителем и предназначен для улучшения условий сматывания нити с прядильного початка. Натяжной прибор создаёт необходимое натяжение нити в зоне наматывания. Контрольно-очистительный прибор контролирует пряжу по толщине и очищает её от сора и пуха. Нитеводитель сообщает нити возвратно-поступательное движение вдоль оси мотальной паковки. Мотальная паковка получает принудительное вращательное движение и вследствие этого наматывает на себя нить. Существует другой вариант технологической схемы процесса перематывания, который применяется для перемотки в конические бобины пряжи поступающей в виде мотков после процесса крашения. В верхней части машины устанавливается мотовила на которой закрепляется расправленный моток пряжи. Пряжа сматывается с мотовила, огибает направляющий пруток и далее по описанной схеме. Однако можно заметить, что по этой схеме пряжа минует натяжное устройство. В данном случае натяжным устройством являются тормозной ремень с грузом, который подвешен на тормозной диск, прикреплённый к мотовилу.

WINDING LAYER = РЫХЛАЯ ПРОСЛОЙКА – The Winding Layer is the first layer of secondary thickening. Also known as S, Layer. It differs in structure from either the primary wall or the remainder of the secondary wall. It is an open netting type pattern of fibrils that is aligned at 40 to 70 degree angles to the fiber axis. See also Lumen. / взаиморасчёт или сведение (netting) . слой или прослойка .

WINDING MACHINE = МОТАЛЬНАЯ МАШИНА – A Winding Machine or Winder is a machine for wrapping string, twine, cord, thread, yarn, rope, wire, ribbon, tape, etc onto a spool, bobbin, reel, etc. In textiles, winders are used heavily in textile manufacturing, especially in preparation to weaving where the yarn is wound onto a bobbin and then used in a shuttle. Ball winders are another type of winder that wind the yarn up from skein form into balls. Ball winders are commonly used by knitters and occasionally spinners. / Мотальные Машины:- Классификация и Основные Рабочие Органы:- по виду наматываемой паковки мотальные машины подразделяются на:- (i) Машины, Наматывающие Бобины; и (ii) Машины, Наматывающие Катушки (шёлк). Мотальные машины наматывающие бобины делятся на 2 группы:- (1) Крестовые Машины (Рассеянной Намотки) – на этих машинах наматывается бобина, которая приводится во вращение посредством трения о вращающийся мотальный барабанчик. Барабанчик одновременно являются и нитеводителем за счёт винтовых канавок на нём (машина М-2). Мотальные Машины Для Крестовой Намотки:- для перематывания всех видов пряжи применяются мотальные машины для крестовой намотки. Основные механизмы этой машины:- (i) наматывающий механизм; (ii) нитеводитель – механизм раскладки нити; (iii) механизм автоматического выключения машины при обрыве нити или полной её доработки; и (iv) привод машины. Кроме того, мотальные машины могут быть оборудованы дополнительными механизмами:- транспортёр для пустых патронов; электродвигатель; сферообразователь; пухоотсос и пухообдувка. (2) Бобинажные машины – на этих машинах бобина устанавливается на специальном веретене, которое получает вращение от специальной передачи, а нитеводитель выполнен в виде отдельного механизма который двигает вдоль поверхности бобины направляющий глазок для нити. Используются для перематывания искусственного шёлка и очень тонких нитей. КПВ мотальных машин 0.7–0.8. Скорость перематывания зависит от линейной плотности пряжи. Мотальная Машина М-150-2:- Кинематическая Схема:- все механизмы приводятся в движение от двух электродвигателей мощностью 4.0 кВт каждый и среднего электродвигателя мощностью 0.6 кВт. Электродвигатели приводят в движение мотальные валы и мотальные барабанчики, а электродвигатель – эксцентриковые валы для механизма электропрерывателя, ленточный транспортёр для доставки освободившихся от пряжи пустых патронов в ящики. Кулачковая муфта служит для выключения механизма самоостанова и мотальных барабанчиков при проведении чистки и обмашки одной стороны машины. Частоту вращения мотальных барабанчиков можно изменить с помощью вариатора скорости и проконтролировать тахометром, который установлен сбоку машины. Мотальные Автоматы:- Классификация:- мотальный автомат выполняет часть операций при перематывании нити автоматически:- (i) Смена Питающей Паковки; (ii) Связывание Узла При Обрыве Нити; (iii) Съём Наработанной Бобины; и (iv) Укладка Бобин На Транспортёр. При обслуживании мотальных барабанов работница заполняет магазин початков и следит за работой автомата. В случае отказа автомата в выполнении какой-либо операции работница устраняет ошибки автомата. В некоторых конструкциях мотальных автоматов нет автоматического съёма наработанных бобин. В таком случае эту операцию выполняет мотальщица. (1) Автоматы Карусельного Типа:- узловязальная заправочная станция (УЗС) располагается неподвижно на торце, а мотальные головки перемещаются по кругу. При подходе мотальной головки к узловязателю производится проверка и если нить отсутствует, то карусель останавливается и происходит связывание или заправка початков. АМК-150 – мотальный автомат карусельного типа с высотой бобины 150 мм; Эббот (Abbott; США); Жильбос (Gilbos NV; Бельгия). (2) Неподвижные Мотальные Головки обслуживает узловязатель, который двигается по монорельсу. Узловязатель обслуживает либо все мотальные головки, либо часть. (Автоконор, Германия). (3) Каждая мотальная головка оборудована автоматическим узловязателем. (Autosuk, бывшая Чехословакия). Мотальный Автомат АМК-150-3:- Кинематическая Схема:- в состав мотальной головки входит мотальный барабанчик, получающий движение от индивидуального электродвигателя с помощью клиноременной передачи. Диаметр мотального барабанчика у малого торца бобины 90 мм, у большого 100 мм, длина 173 мм. Изменение линейной скорости перематывания осуществляется перестановкой ремня барабанчика в одно из четырёх положений коробки передач привода. Нить, сматываясь с початка, проходит через баллоноограничитель, зажимное устройство, нитенатяжитель, нитеочиститель со шкалой, крючок самоостанова при обрыве нити и наматывается мотальным барабанчиком на бобину, находящуюся на бобинодержателе. Баллоноограничитель служит для уменьшения натяжения нити при перематывании и количества слётов нити с початка. Расстояние между вершиной прядильного початка и баллоноограничителем регулируется посредством передвижения его в пазах кронштейна и устанавливается равным 70 мм. Зажимное устройство служит для предотвращения выпадания из баллоноограничителя оборванного конца нити. При обрыве нити от крючка самоостанова включается электромагнит и своим сердечником притягивает плоскую пружину, которая перекрывает щель, прижимая нить к упору. Чёткость работы механизма зажима нити проверяют в подготовительных операциях перед пуском машины в работу. С этой целью включают главный выключатель силовой станции автомата и выключатель на дверце мотальной головки. Нитенатяжитель предназначен для регулирования натяжения нити в процессе перематывания и создания определённой плотности намотки пряжи на бобине. Натяжение движущейся нити создаётся за счёт воздействия подвижных пальцев, закреплённых на рычаге нитенатяжителя, относительно неподвижных элементов нитенатяжителя. Натяжение нити регулируется смещением грузов на рычаге. Для уменьшения колебаний подвижных пальцев и снижения дополнительных динамических нагрузок на нить имеется масляный амортизатор, состоящий из цилиндра, заполненного маслом, поршня, укреплённого на штоке, и рычагов. Плотность намотки пряжи на бобине зависит также от давления бобины на мотальный барабанчик. Силу прижима бобины можно регулировать двумя грузами на бобинодержателе и положением конца пружины на толкателе. Мотальный Автомат Аутосук (Autosuk), бывшая Чехословакия:- Технологическая Схема:- каждая мотальная головка мотального Аутосук имеет магазин для четырёх початков. При дорабатывании рабочий початок автоматически снимается с початкодержателя и отправляется на конвейер, а из магазина по направляющему лотку устанавливается запасной початок. Нить, сматываясь с початка, поступает в баллоноограничитель пруткового типа. Баллоноограничитель устанавливается на расстоянии 35–40 мм от конца патрона, и его можно использовать при перематывании нитей с левой и правой круткой. Затем нить попадает в предварительный чиститель, предназначенный для задержания слётов и больших прядильных пороков. Если эти пороки не устранить, то попадание их в контрольный прибор приведёт к отказу автоматики при включении автоматического цикла. Разводка предварительного чистителя устанавливается равной 3–4 диаметрам нити. Далее нить попадает в гребенчатый нитенатяжитель, имеющий сменные грузовые шайбы, и контрольную щель с метрической шкалой для установки необходимой разводки. Между предварительным чистителем и нитенатяжителем имеются контрольная вилочка для контроля наличия нити в нижней зоне автомата, сопло подвижного отсоса для обнаружения, удержания и передачи оборванного конца нити с прядильного початка к узловязателю и неподвижное сопло, улавливающее нить при её обрыве в верхней зоне. Затем нить проходит между лезвиями ножниц и через щуп, контролирующий наличие нити. В этой же зоне установлено сопло неподвижного подсоса, удерживающее концы нитей, идущих от запасных прядильных початков, которые находятся в магазине. Для парафинирования твёрдым парафином пряжи, используемой в трикотажном производстве, установлен парафинер. Мотальным барабанчиком пряжа наматывается на конический патрон, образуя бобину. Если на барабанчик наматывается пряжа в виде жгута, то срезка его осуществляется ножом. Бобина удерживается приклоном, имеющим на передних концах два зажима. Приклон можно устанавливать под различным углом относительно оси O_1 для установки цилиндрического или конусного патрона. При увеличении диаметра бобины приклон поворачивается относительно оси O_2 вверх и через тягу, стержень перемещает поршень в гидравлическом цилиндре. Приклон мотальной

головки оснащён компенсирующим устройством, позволяющим поддерживать постоянную плотность намотки на бобине и состоящим из планки, двуплечего рычага, вращающегося на оси O_3, крючка подвески, в которую ввёрнут регулировочный винт с пружиной. Опытным путём определяют необходимое натяжение пружины, при котором плотность намотки соответствует заданной. Координация работы всех механизмов мотальной головки осуществляется с помощью 17 кулачков, закреплённых на кулачковом валу. Автоматическое отыскание конца нити на бобине осуществляется за счёт обратного (реверсивного) вращения бобины роликом от главного вала после торможения фрикционом мотального барабанчика, который приводится в движение клиноременной передачей от электродвигателя. Барабанчик совершает в обратном направлении 6–7 оборотов, что соответствует отмотанной длине нити 1–1.5 м. Одновременно соплом пневмосистемы конец нити транспортируется к узловязателю типа URA-4 – URA-7 (цифры 4 и 7 указывают длину в миллиметрах концов нитей в узле после связывания). Процесс связывания узла происходит за 230° поворота кулачкового вала, что по времени соответствует 4 с, а весь процесс образования узла совершается за 10.8–16.8 с в зависимости от места обрыва нити. Если обрыв нити произошёл в верхней зоне контрольного прибора, конец улавливается соплом и контрольная вилочка не передаёт сигнала на смену початка. Сопло удерживает нити с запасных початков, а подвижное сопло подает нить в зону узловязателя в случае, если первая попытка связывания прошла неудачно. Если перематываемая нить оборвалась в нижней зоне или сработался початок, контрольная вилочка действует на рычаг, который включает механизм смены початка. Початок соскальзывает с початкодержателя и попадает на транспортёр автомата, а полная паковка из магазина поступает на початкодержатель, и связывание возобновляется. Если при второй попытке узел не образуется, электродвигатель выключается и загорается сигнальная лампочка на панели управления автоматом. Тогда устранить неполадку нужно вручную, то есть заправить нить, ввести ручкой бобину в соприкосновение с барабанчиком и включить головку.

WINDING UP = СВОРАЧИВАНИЕ ДЕЯТЕЛЬНОСТИ (или ЛИКВИДАЦИЯ, или ЗАКРЫТИЕ, или РОСПУСК) – (1) Cessation of business activity on the part of a company and the start of that company's liquidation. Winding Up:- the process by which the business activities of a company are brought to an end. The process is akin to the administration of a deceased estate and to bankruptcy, however, a company may not be declared bankrupt under the Bankruptcy Act but must be wound up in accordance with the Corporations Law. Liquidation is sometimes synonymous with Winding Up.

(2) Winding-Up:- the termination of a pension scheme by either providing (deferred) annuities for all members or by moving all its assets and liabilities into another scheme.

WINDLASS = БРАШПИЛЬ (или БРАНШПИЛЬ) – Windlass is an anchor engine used for heaving in the chain cable and anchor. Windlass is a device for raising or hauling objects, usually consisting of a horizontal cylinder or barrel turned by a crank, lever, motor, or the like, upon which a cable, rope, or chain winds, the outer end of the cable being attached directly or indirectly to the weight to be raised or the thing to be hauled or pulled; winch.

WINDLE = ЛЕБЁДКА – Windle:- a reel or swift. Windle:- a spindle; a kind of reel; a winch. / :- мотовило или баран мотовила.

WINDMILL = ВЕТРЯК – Windmill or Windbill is an informal name for Accomodation Bill. / Смотрите также Дружеский Вексель (Accomodation Bill).

WINDOW = ОКНО – (1) Window is:- an interval or opportunity for action, e.g., the parliamentary recess offers a good window for a bid; or a favourable opportunity for doing something that must be seized immediately. / Буквально Окно, краткосрочное улучшение конъюнктуры. (1) Ограниченный период времени, когда следует воспользоваться представившейся возможностью, или она будет потеряна. Например, период времени, в течение которого новый выпуск акций приветствуют на рыке, продолжается всего несколько месяцев или максимум год. Этот период времени называется открывшейся возможностью (window of opportunity). Окно:- (1) ограниченный период времени, когда необходимо использовать возможность, иначе она будет упущена. (2) Кассовый отдел брокерской фирмы, где происходят поставка и расчёт по сделкам с ценными бумагами. (3) Возможность получения ссуды в федеральном резервном банке.

(2) Window or Discount Window helps to relieve liquidity strains for individual depository institutions and for the banking system as a whole by providing a reliable backup source of funding. / Учётное Окно (Discount Window) Федерального Резервного банка (Federal Reserve bank).

(3) Window is a brokerage firm's cashier department, where delivery of securities and settlement of transactions take place. / Кассовый отдел брокерской фирмы, где происходят поставка ценных бумаг и завершение сделок по ним.

(4) Window is a translucent portion of the leaves of some succulent plants which allows light to penetrate to the photosynthetic layers.

WINDOW CLOSE = ЗАКРЫТОЕ ОКНО – Window Close:- in patent law, a time period after which a utility patent (that issues from an application filed on or after 12 December 1980) expires if a maintenance fee has not been paid. A petition must be filed along with the appropriate fees to reinstate an expired patent.

WINDOW CONTRACT = КОНТРАКТ С ОКНОМ – Window Contract is a guaranteed investment contract purchased with deposits over some future designated time period (the 'Window'), usually between 3 and 12 months. All deposits made are guaranteed the same credit rating. Related:- Bullet Contract.

WINDOW DRESSING = УКРАШЕНИЕ ВИТРИНЫ (или ВИТРИННОЕ МАНЕКЕНСТВО) – Window Dressing is a strategy used by mutual fund and portfolio managers near the year or quarter end to improve the appearance of the portfolio/fund performance before presenting it to clients or shareholders. To window dress, the fund manager will sell stocks with large losses and purchase high flying stocks near the end of the quarter. These securities are then reported as part of the fund's holdings. Performance reports and a list of the holdings in a mutual fund are usually sent to clients every quarter. Another variation of window dressing is investing in stocks that don't meet the style of the mutual fund. For example, a precious metals fund might invest in stocks that are in a hot sector at the time, disguising the fund's holdings, so clients really have no idea what they are paying for. Window dressing may make a fund appear more attractive, but you can't hide poor performance for long. The term Window Dressing has similar meaning when applied to accounts, but is a broader term that can be applied to other areas. In the United States it is often used to describe the manipulation of investment portfolio performance numbers. In the context of accounts, 'window dressing' is more likely than 'creative accounting' to imply illegal or fraudulent practices, but it need to do so. Window Dressing is a trading activity near the end of a quarter or fiscal year that is designed to improve the appearance of a portfolio to be presented to clients or shareholders. For example, a portfolio manager may sell losing positions so as to display only positions that have gained in value. Financial institutions have also been criticized for a different type of window dressing as many moved debt off the balance sheet near the end of the quarter in a temporary manner. This made the bank appear to have less leverage than it actually did. Window Dressing is a specious (but usually legal) manipulation of a firm's accounting data to make its financial statements look better than they actually are. Window Dressing:- trading activity near the end of a quarter or fiscal year that is designed to improve the appearance of a portfolio to be presented to clients or shareholders. For example, a portfolio

manager may sell losing positions so as to display only positions that have gained in value. Window Dressing is the act or an instance of making something appear deceptively attractive or favorable. Usually using something, e.g., inflated sales projections, to create a deceptively favorable or attractive impression. Window Dressing is actions taken to improve the appearance of a company's financial statements. Window dressing is particularly common when a business has a large number of shareholders, so that management can give the appearance of a well-run company to investors who probably do not have much day-to-day contact with the business. It may also be used when a company wants to impress a lender in order to qualify for a loan. If a business is closely held, the owners are usually better informed about company results, so there is no reason for anyone to apply window dressing to the financial statements. Examples of window dressing are:- (i) Cash:- postpone paying suppliers, so that the period-end cash balance appears higher than it should be; (ii) Accounts Receivable:- record an unusually low bad debt expense, so that the accounts receivable (and therefore the current ratio) figure looks better than is really the case; (iii) Fixed Assets:- sell off those fixed assets with large amounts of accumulated depreciation associated with them, so the net book value of the remaining assets appears to indicate a relatively new cluster of assets; (iv) Revenue:- offer customers an early shipment discount, thereby accelerating revenues from a future period into the current period; (v) Depreciation:- switch from accelerated to straight-line depreciation in order to reduce the amount of depreciation charged to expense in the current period; the mid-month convention can also be used to further delay expense recognition; (vi) Expenses:- withhold supplier expenses, so that they are recorded in a later period. These actions are taken shortly before the end of an accounting period. The window dressing concept is also used by fund managers, who replace poorly-performing securities with higher-performing ones just before the end of a reporting period, to give the appearance of having a robust set of investments. The entire concept of window dressing is clearly unethical, since it is misleading. Also, it merely robs results from a future period in order to make the current period look better, so it is extremely short-term in nature. Window Dressing is special 'cosmetic' adjustments made to improve the balance sheet by building up the cash position, usually just before close of accounts. / Под Украшением Витрины любая попытка представить ситуацию лучше, чем она есть на самом деле. Украшение витрины используется бухгалтерами для создания более благоприятного представления о балансе, хотя эта практика в настоящее время и запрещена. Например, в конце финансового года банки стремятся взыскать выданные ими краткосрочные ссуды и задержать свои платежи, для того чтобы показать в отчётности высокие остатки наличности. Под Украшением Витрины понимается практика совершения сделок незадолго до конца отчётного периода для того, чтобы искусственно поправить статьи отчёта за данный период. Украшение Витрины:- (1) улучшение показателей отчётности. Торговая деятельность в конце квартала или финансового года, которая направлена на то, чтобы сделать портфель вложений более представительным для клиентов и акционеров. Например, управляющий фонда может продать имеющиеся в его портфеле 'плохие' ставки, чтобы отчитываться только по позициям, которые выросли в цене. (2) Бухгалтерская подтасовка данных, чтобы финансовый отчёт (financial statement) отражал более благоприятные условия, чем реально существующие, например, путём изъятия определённых расходов, сокрытия обязательств, отсрочки списаний, указания ожидаемых продаж в качестве реально совершённых и иных подобного рода действий, которые могут составлять или не составлять подлог. 'Украшение Витрины':- (1) торговая активность в конце квартала или налогового года с целью приукрасить портфель для его представления клиентам и/или владельцам акций. (2) Бухгалтерская стратегия создания финансового отчёта, чтобы он выглядел более благоприятно, чем есть на самом деле. Может считаться мошенничеством, а может им и не считаться. 'Украшение Витрины':- торговые операции, осуществляемые взаимным фондом в преддверии конца квартала или года, с целью улучшения результатов деятельности фонда или качества портфеля перед представлением отчёта акционерам или клиентам. Как правило, в этих целях управляющие фондов закрывают позиции в тех акциях, которые значительно упали в цене.

WINDOW OF ENTERPRISE = ОКНО ПРЕДПРИЯТИЯ – Window Of Enterprise depicts the overall structure of accounting.

WINDOW OPEN = ОТКРЫТОЕ ОКНО – Window Open:- in the US patent law, a time period when a maintenance fee can be paid with or without a surcharge.

WINDOW OPTION = ОКОННЫЙ ОПЦИОН (или РАМОЧНЫЙ ОПЦИОН) – Window Option is an option whose outcome depends on the performance of the underlying during the life of the option and whether that price lies between certain parameters on a certain observation day or days.

WINDOW PANING = XX – Window Paning is a fabric defect caused by nonuniform yarn. When thin sections of yarn become grouped together, the resultant increase in the transparency of the fabric is called Window Paning. / Порок или дефект .

WINDOW–PANING EFFECT = ЭФФЕКТ ОСТЕКЛЕНИЯ – Windowpaning Effect:- a distinctive feature caused by young worms eating the surface off the leaf, but not consuming the entire structure. See also Skeletonizing. Adults feed voraciously on the foliage of many host species. Most feeding injury appears as skeletonization ('window-paning effect') of the foliage, often leading to complete defoliation. / Смотрите также Препарирование Скелета (Skeletonizing).

WINDOW SETTLEMENT = РАСЧЁТ У ОКНА – Window Settlement is a form of settlement between dealers whereby trades are settled through the physical comparison of transactions and actual money and stocks are transferred. With the increased role of clearing corporations and depositories, window settlement is not as common as it once was. Typically, this form of settlement will only occur when one or both the participating parties to a trade are not members of the same clearing firm. Window Settlement is the physical settlement of transactions between dealers. Window settlement is used when one or both participants are not members of a clearing firm such as the National Clearing Corporation. Settlement entails an actual physical comparison. Window Settlement is a way to settle a transaction where two dealers physically meet and exchange the underlying asset for the payment. Window settlement occurs when one or both dealers do not belong to a clearing house. Window settlement has become less common with increased computerization of the securities trade. / Расчёт У Окна:- физическая поставка с расчётом по ценным бумагам с брокером на другой стороне сделки.

WIND POWER PLANT = ВЕТРОВАЯ ЭЛЕКТРИЧЕСКАЯ СТАНЦИЯ (или ВЕТРОЭЛЕКТРИЧЕСКАЯ СТАНЦИЯ, или ВЕТРОВАЯ ЭЛЕКТРОСТАНЦИЯ) – Wind Power Plant is a group of wind turbines interconnected to a common utility system through a system of transformers, distribution lines, and (usually) one substation. Operation, control, and maintenance functions are often centralized through a network of computerized monitoring systems, supplemented by visual inspection. This is a term commonly used in the United States. In Europe, it is called a Generating Station.

WINDPROOF = ВЕТРОУПОРНОЕ (или ВЕТРОНЕПРОНИЦАЕМОЕ) – Windproof:- the ability of a fabric to be nonpermeable to wind and air.

WIND RATIO = СООТНОШЕНИЕ НАМОТКИ – Wind Ratio is the number of wraps that an end or ends make in traversing from one side of a wound package to the other side and back to the first side.

WIND RESISTANT = ВЕТРОЗАЩИТНОЕ – Wind Resistant:- the ability of a fabric to act against or oppose the penetration of wind or air, but it is not totally windproof.

WINDROW = ВАЛОК (или РЯД СЖАТОГО ХЛЕБА или РЯД СКОШЕННОЙ ТРАВЫ) – Windrow:- brushwood, slash, etc, concentrated (usually by machine) – along a line, to clear the intervening ground for regeneration. Windrow is a harvested grain pulled together into rows and left to dry. / в рядки .

WINDROWER = ВАЛКОВАЯ ЖАТКА (или ВАЛКОУКЛАДЧИК) – Windrower:- self-propelled or tractor-drawn farm machine for cutting grain and laying the stalks in windrows for later threshing and cleaning. The modern descendant of the header, the windrower is used to harvest grain in parts of the United States, Canada, and the 'new lands' in Siberia in which certain conditions, such as high moisture content and uneven ripening, make direct combine harvesting impractical. Because grain cut by windrowers dries to a moisture content suitable for threshing, harvesting may be done a week or 10 days earlier than by combine, reducing grain losses considerably. A windrower usually consists of a cutter bar driven by an engine or powered by a shaft from the tractor, a reel to sweep the grain onto a platform, and a canvas conveyor to carry it to one side and deposit it in a windrow for drying. / Жатка – машина для скашивания сельскохозяйственных культур и транспортировки скошенной массы к рабочим органам (в комбайне) или укладки её в валки или в расстил на поле (при раздельной уборке). Основные рабочие органы – режущий или теребильный аппарат, мотовило, транспортёр. Жатка для раздельной уборки агрегатируется с тракторами, самоходными комбайнами или самоходными шасси. Применяются также самоходные валковые жатки. Производительность от 1.2 до 8 гектаров в час (га/ч). Жатка, машина для скашивания сельскохозяйственных культур, формирования и транспортирования скошенной массы к последующим рабочим органам (жатка комбайна) или с укладкой её на поле (жатка для раздельной уборки). Сведения о жатках встречаются ещё у Плиния в I веке Нашей Эры. Разработка конструкции жатки относится к XVII веку. По свидетельству Русского академика Василия Фёдоровича Зуева (1754–1794), Тульский оружейник Бобрин изобрёл в 1781 жатку, которая срезала колосья, а солому оставляла в поле. В 1833 в Смоленской Губернии Жегалов изобрёл 'колосожатную машину', получившую широкую известность. В начале XIX века появились жатки в Англии, США. В дальнейшем конструкторы жаток стремились максимально сократить долю ручного труда в процессе уборки. Была разработана конструкция жатки-лобогрейки, которая скашивала хлеб и укладывала на платформу; затем рабочий вручную периодически сбрасывал его на землю. В 1856 была создана жатка-самосброска с грабельным механизмом, которая автоматически сбрасывала порции хлеба на землю. Жатка-сноповязалка, применённая впервые в 1867, автоматически связывала срезанную хлебную массу в снопы. В бывшем СССР в основном применяли Валковые Жатки, которые скашивали стебли, собирали их на платформе и сбрасывали на поле в виде валка. По производству жаток (по количеству и их суммарной ширине захвата) СССР вышел на первое место в мире. В 1970 в СССР изготовлено более 50 000 валковых жаток и 125 000 жаток для комбайнов. Жатки для комбайна подразделяют на платформенные и шнековые. Платформенная Жатка предназначена для уборки длинностебельных культур. Платформу этой жатки оборудуют полотняно- или цепочно-планчатым транспортёром. Транспортирующим органом шнековой жатки является шнек. Шнековыми Жатками оборудованы все современные отечественные и зарубежные зерноуборочные комбайны. Шнековая жатка комбайна может быть переоборудована для уборки различных культур – Зернобобовых, Люпина, Клещевины, а также для подбора скошенных стеблей из валков при помощи подборщика. Валковые жатки, навесные, но имеются и прицепные. Навесные Жатки при работе опираются на копирующие башмаки, выполненные в виде лыж и обеспечивающие хорошую приспособляемость машины к неровностям рельефа поля и заданную высоту среза. Назначение, работа и конструкция основных рабочих узлов жаток комбайна и валковой жатки одинаковы; отличие заключается в устройстве и назначении транспортирующих органов. Основные рабочие органы жатки:- делители, режущий аппарат, мотовило, транспортёры. Различают полевой и внутренний делители, а также для уборки прямостоящих и полёглых растений. Полевой делитель предназначен для отделения скашиваемых стеблей от нескашиваемых. Внутренний делитель жатки обычно используют в качестве ориентира для направления агрегата с максимальным использованием ширины захвата. Для уборки прямостоящих культур жатки оборудуют клиновыми жёстко закреплёнными делителями. Для уборки полёглых культур на жатке жёстко крепят прутковый делитель, прижимающий стебли к земле, или монтируют активный делитель в виде движущегося ножа. Для уборки длинностебельных хлебов применяют жатки с торпедными копирующими рельеф поля делителями, имеющими регулируемые стеблеотводы. Режущий аппарат жатки срезает стебли по принципу ножниц. Неподвижная его часть состоит из чугунных или стальных пальцев с противорежущими пластинками-вкладышами. Подвижная часть (нож) представляет собой стальную полосу с прикреплёнными трапецеидальными ножами-сегментами. Нож движется возвратно-поступательно, и острые кромки сегментов перерезают стебли. Для подъёма полёглых стеблей применяют стебле-подъёмники (лифтёры). Мотовило, применяемое на большинстве жаток, служит для подвода стеблей к режущему аппарату, удержания их во время срезания, очистки режущего аппарата и для сбрасывания стеблей на платформу. Для уборки прямостоящих культур используют мотовило с жёстко закреплёнными лопастями. При работе со скоростью более 10 км/ч мотовило снимают, а над режущим аппаратом по всей его длине натягивают трос. Срезанные стебли, ударившись о трос, падают на транспортёр. Для уборки полёглых хлебов используют жатки с эксцентриковым грабельным мотовилом, которое вместо деревянных планок снабжено трубами с пружинными пальцами. Пружинные пальцы мотовила входят в полёглую массу стеблей, поднимают её и удерживают до срезания. Транспортирующие органы жатки – шнек и наклонный транспортёр (жатка комбайна) либо полотняно- или ремённо-планчатый транспортёр (валковая жатка). В средней части шнека находится пальчиковый механизм. Пальчиковый механизм захватывает поданные шнеком срезанные стебли и сбрасывает их на наклонный транспортёр. Наклонный транспортёр состоит из цепочно-планчатой транспортёрной ленты. Планки ленты захватывают массу, прижимают её к днищу камеры и транспортируют по наклонной плоскости вверх. Полотняно-планчатый транспортёр применяют в валковых жатках для перемещения срезанных стеблей к выбросному окну. Широко применяют бесполотенные транспортёры, выполненные из нескольких рядов ремней с прикреплёнными поперёк короткими планками, которые сдвигают скошенную массу по профилированному листу. Положение рабочих органов всех современных жаток регулируют на ходу гидравлическими, реже механическими и другими устройствами. Основными направлениями совершенствования конструкций жаток является увеличение производительности рабочих органов, повышение надёжности узлов и деталей, снижение затрат на технические уходы.

WIND SHEAR = СДВИГ ВЕТРА (или ОТКЛОНЕНИЕ ВЕТРА) – Wind Shear:- rapid change in wind velocity or direction. A very narrow zone of abrupt velocity change is known as a Shear Line. Wind shear is observed both near the ground and in jet streams, where it may be associated with clear-air turbulence. Vertical wind shear that causes turbulence is closely associated with the vertical and horizontal transport of momentum, heat, and water vapor. / Линия Сдвига (Shear Line).

WINDSHIELD = КОЗЫРЁК (или ВЕТРОЗАЩИТА, или СТЕКЛООЧИСТИТЕЛЬ) – Windshield is the combination of individual units of glazing material of the locomotive, passenger car, or caboose that are positioned in an end facing glazing location.

WINDSOR COLLAR = ВИНДЗОРСКИЙ ВОРОТНИЧОК – Windsor Collar for a cutaway collar:- a dress-shirt collar that is slightly stiff, with a wide spread (space between the points) to accommodate a Windsor knot tie, popularized in the 1930s; for a wing collar, a standard wing collar.

WINDSOR KNOT = ВИНДЗОРСКИЙ УЗЕЛ – Windsor Knot is a fairly loose, bulky necktie knot originated by the Duke of Windsor.

WINDSOR TIE = ВИНДЗОРСКИЙ ГАЛСТУК – Windsor Tie is a broad necktie usually tied in a loose bow.

WIND TOO CLOSE = НАМОТАННОЕ СЛИШКОМ ТЕСНО – Wind Too Close:- thread will not pull off smoothly. Makes package less than uniform size. Thread defects, and namely – Winding. / Порок или дефект ниток.

WIND TOO OPEN = НАМОТАННОЕ СЛИШКОМ РЫХЛО – Wind Too Open:- tends to make thread package too large. Thread defects, and namely – Winding. / Порок или дефект ниток.

WIND TOO TIGHT = НАМОТАННОЕ СЛИШКОМ ТУГО – Wind Too Tight:- tends to over stretch thread, which reduces elongation. Thread defects, and namely – Winding. / Порок или дефект ниток.

WIND TURBINE = ВЕТРОВАЯ ТУРБИНА – Wind Turbine:- wind energy conversion device that produces electricity; typically three blades rotating about a horizontal axis and positioned up-wind of the supporting tower. Wind Turbine is a machine that converts wind energy to mechanical energy; typically connected to a generator to produce electricity. A Wind Turbine is a device that converts kinetic energy from the wind into electrical power. A wind turbine used for charging batteries may be referred to as a Wind Charger.The result of over a millennium of windmill development and modern engineering, today's wind turbines are manufactured in a wide range of vertical and horizontal axis types. The smallest turbines are used for applications such as battery charging for auxiliary power for boats or caravans or to power traffic warning signs. Slightly larger turbines can be used for making small contributions to a domestic power supply while selling unused power back to the utility supplier via the electrical grid. Arrays of large turbines, known as Wind Farms, are becoming an increasingly important source of renewable energy and are used by many countries as part of a strategy to reduce their reliance on fossil fuels. Wind Turbine is a tall structure that has large blades attached to an engine and that is used to produce electricity. A Wind Turbine is a rotary engine that extracts energy from the flow of wind. The simplest turbines have one moving part, a rotor assembly, which is a shaft with blades attached. Wind energy acts on the blades, or the blades react to wind, so that they rotate and impart energy to the rotor. Early wind turbine examples are windmills.

WINDWARD = ПРОТИВ ВЕТРА (или ПО НАПРАВЛЕНИЮ К ВЕТРУ, или В НАВЕТРЕННУЮ СТОРОНУ, или СО СТОРОНЫ НАБЕГАЮЩЕГО ПОТОКА, или В НАПРАВЛЕНИИ ВЕТРА, или НА ВЕТЕР, или НА ВЕТРЕ, или С НАВЕТРЕННОЙ СТОРОНЫ, или НАВЕТРЕННОЕ) – Windward:- toward the wind or side wind is hitting. Windward:- toward the direction from which the wind is coming.

WINDY BOOKING = БЕССОДЕРЖАТЕЛЬНОЕ БРОНИРОВАНИЕ (или БРОНИРОВАНИЕ ПРОСТРАНСТВА) – Windy Booking is a freight booking made by a skipper or freight forwarder to serve space but not actually having a specific cargo at the time the booking is made. Carriers often overbook a vessel by 10 to 20 percent in recognition that 'windy booking' cargo will not actually ship. / Бронирование фрахта, произведённое шкипером или грузовым экспедитором для выделения пространства, а не под фактически имеющийся на момент проведения бронирования конкретный груз. Перевозчики достаточно часто превышают нормы бронирования на 10–20 процентов признавая, что фрахтование пространства вовсе не значит, что груз будет реально перевозиться.

WINE = ВИННОЕ – Wine is a dark red.

WING = ВЫСТУП (или КРЫЛО) – Wing (in pallets) is the overhang of deckboard end from outside edge of stringer or stringer-board. See also Pallet. Wing is a portion of the deck or decks which projects beyond the stringers or blocks, designed for lifting by crane attachment (sling). / Выступ (wing):- часть одного или двух настилов, выступающая за продольные брусья поддона или шашки, предназначенная для заведения захвата при поднятии поддона грузоподъёмным краном.

WING = КРЫЛО – Wing:- in aeronautics, an airfoil that helps lift a heavier-than-air craft. When positioned above the fuselage (high wings), wings provide an unrestricted view below and good lateral stability. Parasol wings, placed on struts high above the fuselage of seaplanes, help keep the engine from water spray. Midwings, positioned in the middle of the fuselage, leave the airplane belly free of spars, with room for bombs or cargo. Placed below the fuselage, low wings reduce the height of the undercarriage and simplify engine maintenance.

WING = КРЫЛО (или ХХ) – Wing is any membranous expansion.

WINGBOARD = ХХ (или СЪЁМНЫЙ ЩИТ) – Wingboard is a 12-by 36-inch daymark formerly used with type 46 wooden structures. Wingboards are now being replaced by passing daymark.

WINGDAM = КРЫЛЬЧАТАЯ ДАМБА (или ХХ) – Wingdam is a rock and sand dike extending from the right or left bank of the river outward toward the channel. Often lies just below the surface of the water at pool stage. Wingdams are used to direct the flow of water into the main channel to assist in its maintenance.

WINGED = КРЫЛАТОЕ – Winged (2-4-year-old twigs, Petioles, Rachises):- having one or more elongate, relatively thin protrusions or appendages that loosely resemble wings, as the twigs of Winged Elm (Ulmus Alata). / Крылатый Вяз (Winged Elm) (или Крылатый Ильм, или Крылатый Вахуо (Winged Wahoo)), или Улмус Алата (Ulmus Alata) на Латинском.

WINGLET = КРЫЛЫШКО (или ХХ) – Winglet (Tip Fin):- an out-of-plane surface extending from a lifting surface. The surface may or may not have control surfaces. Winglet is a small wing; also, is a nearly vertical airfoil at an airplane's wingtip that reduces drag by inhibiting turbulence.

WING PALLET = ПОДДОН С ВЫСТУПАЮЩИМ НАСТИЛОМ – Wing Pallet:- pallet with a top deck and/or bottom deck extending beyond the outer edges of stringers, blocks, posts or stringerboards. Note:- a wing on a pallet should not be confused with a lip on a pallet. Most cost effective single use option when pallet recovery is not an option. Wing decreases span of the top boards increasing rigidity. / Поддон С Выступающим Настилом:- плоский поддон, у которого края верхнего и/или нижнего настилов выступают за опорные детали. Примечание:- термин 'Выступ Поддона' не допускается применять вместо термина 'Край Поддона'.

WINGS = WARRANT INTO NEGOTIABLE GOVERNMENT SECURITIES

WINGS/BODY OF BUTTERFLY TRADE = КРЫЛЬЯ/ТЕЛО ТОРГОВЛИ В СТИЛЕ БАБОЧКА – Wings/Body Of Butterfly Trade:- the short-end and the long-end of a butterfly curve trade are referred to as the Wings, while the middle maturity of the butterfly is referred to as the Body. One would typically buy the body and sell the wings or vice versa. For example, one may buy 5-year bonds and sell 2-year and 10-year bonds.

WING TIP = КРЫЛЬЧАТЫЙ НОСОК – Wing Tip is a shoe having a wing tip, namely a toe cap having a point that extends back toward the throat of the shoe and curving sides that extend toward the shank.

WINS = WINDOWS INTERNET NAMING SERVICE

WINNER–LOSER EFFECT = ЭФФЕКТ ПОБЕДИТЕЛЯ–ПРОИГРАВШЕГО – A Winner-Loser Effect is a correlation between past and future performance. In an investment context, the commonest effect for which there is some evidence is that good performers do too well in the short term, which is naturally followed by a period of under-performance as this is reversed. A winner-loser effect is a longer term effect than momentum, so is perfectly consistent with it. Some models of investor behaviour predict both a momentum effect in the short term and a winner-loser effect in the long term. The evidence for the winner-loser effect not conclusive, but there are a number of studies which show empirical evidence. For example, there is evidence of a winner-loser effect for some types of shares in UK markets, and that they reflect the behaviour of certain types of investor. The commonest explanation of the winner-loser effect is that investors over-react to news. The value effect can be explained in a similar way, and this does seem to be behavioural factor that has a significant effect on markets.

WINNER'S CURSE = ПРОКЛЯТИЕ ПОБЕДИТЕЛЯ – The Winner's Curse is the tendency for winning bidders (in an auction) to over-pay. In a situation where there are a number of bidders, and each bidder makes a bid based on their estimate of the value, then the most optimistic will win. However, the most optimistic is also the one who is most likely to have over-estimated the value. Therefore it is highly likely that the winner overpaid. The most widely cited example is in bidding for drilling rights for oil, but it has been found in areas as far apart as IPOs (for certain mechanism) and labor markets. Analogous effects have been found even in scientific publishing. Because bidders are aware of winner's curse, attempts to compensate for winner's curse can further distort markets:- this can lead to strange effects such as more competition increasing prices. Apart from bidder's own attempts to adjust (e.g., by bidding at less than their estimate, leaving a margin for error), winner's curse can be reduced by better information, or by more complex price setting mechanisms than simply using the level of the winning bid. Winner's Curse:- problem faced by uninformed bidders. For example, in an initial public offering uninformed participants are likely to receive larger allotments of issues that informed participants know are overpriced.

WINNING BID = ВЫИГРЫВАЮЩЕЕ ПРЕДЛОЖЕНИЕ НА ПОКУПКУ – Winning Bid:- the successful bid for a particular issue. Generally, it produces the lowest net interest cost (NIC) to a municipal borrower or offers the highest premium in a single coupon bid. / Выигрывающее Предложение На Покупку:- успешное предложение на покупку конкретного выпуска. Как правило, оно продуцирует самую низкую чистую стоимость процентов для муниципального заёмщика или предлагает самую высокую премию в единственном предложении на покупку купона.

WINNIPEG COMMODITY EXCHANGE = ВИННИПЕГСКАЯ СЫРЬЕВАЯ БИРЖА – The Winnipeg Commodity Exchange (WCE) is the former name of a derivatives market based in Winnipeg, Manitoba, Canada now known as ICE Futures Canada. Futures and options contracts are electronically traded in Western Barley and Canola (Rapeseed). The WCE began its existence as the Winnipeg Grain & Produce Exchange in 1887. In 1904, it introduced its first futures contracts. It was, and remains, Canada's only commodity futures exchange. It also formerly operated the Canadian Financial Futures Market. In December 2004, WCE converted from the traditional 'open outcry' method of trading to an electronic trading format. This made it the first commodity futures exchange in North America to go fully electronic. Until December 2007, futures were traded on the platform of the Chicago Board of Trade. Since September 2007, the WCE has been a subsidiary of the Atlanta-based IntercontinentalExchange Inc. (ICE). Its quotes are now traded on the ICE platform. The Winnipeg Commodity Exchange buildings past and current, have been located within downtown Winnipeg. The first Commodity Exchange building was located on Princess Street and was constructed in 1899. The façade is now part of the Red River College Princess St. Campus. Entrance to the Grain Exchange building at 167 Lombard Ave. The second building was located at 167 Lombard Street and was constructed from 1906 to 1908 by Toronto architects Pearson and Darling. It is still in use as office space, and known as the Grain Exchange Building. The Winnipeg Commodity Exchange then moved to the Commodity Exchange Tower at 360 Main Street in 1979. The tower has since been renamed 360 Main Street in 2008 after the Winnipeg Commodity Exchange was absorbed into an American trading exchange. The present 360 Main Street is home to the Underground Shops of Winnipeg Square. Locally, the building is also known as the Trizec Building since it was originally developed by Trizec. The building was completed in 1979 and is the third tallest building in the city, at 117 m (384 ft) with 31 floors. The construction of the building originally planned to have a twin with a hotel in the middle. The foundation for the other buildings were completed but the second tower and hotel were never built. Based in Winnipeg, Manitoba, Canada, the Winnipeg Commodity Exchange (WCE) is a derivatives market where futures and options contracts are electronically traded. Beginning as the Winnipeg Grain & Produce Exchange in 1887, the WEC introduced its first futures contracts in 1904. Today, the goods traded on WEC market are feed Wheat, Western Barley and Canola. As Canada's only commodity futures exchange, WCE went from the traditional 'open outcry' method of trading to an electronic trading format in 2004. 2007-December-10 (Reuters):- Canola traders reported few hiccups on Monday after the Winnipeg Commodity Exchange switched its futures contracts to the platform of its new owner, The IntercontinentalExchange Inc. (ICE.N). 'It looks like things are moving along fine', said WCE President Will Hill, noting there were some minor technical glitches for some participants. 'I think it's been a really successful transition', he said. Atlanta-based energy exchange ICE acquired the 120-year-old Winnipeg exchange earlier this year for CAD50 million (USD49.5 million) as part of its move to expand agricultural offerings. The WCE had traded its Canola, Barley and feed Wheat derivatives on the electronic platform owned by the Chicago Board of Trade since 2004. The switch involved a change in hours to 08 pm CST to 01:15 pm CST, without the early morning break seen in the allied Chicago Board of Trade soy complex. Chicago trades overnight from 06:30 pm CST to 06 am CST, with the main session from 09:30 am CST to 01:15 pm CST. Volume in the WCE's flagship Canola contract slowed to a trickle between 06 am and 09:30 am on Monday, traders said. 'I don't think anyone's going to really jump out in front of this market and do anything until they see the US market', a commercial trader said. 'I think the bulk of the trade is still going to occur from 09:30 to 01:15'. Another commercial trader said he would have preferred the WCE adopt Chicago's 06:30 pm overnight start time. Traders were still fine-tuning their screens and working out some bugs after the switch on Monday. Several said their 'front end' trading systems were not meshing with the ICE platform as well as they had hoped with the ICE platform. Some European traders had problems seeing quotes, one trader said. The ICE platform does not support 'good-til-canceled' orders, and some traders complained they would have to reenter resting orders each evening when the market reopens. 'The fact that (ICE) doesn't allow open orders is bizarre. This forces traders to place orders each day, unless your front end will hold the ticket open for you', a trader said. Others were wary of the new platform's 'first in, first out' system, which replaces an algorithm that allowed some resting orders to be filled on a pro rata basis. Traders said the new system would encourage players to be more aggressive to get orders filled. One trader said that would penalize smaller players, or those with the best order entry systems. 'This gives an unfair advantage to computer wizards', the trader said. But the WCE's Hill said the first in, first out system should narrow the bid-ask spread. 'Less aggressive players have less of an opportunity, but in the end, what you want to do in the marketplace is have people aggressively bidding and offering', Hill said. ICE Futures Canada was established in 1887 as the Winnipeg Grains and Produce Exchange and has been facilitating futures contract trading since 1904. A wholly-owned subsidiary of ICE since 2007, ICE Futures Canada is Canada's leading agricultural exchange and was the first fully-electronic exchange in North America. ICE Futures Canada offers futures and options contracts for the global benchmark Canola contract and in January 2012 re-introduced Wheat futures to the Canadian market after an absence of nearly 70 years. Milling Wheat, Durum Wheat and Barley contracts priced in Canadian Dollars with Canadian delivery points. Introduced in 1963, the Canola futures contract is the global benchmark for Canola

trading. The Winnipeg Commodity Exchange (WCE) was established in 1887 as the Winnipeg Grain Exchange – the name was changed in 1972 – by western farmers and grain merchants to provide a marketplace for the expanding agricultural production of the Canadian prairies. For its first 18 years, the WCE operated strictly as a cash market, i.e. a marketplace for grains that have already been grown (as distinct from a 'futures market' in which contracts are traded for the delivery of grain at a later date). In this capacity, WCE provides meeting rooms, communications facilities and rules of trade for the grain and produce grown in the West. In 1904 the WCE established a futures market for Wheat. Other futures markets were opened later for Oats and flaxseed (1904), Barley (1913) and Rye (1917). Wheat futures trading was discontinued in 1942. Rapeseed (CANOLA) futures trading opened in 1963, gold in 1972, feed Wheat for domestic use in 1974; silver, Government of Canada bonds and Treasury bill futures markets opened in 1981. Lumber is also traded. The WCE is the only agricultural commodities exchange and futures market in Canada. A voluntary, nonprofit, unincorporated association, its 330 members (farmers, elevator companies, grain processors' merchandisers, exporters, overseas importers and the general public) represent virtually every group with an interest in Canadian grains. The Canadian Wheat Board is also a member. The futures markets of the WCE are used by the grain industry for price protection and price discovery. Through the process known as 'Hedging', producers, handlers and users of grain buy and sell futures contracts to protect themselves against the possibility that prices will change. They trade in an open, competitive auction on the trading floor in Winnipeg, trying to obtain the best price they can for the grain they own or the grain they need to buy later. The market prices established through this process are used throughout the grain industry. Winnipeg Commodities Exchange (WCE) is a commodities exchange in Winnipeg, Manitoba, that serves as Canada's only agricultural futures and options exchange. Canola is the Winnipeg Commodities Exchange's (WCE) primary commodity, but the WCE also trades contracts on many other commodities and provides the world's only flaxseed futures market. On 2004-December-20, the WCE became North America's first commodities exchange to utilize a trading platform that is entirely electronic, and is recognized as a leading global provider of price-discovery and risk-management tools for canola. The WCE does not buy or sell any instruments on its exchange or play any role in price setting or discovery. Its mandate is to provide trading rules and facilities, so that buyers and sellers may conduct transactions and determine prices. The WCE is regulated by the Manitoba Securities Commission under the authority of the Commodity Futures Act of 1996. / Президент Вил Хил (President Will Hill). WINNOWING = ОТВЕИВАНИЕ – Winnowing:- generally, the removal of grain chaff by blowing it with air. Winnow:- to free (grain) from the lighter particles of chaff, dirt, etc, especially by throwing it into the air and allowing the wind or a forced current of air to blow away impurities.

WINSORISATION = ВИНЗОРИЗАЦИЯ – Winsorisation (in statistics) is a transformation of statistics of a batch or sample by transforming extreme values. Named for the engineer-turned-biostatistician Charles P. Winsor (1895–1951). Winsorisation is an imputation rule limiting the influence of the largest and smallest observations in the available data. / Чарлз Пи. Винзор (Charles P. Winsor; 1895–1951).

WINTER CROPS = ОЗИМЫЕ КУЛЬТУРЫ – Winter Crops are the cereals which are sown in the autumn. They germinate before the winter comes, may partially grow during mild winters or simply persevere under a sufficiently thick snow cover to continue their life cycle in spring. They are harvested earlier than the spring-sown grains of the same type. Winter forms are known for Rye (fall Rye or winter Rye), Wheat (fall Wheat or winter Wheat), Barley (fall Barley or Winter Barley) and Triticale (winter Triticale). Also known as Autumn-Sown Grains, Fall Cereals, Fall Grains, Winter Cereals, Winter Grains. A crop which will bear the winter, or which may be converted into fodder during the winter. Winter Crops:- an annual plant whose normal development requires overwintering, that is, exposure to a low temperature (0–10 °C) for 30 to 70 days or longer. Winter crops are planted in the autumn, and their grain is harvested the following year. Winter crops planted in the spring develop a root system and above ground such vegetative organs as leaves and tillering shoots, but they do not bear fruit. Vernalized seed planted in the spring produces a crop in the same growing season. Winter crops have two periods of active vegetation:- autumn (45 to 50 days) and spring-summer (75 to 100 days). Between these periods the plants are dormant. In the autumn, as a result of complex biochemical and physiological processes, the plants harden, that is, become resistant to low temperatures and other unfavorable wintering conditions. There also are forms that are not wintercrops and not spring crops. Such plants, which include some varieties of Wheat, Oats, and Barley, may be cultivated in the autumn or spring. They develop normally and produce grain. Winter crops include such cereals as winter Wheat, Rye, and Barley. A number of oil plants from the family Cruciferae, including winter Rape, winter Cress, and false Flax, are winter crops. An example of a winter legume is hairy vetch. In world agriculture, winter Wheat is the most common winter annual. It is the principal grain crop of Europe and the United States. Winter Rye is raised in Europe, the United States, Turkey, Canada, and Argentina. Winter Barley is grown in the southern regions of Europe and Asia. Winter Rape is cultivated in India, Japan, the German Democratic Republic (GDR), France, Sweden, North Africa, and the United States. Winter Cress is grown mainly in the GDR and the Federal Republic of Germany, and false Flax in Western Europe and North America. Hairy Vetch is raised in Europe, Asia Minor, the United States, and Japan. The raising of winter crops is confined to regions with relatively mild winters and a constant snow cover. Winter Wheat is grown throughout the USSR, from Southern Arkhangel'sk Oblast to the Turkmen SSR. The major regions for its cultivation are the Ukraine, the Northern Caucasus, and Moldavia. Winter Wheat covered 8.3 million hectares (ha) in 1913, 14.3 million ha in 1940, 12.1 million ha in 1960, 15.5 million ha in 1970, 20.7 million ha in 1971, and 15.0 million ha in 1972. Winter Rye is also grown almost everywhere in the USSR, but more than 70 percent of the sown area is in the RSFSR. It occupied 29.1 million ha in 1913, 23.1 million ha in 1940, 16.2 million ha in 1960, 10 million ha in 1970, 9.5 million ha in 1971, and 8.1 million ha in 1972. Winter Barley is grown in the southern RSFSR, Middle Asia, and Moldavia. Winter oil crops are raised in the Ukraine, and hairy vetch in the Ukraine, Byelorussia, and Middle Asia. In the principal growing regions, the winter crops are higher yielding than the spring ones, since they make better use of the spring moisture supply in the soil. For example, the average winter Wheat yield in the USSR (1966–70) was 19.6 quintals per ha, and the average spring wheat yield was 11.1 quintals per ha. In planting in feed rotations, winter Rye produces the earliest green feed. Winter crops are particularly valuable because they are good predecessors for spring plants and they cutdown on the amount of field work necessary in the spring and during harvesting. Winter Crop is a crop (as of oats) fall-sown for growth during the winter and maturing in the spring. / Тритикале (пшенично-ржаные амфидиплоиды или ржано-пшеничные гибриды, формы Пшеницы, полученные при скрещивании её с Рожью). Под Озимыми Культурами понимаются однолетние сельскохозяйственные растения (однолетники) среди которых:- Вика, Пшеница, Рапс, Рожь, Рыжик, Ячмень и другие, нормально развивающиеся при осеннем посеве; дают урожай на следующий год. Имеют 2 периода активной вегетации:- (i) осенний (40–45 суток), во время которого они формируют корневую систему и надземные вегетативные органы, подвергаясь действию пониженных температур, приобретают закалку; и (ii) весенне-летний (75–100 суток), когда развивают генеративные органы. Озимые культуры включают хлеба (озимая

Пшеница, Рожь, Ячмень), масличные растения (озимые Рапс, Сурепица, Рыжик), зерно-бобовые (озимая Вика). В мировом земледелии озимые культуры выращивают в основном в районах с относительно мягкими зимами и устойчивым снежным покровом; наиболее распространена озимая Пшеница – основное хлебное растение Европы и США. В бывшем СССР озимые культуры (Зерновые) высевали на 28.6 миллионах гектар (га) (по данным на 1985). Озимые культуры более урожайны, чем соответствующие яровые, так как лучше используют весенние запасы влаги в почве. Они являются хорошими предшественниками для яровых растений и для других культур севооборота, уменьшают напряжённость весенних посевных и уборочных работ. Озимые культуры часто используют в промежуточных посевах, особенно в районах орошаемого земледелия. Это даёт возможность получить значительное количество кормов для животноводства.

WINTER DOCTRINA = ДОКТРИНА ВИНТЁ – Winter Doctrine is a legal principle announced by the US Supreme Court in the case of Winters v. United States 207 US 564 (1908). The doctrine created a different legal rule for the distribution of water in the arid western states. The rule is that water rights have been reserved to Indian reservations and public lands in order to make sure that there will be enough water to achieve their assigned purposes. The Winters Doctrine contradicts the law of water rights in the western United States that is applied to privately held lands. The rule generally followed in the west is the 'state-based appropriative rights' rule. It is the principle that the rights to water derive from the first time that The .... See also Federal Reserved Water. Henry Winter was known as Winters in some of the valley papers, as indicated by this intriguing item, printed in its entirety, from the January 17, 1906, edition of the Milk River Valley News:- 'Foreclosure proceedings have been instituted in Choteau county to recover about USD27 000 from Henry Winters and wife. Winters has left the county, it is said, as a result of disclosures regarding his scheme to kill Stock Inspector Hall and Judge Tattan. The judicially crafted Winters Doctrine (1908) provides water for the needs of Native Americans who reside on federally reserved lands. This judicial guarantee, while not absolute, is highly significant given the demands for this critical natural resource in a region where water is often not abundantly available. Water policy in the Great Plains is shaped by powerful political forces. Economic demands translate into political pressures and ultimately into water law. State water laws are generally designed to allocate water for 'beneficial uses', following the doctrine of prior appropriation. Stressing uses, rather than needs, is inconsistent with Native American ideals, whereby water, like other aspects of the environment, is connected to a higher sacred order. Consequently, European American water schemes have often been in conflict with Native American concepts. In 1908, however, Native Americans prevailed in the landmark case Winters v. United States. The case involved the Gros Ventres and Assiniboines of the Fort Belknap Reservation in Montana and their right to use the water of the Milk River. When farmers upstream diverted water from the river, the United States brought an injunction against them, reasoning that this left insufficient water for agriculture on the reservation. The farmers appealed. On January 06, 1908, the Supreme Court ruled in favor of the United States and the Native Americans, arguing that the establishment of the Fort Belknap Reservation entitled the Native Americans to perpetual use of the water that it contained. Their rights were 'reserved' at the date of establishment (1888), and, contrary to the doctrine of prior appropriation, those rights could not be lost through nonuse. The Winters Doctrine was a major victory for all Native Americans, serving notice that state laws are secondary to federally reserved water rights and preventing prior appropriation schemes from extinguishing Native American needs. In 1976, in Cappaert v. United States, the doctrine was extended to groundwater use on or near federally created reservations. Subsequently, however, an increasingly conservative Supreme Court has ruled against tribes in a number of water rights disputes. While the Winters Doctrine protects Native American water rights, this protection is still vulnerable to changes in the prevailing political climate. The 'Winter's Doctrine' and how it grew:- a memorandum on the origin, scope and application of reserved rights to the use of water for the benefit of ... lands and enclaves of the United States. / Хэнри Винтё (Henry Winter).

WINTER PEAK = ЗИМНИЙ ПИК – In the United States, Winter Peak is a period at the beginning of the year, usually between December 01 and March 30, when the use of heating systems creates the strongest demand for energy in areas with cold winter weather.

WINTER SURCHARGE = ЗИМНЯЯ НАДБАВКА (или ЗИМНЯЯ ДОПЛАТА, или ЛЕДОКОЛЬНЫЙ СБОР) – Winter Surcharge (WSC) is imposed for all containers to cover extra costs related to serving the port due to harsh weather, convoy restrictions, ice conditions etc. This surcharge is only effective during winter period. Winter Surcharge (WNS or WS) is a surcharge applied to the regions where ice accumulation is expected during the cold seasons, for example, in St. Petersburg, Russia. The Winter Surcharge (WS) is to cover for the heavy weather and ice conditions, seasonal increases in the local tariffs as well as increased vessels costs. Every winter, we are forced to charter additional vessels to compensate for lost voyages, and the significant increase in time charter levels experienced this year leaves us with no option than to increase the winter surcharge. Cargo mix/heavier weights are other factors that have significantly changed. Winter Surcharge (WINT SUR) is a surcharge applied when the access of certain locations / ports is jeopardized due to harsh weather, convoy restrictions, ice conditions etc. Maersk Line will implement a Winter Surcharge (WSC) in St. Petersburg and Ust-Luga, Russia due to an increase in operational costs during winter time. / Надбавка или Доплата (Surcharge) за ледовую проводку в замерзающих портах. Зимняя Надбавка – сбор взимаемый в портах, где существует возможность обледенения акватории порта. Действует в зимний период. Ледокольный Сбор рассчитывается исходя из условного объёма судна, исчисляемого в кубических метрах. Условный объём судна определяется произведением трёх величин, указанных в судовых документах:- наибольшей длины судна, наибольшей ширины судна и наибольшей высоты борта судна. Для судов, перевозящих груз на верхней палубе, или имеющих две и более палуб, используемая в расчёте высота борта судна должна составлять не менее половины наибольшей ширины судна. Для расчёта ледокольного сбора условный объём накатных судов, контейнеровозов умножается на коэффициент 0.7, танкеров с двойным дном, двойными бортами или танками изолированного балласта на коэффициент 0.85. Если к условному объёму применяются несколько понижающих коэффициентов, то используется наименьший из них. Некоторые суда от оплаты ледокольного сбора освобождаются. Грузовые суда, работающие на линиях загранплавания, открытых в установленном порядке, оплачивают ледокольный сбор с коэффициентом 0.8. Ставки ледокольного сбора являются предельно максимальными. Ледокольный сбор должен быть оплачен судном до выхода из порта. Капитан порта имеет право отказать судну в выдаче разрешения на выход из порта в случае неуплаты ледокольного сбора.

WINTER WHEAT = ОЗИМАЯ ПШЕНИЦА – Winter Wheat:- a Wheat that is planted in the fall, lies dormant during the winter, and is harvested beginning about May of the next year. Winter Wheat is a Wheat that is sown in the fall, lies dormant in the winter, and is harvested the following spring or summer. Winter Wheat (Triticum Aestivum) is a crop plant that is cultivated from September to December in the Northern Hemisphere. Winter wheat sprouts before freezing occurs, then becomes dormant until the soil warms in the spring. Winter Wheat needs a few weeks of cold before being able to flower, however persistent snow cover might be disadvantageous. It is ready to be harvested by early July. Due to the timing of the plant's growth and maturation, winter Wheat is valued as a cold crop that can be planted right after the harvest in the fall. Hard winter Wheats have a higher gluten protein content than other Wheats. They are used to make flour for yeast breads, or are blended with soft spring wheats to make the all-purpose flour used in a wide variety of baked products. Soft Wheat is used for specialty or cake flour. Durum, the hardest Wheat, is primarily used for making pasta. Almost all durum Wheat grown in North America is spring-planted. Winter Wheat is grown throughout Europe, North

America, and in Siberia, Russia. Winter Wheat was brought to Kansas by German-Russian Mennonites in the XIX century. Bernhard Warkentin and Mark A. Carleton played a major part in the spread of winter Wheat as a commercial crop. Warkentin organized mills in central Kansas and imported seed from Ukraine to meet growing demand. Carleton worked for the United States Department of Agriculture (USDA) as a crop explorer. He went to Russia to find other Wheat varieties and worked with Kansas State University researchers to develop new ones. Winter Wheat production quickly spread throughout the Great Plains, and was, as it still is, usually grown using the techniques of dryland farming. / Пшеница, которая высевается осенью, находится в состоянии покоя зимой. Сбор урожая такой Пшеницы начинается приблизительно в Мае следующего года. Озимая Пшеница является одной из самых распространённых важнейших продовольственных культур на земном шаре, ценность, зерна которой определяется высоким содержанием белка, жира, углеводов и так далее. По содержанию белка озимая Пшеница превосходит все зерновые. Пшеничная мука широко используется в хлебопечении, кондитерской промышленности, сильные и твёрдые сорта Пшеницы используют для производства качественного хлеба, макаронных изделий, манной крупы и так далее. Для хлебопечения требуется зерно с содержанием белка – 14–15%, для изготовления макаронных изделий – 17–18%. Из зерна получают спирт, крахмал и другое. Отходы мукомольной и спиртовой промышленности являются ценным питательным кормом для животных, грубые (солома, мякина) имеют большую кормовую ценность:- 10 кг соломы – 0.5 кг протеина, 20–22 кормовые единицы. Выращивание озимой Пшеницы выгодно, так как полученная продукция имеет низкую себестоимость. Озимая Пшеница – высокоурожайная культура (уступая лишь Рису). Средняя урожайность по Российской Федерации (РФ) – 30 ц/га, в передовых хозяйствах – 50–60 ц/га, самый высокий урожай в Российской Федерации был получен в Краснодарском Крае – 103.6 ц/га, а в мире, в Канаде – 170 ц/га.

WIRE = ПРОВОЛОКА – (1) Wire:- thread or slender rod, usually very flexible and circular in cross section, made from various metals and alloys, including iron, steel, brass, bronze, copper, aluminum, zinc, gold, silver, and platinum. The processes used are all fundamentally the same. The first known writing relating to wire and its manufacture appears in the Bible (Exodus 39:3):- 'And gold leaf was hammered out and cut into threads ....' Round wire was probably made by cutting plates into narrow strips, which were then hammered and filed round. These wires were very short, and it was necessary to braze or hammer several pieces end to end to make substantial lengths. For several centuries wire was drawn through metal dies by hand, in short lengths. The section to be drawn was hammered to a point so that it could be pushed through the hole in the die. The wiredrawer grasped it with his hands or with tongs and pulled it through the die, the amount of reduction being limited by the strength of the wiredrawer. Various means were used to augment his strength, such as seating him in a hanging chair so that by bracing his legs against the die-holding structure he could pull with his arms and push with his legs. Larger wire had to be made by hammering or rolling or both. In the XIX century requirements for large tonnages and great lengths of steel and copper wire became acute, especially after the invention of wire rope, the development of the telegraph in the 1840s, and the invention of the telephone and barbed wire later in the century. These demands were met by the Bessemer and the open-hearth steelmaking processes and new machinery and methods of rolling rods. Wire nowadays is drawn from a hot-rolled section of steel called a Rod. (Rods of some of the softer metals may be formed by extrusion or casting instead of rolling.) The rods are cleaned of scale (oxides that form on the surface) by immersion in dilute sulfuric acid. Other acids or a molten salt bath, such as of sodium hydride, may be used, as may mechanical scalers, depending on the material. Metallic grit blasting is sometimes used to clean spring wire. After acid cleaning, the metal is washed and immersed in a coating solution, such as a lime emulsion, borax, or phosphate, to neutralize any remaining acid and act as a lubricant in subsequent wire-drawing operations. The wire-drawing process consists of pointing the rod, threading the pointed end through the die, and attaching the end to a drawing block. The block, revolved by an electric motor, pulls the lubricated rod through the die, reducing it in diameter and increasing its length. For smaller sizes of wire, the reduction cannot be performed in a single draft, and a multiple-block machine is used, consisting of a number of single-block machines built together in one unit.

(2) Wire is a nickname for the Copper Market. See also Steel Filament.

WIRE = ПРОВОЛОЧНОЕ – Wire:- gach row of pile or tufts on the surface of a rug. / коврика.

WIRE CLOTH = ПРОВОЛОЧНОЕ ПОЛОТНО – Wire Cloth is a fabric of woven metallic wire (as for strainers).

WIRE FATE ITEM = ОТПРАВЛЕННАЯ ПО ПРОВОДУ СТАТЬЯ (ИЗВЕСТИТЕ ПО ПРОВОДУ О СУДЬБЕ СТАТЬИ) – Wire Fate Item is an archaic term that refers to a request made by a bank when it sends a check or draft for encashment to a bank in a different jurisdiction, for prompt advice or notification of payment or non-payment. It is usually transmitted by bank wire or federal wire, which are high-speed electronic communication networks used for transmitting information on transfers of large dollar amounts and other extremely time-sensitive information. 'Wire Fate' acknowledgments are of critical importance, since notification of non-payment of a check needs to be made to the payee as soon as possible. The term 'Wire' has carried over from previous generations when most time-sensitive information was transmitted by telegraph, but seems increasingly archaic in the current era of instant communication. Wire Fate Item:- notification by one bank to another in a different jurisdiction of payment or non-payment of a check. The term derives from the fact that these notifications were originally sent by telegraph. See also Fedwire. / Документ С Телеграфным Подтверждением.

WIRE HOUSE = ПРОВОДНОЙ ДОМ (или ДОМ НА ПРОВОДЕ, или ТЕЛЕКСНЫЙ ДОМ, или ДОМ, ИМЕЮЩИЙ ШИРОКУЮ КОММУНИКАЦИОННУЮ СЕТЬ) – Wire House is a company whose different branches are linked by a communications system enabling the sharing of financial information, research, and prices. Banks are a good example of this, the different branches are connected to allow a customer's information to be used at any branch of that bank. Etymology:- 1904, wire + house ('company'), from earlier private-wire house (1894). Originally referred to brokerage companies that owned or leased telegraph lines, so that market information could be transmitted more quickly. Later generalized to 'Major Brokerage'. In contemporary use generally used narrowly, referring specifically to the Big 4 retail brokerage firms operating in the United States:- Merrill Lynch Wealth Management, Morgan Stanley Smith Barney, UBS, and Wells Fargo & Co.. In looser usage, applied to any large brokerage. See also Futures Commission Merchant (FCM). Wire House is the informal US term for a large stockbroking firm. Wirehouse:- originally named 'wirehouses' because of an advanced communications system they employed, today the term simply refers to large financial institutions that offer multiple services in various locations, such as a bank. The term typically refers to full-service brokerages that offer research, order execution and investment advice all under the same roof. A wirehouse is a large integrated broker with a national, as opposed to regional, business. Wirehouses once collected trade orders from branch offices in distant cities using dedicated telegraph lines, hence the term wirehouse. Telegraphs were replaced by phones, which in turn were replaced by dedicated proprietary computer lines. Now most traders routinely route their orders directly to their brokers over the internet. The brokers at most wirehouses provide financial research and financial advice to their clients. Many wirehouses also have investment banking divisions. More generally, the term Wirehouse refers to any large financial institution that uses electronic systems to transmit information among its branches. Commercial banks and insurance companies that maintain multiple branch offices thus may be considered wirehouses, but the term now is rarely applied to financial institutions that do not have large brokerage operations. Examples of wirehouses include Morgan Stanley Smith Barney, Bank of America Merrill Lynch, Wells Fargo Advisors, UBS Wealth Management and Charles Schwab. Wire House is a firm operating a private wire to its own branch offices or to other firms, commission houses, or brokerage houses. / Мёрл Лынч (Merrill Lynch), Моргэн Стэнли Смис Бани (Morgan Stanley Smith Barney), Бэньк оф Амэрика (Bank of America), Вэлз Фарго Энд Ко. (Wells Fargo & Co.), Ю.Би.Эс. Вэлс Мэнэдьжмент (UBS Wealth Management) и Чарлз Шваб (Charles Schwab). Проводной Дом или Дом С Линией Связи:- фирма – член биржи, поддерживающая сеть коммуникаций либо путём связи своих филиалов с конторами корреспондентских фирм, либо путём создания системы связи некоторого количества подобных контор. Компания, имеющая широкую коммуникационную сеть. Национальная или международная брокерская фирма, офисы-филиалы которой связаны системой коммуникаций, позволяющих быстро распространять информацию о ценах, данных исследований и иную информацию, относящуюся к финансовым рынкам и конкретным ценным бумагам. Хотя более мелкие розничные и региональные брокеры в настоящее время имеют доступ к аналогичным данным, название Wire House относится к тем временам, когда только крупные организации имели доступ к скоростным средствам коммуникации. Поэтому термин wire house все ещё используется в отношении крупных брокерских фирм.

WIRELESS APPLICATION PROTOCOL = ПРОТОКОЛ БЕСПРОВОДНЫХ ПРИЛОЖЕНИЙ – Wireless Application Protocol (WAP) is a specification for a set of communication protocols to standardize the way that wireless devices, such as cellular telephones and radio transceivers, can be used for Internet access, including e-mail, the World Wide Web, newsgroups, and instant messaging. While Internet access has been possible in the past, different manufacturers have used different technologies. In the future, devices and service systems that use WAP will be able to interoperate. The WAP layers are:- (i) Wireless Application Environment (WAE); (ii) Wireless Session Layer (WSL); (iii) Wireless Transport Layer Security (WTLS); and (iv) Wireless Transport Layer (WTP). The WAP was conceived by four companies:- Ericsson, Motorola, Nokia, and Unwired Planet (now Phone.com). The Wireless Markup Language (WML) is used to create pages that can be delivered using WAP. There are other approaches to an industry standard besides WAP, including i-Mode. Wireless Application Protocol (WAP) is a specification for a set of communication protocols to standardize the way that wireless devices, e.g., mobile phones, can be used to access information on the Internet. Wireless Application Protocol (WAP), a secure specification that allows users to access information instantly via handheld wireless devices such as mobile phones, pagers, two-way radios, smartphones and communicators. WAP supports most wireless networks. These include CDPD, CDMA, GSM, PDC, PHS, TDMA, FLEX, ReFLEX, iDEN, TETRA, DECT, DataTAC, and Mobitex. WAP is supported by all operating systems. Ones specifically engineered for handheld devices include PalmOS, EPOC, Windows CE, FLEXOS, OS/9, and JavaOS. WAPs that use displays and access the Internet run what are called Microbrowsers – browsers with small file sizes that can accommodate the low memory constraints of handheld devices and the low-bandwidth constraints of a wireless-handheld network. Although WAP supports HTML and XML, the WML language (an XML application) is specifically devised for small screens and one-hand navigation without a keyboard. WML is scalable from two-line text displays up through graphic screens found on items such as smart phones and communicators. WAP also supports WMLScript. It is similar to Java Script, but makes minimal demands on memory and central processing unit (CPU) power because it does not contain many of the unnecessary functions found in other scripting languages. Because WAP is fairly new, it is not a formal standard yet. It is still an initiative that was started by Unwired Planet, Motorola, Nokia, and Ericsson. / Иариксон (Ericsson), Моторола (Motorola), Нокиа (Nokia). коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Протокол Беспроводных Приложений (ПБП; Wireless Application Protocol (WAP)) – это протокол беспроводного доступа к Интернет сайтам непосредственно с мобильных телефонов. При помощи этой технологии пользователь получает доступ к Интернет ресурсам из любой точки в любое время. Основное преимущество ПБП заключается в том, что для работы в сети Интернет не нужны дополнительные устройства, достаточно мобильного аппарата с поддержкой ПБП, информация будет отображаться прямо на дисплее мобильного телефона. Однако через ПБП можно посещать не обычные Интернет сайты, а ПБП-страницы. ПБП-ресурсы создаются в специальном формате ЯБР (сокращённо для Язык Беспроводной Разметки; WML (short for the Wireless Markup Language)). Это язык, предназначенный для создания сайтов, адаптированных под возможности мобильного телефона. Обыкновенные ВЭБ-страницы содержат слишком большой объём информации, они насыщены графикой и предназначены для просмотра на мониторах компьютеров. ПБП-страницы также могут быть цветными, но менее насыщенными информацией и оптимизированными для просмотра на дисплее мобильного телефона. С помощью ПБП пользователям предоставляется возможность получения информации по широкому кругу вопросов в интерактивном режиме без компьютера, только с помощью мобильного телефона. С помощью ПБП-телефона можно отправлять и получать электронную почту, скачивать цветные картинки и логотипы, полифонические мелодии и рингтоны, игры и приложения в телефон. Начинающие абоненты часто путаются в понятиях GSM, GPRS и WAP. Попробуем по-простому объяснить их. ПБП – это технология, которая позволяет получить доступ в Интернет непосредственно с мобильного телефона, без участия компьютера. То есть сидя в кафе или автобусе, прогуливаясь по улицам, или валяясь на диване у себя дома, пользователь может просматривать специальные wml страницы в сети и находить массу полезной информации. Для того, чтобы эта технология (ПБП) получила доступ в сеть Интернет, ей необходим канал данных. Каналом данных, как раз и служат – GSM и GPRS. Разница в этих каналах в скорости обмена данными, тарификации и некоторых характеристиках. Теоретическая максимальная скорость в GPRS-канале 171.2 кб/с, а в GSM-канале 9.6 кб/с. Как видно, разница значительна, следовательно, ПБП через канал GPRS работать будет быстрее. Более того, тарификация передачи данных по этим каналам принципиально отличается. При получении данных через GSM-канал оплачивается стоимость

минуты, в течение которой был сеанс связи, а в GPRS-канале оплачивается только трафик (количество скаченной и закаченной информации).

WIRELESS APPLICATION PROTOCOL IDENTITY MODULE = МОДУЛЬ ИДЕНТИФИКАЦИИ ПРОТОКОЛА БЕСПРОВОДНЫХ ПРИЛОЖЕНИЙ – Wireless Application Protocol Identity Module (WAP Identity Module or WIM) is a tamper-resistant device which is used in performing WTLS (Wireless Transport Layer Security) and application level security functions, and especially, to store and process information needed for user identification and authentication.

WIRELESS APPLICATION PROTOCOL IDENTITY MODULE CARD = КАРТА МОДУЛЯ ИДЕНТИФИКАЦИИ ПРОТОКОЛА БЕСПРОВОДНЫХ ПРИЛОЖЕНИЙ – Wireless Application Protocol Identity Module Card (WAP Identity Module Card or WIM Card) is WIM implemented on a smart card.

WIRELESS DATA SYSTEM = БЕСПРОВОДНАЯ СИСТЕМА ДАННЫХ – Wireless Data System is a new technology for transmitting orders, reports, and administrative messages between brokers and clerks. Also used by Card Reader Replacement as path to Integrate Technology Plan Network. / Новая технология для передачи распоряжений, отчётов и административных сообщений между брокерами и клерками. Используется также .

WIRELESS LAN = БЕСПРОВОДНАЯ ЛАС – Wireless LAN is short for the Wireless Local Area Network; a wireless (radio) network used for transfering data; is also used in offices. / Беспроводная Локальная Автономная Сеть (ЛАС) .

WIRELESS PUBLIC KEY INFRASTRUCTURE = БЕСПРОВОДНАЯ ИНФРАСТРУКТУРА ПУБЛИЧНОГО КЛЮЧА – Wireless Public Key Infrastructure provides the means to establish public key security features between clients and servers such as authentication, confidentiality and integrity of exchanged messages. Security features can be established either in the transport layer, in the application layer, or in both. It is also possible for clients to authenticate themselves to servers using strong public key authentication methods. Wireless Public Key Infrastructure (WPKI or Wireless PKI) is the public key infrastructure optimized for the Wireless Application Protocol (WAP). Wireless Public Key Infrastructure (WPKI) is a two-factor authentication scheme using mainly the mobile phone and a laptop. It is mainly promoted by banks, mobile operators, and mobile network manufacturers.

WIRELESS TRANSPORT LAYER SECURITY = БЕЗОПАСНОСТЬ БЕСПРОВОДНОГО ТРАНСПОРТНОГО СЛОЯ – Wireless Transport Layer Security (WTLS) is the security level for Wireless Application Protocol (WAP) applications. Based on Transport Layer Security (TLS) v1.0 (a security layer used in the Internet, equivalent to Secure Socket Layer 3.1), WTLS was developed to address the problematic issues surrounding mobile network devices – such as limited processing power and memory capacity, and low bandwidth – and to provide adequate authentication, data integrity, and privacy protection mechanisms. Wireless transactions, such as those between a user and their bank, require stringent authentication and encryption to ensure security to protect the communication from attack during data transmission. Because mobile networks do not provide end-to-end security, TLS had to be modified to address the special needs of wireless users. Designed to support datagrams in a high latency, low bandwidth environment, WTLS provides an optimized handshake through dynamic key refreshing, which allows encryption keys to be regularly updated during a secure session. Wireless Transport Layer Security (WTLS) is the Wireless Application Protocol (WAP) equivalent of the Transport Layer Security (TLS). Wireless Transport Layer Security (WTLS) refers to the security level for applications that use the Wireless Application Protocol (WAP). The concept behind WTLS is largely based on Transport Layer Security (TLS) version 1.0, which was modified to allow WTLS to provide sufficient privacy management, efficient authorization of data and data integrity while the message is in the transport layer. WTLS was needed because mobile networks were not able to guarantee an end-to-end security of their data. The then available TLS was especially modified for wireless users. Initially, mobile network devices showed issues like low processing ability, limited bandwidth and inadequate memory size. WTLS was designed to overcome these issues and to provide high security to the data. WTLS supports datagrams in low-bandwidth conditions; it also provides an adequate handshake through dynamic key reloading, which makes it possible for encryption keys to be regularly updated during a secure connection time. This encryption method leads to a secure environment for clients and servers to communicate over a secure authenticated connection. Wireless Transport Layer Security (WTLS) is a security protocol, part of the Wireless Application Protocol (WAP) stack. It sits between the WTP and WDP layers in the WAP communications stack. WTLS is derived from TLS. WTLS uses similar semantics adapted for a low bandwidth mobile device. The main changes are:- (i) Compressed data structures – Where possible packet sizes are reduced by using bit-fields, discarding redundancy and truncating some cryptographic elements; (ii) New certificate format – WTLS defines a compressed certificate format. This broadly follows the X.509 v3 certificate structure, but uses smaller data structures. (iii) Packet based design – TLS is designed for use over a data stream. WTLS adapts that design to be more appropriate on a packet based network. A significant amount of the design is based on a requirement that it be possible to use a packet network such as SMS as a data transport. WTLS has been superseded in the WAP Wireless Application Protocol 2.0 standard by the End-to-end Transport Layer Security Specification. WTLS uses modern cryptographic algorithms and in common with TLS allows negotiation of cryptographic suites between client and server. Interoperability:- as mentioned above the client and server negotiate the cryptographic suite. This happens when the session is started, briefly the client sends a list of supported algorithms and the server chooses a suite, or refuses the connection. The standard does not mandate support of any algorithm. An endpoint (either client or server) that needs to be interoperable with any other endpoint may need to implement every algorithm (including some covered by intellectual property rights.

WIRE ROD COIL = БУХТА КАТАНКИ (или МОТОК ПРОВОЛОЧНОЙ КАТАНКИ) – Wire Rod Coil is a steel product made in rod wire rolling mills with varying cross-sections. German standards refer to wire rod as a product that can be wound immediately into coils from the rolling mill whilst still hot. Coils of wire rod:- depending on the nature of the goods and any intended subsequent processing these coils are corrosion-sensitive and sensitive to mechanical damage, for example, kinks forming in the wire. The length of the winding axis is a critical factor in determining the way they are stowed. / прокатка (rolling). Катанка (wire rod).

WIRE ROOM = ПРОВОДНАЯ КОМНАТА (или КОМНАТА НА ПРОВОДЕ, или ИСПОЛНИТЕЛЬНЫЙ ОТДЕЛ) – Wire Room is a financial institution's funds transfer operation, or its operating department. This department is responsible for receiving customer orders from a registered representative, transmitting the order to the exchange floor or the firms trading department, relaying notices of executed trade orders to the appropriate registered representative, and receiving payment orders. Also called an Order Department or Order Room. A wire room is the operation within a financial institution, such as a brokerage firm, that handles customer orders. Orders are received and processed, and the corresponding notices and payments are executed. Certain larger firms have entire staffs dedicated to the wire room; smaller firms may have staff rotate between the wire room and other responsibilities. In a bank, the wire room refers to the department that handles wire transfers between accounts. Wire Room is a room or establishment where bookmaking is carried on under cover of legitimate business. So called from its being provided with apparatus for the receipt of race results by wire. Wire Room is a department within a brokerage firm that receives customers' orders and transmits the orders to the exchange floor or the firm's trading department. / Комната Связи:- оперативный отдел брокерской фирмы, который получает распоряжения клиентов от представителя, принимающего заказы на фондовой бирже, и передаёт важнейшую информацию в операционный зал биржи, где подготовлен документ брокера с записью распоряжения клиента, или торговый отдел фирмы для исполнения.

Синоним терминов Комната Распоряжений (Order Room); Отдел Распоряжений (Order Department); и Передавай И Распоряжайся (Wire And Order). Отдел Связи (Wire Room) – оперативный отдел брокерской фирмы, который получает распоряжения клиентов от зарегистрированного представителя (registered representative) и передаёт основную информацию в торговый зал биржи, где подготавливается 'торговый билет' (floor ticket) – документ с деталями распоряжения брокеру, или в торговый отдел фирмы для исполнения. Отдел связи также получает информацию об исполненных сделках и передаёт её соответствующим зарегистрированным представителям. Называется также Отделом Распоряжений (Order Department, Order Room) или Отделом Связи и Распоряжений (Wire and Order).

WIRES = ТРОСЫ – Wires:- short lengths of wire rope of varying sizes used to couple up the many barges within a tow. They are usually of standard length to span the distance from one timberhead to another on the barges and are used with ratchets. Named as follows:- tow wire, backing wire, face wire, stem wire, scissor wire, lashing.

WIRES CHARGE = ПРОВОДНОЙ СБОР – Wires Charge is a broad term referring to fees levied on power suppliers or their customers for the use of the transmission or distribution wires.

WIRE TRANSFER = ЭЛЕКТРОННЫЙ ПЕРЕВОД (или ПЕРЕВОД ПО ПРОВОДУ) – A Wire Transfer is the direct transfer of funds from the payer's account at one bank to the payee's account at another bank. This is the most rapid form of payment, but is also the most expensive. Banks typically charge high fees to both the payer and the payee. Despite the supposedly fast payment time of a wire transfer, funds may not be available in the payee's bank account for several days, particularly when the initiating bank does not have a direct correspondent relationship with the receiving bank; in this case, it must route the payment through a third bank that does have a correspondent relationship with the receiving bank. The time of day when a wire is initiated can be a factor in delayed payments; if the wire initiation is near the close of business, then the banks may add an extra day to the transaction. Wire Transfer is the electronic transfer of funds; usually involves large Dollar payments. Electronic transfers of money (credits and debits), to checking accounts saved in computers. The payment of funds by wire, cable, telex, SWIFT, or other electronic means. Wire Transfer is an electronic payment service for transferring funds by wire. Electronic transfer of funds. Wire Transfer is an electronic payment service for transferring funds from an account in one bank to an account at another bank. / В дословном переводе с Английского языка этот термин звучит как Перевод По Проводу. WIREWORM = ПРОВОЛОЧНИК – Wireworm:- pest type:- insect; crops affected:- Wheat, Corn, Cereals, Soybeans, Cotton, Peanuts; scientific name:- Melanotus spp. or Agroites spp. or Limonius spp.; pest order:- Coleoptera. Description:- Wireworms go through four stages of growth consisting of egg, larva, pupa and adult; and most wireworm species require two or three years to complete development. Adults emerge in the spring. Shortly after mating, the female beetles lay up to 300 eggs in the soil, generally around the roots of grass plants. Larvae/wireworms emerge from the eggs. Depending on the environmental conditions, the larvae of some wireworms require two to six years to reach full size of approximately 0.8 to 1.5 inches, so numerous stages and sizes of larvae may be found at any one time. The pupal stage is also spent in the soil. Some species of wireworm can overwinter in any of the stages, but most do so in the larval and pupal stages. Damage:- Wireworms can attack the crop as soon as the seed is planted into the soil. Injury includes boring into the seed and young seedling plants. Seedlings are usually not completely severed as with cutworm, but suffer severe scaring which weakens the plant. The open wounds also provide paths for other plant diseases. Wireworms/larvae feed on the roots and underground shoots of small grains, especially those planted on land that was previously in sod. Life Cycle:- Wireworms are the larval stages of several species of beetles. (i) Egg:- the eggs are generally pearly white, round and difficult to see in the soil. (ii) Larvae:- newly hatched wireworms are white with dark jaws. After feeding and molting several times, these larvae become hard, slender, jointed and shiny; and generally orange, brown or yellow in color. They can be 0.4 to 1.6 inches long, and legs are present on the first three body segments behind the head. (iii) Pupae:- pupae are generally white and soft-bodied. (iv) Adult:- adults of some species are called 'Click' Beetles because of their habit of snapping or clicking when placed on their backs. The adults/beetles are normally 0.06 to 1.5 inches long, are tapered toward both ends, are brown to nearly black and have a loose, flexible joint just ahead of the wings. Control Measures:- through crop rotation, tillage, soil applied insecticides and seed treatment insecticides, wireworms can usually be managed. Infestations are most severe on land not previously in row crops, especially following sod. Wireworms are difficult to control, partially because they usually live and do their damage several inches deep in the soil. Sometimes baits can be used to determine population levels. If wireworm infestations are high, talk to your local advisers for recommendations in your area. Geography:- Wireworm species can be found throughout North America and are damaging to a wide array of crops. Most species tend to prefer heavy, moist soils, especially muck soils. In the United States, serious wireworm damage to small grains is largely a problem in the northern wheat-growing areas west of the Mississippi River. Wireworms:- insect larvae of small- to medium-sized beetles. The larvae feed primarily on germinating seeds and roots. Wireworms can cause death of scattered seedlings throughout a field. Either single plants or small groups of just a few seedlings may be affected. The wireworm, which is the larvae of a beetle, attacks the plant 10–30 mm below the soil surface by 'chewing' a hole in the taproot or lower stem leaving a characteristic wound. Wireworm:- any of certain Millipede Species. / Проволочник, находящийся в стадии личинки жука щелкуна, . или в прикорневой части стебля (lower stem), оставляя характерную рану. Под Проволочниками понимаются личинки жуков семества Щелкунов. Опасные вредители многих сельскохозяйственных культур и дикорастущих растений. Бурые, жёлтые, коричневые; твёрдые, длиной до 25 миллиметров. Питаются высеянными семенами и подземными частями молодых растений.

WIRY END = ЖЁСТКАЯ ПРОДОЛЬНАЯ НИТЬ – Wiry End:- xxxxx. See also Tight Twist End. Fabrics defect.

WIRY WOOL = ПРОВОЛОЧНАЯ ШЕРСТЬ (или ОЧЕНЬ ГРУБАЯ ШЕРСТЬ, или ЖЁСТКАЯ ШЕРСТЬ) – Wiry Wool is a wool that is in-elastic and has poor spinning capacity. It is usually straight and may be the result of poor breeding.

WISE = WOMEN IN SCIENCE AND ENGINEERING

WITCHING HOUR = ЧАС ВЕДЬМОВСТВА – Witching Hour:- with a modern literal meaning of 'midnight', the term Witching Hour refers to the time of night (03:00–04:00 am is commonly speculated) when creatures such as witches, demons, and ghosts are thought to appear and to be at their most powerful and black magic to be most effective. It may be used to refer to any arbitrary time of bad luck or in which something bad has a greater likelihood to occur (e.g., a baby crying, or a computer crashing, or stock market volatility, crimes, supernatural, etc). The witching hour from medieval times is the time believed that witches came out to do their 'unholy' practices. The time ascribed to the witching hour was generally viewed after midnight. Women caught out late at night could have been suspected of witchcraft if they did not have a legitimate reason to be out. See also Triple Witching Hour. Witching Hour is the hour before the closing of the stock market on the third Friday of the month, when two or more classes of options or futures expire, known for its high trading volume and volatile prices. / Час Ведьмовства:- час до закрытия фондового рынка в третью Пятницу месяца, когда два или более классов опционов или фьючерсов прекращают признание; известен за свой высокий объём торговли и

лихорадочные цены. Смотрите также Час Двойного Ведьмовства (Double Witching Hour); и Час Тройного Ведьмовства (Triple Witching Hour).

WITH APPROVED CREDIT = С ОДОБРЕННЫМ (или УТВЕРЖДЁННЫМ) КРЕДИТОМ – With Approved Credit (WAC) is a condition requiring a purchaser using financing to have adequate credit – as approved by his or her financial lending institution – for the transaction to go through. The use of the condition of 'With Approved Credit' can be found in the financing of houses, cars and furniture. Companies who lease their products will also require their customers to fulfill the with-approved-credit condition. With Approved Credit (WAC) is a financial transaction will be recorded once it has been made known that the consumer has the funds to pay for the transaction.

WITH AVERAGE = С АВАРИЕЙ (или ВКЛЮЧАЯ ЧАСТНУЮ АВАРИЮ) – With Average (WA) is an ocean marine policy provision that covers partial loss of below deck cargo on the same basis as a total loss – that is, for loss by the same perils and regardless of what percentage of the total insured value is damaged or lost. See also Average. With Average is a marine insurance term meaning that a shipment is protected from partial damage whenever the damage exceeds 3 percent or some other percentage (a stated percentage). With Average (WA) is an insuring condition on cargo that agrees to pay losses due to certain named marine periods, provided the loss equals or exceeds a specific percentage (see also Franchise). Losses less than this amount are paid only if the vessel meets with a specified accident. With Average (WA):- marine cargo insurance coverage providing for partial loss or damage to goods, either with or without a deductible. Also called With Particular Average (WPA). With Average (WA) is a provision in maritime transport insurance stating that the insurer is responsible for partial losses on the value of the covered products. Sometimes with-average plans include deductibles, and sometimes they do not. Depending on the amount of the deductible, the insurer of a with-average plan will be liable for losses if some of the products break in transit. For example, if one is transporting USD10 000 worth of goods over sea and USD2 000 in goods are washed overboard, the with-average policy covers the owner of the goods for USD2 000 (assuming no deductible). This contrasts with a free of particular average plan, in which the insurer is generally only responsible for catastrophic losses. With Average policy (WA policy) covers partial loss if the franchise is exceeded but is otherwise similar to an free of particular average policy (FPA policy). With Average is a marine insurance term meaning that shipment is protected for partial damage whenever the damage exceeds a stated percentage.

WITH DIVIDEND = С ДИВИДЕНДОМ – With Dividend:- purchase of shares that entitle the buyer to the forthcoming dividend. Related:- Ex-Dividend. / С Дивидендом (With Dividend):- покупка акций, при которой покупателю передаётся право на получение всех дальнейших дивидендов.

WITHDRAWAL = ИЗЪЯТИЕ (или СНЯТИЕ, или ОТЗЫВ) – (1) Withdrawal is a removing funds from an account, plan, pension or trust. In some cases, conditions must be met in order to withdraw funds without penalization. There are two ways to withdraw money:- in cash or in kind. Withdrawal can be done over a period of time in fixed or variable amounts or in one lump sum. Penalization for early withdrawal usually arises when a clause in an investment contract is broken. Cash withdrawal requires converting the holdings of an account, plan, pension or trust into cash, usually through a sale. In kind withdrawal is simply taking possession of assets and does not require conversion to cash. Owners' Withdrawals are the sums of money the proprietor or partners of a firm choose to take out of the cash flow of the business for personal use. Withdrawals or Drawings is a basic concept in financial accounting that governs the relationship between the owner(s) of a business and the business' operations. It refers to anything that the owner takes from the business, regardless of what the owner calls it. As such, there are two important aspects of that definition:- anything:- this means that whether the owner takes cash, stock or equipment is immaterial. Any withdrawal – or even personal use of business property – of items of material value should constitute drawings. Regardless of what the owner calls it:- sometimes, owners work within the business and pay themselves a salary or wage. Perhaps the owner takes a 'Loan' from the business. It does not matter what the form of the withdrawal is; the substance is critical. Therefore, the 'Wages' or the 'Loan' would effectively be a withdrawal as well. The Effect of Drawings:- drawings affect the capital of the business, i.e. what the business owes to the owner. Normally businesses might open a Drawings Account (or Directors Account) to account for withdrawals by the owner. An increase in drawings would decrease the assets of the business and capital as well (Dr Drawings, Cr Cash/Stock). Drawings are the opposite of addition of capital to the business (capital introduced). Drawings are also introduced in the business equation:- Profit = Increase In Net Assets + Drawings – New Capital Introduced During The Period. Drawings and The Business Entity Concept:- the concept of drawings is inextricably linked to the business entity concept, which states that the activities of the owner are separate from the activities of the business. Therefore, the business recognizes the withdrawal as a reduction in what it owes to the owner. In the same way that profit increases the obligation of the business to the owner, drawings decrease that obligation. This happens because the owner is treated as a separate entity for accounting purposes – regardless of the legal status. If the owner withdraws the profit from a business, that profit withdrawal – although it is the owner's privilege – constitutes drawings. That is why the business equation factors in drawings to calculate a business' profit for a period. For example, if John invested USD10 000.00 into a business. During the year, he withdraws USD2 000.00, in goods and cash, and invested new capital of USD1 500.00. There was a net asset decrease of USD200.00 (assets – liabilities) in the period. What is the profit accrued by John's business during that period? Here, the business equation P = I + D – C is applicable. We do not know the profits, but we can substitute the values in the rest of the formula:- P = (–200) + 2 000.00 – 1 500. Therefore, Profit = USD300.00. You can manipulate the formula above by simply changing the subject of the formula to the unknown variable, demonstrating the importance of drawings in financial accounting. Withdrawal is a removal of funds from an account. A Withdrawal occurs when funds are removed from an account. Withdrawals can be triggered for many types of accounts, including bank accounts and pension accounts. A withdrawal may not be allowed unless certain conditions are met, such as the passage of time. For example, funds cannot be withdrawn from a certificate of deposit until one year has passed, or a person cannot withdraw funds from a pension account until he reaches retirement age. If these requirements are not met but a withdrawal is still made, this can result in penalties, which offset the amount paid out, resulting in a smaller net payment. From the perspective of the entity managing an account, a withdrawal can require that investment instruments be liquidated before cash can be paid to the owner of the account. This can present an investment planning issue for the institution, which cannot invest funds in longer-term investment instruments if there is an expectation that withdrawals will occur in the near future. This issue is the reason for withdrawal penalties, which are intended to prevent account holders from withdrawing funds until the associated investments have been liquidated. In rare cases, an in kind withdrawal is made, which means that the account holder accepts as payment the type of asset in which the account funds are currently invested. A withdrawal can also refer to the draw down of an owner's account in a sole proprietorship or partnership. In this situation, the funds are intended for personal use. The withdrawal is not an expense for the business, but rather a reduction of equity. A withdrawal transaction is not possible in a corporate structure; instead, the company either issues a dividend or buys back the shares of an investor. Similar Terms:- a withdrawal of funds from a partnership or sole proprietorship is also known as a Draw. Withdrawal is:- (i) the act of taking out money or other capital from a controlled account; or (ii) a retraction of a previously held position. / Дьжон (John). Под Изъятиями понимаются выплаты собственникам. Изъятия активов собственниками предприятия – практика, характерная для индивидуальных частных хозяйств и товариществ. Также под Изъятиями понимается счёт для их отражения, ведение которого

позволяет разделить влияние на собственный капитал результатов хозяйственной деятельности и собственно изъятий. В корпорациях такой счёт не используется. В широком смысле означает все изъятия из бизнеса, в том числе и дивиденды.

(2) Withdrawal (of a license) is a removal of a license by the insurance supervisory authority.

WITHDRAWAL PLAN = ПЛАН ИЗЪЯТИЯ – Withdrawal Plan is:- (1) a payment structure arranged with a mutual fund in which the investor receives a set amount of funds from the fund on a periodic basis. This is also called a 'Systematic Withdrawal Plan'. This type of arrangement with a mutual fund affords the investor an income stream during their retirement years while also maintaining exposure to further growth by keeping their remaining funds invested in the mutual fund for as long as possible. (2) Any strategy in which an investor liquidates a portion of their portfolio and extracts cash periodically, such as an investor selling equity shares every year to help supplement their retirement. Once an investor has finished the accumulation phase, most generally prefer to structure their spending so that their funds will last for an extended period of time. This can be done by managing a portfolio and periodically selling assets, investing in income-producing securities, purchasing an annuity, etc. The Regular Withdrawal Plan allows you to withdraw capital from your funds when you need it. A Systematic Withdrawal Plan (SWP) is a facility that allows an investor to withdraw money from an existing mutual fund at predetermined intervals. The money withdrawn through a systematic withdrawal plan can be reinvested in another fund or retained by the investor in cash. When is a SWP generally used? Systematic withdrawal plans are used by investors to create a regular flow of income from their investments. Investors looking for income at periodical intervals for, e.g., funding a travel plan during the childrens' summer vacations, also set up their withdrawals in such a way that the cash is available when most required. What makes SWP a wise strategy? Withdrawals (also referred to as 'Redemption') attract no Tax Deducted at Source. Please note that Capital Gains Tax will chargeable on the withdrawn amount. SWP can be set up to withdraw only the appreciation made on a particular investment. In this way your capital stays invested while you continue to enjoy the gains periodically. SWP is available in two options:- (i) Fixed Withdrawal:- where you specify amounts you wish to withdraw from your investment on a monthly/quarterly basis; and (ii) Appreciation Withdrawal:- where you can withdraw your appreciated amount on a monthly/quarterly basis. Post-dated warrants sent to investors are dated 1st of every month. Withdrawal Plan is an agreement that a mutual fund will disburse automatic periodic redemptions to the investor. / План Изъятия:- мероприятие, проводимое определёнными компаниями открытого типа, согласно которому инвестор может получать ежемесячные платежи в оговорённом количестве, которые могут быть больше или меньше по сравнению с реальным инвестиционным доходом. План Изъятия Средств (withdrawal plan) – программа, которой можно воспользоваться в большинстве взаимных фондов (mutual fund) с неограниченным участием. По этой программе акционеры могут регулярно получать фиксированные выплаты из дохода или прибыли на капитал (capital gains) – или из обеих источников, обычно ежемесячно или ежеквартально.

WITHDRAWALS FROM INCOME OF QUASI–CORPORATIONS = ИЗЪЯТИЯ ИЗ ДОХОДА КВАЗИ–КОРПОРАЦИЙ – Withdrawals From The Income Of Quasi-Corporations consist of the amounts which entrepreneurs actually withdraw for their own use from the profits earned by the quasi-corporations which belong to them. These amounts are to be recorded before the deduction of any current taxes on income, wealth, etc which are deemed always to be paid by the owners of the businesses. When a quasi-corporation makes a trading profit, the unit which owns it may choose to leave part or all of the profit in the business, especially for investment purposes. This income left in the business appears as saving by the quasi-corporation, and only the profits actually withdrawn by the owner units are recorded in the accounts under the heading withdrawals from the income of quasi-corporations. When profits are earned in the rest of the world by the branch-offices, agencies, etc of resident enterprises, in so far as these branch-offices etc are treated as non-resident units, retained earnings appear as reinvested earnings on direct foreign investment. Only the income actually transferred to the parent enterprise is treated in the accounts as withdrawals from the income of quasi-corporations received from the rest of the world. The same principles are applied to deal with the relations between branch-offices, agencies, etc operating on the economic territory and the non-resident parent enterprise to which they belong. This heading includes the net operating surplus received by residents as owners of land and buildings in the rest of the world, or by non-residents as owners of land or buildings on the economic territory. In effect, in respect of all transactions in land and buildings carried out on the economic territory of a country by non-resident units, the latter are considered, in accordance with the conventions adopted in the ESA (European Space Agency), to be notional resident units in which the non-resident owners own the equity. The rental value of owner-occupied dwellings abroad is registered as imports of services and the corresponding net operating surplus as primary income received from the rest of the world; the rental value of owner-occupied dwellings belonging to non-residents is registered as exports of services and the corresponding net operating surplus as primary income paid to the rest of the world. The heading withdrawals from the income of quasi-corporations does not include amounts which their owners receive:- (a) from the sale of existing fixed capital goods; (b) from the sale of land and intangible assets; and (c) from withdrawals of capital (e.g., the total or partial liquidation of their equity in the quasi-corporation). These amounts are treated as withdrawals from equity in the financial account. Conversely, any funds provided by the owner(s) of a quasi-corporation for the purpose of acquiring assets or reducing its liabilities is treated as additions to its equity. However, if the quasi-corporation is owned by government, and if it runs a persistent operating deficit as a matter of deliberate government economic and social policy, any regular transfers of funds into the enterprise made by government to cover its losses should be treated as subsidies. Time of recording:- withdrawals from the income of quasi-corporations are recorded when they are made by the owners. In the system of accounts, withdrawals from the income of quasi-corporations appear:- (a) among uses in the allocation of primary income account of the sectors in which the quasi-corporations are classified; (b) among resources in the allocation of primary income account of the owner sectors; and (c) among uses and resources in the external account of primary incomes and current transfers. Withdrawals From Income Of Quasi-Corporations:- the income that the owners of quasi-corporations withdraw from them is analogous to the income withdrawn from corporations by paying out dividends to their shareholders. Withdrawals From The Income Of Quasi-Corporations consist of the amounts which entrepreneurs actually withdraw for their own use from the profits earned by the quasi-corporations which belong to them.

WITHDRAWN CLAIM = ОТОЗВАННАЯ ПРЕТЕНЗИЯ (или ИЗЪЯТАЯ ПРЕТЕНЗИЯ) – Withdrawn Claim is a non-elected claim. 'Withdrawn' is the status identifier that should be used for claims that were not elected (chosen by the applicant to remain under consideration) in response to a restriction requirement. Further, an appellant (one who is appealing an examiner's final rejection to the Board of Patent Appeals and Interferences) may withdraw some of the appealed claims, resulting in cancellation of the withdrawn claims.

WITHDRAWN PATENT = ОТОЗВАННЫЙ ПАТЕНТ (или ИЗЪЯТЫЙ ПАТЕНТ) – Withdrawn Patent:- an allowed application for patent in which the applicant files correspondence to withdraw the patent from issue; thus preventing it from issuing on the patent issue date. The printed document is sometimes available on the day of publication, but is later retracted and will not be available in the patent database. No copy of the patent document will appear on the official USPTO (short for the United States Patent and Trademark Office) web site.

WITHERITE = ВИТЕРИТ – Witherite:- a carbonate mineral, barium carbonate ($BaCO_3$), that is, with the exception of barite, the most common barium mineral, despite its rarity. It is ordinarily found in fairly pure form in association with barite and galena in low-temperature hydrothermal veins, as in the north of England and in Scotland. Because of its solubility in common acids, witherite is preferred to barite in the preparation of other barium compounds. It is also used in case-hardening steel and in refining sugar. For detailed physical properties, see Carbonate Mineral (table). / Витерит – минерал класса карбонатов, $BaCO_3$. Белые, серые, жёлтые шаровидные агрегаты, реже кристаллы. Твёрдость 3.5; плотность около 4.3 г/см^3. Гидротермальные месторождения. Руда бария и его солей.

WITHHOLDING = УДЕРЖАНИЕ – Withholding is:- (1) in securities:- violation of the rules of fair practice of the National Association of Securities Dealers whereby a participant in a public offering fails to make a bona fide public offering at the public offering price-for example, by withholding shares for his or her own account or selling shares to a family member, an employee of the dealer firm, or another broker-dealer-in order to profit from the higher market price of a hot issue. See also Immediate Family, and Investment History. (2) In taxes:- a deduction from salary payments and other compensation to provide for an individual's tax liability. Federal income taxes and Social Security contributions are withheld from paychecks and are deposited in a Treasury tax and loan account with a bank. The yearly amount of withholding is reported on an income statement (Form W-2), which must be submitted with the federal, state, and local tax returns. Liability not provided for by withholding must be paid in four estimated tax payments. Withholding by corporations and financial institutions of a flat 10% of interest and dividend payments due securities holders, as required under the Tax Equity and Fiscal Responsibility Act of 1982 (TEFRA Act of 1982). The purpose was to levy a tax on people whose earnings escaped tracking by the Internal Revenue Service. The 10% withholding requirement was repealed in 1983. As a compromise, 'backup withholding' was instituted, whereby, using Social Security numbers, payments can be reported to the US Internal Revenue Service (IRS) and matched against the actual income reported. Withholdings from pension and annuity distributions, sick pay, tips, and sizeable gambling winnings, as stipulated by law. 30% withholding requirement on income from US securities owned by foreigners-repealed by the tax reform act of 1984. Withholding is an amount withheld or deducted from employee salaries by the employer and paid by the employer, for the employee, to the proper authority. Withholding is the portion of an employee's wages that is not included in his or her paycheck because it is remitted directly to the federal, state and local tax authorities. Withholding reduces the amount of tax employees must pay when they submit their annual tax returns. The amount withheld is based on the employee's income, marital status, number of dependents and number of jobs. When too much money is withheld, it is returned to the employee as a tax refund. In the United States, the tax authorities require employers to withhold tax from their employees' paychecks because the income tax must be paid throughout the year as income is earned. As an employee, it cannot be paid in one lump sum at the end of the year. Workers who don't pay enough tax on income as it is earned are subject to penalties and interest. Workers who are self-employed aren't subject to withholding, but must make quarterly estimated tax payments instead. In the United States, Withholding:- monies that payers are required to withhold from dividends, interest payments or sales. A paying agent will withhold for a number of reasons, including the failure of a security holder to certify his/her TIN or if they are instructed to do so by the US Internal Revenue Service (IRS). The withholding rate for and uncertified Taxpayer Identification Number (TIN) is 31%. All funds withheld are turned over to the IRS. Withholding:- used in the context of securities, the illegal practice of a public offering participant keeping some shares in a private account or with a family member, employee, or dealer to profit from the higher market price of a hot issue. Used in the context of taxes, the withholding by an employer of a certain amount of an employee's income in order to cover the employee's tax liability. Also used to refer to the withholding by corporations and financial institutions of a flat 10% of interest and dividend payments due to security holders. Withholding, dependent upon application, is:- (a) income tax withheld from employees' wages and paid directly to the government by the employer; or (b) a tax deducted from dividends on investments which are paid to foreign investors. This can be claimed back if there is a Double Taxation Agreement in place between the countries. See also Withholding Tax. A Withholding is that portion of an employee's gross pay that is not actually paid to an employee. Instead, the funds are remitted to a third party. The withholding concept is a crucial one for taxing authorities, which rely upon it to obtain the bulk of their income tax remittances. The withholding concept is used for both state income taxes and federal income taxes, except in those states that do not have a state income tax. The amount withheld from employee pay depends upon a number of factors, including the following:- (i) Income Level:- the tax rate increases as income increases, so the proportion withheld will increase for larger gross pay amounts; (ii) Marital Status:- the amount withheld varies, depending on whether an individual is filing taxes as a single or married person; (iii) Exemptions:- an individual can claim any number of exemptions on the Form W-4, which alters the amount withheld. If too much money is withheld from an employee's gross pay, it can be claimed as a refund as part of the year-end tax return filing process. A self-employed individual does not engage in withholding activities. Instead, he or she remits an estimated income tax payment to the government on a quarterly basis. / заслуживающий доверия или действительный (bona fide). В Соединённых Штатах Америки, денежные суммы, которые плательщик обязан удержать из дивидендов, платежей по процентам или с продаж. Агент по платежам будет удерживать такие суммы по ряду причин, включая и случай отказа держателя ценной бумаги от указания своего ИНН (Идентификационного Номера Налогоплательщика) или если на то будет инструкция СВД (Службы Внутренних Доходов). Ставка удержания как в последнем случае, так и при неуказании своего ИНН составляет 31%. Все удержанные средства перечисляются в СВД. Удержание:- любое нарушение правил добросовестной торговли Национальной Ассоциации Дилеров по Ценным Бумагам, когда участник публичного предложения не делает добросовестного предложения по цене публичного предложения, руководствуясь целью получения выгоды от более высокой рыночной цены на ценные бумаги 'горячего' выпуска. Удержание или Изъятие или Вычет:- ценные бумаги; нарушение Правил Добросовестной Конкуренции (Rules of Fair Practice) Национальной Ассоциации Дилеров по Ценным Бумагам (National Association of Securities Dealers), когда участник предложения ценных бумаг в открытой продаже (public offering) не делает предложения об открытой продаже акций с честными намерениями по цене предложения в открытой продаже (public offering price), а, например, удерживает акции для покупки по своему счёту или продаёт их членам семьи, работнику дилерской фирмы или другому брокеру-дилеру, чтобы получить прибыль на более высокой рыночной цене на 'горячий' выпуск (hot issue). Смотрите также Immediate Family, и Investment History. Налоги:- удерживаемый налог; налог, удерживаемый в момент получения дохода. (1) Вычеты из зарплаты и иной компенсации для уплаты личных налогов. Федеральный подоходный налог и взносы в фонд социального страхования вычитаются из зарплаты до выписывания чека и заносятся на налоговый и ссудный счёт Казначейства (tax and loan accoint) в банке. Ежегодный размер удержаний указывается в декларации о доходах (Форма W-2), которая должна представляться при заполнении федеральной налоговой декларации, штатовской налоговой декларации и местной налоговой декларации. Обязательства по уплате налогов, не покрываемые удержаниями, должны погашаться при внесении расчётной величины налогов (estimated tax). (2) Удержание корпорациями и финансовыми организациями доли, равной 10% от процентов и дивидендов, выплачиваемых владельцам ценных бумаг, как требуется в соответствии с Актом о Справедливом Налогообложении и Финансовой Ответственности от 1982 (Tax Equity and fiscal Responsibility Act of 1982). Целью этих вычетов является налогообложение лиц, доходы которых не могут быть установлены налоговым управлением США – Службой Внутренних Доходов (Internal Revenue Service). Требование о 10% удержании было отменено в 1983, но вместо него было введено 'дополнительное удержание'. Чтобы произвести 'дополнительное удержание', необходимо указать номер полиса социального страхования и представить в налоговое

управление США информацию о доходах, которая сопоставляется с реально указанными доходами. (3) Удержания из пенсионных выплат и выплат по планам получения дохода, оплаты больничных, чаевых и больших выигрышей в азартных играх – в соответствии с законом. (4) Требование об удержании 30% из дохода по Американским ценным бумагам, принадлежащим иностранцам, отменённое Актом о Налоговой Реформе от 1984 (Tax Reform Act of 1984).

WITHHOLDING ALLOWANCE = УДЕРЖИВАЕМОЕ ОТЧИСЛЕНИЕ – What's a Withholding Allowance? The math for the calculator and the worksheets may seem a bit confusing at first. Basically, these tools are attempting to find your 'withholding allowances'. Withholding allowances are not the same as how many dependents you have, although the two concepts are related mathematically. A withholding allowance is a way for your payroll department to use the look-up tables provided by the US Internal Revenue Services (IRS) to figure out how much tax to withhold. Roughly, a withholding allowance represents your total tax deductions divided by the personal exemption amount. This results in a ratio, and this ratio is how many withholding allowances you should claim. Example:- Mary is a single parent, qualifies as head of household, and has one dependent. Let's further assume that her deductions will consist of the standard deduction and two personal exemptions (one for herself and one for her child. The math for her withholding allowances would look like this (all figures below are for the 2012 tax year):- (i) standard deduction:- 8 700; (ii) personal exemptions:- 2 x 3 800 = 7 600; (iii) total tax deduction:- 8 700 + 7 600 = 16 300; and (iv) deductions divided by personal exemption amount:- 16 300 / 3 800 = 4.289. In this example, Mary would claim Single and four withholding allowances on her W-4 Form. It's advisable to round down the ratio to avoid having too little tax withheld from your paycheck. In other words, Mary would check the Single box on line 3 of the Form W-4 and would write '4' on line 5 of the Form W-4 where it asks for 'Total number of allowances you are claiming'. / Мэри (Mary).

WITHHOLDING TAX = УДЕРЖИВАЕМЫЙ НАЛОГ – Withholding Tax is payable in many countries, e.g., in France, the United Kingdom, the United States of America. It is usually between 20% and 30% and is deducted at source on capital income such as interest and dividends. Companies pay tax deducted from interest payments and dividends directly to the tax authorities. For investors receiving interest and dividends, withholding tax paid is an advance income tax payment. Income tax is also a withholding tax. A tax on income deducted at the source. A paying agent is legally obliged to deduct withholding tax from its payments of interest on deposits, securities or similar financial instruments. The depositor or investor receives net interest. Withholding Tax is a tax on dividends that is paid by investors. While the withholding tax rates applied to each shareholder vary based on their country of domicile, for example Standard & Poor's applies the maximum possible tax rate, using the rate applied to individuals who do not benefit from double taxation treaties or tax concessions. As such, the net total return indices are calculated based on approximations of the minimum possible dividend reinvestment. Current tax rates applied are as follows:- Argentina 0%, Australia 15%, Austria 25%, Bahrain 0%, Belgium 25%, Brazil 0%, Bulgaria 15%, Canada 25%, Chile 35%, China 10%, China Offshore 0%, China Shenzhen 0%, Columbia 7%, Cyprus 0%, Czech Republic 15%, Denmark 28%, Dominican Republic 0%, Egypt 0%, Estonia 0%, Finland 28%, France 25%, Germany 26.375%, Ghana 10%, Greece 0%, Hong Kong – Local Shares* 0%, Hong Kong – A Shares** 10%, Hong Kong – H Shares*** 10%, Hungary 10%, Iceland 15%, India 0%, Indonesia 20%, Ireland 20%, Israel 20%, Italy 27%, Japan 10%, Jordan 0%, Kenya 10%, Korea (Republic of) 27.5%, Kuwait 0%, Latvia 10%, Lebanon 10%, Lithuania 15%, Luxembourg 15%, Malaysia 27%, Malta 35%, Mauritius 0%, Mexico 10%, Morocco 10%, the Netherlands 15%, New Zealand 30%, Norway 25%, Oman 0%, Pakistan 10%, Panama 10%, Peru 4.1%, Philippines 35%, Poland 19%, Portugal 20%, Qatar 0%, Romania 16%, Russia 15%, Saudi Arabia 5%, Singapore 0%, Slovakia 0%, Slovenia 20%, South Africa 0%, Spain 18%, Sri Lanka 15%, Sweden 30%, Switzerland 35%, Taiwan 20%, Thailand 10%, Tunisia 0%, Turkey 15%, United Arab Emirates 0%, United Kingdom Corporations 0%, United Kingdom REITS 20%, United States of America 30%, Venezuela 20%, and Vietnam 0%. Notes:- *Companies incorporated in Hong Kong and listed on the Hong Kong Stock Exchange; **Companies incorporated in mainland China and listed in Shanghai and Shenzhen; these companies are quoted in Renminbi and are only available to mainland and selected foreign institutional investors; *** Companies incorporated in mainland China and listed on the Hong Kong Stock Exchange (and other foreign exchange). Withholding Taxis a foreign tax which is deducted in the foreign country when income is paid to you. In Switzerland, Withholding Tax is payable by the debtor on income from movable property (interest and dividends) at a tax rate of currently 35 per cent. If the creditor is a Swiss resident, a total refund will be available based on the filing of a tax return. Foreign creditors may benefit from a (partial) relief in the form of a refund or a tax credit in accordance with the applicable double tax treaty (if any) between Switzerland and the creditor's country of residence. Zero per cent tax rates apply for example with respect to Denmark (tax credit for interest payments and dividends), France (tax credit for interest payments and dividends relating to holdings exceeding 10 per cent), Germany (tax credit for interest payments), and the United States (tax credit for interest payments). Since 2005-January-01 dividends of a Swiss subsidiary to its Swiss parent company are subject to a reporting procedure, which replaced a cash collection and refunding system, with the effect that cash dividends may now be paid without a withholding tax deduction, provided the parent owns at least 20 per cent of the subsidiary's capital. Anti-avoidance provisions may apply relating to withholding tax relief. The competent tax authorities often treat transactions avoiding withholding tax on undistributed reserves as tax avoidance. Because there is a degree of uncertainty as to what the authorities will consider to be illegitimate tax structuring, obtaining a tax ruling is useful if foreign residents are involved. Withholding Tax Amount is the federal income tax Dollar amount withheld from the proceeds, after an order to exercise non-qualified stock options executes. Your employer is required to report taxable income from the sale of stock options and to remit the withholding amount to the appropriate regulatory agencies. Withholding Tax Rate is the rate used to calculate the federal income tax withholding after an order to exercise non-qualified stock options executes. Your employer is required to report taxable income from the sale of stock options and to remit the withholding amount to the appropriate regulatory agencies. For restricted stock awards and restricted stock units, the tax rate used to calculate the federal income tax withheld from the proceeds upon vesting. For performance share/units, the tax rate used to calculate the federal income tax withheld from the proceeds upon payment. Withholding Tax is an employee income tax (such as PAYE) and other government imposed deductions from dividends, salaries, wages, and other incomes. Withholding taxes are levied at the point of disbursement of incomes, and are passed on to the government by the entities collecting them. Withholding Tax is:- (1) an income tax withheld from employees' wages and paid directly to the government by the employer. The amount withheld is a credit against the income taxes the employee must pay during the year. (2) A tax levied on income (interest and dividends) from securities owned by a non-resident. Tax is deducted not only from dividends, but from other income paid to non-residents of a country. Withholding Tax usually refers to those taxes that are withheld from an employee's compensation to account for that individuals tax liability on his/her compensation. In Switzerland, this tax is imposed at the current rate of 35% on domestic income from capital gains, lottery winnings and certain insurance benefits in excess of CHF50.00. Tax payments can be reclaimed by persons filing Swiss federal tax returns or credited against cantonal tax liabilities. Individuals and companies domiciled abroad may claim a refund of the Swiss withholding tax under double taxation treaties concluded between their country of domicile and Switzerland. Withholding Tax is a tax levied by a country of source on income paid, usually on dividends remitted to the home country of the firm operating in a foreign country. Withholding Tax is a tax on income deducted at source, which a paying agent is legally obliged to deduct from its payments of interest on deposits, securities or similar financial instruments. / Стэндод энд Поз (Standard & Poor's). Удержанный Налог – налог на доход, удерживаемый у источника дохода, который платёжный агент обязан по закону вычесть из своих процентных платежей по депозитам, ценным бумагам или аналогичным финансовым инструментам. Удержанный Налог – налог, удерживаемый из выплачиваемого вознаграждения. Обычно применяется при

выплате вознаграждения иностранным контрагентам, а также сотрудникам компаний. Для компаний наиболее частые удерживаемые налоги:- налог на добавленную стоимость (НДС) и налог на доходы. НДС обычно удерживается из вознаграждения иностранного контрагента при приобретении товаров, работ, услуг и имущественных прав. Налог на доходы может удерживаться при выплате вознаграждения, уплате процентов, роялти, дивидендов, продаже недвижимости. Если существует соглашение об избежании двойного налогообложения между юрисдикциями участников сделки, то ставка налога на доходы у источника может быть или уменьшена или доход может быть освобождён от обложения в юрисдикции возникновения дохода. Для физических лиц наиболее характерна ситуация, когда работодатель удерживает налог на доходы физических лиц из заработной платы и напрямую уплачивает налог за сотрудников в бюджет. Удерживаемый Налог – налог, взыскиваемый у источника с дивидендов или другого дохода, получаемого не резидентом страны. Если между страной, в которой получен доход, и страной, резидентом которой является получатель дохода, существует соглашение об избежании двойного налогообложения, можно потребовать возвращения взысканного налога.

WITHHOLDING TAX AT THE SOURCE = УДЕРЖИВАЕМЫЙ НАЛОГ У ИСТОЧНИКА – Withholding Tax At The Source is the withholding of tax by a payer prior to payment of various types of income as required by the tax Code. The recipient of the income claims the amount withheld as a tax payment on his or her tax return. / Удерживаемый Налог У Источника:- требование для отечественных эмитентов, чтобы они удерживали часть выплачиваемых дивидендов и процентов у подданных других государств, временно проживающих в стране, в пользу иностранных корпораций для платежа в качестве налога, взимаемого в США с подобных распределений.

WITHHOLDING TAX ON INTEREST INCOME = УДЕРЖИВАЕМЫЙ НАЛОГ НА ДОХОД ПО ПРОЦЕНТАМ (или УДЕРЖИВАЕМЫЙ НАЛОГ НА ПРОЦЕНТНЫЙ ДОХОД) – Withholding Tax On Interest Income is a special form of investment income tax payable on interest from balances and deposits at domestic banks. Tax is withheld by the banks when interest is credited or paid to the account (hence the term withholding tax) and paid over to the tax authorities. For investors, withholding tax on interest income is, like a tax prepayment, counted towards the final income tax liability.

WITHHOLDING TIMES = СРОКИ УДЕРЖАНИЯ (или СРОКИ УДЕРЖИВАНИЯ) – Withholding Times:- the amount of time (hours, days, or number of milkings) before milk or meat may be sold from an animal treated with drugs.

WITH ICE = СО ЛЬДОМ (или XX) – With Ice:- when issued. See also When Issued. Ice is a slang term for a payment over the listed price of a ticket for a public event.

WITH INTEREST = С ПРОЦЕНТОМ – With Interest:- xxxxx. / С Процентом или Включая Процент:- указание в сделках с облигациями о том, что покупатель должен выплатить продавцу все накопленные проценты, начиная с даты последних процентных платежей вплоть до даты расчёта, но исключая её.

WITH OR WITHOUT = С ИЛИ БЕЗ – With Or Without (WOW):- used to designate an odd-lot order in which the customer asks for an immediate execution at the best available price. An odd-lot purchase order marked WOW will be executed at the current offering price plus any odd-lot differential, and an odd-lot sell order will receive the current bid price minus any odd-lot differential. An odd-lot order marked with or without is likely to result in a lower sale price or in a higher purchase price than an ordinary odd-lot order. With Or Without (WOW) is an odd-lot limit order to buy or sell either at a price derived from an effective round lot quotation (with a sale) or at the existing round lot quotation plus differential (without a sale), whichever occurs first in accordance with the customer's limit. / С Или Без:- инструкция по лимитированному приказу о покупке неполного лота ценных бумаг – использовать эффективную продажу на рынке лотов или котировку на акции в зависимости от того, что появится первым, для совершения сделки. Цена для клиента должна соответствовать ограничивающим условиям клиента.

WITHOUT = БЕЗ – Without:- indicates a one-way market if 70 were bid in the market and there was no offer, the quote would be '70 bid without'.

WITHOUT AN OFFER = БЕЗ ОФЕРТЫ – Without An Offer:- xxxxx. / Без Оферты или без предложения на продажу:- данный термин используется для завершения односторонней котировки, например, дилер назначает цену за ценную бумагу в качестве 'цены предложения за 10 без оферты' с целью создания впечатления, что дилер желает купить ценную бумагу за 10, но не желает её продавать либо из-за того, что дилер не обладает ценной бумагой, либо не желает продавать её 'вкороткую', то есть не имея её.

WITHOUT AVERAGE = БЕЗ АВАРИИ – Without Average:- in marine insurance, a shipment is protected from partial damage when the damage exceeds a specified percentage. / В морском страховании партия груза считается защищённой от частичного повреждения, если убыток от данного повреждения превышает указываемый процент.

WITHOUT BENEFIT OF SALVAGE = БЕЗ ВЫПЛАТЫ ПО СПАСАНИЮ – Without Benefit Of Salvage (WBS) is a term in a marine insurance policy, whereby the underwriters forgo their subrogation rights. A policy incorporating such a term is deemed by the Marine Insurance Act to be a gambling policy in law, and is therefore invalid in a court of law. Without Benefit of Salvage is a clause whereby the insurance company undertakes that salvage which may be realized from the property involved will not be deducted from the claim in the event of loss or damage. By the Marine Insurance Act 1906 (s.4), a marine policy effected 'without benefit of salvage to the insurer' is deemed to be a gaming or wagering contract. The issuing or effecting of such a policy is a criminal offence under the Marine Insurance (Gambling Policies) Act 1909.

WITHOUT INTEREST = БЕЗ ПРОЦЕНТОВ – Without Interest:- xxxxx. See also Ex Interest. / Без Процентов:- ценные бумаги и другие долговые инструменты с просроченными платежами продаются Без Процентов или на беспроцентной основе, когда покупатель не осуществляет дополнительный платёж по накопленным процентам. Облигации, проценты по которым выплачиваются только при наличии прибыли у компании, даже в том случае, если платежи не просрочены, из-за того, что требование по выплате процента возникает не раньше появления дохода, также продаются Без Процентов или на беспроцентной основе.

WITHOUT OUR LIABILITY = БЕЗ НАШЕЙ ОТВЕТСТВЕННОСТИ – Without Our Liability:- this or a similar notation refutes any liability in connection with information provided to a third party. It can also be used by a bill endorser to refuse liability under recourse. Also known as Without Our Guarantee.

WITHOUT PREJUDICE = БЕЗ УЩЕРБА (или БЕЗ ВРЕДА, или БЕЗ ПРЕДУБЕЖДЕНИЯ, или БЕЗ ПРЕДВЗЯТОСТИ) – Without Prejudice (WP):- the claim is paid on this occasion, although the underwriter feels it does not attach to the policy, but this action must not be treated as a precedent for future similar claims. Without Prejudice is a reservation made on a statement or offer that it is not an admission or cannot otherwise be used against the issuing party in future dealings or litigation with any determinative legal effect. A statement set onto a written document such as a letter, which qualifies the signatory as exempt from the content to the extent that it

may be interpreted as containing admissions or other interpretations which could later be used against him or her; or as otherwise affecting any legal rights of the principal of, or the person signing. In Castano v Gabriel, a 1969 residential tenancy case, Justice Wahl of the Civil Court of New York City wrote:- 'When a dispute arises between parties and they desire to preserve their respective rights and positions, then such reservation is readily accomplished by the performance of the acts between the parties where such is done without prejudice as to the existing controversy. Thus, no determinative legal effect is completed; it is reserved for future determination'. In an 1882 decision, Re Leite, Justice Fry wrote:- 'The words Without Prejudice when added to letters, only mean that in the event of the negotiations carried on by those letters not resulting in any agreement, nothing in them is to be taken as an admission. Where letters written without prejudice contained an undertaking on certain terms which were agreed to by the other side, and afterwards the parties giving the undertaking wished to introduce a fresh condition, the original undertaking was enforced'. In Cross & Tapper on Evidence, the authors wrote:- 'As part of an attempt to settle a dispute, the parties frequently make statements without prejudice. When this is done, the contents of the statement cannot be put in evidence without the consent of both parties .... The statements often relate to the offer of a compromise and, were it not for the privilege, they would constitute significant items of evidence on the ground that they were admissions. Obviously, it is in the public interest that disputes should be settled and litigation reduced to a minimum so the policy of the law has been in favour of enlarging the cloak under which negotiations may be concluded without prejudice'. In Halsbury's Laws of England:- 'Letters written and oral communications made during a dispute between parties which are written or made for the purpose of settling the dispute, and which are expressed or otherwise proved to have been made without prejudice cannot generally be admitted in evidence. The rule does not apply to communications which have a purpose other than settlement of the dispute'. Solicitor David Burrows wrote:- 'The without prejudice privilege rule enables a party to proceedings to claim privilege from disclosure to the court of documents covered by the privilege. The privilege rests first, upon the express or implied agreement of the parties themselves that communications in the course of the negotiations should not be admissible in evidence. Second, it derives from a public policy that rests upon the desirability of preventing statements or offers made in the course of negotiations being brought before the court on trial as admissions of liability'. An attorney or a lawyer will often send a letter without prejudice in case the letter makes admissions which could later prove inconvenient to the client. When without prejudice is contained within an order of the court, especially dismissal orders, the import is to avoid the application of res judicata against whatever has been thus reserved. Thus, in Sager, Illinois judge Getzendanner wrote:- 'A dismissal without prejudice means only that the Court has not adjudicated the merits of the claim so that dismissal cannot have any res judicata effects in a later action'. The privilege of adding without prejudice to lawyer letters has been thoroughly over-used. Without prejudice has become a customary addition to all attorney letters, almost as if it were a professional trade-mark, and designed more to intimidate than to settle or negotiate. In some cases, attorneys stick a without prejudice on every letter they write, more times than not simply to add sting, as a badge of temerity or brashness, so much so that you will routinely see it stamped or printed on letters clearly intended to be with prejudice, such as a letter which purports to confirm a settlement. If a letter is written without prejudice, the rule of thumb is that it is privileged and cannot be used in Court as evidence. However, in some jurisdictions, there has been so much abuse of this caution that no such privilege is extended to any letter marked without prejudice unless in fact the letter actually advances a settlement or otherwise is part of some such negotiation towards settling. A prejudice is a prejudgment, an assumption made about someone or something before having adequate knowledge to be able to do so with guaranteed accuracy. A term Without Prejudice is used in discussion and correspondence. Where there is a dispute or negotiations for a settlement and terms are offered 'Without Prejudice' an offer so made or a letter so marked and subsequent letters in an unbroken chain cannot be admitted in evidence without the consent of both parties concerned. / Рэй Xxxx, Дьжастис Фрай (Re Leite, Justice Fry). Без Отказа (Without Prejudice) – без отказа от права, без отказа от обязательства, без ущерба, вне зависимости от того, не ущемляя права. Оговорка в юриспруденции, означающая, что стороны-участники контракта отказываются ссылаться на данный метод как прецедент в разрешении спора. Без Предубеждения или Без Ущерба:- слова, которые пишутся в начале документа или письма, обозначающие, что всё ниженаписанное никоим образом не может быть использовано во вред существующему праву или требованию, не может рассматриваться как последнее слова лица, подписавшего документ, ни к чему не обязывает подписавшее лицо и не может служить доказательством в суде. Например, адвокат может написать эти слова, когда составляет от имени своего клиента письменное предложение об урегулировании претензии, подразумевая, что его клиент может снять своё предложение. Кроме того, эти слова означают, что хотя в данном конкретном случае соглашение и может быть достигнуто на оговорённых в документе условиях, лицо, подписывающее его, не считает себя обязанным урегулировать другие подобные разногласия на тех же самых условиях.

WITHOUT PROTEST = БЕЗ ПРОТЕСТА – Without Protest:- notation or equivalent clause (such as 'Without Costs') used by the issuer, endorser or bill guarantor to protect the holder against protest as a result of the bill not being paid or acceptance having been refused. / Нотация или равноценная оговорка (такая как 'Без Издержек'), используемая эмитентом, индоссантом или гарантом векселя для защиты владельца векселя от протеста в случае неуплаты по векселю или отказа от акцепта векселя. Без Протеста:- наиболее употребительная формулировка оговорки векселедателя или индоссанта, освобождающей векселедержателя от совершения протеста в неакцепте и неплатеже.

WITHOUT RECOURSE = БЕЗ РЕГРЕССА – Without Recourse is a note on a bill of exchange indicating that in the event of non-payment of the bill, the current holder may not blame the person from whom he or she bought it. It is also sometimes written in French as Sans Recours. Used on negotiable instruments to indicate the endorser is not liable to subsequent holders. Negotiation of a draft, or other negotiable instrument, or letter of credit documents without the normal warranty on the part of the seller of the instrument/documents that the obligor named in the instrument (the drawee, payor, or maker) will pay. Although the seller is still responsible for the genuineness of the instrument and documents, the purchaser takes on the credit risk of being able to collect payment from the obligor when due. Unless negotiation is without recourse, the purchaser of the instrument/documents has the right to recover the face amount from the seller if the obligor fails or refuses to pay for any reason. Without Recourse is a phrase preceding the signature of a drawer or endorser of a negotiable instrument; signifies that the instrument is passed onto subsequent holders without any liability to the endorser in the event of nonpayment or nondelivery. Without Recourse:- giving the lender no right to seek payment or seize assets in the event of nonpayment from anyone other than the party specified in the debt contract (such as a special-purpose entity). Without Recourse:- when added to a Bill of Exchange (Draft), these words indicate that the holder has no recourse to the person from whom he took the Bill, should it not be paid. It often appears after an endorsement. / Примечание на переводном векселе, указывающее на то, что в случае неплатежа по данному векселю текущий владелец не может обвинять лицо, у которого он или она приобрела его. Надпись, используемая на оборотных инструментах для указания того, что индоссант не отвечает перед последующими владельцами. Отчуждение (или негоциация) тратты или иного оборотного инструмента, или документов по аккредитиву без обычного ручательства со стороны продавца инструмента/документов, которые . Без Регресса или Без Оборота:- (1) ситуация, когда при переводе обращающегося инструмента – векселя – на другое лицо индоссант более не отвечает по нему, если вексель не будет оплачен. (2) Соглашение, по которому покупатель берёт на себя весь риск сделки и отказывается от каких-

либо прав регресса. Без Оборота или Без Обязательства:- слова на переводном векселе (bill of exchange), указывающие на то, что держатель векселя не имеет права вернуть его лицу, у которого он купил этот вексель, если последний не будет оплачен. Эти слова пишутся на лицевой стороне векселя или присутствуют в передаточной надписи. Без этих слов держатель векселя может вернуть его трассанту или индоссанту, если окажется, что по истечении срока обращения он не будет оплачен. Без Оборота (Without Recourse):- оговорка индоссанта, исключающая его из числа должников по векселю. Наиболее употребительная формулировка – 'Без Оборота На Меня'. Без Регресса или Без Оборота (Without Recourse):- оговорка в долговом соглашении, согласно которой в случае неплатежей кредитор не имеет права требовать выплат или удерживать активы у кого-либо, кроме стороны, указанной в долговом соглашении.

WITHOUT RECOURSE FINANCING = ФИНАНСИРОВАНИЕ БЕЗ РЕГРЕССА – Without Recourse Financing is a financing in which the right of recourse to the party receiving funds is forfeited to the party advancing funds. This may be evidenced by conditions added to the endorsement of a draft being sold by an exporter in order to protect the exporter, if the instrument is not paid at maturity by the original obligor.

WITHOUT RESERVE = БЕЗ ОГОВОРОК – Without Reserve:- (1) in contracts:- these words are frequently used in conditions of sale at public auction, that the property offered, or to be offered for sale, will be sold without reserve. (2) When a property is advertised to be sold without reserve, if a puffer be employed to bid, and actually bid at the sale, the courts will not enforce a contract against a purchaser, into which he may have been drawn by the vendor's want of faith. Without Reserve:- situation where an agent or representative has the authority to make definitive decisions without first seeking approval of the principal or the entity being represented. Without Reserve is a term indicating that a shipper's agent or representative is empowered to make definitive decisions and adjustments abroad without approval of the group or individual represented. See also Advisory Capacity. / Термин, указывающий на то, что агент или представитель отправителя уполномочены принимать окончательные решения и переоценки за рубежом без одобрения представляемой группы или отдельного лица. WITH PARTICULAR AVERAGE = С ЧАСТНОЙ АВАРИЕЙ (или ВКЛЮЧАЯ ЧАСТНУЮ АВАРИЮ, или С ОТВЕТСТВЕННОСТЬЮ ЗА ЧАСТНУЮ АВАРИЮ) – With Particular Average (WPA):- an insurance term meaning that partial loss or damage of goods is insured. The damage generally must be caused by sea water, and many terms specify a minimum percentage of damage before payment. It may be extended to cover loss by theft, pilferage, delivery, leakage, and breakage. See also With Average. With Particular Average (WPA):- where insured cargo is covered for partial damage from sea water or loss from breakages, theft etc. With Particular Average (WPA) is a marine insurance provision under which the insured cargo is covered for partial damage from seawater or loss from breakage, leakage, theft, etc. This cover, however, comes into force only when the damage or loss exceeds a certain percentage (usually 3 percent) of the cargo's value. Also called With Average. See also Particular Average.

WITH–PROFITS POLICY = ПОЛИС С ПРИБЫЛЯМИ – A With-Profits Policy (Commonwealth) or Participating Policy (US) is an insurance contract that participates in the profits of a life insurance company. The company is often amutual life insurance company, or had been one when it began its with-profits product line. Similar arrangements are found in other countries such as those in continental Europe. With-profits policies evolved over many years. Originally they developed as a means of distributing unplanned surplus, arising, e.g., from lower than anticipated death rates. More recently they have been used to provide flexibility to pursue a more adventurous investment policy to aim to achieve long-term capital growth. They have been accepted as a form of long-term collective investment whereby the investor chooses the insurance company based on factors such as financial strength, historic returns and the terms of the contracts offered. The premiums paid by with-profits and non-profit policyholders are pooled within the insurance company's life fund (Commonwealth) or general account (USA). The company uses the pooled assets to pay out claims. A large part of the life fund is invested in equities, bonds, property to aim to achieve a high overall return. The insurance company aims to distribute part of its profit to the with-profits policy holders in the form of a bonus (Commonwealth) or dividend (USA) attached to their policy (see the bonus section). The bonus rate is decided after considering a variety of factors such as the return on the underlying assets, the level of bonuses declared in previous years and other actuarial assumptions (especially future liabilities and anticipated investment returns), as well as marketing considerations. Compare with Unit-Linked Policy. There are two main categories of with-profits policies:- (i) Single Premium Contracts:- insurance bonds (with-profit bonds), single premium endowments, single premium pension policies; and (ii) Regular Premium Contracts:- in which premium payments are usually made monthly – endowment policies, pension policies. Conventional With-Profits Contracts have a basic sum assured to which bonuses are added. The basic sum assured is the minimum amount of life assurance payable on death; for endowment contracts it is also the minimum lump sum payable at maturity. The basic sum assured attracts reversionary bonuses which are used to distribute profits to the policy. Once a reversionary bonus is added it cannot be removed from the policy. The required premiums must have been maintained to receive payment of the basic sum assured and bonuses. If the premiums have not been maintained a reduced amount (or in some cases none) will be paid. For insurance bonds the basic sum assured plus bonuses represents the plan value. When the policy matures, a final bonus may be added to reflect the policy's share of profits which have not yet been distributed. Unitised With-Profits Policies work in a similar way except that the policy value is expressed as a number of units. Various models have been adopted by different insurers, but typically either:- (i) the fund value is represented by the bid value of units, which may increase with time, or (ii) the number of units increases each year to represent the increase in value and the unit price remains fixed. Endowments still retain a basic sum assured (in most cases) although this may be notional rather than a structural part of the policy. Unitised with-profits policies were introduced as a response to competition from unit-linked life policies that became available in the 1970s. The unitised version was somewhat less opaque than the conventional version, with less surplus being held back, and also made possible switching between with-profits and unit-linked funds. The conventional policies have an element of guarantee conferred by the contractual nature of their basic sum assured. This guaranteed element, which is not profit related, has caused issues for insurers in the realistic reporting regime (see below). Most policies issued today are unitised and often are held in ring-fenced sub-funds of the life fund rather than participating in the full profits of the life company. With-profits funds employ the concept of Smoothing. That is, a proportion of the profits earned during good years is held back to aim to ensure that a reasonable return is paid during years of poor performance. This may result in a smoothed effect on the increase of the unit price, as opposed to fluctuations that would normally occur in the daily price for other stocks or shares. An important difference between this and the normal statistical sense of smoothing is that it has to be attempted without knowledge of future developments, which may cause the 'smoothed' value to move further and further out of line with the 'unsmoothed' value, necessitating a sharp correction at some point in the future. Types Of Bonus:- a Reversionary Bonus is awarded during the term of the insurance contract, and guaranteed to be paid at maturity. It cannot be removed after declaration. The annual bonus may consist of two parts. The Guaranteed Bonus is an amount normally expressed as a monetary amount per £1 000 sum assured. It is set at the outset of the policy and usually cannot be varied. The rest of the annual bonus will depend on the investment return achieved by the fund subject to smoothing. The Terminal Bonus is awarded and paid at the maturity and sometimes the surrender of the policy. Thus, it is

unknown before the maturity of contract. It is sometimes referred to as the Final Bonus. The terminal bonus represents the member's entitlement to a proportion of the fund that has been held back for the purpose of smoothing. In certain circumstances a Market Value Adjustor may be applied to reduce the overall policy value to limit the payout to a reasonable multiple of the member's fair share. The insurance company has some freedom to decide what mix of bonuses to pay. An insurance company may decide to pay low annual bonuses and a high terminal bonus. Such a policy will protect the insurance company from falls in the investment markets because annual bonuses cannot be taken away once given. However, this policy might be unattractive to investors because it does not contain many guarantees and offers a low rate of return (until the maturity of the policy). Occasionally an insurer may decide to pay an Exceptional Bonus possibly due to restructuring of the company or exceptional investment returns. This is almost unheard of these days. A Market Value Reduction (MVR) or Market Value Adjustor is a mechanism used by the insurance company to ensure that policy withdrawal payments are reasonable in relation to the policy's fair entitlement to the assets of the life fund. After a period of poor investment performance the value of the withdrawal is reduced to reflect the reduction in the underlying value of the assets of the life fund. Perceived Risk And Actual Risk:- For many years with-profits policies were seen as a safe alternative to deposit accounts for many investors (especially elderly investors). Years of steady reliable returns in combination with unscrupulous sales tactics from insurers fostered the impression that a 'low-risk' investor should invest in with-profits. This perceived low risk belied the reality of the underlying investment strategies of many insurers who used high equity exposure and high-risk financial instruments to achieve the returns. In the middle of the bear market of the early 2000s the UK regulator (the Financial Services Authority) imposed a new regulatory regime for with-profit providers, in response to growing consumer complaints following the introduction of market value reductions. The realistic reporting regime had the combined effect of requiring the insurers to move more of their funds into lower-risk investments (corporate bonds, and gilts) to cover liabilities; and to lower projection rates in line with the new asset mix of the fund to more accurately predict future returns. Industry commentators cite this as the death knell for the with-profits policy. Regulation:- The policy value is either the present value of the basic sum assured plus the bonuses given, less future premiums (for conventional contracts) or the bid value of a unitised with-profits policy. This value is broadly equivalent to the value of the underlying assets. However, because of investment fluctuations, and also because of the expenses incurred when the policy is issued, this value may exceed the market value of the underlying assets. Without appropriate regulation an insurance company might not have enough money to pay the value of its policies. This was the case with The Equitable Life Assurance Society in the UK when the costs of annuity guarantees determined by the courts as having been promised to some policyholders meant that the company was forced to cease the introduction of new business and nearly led to the collapse of the company. The Financial Services Authority (FSA) in the UK altered regulation as a consequence of this and other management failures to ensure that an insurance company keeps enough free reserves to protect the company in the event of falls in the markets. The new valuation method requires, as an additional 'pillar', a realistic valuation of the fund's assets and growth prospects. In addition each firm must now publish a document called the Principles and Practices of Financial Management (PPFM) for each with-profits fund with a breakdown of the assets and an explanation of the management processes for the fund. These documents, although very detailed, are largely incomprehensible for consumers and are thought to be of use only for Independent Financial Advisers and other industry professionals, and also to act as a constraint on how the company distributes surplus. The realistic reporting method has been cited as a factor contributing to the demutualisation of Standard Life Assurance Company. In the USA, insurance companies are regulated on a state-by-state basis. However, they must not only comply with the requirements of the state in which they are incorporated, but also with the regulations of each state in which they are licensed. The National Association of Insurance Commissioners (NAIC) provides suggested guidelines which each state is free to follow or not. For example, the Insurance Information Institute, 'Life insurers are the object of the NAIC's Intestate Insurance Product Regulation Compact, launched in 2002 as a way to develop uniform standards and a central clearinghouse to provide prompt review and regulatory approval for life insurance products'. Reputation:- for many years with-profit funds were very popular and large numbers of such policies were sold within the United Kingdom and in the United States. Recently with-profit funds have had a large amount of negative press due to the introduction of MVRs. This has led people to question the opacity in setting bonus rates and the over-complexity of the product in general. Simple to understand products have been encouraged recently and the nature of the conventional with-profit fund does not fit with such simple policies. Alternatives such as a more fund-type product, CPPI (short for the Constant Proportion Portfolio Insurance) or smoothed managed funds are yet to show a significant popularity amongst consumers. Secondly the Equitable Life company sold a large number of policies with guarantees in the contract. After a series of court cases the nature of the guarantees for some policies was reinterpreted, becoming more onerous. As the company was required to meet these guarantees, the amount available to allot bonuses to its policyholders in general was drastically reduced, although the company had provided illustrations of projected benefits on the basis that these bonuses would be maintained. This resulted in a reduction in the value of many policies issued by the company. This reduction received considerable negative publicity and damaged the reputation of with-profit policies. / Полис С Прибылью – полис страхования жизни, по которому к страховой сумме может быть добавлена дополнительная сумма либо дополнительные деньги будут выплачены в виде бонусов отдельно от страховой суммы, так как инвестирование фонда или фондов компании по страхованию жизни принесло прибыль. Since February 23, 1979, when the facility became operative, it has been used for loans to developing countries with serious debt problems. Originally called the Witteveen Facility, after Hendrikus Johannes (Johan) Witteveen (1921–), then Managing Director of the IMF (1973–78), its official name is the Supplementary Financing Facility. Seven developed countries, including the United States, plus seven OPEC countries provided funds for the facility. By March 1981, these funds were fully committed to borrowers. Following the First Oil Crisis 1973–74 Witteveen created the Supplementary Financing Facility, unofficially known as the Witteveen Facility, to channel revenues from oil producers back to the consuming countries, to prevent a liquidity crisis amongst those consumers. / Нидерландский политик Хэндрикюс Ёханэс (Ёхан) Витэвэнь (Hendrikus Johannes (Johan) Witteveen; 1921–). WOAD = ВАЙДА (или ВОУД) – Woad is a glue dye produced from Isatis Tinctoria. Not as strong as Indigo. Isatis Tinctoria, also called Woad, Dyer's Woad, or Glastum, is a flowering plant in the Family Brassicaceae. It is occasionally known as Asp of Jerusalem. Woad is also the name of a blue dye produced from the leaves of the plant. Woad is native to the steppe and desert zones of the Caucasus, Central Asia to Eastern Siberia and Western Asia (per Hegi) but is now also found in Southeastern and Central Europe and Western North America. Since ancient times, woad was an important source of blue dye and was cultivated throughout Europe, especially in Western and Southern Europe. In medieval times there were important woad-growing regions in England, Germany and France. Towns such as Toulouse became prosperous from the woad trade. Woad was eventually replaced by the more colorfast Indigofera Tinctoria and, in the early XX century, both woad and Indigofera Tinctoria were replaced by synthetic blue dyes. Woad has been used in traditional Chinese medicine for centuries. There has also been some revival of the use of woad for craft purposes. Woad And Indigo:- The dye chemical extracted from Woad is indigo, the same dye extracted from 'true indigo', Indigofera Tinctoria, but in a lower concentration. Following the European discovery of the seaway to India, great amounts of indigo were imported from Asia. Laws were passed in some parts of Europe to protect the Woad industry from the competition of the indigo trade. It was proclaimed that indigo caused yarns to rot:- 'In 1577 the German government officially prohibited the use of indigo, denouncing it as that pernicious, deceitful and corrosive substance, the Devil's dye'. '... a recess of the Diet held in 1577 prohibited the use of 'the newly-invented,

deceitful, eating and corrosive dye called the devil's dye'. This prohibition was repeated in 1594 and again in 1603. In France, Henry IV, in an edict of 1609, forbade under pain of death the use of 'the false and pernicious Indian drug'. With the development of a chemical process to synthesize the pigment, both the woad and natural indigo industries collapsed in the first years of the XX century. The last commercial harvest of woad until recent times occurred in 1932, in Lincolnshire, Britain. Small amounts of woad are now grown in the UK and France to supply craft dyers. The classic book about woad is The Woad Plant and its Dye by J. B. Hurry, Oxford University Press of 1930, which contains an extensive bibliography. A method for producing blue dye from woad is described in The History of Woad and the Medieval Woad Vat (1998) ISBN 0-9534133-0-6. Woad is biodegradable and safe in the environment. In Germany, there have been attempts to use it to protect wood against decay without applying dangerous chemicals. Production of woad is increasing in the UK for use in inks, particularly for inkjet printers, and dyes. The plant can cause problems, however:- Isatis Tinctoria is classified as an invasive Species in parts of the United States. / Во Франции Ори IV (Henry IV). Дьжей.Би. Хари (J.B. Hurry). WOBBE INDEX = ИНДЕКС ОТ ВОББЕ (или ИНДЕКС ВОББЕ) – The Wobbe index is an indicator of the interchangeability of fuel gases and is named after Italian physicist Goffredo Wobbe (in 1927). The Wobbe Index (WI) is a measure of the interchangeability of gases when they are used as a fuel. It compares the energy output of different gases during combustion. The Wobbe index is essential for analyzing the impact of a fuel changeover and is also a common specification of appliances that use gas and of devices that transport gas. The Wobbe index may be calculated from the higher heating value (HHV) and the specific gravity of the gas. Classify fuel gasses according to their Wobbe index. The Wobbe index is used internationally to create 3 families of gasses. Family 1 consists of manufactured gasses, Family 2 is natural gasses and Family 3 includes liquid petroleum. Wobbe Index (WI) is an index to indicate the interchangeability of fuel gases and is the best indicator of the similarity between natural gas and a specific propane-air mixture. Since this index relates heating characteristics of blended fuel gases, it can also be used to obtain constant heat flows from gases of varying compositions. The Wobbe Index, however, does not relate flame temperatures, heat transfer co-efficients or temperature gradients. The Wobbe Index (WI) is the main indicator of the interchangeability of fuel gases and is frequently defined in the specifications of gas supply and transport utilities. Wobbe Index is used to compare the combustion energy output with different composition of fuel gases. If two fuels have identical Wobbe Indices then for given pressure and valve settings the energy output will also be identical. The Wobbe Index is a critical factor to minimize the impact of fluctuations in your fuel gas supply and can therefore be used to increase the efficiency of your burner or gas turbine applications. Wobbe Index = Heating Value / √Specific Gravity. / Итальянский физик Гоффредо Воббе (Goffredo Wobbe) в 1926 . Индекс Воббе (Wobbe Index) – синонимом Числа Воббе (Wobbe Number).

WOBBLE = ПРЕЦЕССИЯ – Wobble:- the ability of the third base in a tRNA (transfer RNA) anticodon to hydrogen bond with any of two or three bases at the 3' end of a codon. This wobble (nonspecificity) allows a single tRNA species to recognize several different codons. / Прецессия – неоднозначное узнавание некоторыми антикодонами тРНК соответствующих кодонов мРНК, вызванное неоднозначностью спаривания один и три нуклеотидов кодона.

WOG = WITHOUT GUARANTEE

WOLF = ВОЛК – Wolf:- these are the brokers who are fast speculators called Wolves. These brokers are very quick to perceive changes in the trends in the market. They are not generally caught in the wrong foot. / Волк – опытный и зачастую ловкий спекулянт.

WOLFE WAVE = ВОЛФОВСКАЯ ВОЛНА (или ВОЛНА ВОЛФОВ) – A Wolfe Wave (in technical analysis) is a predictive pattern used in technical analysis. It is said to be present in all securities markets and all time frames. Because Wolfe Waves rely on time as one component it may not be as reliable when using it on a non-time based chart, such as a tick, volume, or range chart. The Wolfe Wave is named after Bill Wolfe and Brian Wolfe who say that they 'discovered it, and did not invent it'. In its most simplistic terms the Wolfe Wave pattern consists of five waves with the fifth wave extending beyond the equilibrium line. Traders will then extrapolate a line from wave 1 to beyond wave 4 in order to ascertain a predictive price at point 6. Wolfe Waves have the following characteristics:- (i) points three and four should stay within the channel created by one and two; (ii) the symmetry of waves one to two is the same as waves three to four; (iii) wave (point) four is within the channel created by waves one to two; there is regular time between all waves. (This is why tick, volume and range charts may not produce accurate Wolfe Waves.); and (iv) wave five goes pass the channel created by waves one and three and is the trade entry signal. The target exit point for the trade is a price along the line created by waves one and four at point six. / Бил Волф (Bill Wolfe) и Брайэн Волф (Brian Wolfe).

WOLFRAMITE = ВОЛЬФРАМИТ – Wolframite:- chief ore of tungsten, commonly associated with tin ore in and around granite. Such occurrences include Cornwall, England, the United Kingdom; Northwestern Spain and Northern Portugal; Eastern Germany; Myanmar (Burma); the Malay Peninsula; and Australia. Wolframite consists of a mixture in varying proportions of the tungstates of iron and manganese, $FeWO_4$ and $MnWO_4$; varieties with dominant iron (Fe:Mn≤4:1) are called Ferberite, and those with dominant manganese (Mn:Fe≤4:1) are called Hübnerite. Wolframite's color is brown to black, and it has a submetallic to metallic lustre and a perfect cleavage. The Mohs hardness is 5–5-1/2; specific gravity, 7–7.5; and crystal system, monoclinic. / Вольфрамит – минерал группы вольфраматов, (Fe, Mn)(WO4). Примеси:- Zn, Mg, Ta, Nb и другие. Разновидности:- (i) гюбнерит $Mn(WO_4)$, красноватого цвета, плотность 7.2 г/см^3; и (ii) ферберит $Fe(WO_4)$, чёрного цвета, плотность 7.6 г/см^3. Твёрдость 5–5.5. Встречается в грейзенах и высокотемпературных гидротермических жилах, россыпях. Основная руда вольфрама.

WOLLASTONITE = ВОЛЛАСТОНИТ (или ДОЩАТЫЙ ШПАТ) – Wollastonite:- white, glassy silicate mineral that commonly occurs as masses or tabular crystals with other calcium-containing silicates (e.g., diopside, tremolite, garnet, and epidote) in metamorphosed limestones. Deposits are found in Ciclova Română, Romania; Monte Somma, Italy; and Pargas, Finland. Occurrences in the United States include Utah; Isle Royale, Michigan; Riverside, California; and Essex County, New York, where it is mined. For detailed physical properties, see Silicate Mineral (table). Wollastonite, the most common of the three forms of calcium silicate, $CaSiO_3$, is used in many ceramic products, including floor and wall tiles, electrical insulators, and porcelain fixtures. It is also used in welding rod coatings and in paints. / Волластонит или Дощатый Шпат – минерал подкласса цепочечных силикатов, $Ca_3(Si_3O_9)$. Белые, лучистые и скорлуповатые агрегаты. Твёрдость 5–5.5; плотность 2.9–3.0 г/см^3. По происхождению – контактово-метаморфический. Сырьё для тонкой керамики; звуко- и теплоизоляционный материал.

WOMEN, INFANTS, AND CHILDREN PROGRAM = ПРОГРАММА ПО ЖЕНЩИНАМ, МЛАДЕНЦАМ, И ДЕТЯМ – Women, Infants, and Children Program (WIC Program):- first created in 1972 under the authority of the Child Nutrition Act of 1966 and currently operating under the authority of the Healthy Meals for Healthy Americans Act of 1994. A program designed to improve the health of nutritionally at-risk, low-income pregnant, breastfeeding, and postpartum women; infants; and children up to their fifth birthday. WIC combines direct commodity distributions with nutrition education and referrals to health services. Participants must meet income, residency, and risk assessment eligibility requirements. Local WIC agencies provide participants with either vouchers redeemable for

specified foods at participating retail food stores or for a food package prepared according to federal guidelines. Also Special Supplemental Food Program for Women, Infants, and Children.

WOMEN INVOLVED IN FARM ECONOMICS = ЖЕНЩИНЫ, ВОВЛЕЧЁННЫЕ В ФЕРМЕРСКУЮ ЭКОНОМИКУ – Women Involved In Farm Economics (WIFE), a national organization devoted to agriculture, was founded in 1976. The group has been involved with lobbying for agricultural issues at the state and national levels, establishing communication among farm women throughout the United States, and educating women about legislative issues and economic needs. Over 30 years ago, a group of farm women in Nebraska recognized a need to speak up for agriculture and formed Women Involved in Farm Economics (WIFE). Today, it is a national organization with local chapters and state associations in 15 states across the country. 'Most of our members are ladies who get the dirt under their fingernails', says Tammy Basel, national WIFE president from Union Center, South Dakota. These farm women devote time away from their daily chores to come together and serve the industry. WIFE is dedicated to improving profitability in production agriculture through educational, legislative, communicative and cooperative efforts. It is policy-oriented and non-partisan. From an educational standpoint, WIFE members organize field trips and learning opportunities for youth in their states and communities. Youth education is a benefit to all of agriculture, Basel says, because it will help people understand where their food and fiber come from. WIFE members also strive to educate themselves to be factual and professional when communicating on agricultural issues. They take part in legislative work and recently sent members to Washington, DC, for subcommittee hearings on animal identification and rural broadband Internet connections. Basel says that as a multi-commodity group a lot of doors open to them for others to hear what they have to say:- 'We are a strong voice of agriculture and a voice of reason'. 'There are so few of us left in agriculture, we should all work together', she adds. In order to keep tabs on what is happening with various commodities, WIFE has national chairwomen of each, ranging from dairy and beef to energy and rural health. The chair members write newsletter articles each month to keep all members abreast of what's happening in their areas. Dianna Reed serves WIFE as the national dairy chair woman. Reed and her husband farm with their son and daughter-in-law in Esbon, Kansas. They milk 100 cows and grow feed for the dairy. Reed keeps an eye on what dairy initiatives are taking place in the legislature and identifies the issues the organization is able to address. If the measure is good for dairy, WIFE will stand in support of it. If the measure is not good for dairy producers, they state their opposition and the reasoning behind it. Currently, WIFE is involved in dairy-related legislation regarding gas emissions and animal identification. They've also just started to deal with issues regarding the disposal of animals that could pose health concerns and increased costs for producers and rendering plants, Reed reports. In terms of dairy education, WIFE works to educate consumers that dairy products are healthy and to encourage consumers to purchase US products. Their message is clear:- 'We need dairy farms here in the United States, and everyone needs to support them', Reed says. 'So many people think all you do is go out to the barn and milk a cow', she says. 'Education is really the key to getting more dairy issues out into the public'. Reed enjoys her involvement in WIFE because it keeps her informed of what's happening in other aspects of agriculture besides dairy, like the beef, sheep, goat and feed industries. Sometimes items come up in legislatures that affect multiple commodities and WIFE members from various farm enterprises are able to work together to address them. The national organization gathers three times a year, including a fly-in to Washington, DC, to talk with political leaders and influencers. At member events, the organization offers leadership and communications workshops and a time to come together as women in agriculture, sharing stories and offering camaraderie. Women Involved In Farm Economics (WIFE):- organized in 1976 as a grass-roots organization representing professional women in agriculture. Its mission is to promote economic prosperity in agriculture. Women Involved In Farm Economics (WIFE) began in Sidney, Nebraska in December, 1976, when several farm wives were discussing low prices and other problems in the agricultural economy. Within a few months the group had organized, established chapters in neighboring states and in spring, 1977, sent its first delegation to lobby in Washington, DC. This is a grass-roots, non-political lobbying group. Among the issues WIFE has addressed are parity, freight rates, state and national farm legislation, loan rates, and inheritance laws. The organization's goal is to call attention to agricultural conditions, educate consumers and work for better farm product prices. The records of Wife reflect the farm crisis of the 1970s and '80s. WIFE Does:- (i) Educates:- members educate themselves to be factual when communicating on agricultural issues. Members regard this responsibility with utmost integrity and professionalism; (ii) Communicates:- members believe in informed action which results in letters and telephone calls to elected and appointed officials and individuals in a position to have an impact on agriculture. WIFE members are the leaders within their communities. (iii) Represents:- members testify at state and national hearings regarding topics which directly affect the agricultural community; and (iv) Cooperates:- members work with agricultural and non-agricultural organizations toward better understanding of mutual concerns. / Тэми Базэл (Tammy Basel). Дайэнэ Рид (Dianna Reed). коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо).

WON'T LOCK = НЕ ХОЧЕТ ЗАСТЁГИВАТЬСЯ – (1) Won't Lock:- not apparent without testing by placing zipper slider in locked position and applying tension. Closure defects, and namely – Zippers:- Slider Defects. / Порок или дефект застёжки.

(2) Won't Lock:- same as for metal zippers. Not apparent without testing by placing zipper slider in locked position and applying tension. Closure defects, and namely – Nylon Spiral Zipper:- Slider Defects. / Порок или дефект застёжки. Найлан^{T3} (Nylon^{TM}).

WOOD = ДРЕВЕСИНА – (1) Wood is:- (i) a hard fibrous substance composed of cellulose bonded together with lignin formed as the main fluid conducting tissue or xylem making up the greater part beneath the bark of the trunk, branches and roots of trees, shrubs and other woody plants; and (ii) a dense growth of trees, somewhat smaller in extent than a forest. Wood is a commodity class for round wood, sawn wood, wood chips or dunnage, with or without bark. Wood:- the principal strengthening and nutrient-conducting tissue of trees and other plants and one of the most abundant and versatile natural materials. Produced by many botanical species, wood is available in various colors and grain patterns. It is strong in relation to its weight, is insulating to heat and electricity, and has desirable acoustic properties. Furthermore, it imparts a feeling of 'warmth' not possessed by competing materials such as metals, and it is relatively easily worked. As a material, wood has been in service since humans appeared on Earth. Today, in spite of technological advancement and competition from metals, plastics, cement, and other materials, wood maintains a place in most of its traditional roles, and its serviceability is expanding through new uses. In addition to well-known products such as lumber, furniture, and plywood, wood is the raw material for wood-based panels, pulp and paper, and many chemical products. Finally, wood is still an important fuel in much of the world. Production And Consumption Of Wood:- in botanical terms, wood is part of the system that conveys water and dissolved minerals from the roots to the rest of the plant, stores food created by photosynthesis, and furnishes mechanical support. It is produced by an estimated 25 000 to 30 000 species of plants, including herbaceous ones, though only 3 000 to 4 000 species produce wood that is suitable for use as a material. Wood-producing forest trees and other woody plants are of two categories:- gymnosperms and angiosperms. Gymnosperms, or cone-bearing trees, produce softwoods, such as pine and spruce, and angiosperms produce temperate and tropical hardwoods, such as oak, beech, teak, and balsa. Softwoods account for about 40 percent and hardwoods about 60 percent of the world's production of lumber. It should be noted that the distinction implied by hardwood and softwood is not true in all cases. Some hardwoods – e.g., balsa – are softer than some softwoods – e.g., yew. Wood is a material of great economic importance. It is found throughout the world and is a renewable resource – in contrast to coal, ores, and petroleum, which are gradually exhausted. By means of its harvesting in forests, its transportation, its processing in workshops and industries, and its trade and use, wood

provides jobs and supports economic development and, in some countries, basic subsistence. Indicative of this importance is the high demand for wood and wood products and the projected growth in consumption. In the late 1990s yearly world production (and consumption) of wood in the form of roundwood, or logs, was about 3.5 billion cubic meters, up from 1.5 billion cubic meters in 1950. (A cubic meter is about 35 cubic feet.) Consumption of roundwood is projected to approach 4 billion cubic meters in 2010. On a weight basis, the consumption of wood exceeds by far that of other materials. In the mid-1990s the average daily consumption of wood per person was 1.8 kg (about 4 pounds), which was 3 times that of cement, 5 times that of steel, 30 times that of plastics, and 200 times that of aluminum. More than half of roundwood production is consumed as fuel, mainly in less-developed countries. Production of paper and paperboard has shown the most rapid increase among wood products; this trend is expected to continue as consumption per person in the less-developed countries approaches that in the developed nations. Rising world population is the driving force of increasing consumption of wood and consequent reduction of forest area. The depletion of many forests, especially in the tropics, makes uncertain the provision of an adequate wood supply to satisfy the anticipated need. Efforts to stop the reduction of Earth's forest cover and increase the productivity of existing forests, establishment of extensive reforestation programs and plantations of fast-growing tree species, recycling of paper, and improved utilization of wood through research could ease the problem of wood supply. Harvesting Of Wood:- Management:- harvesting of wood differs radically from harvesting of other crops. The yearly growth of each individual tree cannot be detached from the living plant. Rather, new wood is added inseparably to preexisting growth until the entire tree is harvested, after a waiting period that varies widely depending on intended use of the wood – for example, 2–3 years on energy plantations (where biomass is produced as fuel for power generation), 6–8 years for pulpwood (eucalypts), 12–15 years for fast-growing poplar hybrids, 30–50 years for fast-growing pines, and 100 years or more in temperate and tropical forests producing wood of large dimensions. A prerequisite to harvesting is a management plan, which determines the yearly yield and the method of removal. The harvest method chosen can involve clear-cutting large areas or selective cutting of individual trees or groups of trees. For a forest harvested under the sustained-yield concept, the volume of timber removed at periodic intervals is dependent on the net growth of all trees – as estimated by statistical sampling – during that interval. This concept, combined with natural and artificial seeding and planting, ensures a continuous production of wood and conservation of forests. To promote sustained-yield management, efforts have been made to introduce appropriate ecological labeling (ecolabeling) of marketed wood and wood products. Ecolabeling is intended to ensure that goods offered to the consumer have not been produced in a way detrimental to the environment. The season of harvest is not determined by the time of ripening, as it is for agricultural crops, but by such factors as the conditions of work for personnel, machines, and animals and the danger of damage to the remaining forest and to the harvested wood. Because felled trees are vulnerable to attack by fungi and insects, the harvest may be timed to avoid conditions favorable for these organisms. Time of harvesting becomes a consideration mainly when the felled trees will not be removed quickly from the forest for processing. Otherwise – for example, in the United States – harvesting is a year-round activity. Marking, Felling, And Processing:- harvesting includes marking the trees to be removed (in selective cutting), felling and processing (conversion) of trees, and transportation of the wood from the felling site, or stump area, to a roadside storage site or a central processing yard (landing) in the forest. Processing includes top removal (topping), delimbing, crosscutting into logs (bucking), debarking, and sometimes chipping of undesirable trees or logging residues. Processing may be done totally or partially in the forest; in the latter case, the remaining work is completed in a sawmill or other woodworking facility. Felled trees are handled by one of three harvesting systems: shortwood, longwood (or tree-length), or whole-tree. In shortwood harvesting, trees are completely processed (except perhaps for debarking) at the felling site; the logs are then transported to a storage yard or site and eventually to the factory where, if needed, they are debarked by machine. In longwood harvesting, the trees are only topped and delimbed at the felling site; the resulting long logs are then transported to the factory to be debarked and bucked. The whole-tree system omits processing at the felling site; topping and delimbing are done in a central processing yard, and debarking and bucking are performed either there or at the factory. In general, the shortwood system has the widest application. Marking of trees is done with a branding hammer or paint. Felling is commonly accomplished by chain saw; ax and handsaw are seldom used today. The standard technique for felling is to make an angular front cut, or undercut, on the side of the tree in the chosen direction of felling and then to saw a back cut so that the narrow strip of wood left between undercut and back cut breaks when the tree falls. The chain saw is also used for delimbing and bucking, and debarking is sometimes done in the forest by ax or spud (a combination of spade and chisel). In various forests of the world, animals such as horses, mules, oxen, and elephants are employed for skidding (dragging) the wood from the felling site to a concentration yard. In contrast to the labor intensiveness of such traditional harvesting, a great variety of machines are available for all the above operations. Felling machines (fellers) are equipped with shears, chain saws, or circular saws; they are usually employed on small-diameter trees (e.g., for pulpwood), but larger machines are available for trees up to about 50 cm (20 inches) in diameter. Some machines are specialized to perform separate operations such as delimbing or debarking, whereas others carry out combined operations. For example, feller-bunchers fell and pile (bunch) trees. Harvesters combine felling, delimbing, and bucking; the logs are then loaded on forwarders for transport to a landing. Processors top, delimb, and bunch felled trees and pile the logs after the trees are bucked. Feller-skidders combine felling and skidding operations. Chippers can chip whole trees and load the chips into trucks or trailers. Also available are portable debarkers and portable machines called Tree Monkeys that can delimb (actually prune) and debark standing trees. Mechanical transportation is by wheeled or crawler (tracked) equipment, by cable systems, and seldom by helicopter or giant balloon. In cable systems (also called Highland, or Skyline, Systems) the logs are transported while lifted partially or wholly off the ground. In the northwestern United States tall trees 80–100 meters (about 250–300 feet) high, their tops cut off by a climbing logger, are employed as masts, or spar trees, to attach the cables. Pulpwood logs are sometimes bundled at the felling site and transported on trailers to storage yards or directly to pulp mills. Loading is generally mechanized. If an operation, such as bucking or debarking, is not completed in the forest, it is performed in the factory by stationary machines or, in the case of debarking, by water jets. Mechanization of harvesting is the trend, but regions of small annual yield and unfavorable topography restrict the potential of expensive machines, and in many countries human and animal labor is still commonly used. High mechanization in combination with extensive clear-cutting has very adverse environmental consequences. (For a detailed discussion of the management and conservation of forested land, see Forestry.) Utilization Of Wood:- this section discusses the products of primary mechanical processing of wood – roundwood products (e.g., poles and pilings), sawn wood (primarily lumber), veneer, plywood and laminated wood, particleboard, fiberboard, and pulp and paper. It also discusses treatments (drying and preservation) that have been devised to improve the performance of wood in use and the chemical products that are derived or extracted from wood. Some products of primary manufacture, such as poles and posts, are used directly, but many constitute intermediate materials that by further processing are turned into secondary products such as furniture, building structures and components, containers, and musical instruments. Primary Products:- Roundwood Products:- poles, posts, and certain mine timbers are products in round form. Poles are used in supporting telegraph and telephone lines and as pilings (foundations for wharves and buildings); posts are used in fences, highway guards, and various supports. As a rule, roundwood products are subjected to preservative treatment. The bark is removed in the forest or factory, and poles and posts are further processed by shaving to remove surface irregularities, by framing (boring holes and making necessary cuts), and by incising (punching slitlike depressions to facilitate the entrance of preservative chemicals). Sawn Wood:- lumber is the main sawn wood product. Lumber of large dimensions – more than about 10 cm (4 inches) in width and thickness – and suitable for heavy constructions is called Timber. This loose term, however, is

also applied to wood of a forest stand and to products of round form. Another important product made by sawing, and sometimes by hewing, is railroad ties. Although this section concentrates on lumber, production of other sawn products (such as parquet flooring) is similar in principle. Production At The Sawmill:- lumber is the product of the sawmill and ordinarily is not manufactured further than by sawing. It is produced in varying sizes, the usual approximate dimensions being 2–10 cm (about 3/4–4 inches) in thickness, 8 cm (about 3 inches) and greater in width, and 2–6 meters (about 6–20 feet) in length. The conversion of logs to lumber involves breaking them down into boards of various thicknesses, resawing, ripping (edging), and crosscutting. The organization of production varies in its detail in different manufacturing plants but can be described in general terms. After transport from the forest, logs are stored in water, usually a pond or river, or in a ground storage yard. Each log enters the mill on a conveyor; in large operations it is mechanically debarked, and in some it is crosscut to length. Supported on a carriage, it is brought to a headsaw (the first saw), which is one of three types:- band saw, frame (gang) saw, or circular saw. A band saw consists of an endless band of steel, equipped with teeth usually on one edge only, that moves around two wheels – one powered and the other free-running. Frame saws commonly consist of a reciprocating frame in which a number of saw blades are mounted parallel to each other at predetermined lateral distances. A circular saw consists of a circular blade having teeth on its periphery and mounted on a shaft. Band and frame saws have relatively thin blades and are therefore less wasteful than circular saws. Band and circular saws permit changing board thickness and turning the log after each cut; therefore, breakdown is more advantageous in terms of yield and grade. Frame saws require that logs be sorted according to diameter, because the position of the blades (and thus the thickness of the lumber) is determined accordingly. Frame saws are being largely replaced by band saws. Machines for other operations can be sited behind the headsaw in the production flow; they include resaws (band or circular saws), edgers (band or circular saws, or chippers equipped with knives), and trimmers (circular saws for transverse cutting). Breakdown is accomplished in one or more operations. For example, a combination of circular and frame saws, or two frame saws in series, may be used. The first saw removes slabs (the outside pieces cut from a log) and, in certain cases, some boards. The piece produced is then turned 90° and introduced into the second saw, which converts it into boards (cant sawing). The second operation may be considered resawing; in general, resawing consists of either dividing thick boards into thinner ones or producing boards from slabs. Ripping, or edging, is the removal of wane (edge areas with bark or some missing wood) from the sides of boards, frequently done by passing the board through a machine that has two small circular saw blades mounted on a shaft; one blade is stationary and the other can be moved sideways to set board width. Edging can also be done by chipping in a simultaneous sawing and chipping operation, with the chips directed to pulp, fiberboard, or particleboard manufacture. (Some valuable furniture woods are not edged in the sawmill.) Finally, certain boards are crosscut with trimmers to square their ends and remove defects. Other examples of combinations of machines used for breakdown include two band saws (used as headsaw and resaw), followed by edger and trimmer, or a series of double band saws with chipping edgers. In some sawmills (and other wood-using industries) computers are employed to regulate positioning of logs and other operations. Yield And Grading:- the yield of lumber in a sawmill (lumber volume compared with roundwood input) varies widely, from about 30 to 70 percent, depending on the types of machines used, the diameter of logs (the larger the diameter, the higher the yield), and the quality of wood (the more defects, the lower the yield). The rest is changed to sawdust, slabs, trimmings, or chips. Residues that cannot be turned into products (usually including bark) are burned to produce energy. It should be noted that, if the lumber is to be marketed as planed (dressed), it is sawed ‘oversize’ in thickness to compensate for subsequent shrinkage and planing. After production the lumber may be treated with a preservative chemical to prevent attack by fungi and insects and is measured (classified according to dimensions), graded, and piled to dry. Grading of lumber is usually visual and based on defects. The grading rules for softwood lumber differ from those for hardwoods. Softwood grading is based on the kind, number, and size of defects; it does not take into account the further processing of the wood into final products. Most structural lumber is graded this way. Hardwood grading is based on the proportion of a board that is usable in smaller clear pieces (‘units’) and requires only that one surface be clear. Such grading is made on the assumption that the lumber will be cut into smaller pieces for the manufacture of furniture or parts of other woodwork. (The relationship of wood’s strength to grading is discussed in the section Mechanical Properties.) Veneer:- veneer is a thin sheet of wood of uniform thickness – commonly 0.5–1.0 mm (about 0.02–0.04 inch) and sometimes as much as 10 mm (about 0.4 inch). According to the method of production, it is classified as rotary-cut (cut on a lathe by rotating a log against a knife blade in a peeling operation), sliced (cut with a knife blade sheet by sheet from a log section, or flitch), or sawn (produced with a special tapered saw). More than 90 percent of all veneer is rotary-cut, but figured woods producing veneer for furniture and other decorative purposes are sliced. Sawn veneer is seldom produced, because it is a wasteful operation. Logs of harder species of wood, intended for rotary-cut or sliced veneer, are first softened by submersion in hot water or treatment with steam. After production, the veneer is passed through specialized dryers, usually prefabricated metallic chambers where temperature, air circulation, and speed of transport are controlled. Rotary-cut veneer is ‘clipped’, either before drying or afterward (when the continuous sheet goes directly to a dryer), by a guillotine-type knife to remove defects and produce individual sheets of acceptable size for the intended use. In some modern factories all operations, from handling the logs (bolts) to cutting, clipping, and drying, are automated by use of computers. Veneers are used primarily for plywood and furniture, but they are also used in toys, various containers, matches, battery separations, and other products. The yield of veneer can be less than 50 percent of the original roundwood volume, but veneer sheets, especially decorative ones, are much more valuable than lumber. Plywood And Laminated Wood:- plywood and laminated wood are both made of layers (laminae) of wood glued together. The basic difference is that in plywood the grain of alternate layers is crossed, in general at right angles, whereas in laminated wood it is parallel. The development of these products (as well as particleboard, described in the next section) was made possible by the production of improved adhesives – especially synthetic resins – in the 1930s and ’40s. Plywood:- plywood is a panel product manufactured by gluing one or more veneers to both sides of a central veneer layer or a lumber-strip core. Most plywood is all-veneer; lumber-core plywood is produced only in small quantities. Lumber cores are made by the lateral gluing of strips of wood. In both plywood products, the species, thickness, and grain direction of each layer are matched with those of its counterpart on the other side of the central layer. Consequently, the total number of layers is usually odd (three, five, or more), the exception being when the central veneer layer consists of two sheets glued together with their grains parallel. After the glue is spread, the panels are assembled and brought for pressing, usually in large, multistoried hot presses, where loading is automatic. Adhesives are thermosetting synthetic resins – phenol-formaldehyde for exterior-use plywood and urea-formaldehyde for interior-use plywood. Phenol-formaldehyde resin can produce joints more durable than the natural wood itself – highly resistant to weather, microorganisms, cold water, hot water, boiling water, seawater (‘marine’ plywood), steam, and dry heat. After pressing, the panels are stacked to cool and then are sanded, graded, and stored. Plywood ranges in thickness from 3 mm (about 0.12 inch) for all-veneer to 30 mm (1.2 inches) for lumber-core. Plywood has many advantages over natural wood; among them are dimensional stability (the primary advantage), uniformity of strength, resistance to splitting, panel form, and decorative value. These characteristics make it adaptable to various uses. Plywood (and the panel products particleboard and fiberboard) serve in building construction, including walls, floors, roofs, and doors; exterior siding and interior finishing (e.g., wall paneling); furniture; shelving; shipbuilding; automobile manufacture; refrigeration cars; toys; concrete formwork; and many other applications. Special types combine decorative value with thermal- and sound-insulating properties. In addition to being made into flat panels, plywood is manufactured in curved form (molded plywood), which is used for boats, furniture, and other products. Molded plywood is made by bending and gluing veneer sheets in one operation; the process employs curved forms in a press or fluid pressure applied with a flexible ‘bag’ or ‘blanket’

of impermeable material. Some panels of special construction are overlaid with aluminum or reinforced plastics; others are made with hollow cores (parallel or crossed wooden strips, planer shavings, undulating veneer, honeycombed paperboard, or foamed plastic) or cores of particleboard or fiberboard. Many of these products are not plywood by definition, because they lack the characteristic crossing of wood grain in alternate layers. Laminated Wood:- laminated wood is usually built by the parallel gluing of lumber boards in a variety of sizes and shapes according to intended use. The main products are load-carrying members, such as beams and arches. Parallel-glued veneers are sometimes used to produce specialized items (for example, furniture, sporting goods, and novelties). Laminated wood possesses several advantages over solid wood. It can be used to fabricate large members that are impossible to make from solid wood. The individual boards used in laminated wood, because of their relative thinness, can be properly dried without checking (cracking), and defects, such as knots, can be removed. Structures can be designed with laminated wood on the basis of required strength, and wood of low grade can be positioned accordingly. In addition, because laminated wood is glued, wood of small dimensions can be used, thus reducing waste. Particleboard:- particleboard, another panel product, is manufactured of particles of wood glued together. Particles are flakes or flakelike forms such as wafers and strands, planer shavings, slivers (or splinters), and fines produced from wood by cutting, breaking, or friction. Sources of particles include residues from sawmills (including sawdust) and other wood-using industries, small-diameter roundwood, defective logs, and harvesting residues. Bark is tolerated in limited amounts, and debarking is not necessary if the bark is thin and the particles are placed in the interior of the panel. Particle production or delivery to the factory is followed by screening, drying, classification of particles, mixing with resin adhesive and such additives as water repellents and preservatives, board formation (either in batches or in a continuous process), and pressing. Particleboard is made in several forms – single-layer, in which particle size is practically homogeneous throughout; three-layer, in which particle size is different in core and surface layers; and graded, in which there is a gradual, symmetrical reduction of particle size from the centre of a board to its surface layers. Particle grain is usually parallel to the surfaces, and panels are produced as separate boards, as in plywood manufacture. Perpendicular arrangement of particle grain exists only in so-called extruded boards, made from a continuous supply of particles and simultaneous pressing; the continuous product is sectioned to desired lengths as it exits a special press. Variation in such characteristics as particle morphology and arrangement, method of production, board thickness (2–40 mm [about 0.08–1.6 inches]), presence of perforations, and type and amount of adhesive allow the production of particleboards with different properties. They are classified as low-density (used for insulation), medium-density, and high-density. Low- and high-density boards are rare. Particleboard is made for interior use (for example, for furniture, paneling, and doors) or for structural purposes (to support loads). Interior-type boards are usually overlaid with veneer or plastic laminate (such as melamine). Two relatively new products, waferboard and oriented strand board (OSB), belong to the structural type. Waferboard is made with large, nearly square flakes, whereas OSB is a three-layer product in which the particles (strands) of surface layers are parallel to the direction of panel production and those of the middle layer are crosswise. Both products are used as nonveneered panels. Strands are also employed in making certain structural, lumber-type products – parallel structural lumber (PSL), laminated strand lumber (LSL), and oriented strand lumber (OSL). PSL, or paralam, is produced from oriented long strands of veneer, LSL from shorter strands, and OSL from strands similar to those in OSB. Another structural product, made of thin lumber and veneer and called Lumber-Veneer-Lumber (LVL), is used to produce a variety of I-beam products in combination with OSB. In addition to being produced in its flat-board form, particleboard is sometimes molded under high pressure and temperature to various shapes. Some forms of particleboard are consolidated with mineral binders, such as cement or gypsum, rather than synthetic resins; the wood in this product is usually in the form of excelsior (long, thin ribbons), although particles also can be used. Fibreboard:- the panel product fiberboard is made of wood fibers. (In the pulp, paper, and fiberboard industry fiber refers to all cells of wood and is not limited to the specific cell type found in hardwoods; see the section Microstructure.) A resin adhesive is not always used in fiberboard manufacture; in some cases the boards are held together by physical forces (hydrogen bonding), the flow of the natural lignin present among the fibers, or interweaving of the fibers. As in the case of particleboard, residues and wood of low quality can be used, and bark is usually tolerated. Production of fiberboard involves reduction of the wood to particles, pulping, sheet (mat) formation, pressing, and finishing treatment. Pulping is mechanical; the main method is the thermomechanical process, in which wood particles are steamed and then reduced to fibers by the action of special mills. Some factories use a so-called explosion (Masonite) process, in which steamed chips are transformed into fibers by the application and sudden release of pressure. Before sheet formation, the pulp is blended with certain materials to improve water resistance, strength, and other properties. Either of two basic processes, dry or wet, is employed in the formation of the fiber mat. In dry (or air) forming, fibers are transported by air, and a synthetic resin is added. In wet forming, the fibers are carried in a water suspension, and a resin adhesive is not used. Because dry forming consumes no water and is less polluting, it is preferred over the wet process. Pressing is considered either wet or dry depending on the moisture content of the fiber mat. The properties of wet-pressed boards are improved by ‘tempering’ treatments (exposure to heat or application of drying oils). The appearance of fiberboard can be enhanced by overlays or patterns of perforations, tiles, simulated leather, and other designs. There are two types of fiberboard, insulation and compressed (represented mainly by hardboard); the distinction is based on density and the method of production. Insulation board is used in construction as insulation and cushioning; hardboard has a wide variety of uses, including furniture, house siding, wall paneling, and concrete forms. A relatively new compressed product is medium-density fiberboard (MDF). MDF is manufactured in a range of thicknesses (6–40 mm [about 0.2–1.6 inches]), usually by the dry process, and it is less dense than hardboard. It can be machined as solid wood and has many uses, including furniture, paneling, and siding. Pulp And Paper:- wood is the main source of pulp and paper. Preliminary production steps are debarking and chipping. Pulping processes are of three principal types:- mechanical, or grinding; chemical, or cooking with added chemicals; and semichemical, or a combination of heat or chemical pretreatment with subsequent mechanical reduction to fibres. The yield of pulp ranges from about 40 percent by chemical methods to 95 percent by mechanical ones. Chemical processes are based on either acids (i.e., sulfite pulping) or alkalies (alkaline pulping, including soda and sulfate (kraft) processes). The pulp so produced is washed, screened, thickened by the removal of most of the water, and bleached. Paper manufacture involves beating or refining (defibring) the pulp, sizing and filling or loading (introducing various additives), and running the pulp into the proper machine (see Papermaking). Treatments:- Drying:- lumber and other wood products usually contain considerable moisture after their production, and drying is essential to prepare them for further use. Proper drying reduces the magnitude of dimensional changes due to shrinkage and swelling, protects wood from microorganisms, reduces weight and transportation costs, better prepares wood for most finishing and preservation methods, and increases its strength. Drying is accomplished in yards in the open air or in closed kilns. Other methods of drying also exist. The object of open-air drying is to reduce the moisture content of wood to the lowest value permitted by weather conditions in the shortest time without producing defects. The level of moisture reduction attainable depends on temperature and relative humidity. Wind reduces the time required, but direct contact with rain and snow hinders the progress of drying. The air-drying yard is located close to the lumber plant, on a dry site where air movement is not obstructed by tall trees or buildings. The ground surface is kept free of debris and vegetation, and alleys are provided for working areas and air movement. The bottom row of lumber is kept about 40 cm (16 inches) above the ground, with space for air circulation provided as layers are added. When piling is done mechanically, the lumber is first prepiled in packages. A suitable roof, usually made of low-grade lumber or panel material, is placed on top of each pile. The time required to air-dry from green condition to 20 percent moisture content varies from about 20 to 300 days for wood 2.5 cm (1 inch) thick, depending on species, place, and time of year. Air drying can be accelerated by means of fans, sometimes

in combination with low-temperature heating. When this technique is used, the piled lumber is placed in sheds. In the case of beech, walnut, and some other woods, steaming is employed before air drying. This practice reduces drying time by increasing the rate of drying and at the same time darkens the wood, making it more desirable for use in furniture. Kiln drying is conducted in a closed chamber, under artificially induced and controlled conditions of temperature, relative humidity, and air circulation. This method permits much faster reduction of moisture content to levels that are independent of weather conditions. In wood 2.5 cm (1 inch) thick, moisture is reduced from 20 to 6 percent in 2–15 days and from green condition to 6 percent in 2–50 days. The source of heat is usually steam circulating in pipe coils. Relative humidity is controlled by allowing steam to enter the chamber through a perforated pipe; such control regulates the exit of moisture from the wood and so avoids defects such as splitting and warping. For satisfactory results, air movement is needed to carry the heat from its source to the lumber and to carry away the evaporated moisture. Air circulation is produced by fans located within the kiln and sometimes by blowers placed outside. Regulation of conditions is usually automatic, and drying is accomplished by the use of drying schedules that have been derived experimentally for various species and thicknesses of wood. Schedules start with high humidity and low temperature and end inversely with high temperature and low humidity. As moisture removal proceeds, samples of wood are removed periodically and weighed. Sometimes moisture content is read from outside the kiln by way of samples wired to moisture meters. Kiln drying normally involves temperatures in the range of 40–75 °C (about 100–170 °F). Such temperatures are high enough to kill insects – another advantage of kiln drying over air drying. In addition, wood can be dried by special methods that include solar drying (use of greenhouse-type dryers or those equipped with solar collectors), high-temperature drying, dehumidification kiln drying (in which the evaporated wood moisture is condensed and the latent heat recaptured and used for additional evaporation), and boiling in oils (a combination of drying and preservation, usually with creosote). Some other methods, such as drying with applied chemicals (salt seasoning), organic vapours (e.g., xylene), a solvent (specifically acetone), high-frequency electricity, centrifuging, infrared radiation, a vacuum, and microwaves, are inhibitively expensive and therefore are not commercially applicable. Preservation:- wood can be protected from the action of destructive agents such as fungi, insects, and marine organisms (see the section Degradation) by impregnation with toxic chemicals. Preservatives used against such organisms are of three groups: oils, oil-soluble chemicals, and water-soluble chemicals. Oils are exemplified by coal tar Creosote (i.e. creosote obtained from bituminous coal). Creosote is very effective for treatment of railroad ties, poles, and pilings and can extend their useful life severalfold. Creosote-treated wood, however, resists painting and gluing and can exude the preservative, which is a pollutant. The main representative of oil-soluble preservatives is pentachlorophenol (see Chlorophenol). When used with a suitable organic solvent, pentachlorophenol has advantages over creosote in that the preserved wood is kept clean and can be painted or glued. The compound is also polluting, however, and its use is banned in several countries, including the United States. Water-soluble preservatives are salt solutions of various inorganic chemicals such as copper, chromium, arsenic, and mercury. Their main disadvantage is that they leach from the wood under damp conditions, but this can be overcome by the formation of insoluble compounds in the wood – for example, with preservatives prepared from a combination of copper, chromium, and arsenic (CCA). Wood can be made resistant to fire with chemical retardants. Fire retardants are water-soluble and not toxic. They contain silica and other chemical compounds and act by creating a barrier (charred wood or foam) to the spread of flame or by generating noncombustible gases. Wood to be treated with preservative is prepared by removing bark (as a rule) and excess moisture (to below the fiber saturation point; see the section Hygroscopicity), machining to final shape, and drilling holes or making incisions to facilitate entrance of the preservative. Preservatives can be applied by brushing, spraying, dipping, steeping, sequential immersion in hot and cold baths, and diffusion (applied to green wood), but impregnation under pressure in closed tanks or cylinders is the most efficient method. (Bark is retained in treating by hydrostatic pressure.) Factors that affect penetration of preservatives include species and structure of wood, density, moisture content, direction of grain, preparation of wood for treatment, type of preservative, and the treatment process used. Chemical Products:- wood is a source of a wide variety of chemical products. In theory, at least, the number and kind of possible chemical products are equal to those of the products made from petroleum. In practice, however, the chemical products of wood fall into two general groups:- products of the chemical processing of wood or its components and wood extractives and their derivatives. Products Of Chemical Processing:- products of chemical processing, made by chemical modification of wood and wood components, include pulp and paper (if pulp is produced by chemical or semichemical methods; see the section Pulp And Paper), products of cellulose and other molecular constituents of wood (see the section Ultrastructure And Chemical Composition), and products of pyrolysis, gasification, and hydrolysis. Cellulose is produced from chemical pulp after complete removal of the other constituents (lignin, hemicelluloses, and extractives). It is used in the production of synthetic fibers (e.g., rayon), cellophane, plastics, varnishes, lacquers, inks, adhesives, photographic films, magnetic tapes, artificial sponges, explosives, and many other products. The uses for lignin continue to grow, although great quantities are wasted or burned as fuel because its molecular structure and chemistry are not completely known. Lignin is used in making vanillin (synthetic vanilla), pharmaceuticals, plastics, solvents, ceramics, adhesives, synthetic rubber, foam materials, insecticides, fungicides, herbicides, soil conditioners, and other products. Pyrolysis involves heating wood at temperatures as high as 1 000 °C (about 1 800 °F) in the absence of air. It includes carbonization, destructive distillation, and liquefaction. Carbonization is carried out either by the traditional method of building cone-shaped stacks of wood that are then covered with earth and fired or or by heating the wood in metallic kilns. This process yields charcoal, which is used as a fuel, as activated (highly porous and absorptive) charcoal, and in dynamite, fireworks, and pharmaceuticals. In destructive distillation the wood is heated by a stepwise raising of temperature in closed ceramic or stainless-steel chambers. Products of destructive distillation include tar and pitch (which, in turn, are used in the manufacture of such products as wood creosote, plastics, and insulating materials), acetic acid (as wood vinegar), methanol (also called Wood Alcohol), acetone, and phenols. Liquefaction is conducted in tanks and produces pyrolytic oil, a liquid fuel. Gasification of wood, a high-temperature process conducted with limited and controlled air or oxygen, produces wood gas – mainly methane, carbon monoxide, and hydrogen – which can be used as a fuel or to produce methanol and other organic compounds. A chemical process called Hydrolysis – more specifically, saccharification, or breakdown into simple sugars by the action of acids – yields sugars that are used in the manufacture of such products as animal feeds, ethanol (ethyl alcohol), plastics, and glycerol (glycerin). Extractives:- the main wood extractives of practical importance are pine resin and tannins. Resin is produced inside living trees by epithelial cells (specialized parenchyma) lining the resin canals (see the section Rays And Resin Canals), and it exits when the trees are wounded. In resin harvesting, the trunk is usually debarked systematically in strips, and resin is collected in plastic bags. Not all pine species produce significant amounts of resin to justify harvesting; the main harvestable species occur in Mediterranean countries, the United States, China, India, Pakistan, Indonesia, and the Philippines. Resin produced as above is called Oleoresin and is an exudate rather than an extractive; other examples of tree exudates are sugar maple sap, which is concentrated to make maple syrup, and latex, which can be made into rubber. Resin, however, can also be obtained as an extractive by distillation of wood or as a by-product of pulping (by the alkaline process); these processes give the components of resin:- rosin (colophony) and turpentine. Production of resin by tapping living trees is a declining operation, but pulping offers the alternative of deriving the components of resin even from such species as Scotch pine and Douglas fir, which do not produce appreciable amounts of resin by tapping. Chemically, rosin and turpentine are terpenoid acids and monoterpenes, respectively. Rosin dissolved in turpentine constitutes resin. Turpentine is volatile, and, when it separates from resin, solid rosin remains. Rosin is used in the production of paper (as sizing to control water absorption), soap, synthetic resins, synthetic rubber, paints, and varnishes. Turpentine is employed as an industrial solvent and is increasingly used as a

raw material for the manufacture of adhesives, synthetic vitamins, perfumes, and flavorings. Tannins are phenolic substances contained in wood, bark, and other plant materials. Among the major sources are oak, chestnut, quebracho (Schinopsis Species), wattle (Acacia Species), pine, and hemlock. Tannins are extracted with water or organic chemicals. There are two types – hydrolyzable and condensed. Hydrolyzable tannins are usually mixtures of simple phenols, and their decomposition often occurs simply in warm water, with which they react to form other substances. Condensed tannins are mainly condensation products of various types and form insoluble precipitates. Tannins are used in the tanning of leather, preservation of fishing nets, and manufacture of inks, plastics, and adhesives. Condensed tannins, when reacted with formaldehyde, form adhesives that can replace synthetic resins in the production of plywood and particleboard. Wood's content of extractives influences its utilization both positively and negatively. Extractives impart durability to wood, confer color and odor, and affect painting, varnishing, and glue adhesion. They can also interfere with pulp and paper manufacture by causing pitch trouble (contamination with resin or other extractives) and bleaching problems and by increasing the consumption of chemicals, and they can cause health problems (e.g., bronchitis, dermatitis, and other irritant or allergic reactions in workers in wood-processing industries). Many tropical woods are rich in extractives. Wood As A Material:- as is indicated in the preceding sections of this article, the total number of products made from wood is enormous – as high as 10 000, by some estimates. Such wide application is made possible by the versatility of wood and its many desirable qualities, such as high strength for its weight, workability, and aesthetic appeal. But wood also has certain undesirable characteristics. It can burn and decay, for instance. It is hygroscopic (moisture-absorbing), and in gaining or losing moisture it changes dimensions. As a biological product, moreover, wood is variable in quality. In order to reduce the effects of these inherent undesirable properties and also to make proper use of the many existing wood-producing plant species and produce the best possible wood quality in the forest, it is essential to understand the complex nature of this material. Such an understanding can be gained by a study of the structure, chemical composition, and properties of wood. Structure And Composition:- Macrostructure:- examination of a stump or the transverse section (cross section) of a tree trunk shows three parts – pith, wood, and bark. Between the wood and bark is the cambium, although this thin layer of tissue is indistinguishable with the naked eye or a hand lens. Pith is normally small and located at the centre of the transverse section. Wood is marked by the presence of concentric layers known as growth rings or annual rings. In temperate regions one growth ring is normally produced during each season of growth, but false rings may also be present, and in some cases certain rings may be locally discontinuous. In tropical regions growth rings are formed in response to wet and dry periods or other, incompletely understood factors. For these reasons the term Growth Ring is preferred over annual ring. Barring the above deviations, however, the number of growth rings, as counted in a transverse section near the ground, can be used to find the age of a tree. Bark surrounds the central cylinder of wood. It is differentiated into inner bark, which is relatively light-coloured and conducts synthesized food from the leaves downward, and outer bark, which is dark-colored and dry, with an insulating function (see the section Bark And Bark Products). Earlywood, Latewood, And Pores:- growth rings are visible because of macroscopic differences in structure between earlywood and latewood, i.e. wood produced in the spring and later in a season of growth. The two kinds of wood may differ in density, color, or other characteristics. In coniferous species, latewood is darker in color and has a greater density. In the wood of broad-leaved species, the presence of pores is a characteristic macroscopic feature of growth rings. According to the relative size and distribution of pores, woods of broad-leaved species are further classified into ring-porous and diffuse-porous types. In ring-porous woods, such as oak and chestnut, the pores of earlywood are large compared with those of latewood. In diffuse-porous woods, such as basswood and poplar, all pores are about the same size and evenly distributed. Heartwood And Sapwood:- in many tree species the central part of the transverse section of trunk is darker in color than the peripheral wood. This inner part is called Heartwood, and the surrounding zone sapwood. Sapwood comprises the newer growth rings and participates in the life processes of a tree. As the diameter of the tree increases with growth, the older, inner layers no longer take part in the transport and storage of water and nutrients and become heartwood. After a certain age, heartwood exists in all species, even though there may be no color change. Rays And Resin Canals:- a transverse section of trunk also shows linear features called rays radiating from pith to bark and ranging in width from very distinct, as in oak, to indistinct to the naked eye, as in pine and poplar. Certain softwoods, such as pine, spruce, larch, and Douglas fir, possess resin canals. In a transverse section examined with the naked eye or a hand lens, resin canals appear as small dark or whitish dots. Radial And Tangential Sections:- sections of trunk that are made perpendicular to the transverse section present a different picture of macroscopic features. Radial sections – that is, longitudinal sections passing through the pith – are characterized by parallel arrangement of growth rings and the appearance of rays in the form of streaks called Flecks (in species with conspicuous rays, such as Oak). In tangential sections – longitudinal sections cut at a tangent to the rings – growth-ring arrangement takes the form of a series of arches or parabolas. Microstructure:- the microscope reveals that wood is composed of minute units called Cells. According to estimates, 1 cubic metre (about 35 cubic feet) of spruce wood contains 350 billion–500 billion cells. The basic cell types are called Tracheids, vessel members, fibers, and parenchyma. Softwoods are made of tracheids and parenchyma, and hardwoods of vessel members, fibers, and parenchyma. A few hardwood species contain tracheids, but such instances are rare. Tracheids are considered a primitive cell type that gave rise, through evolution, to both vessel members and fibers. The wood of softwood species is composed predominantly of tracheids. These cells are mainly longitudinal, or axial – their long axis runs parallel to the axis of the trunk (vertical in the standing tree). Axial parenchyma is present in certain softwood species, but radial parenchyma is always present and constitutes the rays, sometimes together with radial tracheids. In hardwoods the proportion of constituent cell types – vessel members, fibers, and parenchyma – depends mainly on species. Vessel members and fibers are always present and axially oriented; axial parenchyma is seldom absent. Rays in hardwoods are made entirely of radial parenchyma cells. Axial tracheids of softwoods are the longest cells of wood; they average 3–5 mm (about 0.12–0.2 inch) in length and are seldom more than 1 cm (about 0.4 inch). Fibers are shorter, usually 1–2 mm (0.04–0.08 inch). Vessel members vary widely in length, from 0.2 to 1.3 mm (0.008 to 0.05 inch), mainly between earlywood and latewood of ring-porous hardwoods. Diameters range, in general, from about 0.01 to 0.5 mm (0.000 4 to 0.02 inch); the narrowest are fibers, and the largest are vessel members of earlywood. All the above cells are tubelike. Tracheids and fibers have closed ends. Vessel members have ends wholly or partly open; in wood tissue, vessel members are connected end to end to form vertical pipelike stacks (vessels) of indeterminate length. The characteristic pores visible in the transverse section of hardwoods are actually vessel members. Axial tracheids in softwood species and vessel members in hardwood species are the principal water-conducting cells. Although fibers in hardwood trees may also participate in conduction, their main function is to provide mechanical support. Parenchyma cells are bricklike in shape and very small, with a length of 0.1–0.2 mm (about 0.004–0.008 inch) and a width of 0.01–0.05 mm (0.000 4–0.002 inch). They are mainly concerned with the storage of food and its transport (horizontally in the case of radial parenchyma). Radial tracheids somewhat resemble parenchyma in shape and length, although their shape can be more irregular. Almost all wood cells, even in living trees, are dead – that is, devoid of protoplasm and nucleus. The exceptions are a few layers of young cells produced during current growth by the cambium and by parenchyma cells located in sapwood. Cambium derives by differentiation of cells of the apical meristem, generative tissue that comprises the growing tips (stem, branches, and roots) of the plant and is responsible for primary growth, or growth in length. Cambium is considered to be lateral meristem; by producing new wood and bark, it carries out secondary growth, or growth in diameter. Microscopic observation of thin transverse sections shows the cambium to be a one-cell-wide layer of dividing initials and of a small but varying number of undifferentiated derivative cells, which together form the cambial zone. Further division and differentiation of the derivative cells gives rise to wood and bark. Observed

microscopically, the cells of wood appear to be composed of cell wall and cell cavity; in dead cells the cavity is empty. Gaps of various shapes, called pits, are often seen in great numbers in the cell walls. Pits serve as passages of communication between neighbouring cells and come in pairs – one in each of the adjoining cell walls – separated by a membrane. Other microscopic features are tyloses, plugs comprising various plant materials that obstruct the vessel members of hardwoods and that form mainly when sapwood is transformed to heartwood. Under the microscope, the resin canals of softwoods are revealed to be not cells but tubular spaces between cells, lined with specialized parenchyma; they also are plugged in heartwood. Ultrastructure And Chemical Composition:- polarization microscopy, X rays, electron microscopy, and other techniques provide information regarding the structure of cell walls and other features hidden to light microscopes. Cell walls are crystalline. They are composed of a thin, outer primary wall and a much thicker secondary wall, the latter made of three layers. The smallest visible building units of cell walls are the microfibrils, which appear stringlike under the electron microscope, about 10–30 nanometers (billionths of a meter) in diameter and of indeterminate length. The orientation and weaving of microfibrils varies; this makes possible the distinction of three layers (called S_1, S_2, and S_3), with the microfibrils having an axial direction in the middle (S_2) layer and a generally transverse direction in the outer layers. The inner surface of cell walls is covered by a warty layer. Pit membranes vary in structure; in softwood tracheids they possess a central thickening (torus), whereas in other cell types they are made of randomly arranged microfibrils. Chainlike cellulose molecules, which constitute the microfibrils, provide the skeleton of wood. Noncellulosic constituents (hemicelluloses, lignin, and pectic substances) are located among microfibrils but do not form microfibrils. Cellulose is mostly concentrated in the secondary cell wall, and lignin in the middle lamella, the layer that separates the walls of adjacent cells. Quantitatively, cellulose and the other chemical constituents are contained in wood in the following proportions (in percentage of the oven-dry weight of wood): cellulose 40–50 percent (about the same in softwoods and hardwoods), hemicelluloses 20 percent in softwoods and 15–35 percent in hardwoods, lignin 25–35 percent in softwoods and 17–25 percent in hardwoods, and pectic substances in very small proportion. In addition, wood contains extractives (gums, fats, resins, waxes, sugars, oils, starches, alkaloids, and tannins) in various amounts (usually 1–10 percent but sometimes 30 percent or more). Extractives are not structural components but inclusions in cell cavities and cell walls; they can be removed without changing the wood structure (see the section Extractives). Variation Of Structure And Defects:- because of differences in cellular composition and arrangement, the structure of wood varies among species. This variation influences appearance and properties and makes for a wide choice of woods for different uses, and it provides the basis for wood identification. Variation also exists among trees of the same species (because of environmental and genetic influences) and within a single tree. Characters that vary within a tree are mainly cell length, proportion of latewood, angle of microfibrils, and proportion of cellulose. In most woods, from the pith outward, their values all increase progressively and rapidly until, after a number of growth rings (20 or more), they attain a 'typical' level; in the outer rings (200^{th} and beyond) of very old trees, they decrease again. The atypical wood near the pith is called Juvenile Wood, having been produced in the earliest stages of tree development. Another source of variation is the progressive formation of heartwood from sapwood by deposition of extractives and structural changes. Relatively more important from the practical point of view is variation caused by the presence of defects such as knots, spiral grain, compression and tension wood, shakes, and pitch pockets. Knots are caused by inclusion of dead or living branches. Because branches are indispensable members of a living tree, knots are largely unavoidable, but they can be reduced by silvicultural means, such as spacing of trees and pruning. Spiral grain is the spiral arrangement of cells with respect to the tree axis. Compression and tension wood are structural abnormalities in trees (softwoods and hardwoods, respectively) that are caused to deviate from their normal, vertical position by wind or other forces. Shakes are separations of wood tissue, and pitch pockets (in softwoods with resin canals) are separations filled with resin. Defects, depending on their kind and extent, can adversely affect the appearance, strength, dimensional stability, and other properties of wood. Properties Of Wood:- Sensory Characteristics:- sensory characteristics include color, luster, odor, taste, texture, grain, figure, weight, and hardness of wood. These supplementary macroscopic characteristics are helpful in describing a piece of wood for identification or other purposes. Color covers a wide range – yellow, green, red, brown, black, and nearly pure white woods exist, but most woods are shades of white and brown. Variations may show on a single piece of wood, depending on color differences between heartwood, sapwood, earlywood, latewood, rays, and resin canals. Natural color is subject to change by prolonged exposure to the atmosphere and by bleaching or dyeing. Some woods (for example, black locust, honey locust, and several tropical species) are fluorescent. Natural luster is characteristic of some species (for example, spruce, ash, basswood, and poplar) and more prominent on radial surfaces. Odor and taste are due to volatile substances contained in wood. Although difficult to describe, they are helpful distinguishing characteristics in some cases. The term texture describes the degree of uniformity of appearance of a wood surface, usually transverse. Grain is often used synonymously with texture, as in coarse, fine, or even texture or grain, and also to denote direction of wood elements, whether straight, spiral, or wavy, for example. Grain sometimes is used in place of figure, as in silver grain in oak. The term figure applies to natural designs or patterns of wood surfaces (normally radial or tangential). As sensory characteristics, weight and hardness are included in a diagnostic rather than technical sense – weight as judged by simple hand-lifting and hardness by pressing with the thumbnail. Common temperate-climate woods range in weight from about 300 to 900 kg per cubic meter (about 20 to 55 pounds per cubic foot) in air-dry condition, but lighter and heavier woods exist in the tropics, ranging from 80 to 1 300 kg per cubic meter (5 to 80 pounds per cubic foot) for balsa and lignum vitae, respectively. Density And Specific Gravity:- density is the weight or mass of a unit volume of wood, and specific gravity the ratio of the density of wood to that of water. In the metric system of measurement, density and specific gravity are numerically identical; for example, the average density of the wood of Douglas fir is 0.45 gram per cc, and its specific gravity 0.45, because 1 cc of water weighs 1 gram. (Expressed as weight per unit volume, 1 gram per cc is about 62.4 pounds per cubic foot.) Determination of the density of wood is more difficult than for other materials because wood is hygroscopic (see the section Hygroscopicity); both its weight and volume are greatly influenced by moisture content. In order to obtain comparable figures, weight and volume are determined at specified moisture contents. Standards are oven-dry weight (practically zero moisture content) and either oven-dry or green volume (green referring to moisture content above the fiber saturation point, which averages about 30 percent). Other expressions of density, such as those based on air-dry weight and volume or on weight and volume of green wood, have a certain practical importance, as in shipping wood, but are not accurate. The dry mass of wood in a given volume is determined by density, which is obtained by dividing the oven-dry weight by the volume, either oven-dry or green. Oven-dry volume is difficult to determine, at least by immersion in water, because of wood's hygroscopicity. Oven-dry samples are first immersed in hot molten paraffin, to build a thin protective coating, before being immersed in water. With small wood samples, mercury is sometimes used instead of water; a special apparatus (Breuil Volumeter) is available. For specimens that are regular in shape, volume can be calculated on the basis of their dimensions. In addition, radiation methods are used for direct measurement of density. The density of a sample of wood can be appraised visually by observing the width (thickness) of growth rings and the proportion of latewood. In general, latewood, because of its thicker cell walls and smaller cell cavities, is denser than earlywood, and with increasing ring width its proportion decreases in softwoods and increases in ring-porous hardwoods. Therefore, wider rings indicate lower density in softwoods and higher density in ring-porous hardwoods. In diffuse-porous hardwoods latewood is not clearly distinct, and ring width is not an indication of density. The density of temperate woods varies from about 0.3 to 0.9 gram per cc, but the range worldwide is approximately from 0.2 to 1.2 grams per cc. Differences among species or samples of the same species are due to varying proportions of wood substance and void volume and to content of extractives. The density of wood substance is about 1.5 grams per cc, and practically no differences in this value exist among species.

Density affects the amount of moisture that wood can hold, its shrinkage and swelling, and its mechanical and other properties. In general, density is a measure of the quality of clear wood – that is, wood without defects. Hygroscopicity:- wood can absorb water as a liquid, if in contact with it, or as vapor from the surrounding atmosphere. Although wood can absorb other liquids and gases, water is the most important. Because of its hygroscopicity, wood, either as a part of the living tree or as a material, always contains moisture. (The terms Water and Moisture are used here without distinction.) Moisture affects all wood properties, but it should be noted that only moisture contained in cell walls is important; moisture in the cell cavities merely adds weight. The amount of moisture held in cell walls varies from about 20 to 40 percent, but for practical purposes it is taken to be 30 percent (expressed as percentages of the oven-dry weight of wood). The theoretical point at which cell walls are completely saturated and cell cavities are empty is known as the Fiber Saturation Point. Beyond this point, moisture goes into the cavities, and, when they are completely filled, the maximum moisture content that wood can hold is reached. This maximum, which depends mainly on density, can be very high. For example, a very light wood, such as balsa, can hold as much as 800 percent moisture, pine 250 percent, and beech 120 percent. The moisture content of the wood of living trees varies from about 30 to 300 percent depending on species, position of the wood in the tree, and season of the year. When green wood is exposed to the atmosphere, its moisture content gradually decreases. Moisture in the cell cavities is lost first. In time, moisture content falls to levels ranging (for temperate-zone localities and under shelter) from about 6 to 25 percent (average 12 to 15 percent). Local conditions of air temperature and relative humidity dictate the final moisture level. Species and dimensions of wood have no practical influence on the final moisture level, although refractory species and wood of larger dimensions require more time to reach it. It is important to note, however, that, because of hygroscopicity, the moisture content of air-dry wood does not remain unchanged, even when the wood is kept under shelter. On the contrary, it is subject to continuous change, within certain limits, as a result of changing air temperature and relative humidity. The moisture content of a sample of wood is calculated on the basis of its current and oven-dry weight. It also can be determined directly with portable electric moisture meters, which measure the change of electrical properties of wood as a function of changing moisture content. Hygroscopicity is of primary importance because moisture in wood affects all wood properties. For example, moisture content can increase weight 100 percent or more, with consequent effects on transportation costs. Variation in moisture content causes wood to shrink or swell, altering its dimensions. Resistance to decay and insects is greatly affected. The working, gluing, and finishing of wood and its mechanical, thermal, and acoustic properties are all influenced by moisture content. Also affected are processing operations, such as drying, preservative treatment, and pulping. Shrinkage And Swelling:- wood undergoes dimensional changes when its moisture fluctuates below the fiber saturation point. Loss of moisture results in shrinkage, and gain in swelling. It is characteristic that these dimensional changes are anisotropic – different in axial, radial, and tangential directions. Average values for shrinkage are roughly 0.4 percent, 4 percent, and 8 percent, respectively. Shrinkage in volume averages 12 percent, but large variations are exhibited among species. These values refer to changes from green to oven-dry condition and are expressed in percentage of green dimensions. The differential shrinkage and swelling in different growth directions is attributed mainly to cell wall structure. The difference between axial and the two lateral (radial and tangential) directions can be explained on the basis of respective orientation of microfibrils in the layers of the secondary cell wall, but the reasons for the differences between radial and tangential directions are not well understood. In general, the factors that affect shrinkage and swelling are moisture content, density, content of extractives, mechanical stresses, and abnormalities in wood structure. The amount of shrinkage or swelling that occurs is approximately proportional to the change in moisture content. The higher the density of wood, the greater is its shrinkage and swelling, because denser (heavier) woods contain more moisture in their cell walls. For example, at the same moisture content, say, 15 percent, 1 cubic meter of a wood having a density of 0.8 gram per cc contains 120 kg of water, whereas the same volume of a wood having a density of 0.4 gram per cc contains only 60 kg of water. Extractives reduce shrinkage and swelling because they occupy spaces within cell walls that otherwise could be taken by water. Mechanical stresses (compression or tension) may cause permanent deformation of wood cells, which in turn affects shrinkage and swelling. Finally, abnormal structure results in greater shrinkage longitudinally but less in radial and tangential directions; change in volume remains about the same. Dimensional changes in wood caused by shrinkage and swelling can result in opening or tightening of joints, change of cross-sectional shape, warping, checking (formation of cracks), case-hardening (release of stresses in resawing or other machining, with consequent warping), honeycombing (internal checking), and collapse (distortion of cells, causing a corrugated appearance of the surface of lumber). Thus, the fact that wood shrinks and swells constitutes a great obstacle to its utilization. Several methods are used to improve the dimensional stability of wood. They include mechanical modification (reconstruction into such products as plywood, particleboard, and fiberboard), application of water-repellent coatings (paint or varnish), bulking treatment (maintaining the wood in swollen condition by use of salts, sugars, polyethylene glycol, synthetic resins, or other substances), and other (thermal or chemical) treatments. Except for reconstructing into products and surface coating, however, other methods are experimental or sufficiently expensive to limit their application to specialty items. Coatings do not reduce the quantity of moisture the wood can hold, but they slow the exchange of moisture between wood and atmosphere and, therefore, reduce the magnitude of dimensional changes of the wood in use. Most dimensional problems are caused by the use of wood with excessive moisture content. Instead, at the time of use the wood should have a moisture content at the approximate midpoint of the expected range in a particular location. This practice minimizes moisture content changes and, therefore, the adverse effects of shrinkage and swelling. Mechanical Properties:- the mechanical, or strength, properties of wood are measures of its ability to resist applied forces that might tend to change its shape and size. Resistance to such forces depends on their magnitude and manner of application and to various characteristics of the wood such as moisture content and density. It is important to note that wood has drastically different strength properties parallel to the grain (i.e. in the axial direction) than it does across the grain (in the transverse direction). The mechanical properties of wood include strength in tension and compression (as measured in axial and transverse directions), shear, cleavage, hardness, static bending, and shock (impact bending and toughness). Respective tests determine stresses per unit of loaded area (at the elastic limit and maximum load) and other criteria of strength, such as the modulus of elasticity (a criterion of stiffness), the modulus of rupture (bending strength), and toughness. Tests are normally conducted with small, clear specimens, usually 2 x 2 cm or 2 x 2 inches in cross section. Laboratory data are analyzed to produce working values of stresses, which are made available for use by engineers and architects in designing wooden structures. Tests are sometimes conducted with structural components of actual size. Individual cells (tracheids and fibers) also are subject to testing, since their strength relates to the strength of products – paper, for example. (The testing of materials to ascertain their mechanical, thermal, electrical, and other properties is discussed in the article Materials Testing.) Density is the best index of the strength of clear wood; higher density indicates greater strength. The strength of wood is also influenced by its moisture content when it fluctuates below the fiber saturation point. Generally, a decrease in moisture content is accompanied by an increase in most strength properties. Temperature and duration of loading also affect strength. In general, strength falls as temperature rises. Wood loaded permanently will support a smaller maximum load than that indicated by short-term laboratory tests. The most important strength-reducing factors are wood defects, such as knots, compression and tension wood, and grain deviations. Their adverse effect depends on the kind and extent of the defects, their position, and the manner in which the wood is loaded. Defects constitute the basis for rules by which lumber and other wood products are visually graded. These rules set limits on sizes of defects and other wood characteristics that affect strength – for example, rate of growth, which is expressed as rings per centimeter or inch. Also available are nondestructive grading techniques based on vibration, sound transmission, and mechanics. The latter technique makes use of a correlation

established between the modulus of rupture and the modulus of elasticity. This relationship allows the strength of a wooden member (e.g., a lumber board) to be determined with fair accuracy simply by passing it through a machine that applies a bending force. The less the deflection, the higher the predicted strength. Use of such machines in industry is still limited, however, and the main method remains the visual inspection of wood by skilled graders. Grading leads to more efficient utilization of wood and is essential in order to achieve adequate standards of safety in wooden structures. (Grading of hardwood and softwood lumber is discussed in the section Yield And Grading.) Thermal Properties:- although wood expands and contracts with varying temperature, these dimensional changes are small compared with shrinkage and swelling caused by varying moisture content. In most cases, such temperature-related expansion and contraction are negligible and without practical importance. Only temperatures below 0 °C (32 °F) have the potential to cause surface checks; in living trees, unequal contraction of outer and inner layers may result in frost cracks. Wood exhibits a low thermal conductivity (high heat-insulating capacity) compared with materials such as metals, marble, glass, and concrete. Thermal conductivity is highest in the axial direction and increases with density and moisture content; thus, light, dry woods are better insulators. When exposed to sufficiently high temperatures, wood burns. This property makes wood suitable for heating purposes but is disadvantageous for its technical utilization. The maximum heating value of one kilogram of oven-dry wood averages about 4 500 kilocalories (with a range of 4 100–6 800 kilocalories). In general, softwoods possess a higher heating value than hardwoods, and extractives have an important influence; for example, a kilogram of the oleoresin in pines has a heating value of about 8 500 kilocalories. Moisture reduces the heating value; air-dry wood has about 15 percent less heating value than oven-dry wood. Wood must be raised to a temperature of about 250 °C (about 480 °F) for a spark or flame to ignite it, but at a temperature of about 500 °C (about 930 °F) ignition is spontaneous. The flammability of wood can be reduced by chemical treatment (see the section Preservation). Electric Properties:- oven-dry wood is electrically insulating. As moisture content increases, however, electric conductivity increases such that the behavior of saturated wood (wood with maximum moisture content) approaches that of water. Noteworthy is the spectacular decrease of electric resistance as moisture content increases from zero to the fiber saturation point. Within this range, electric resistance decreases more than a billion times, whereas from the fiber saturation point to maximum moisture content, it decreases no more than about 50 times. Other factors, such as species and density, have little effect on the electric resistance of wood; differences among species are attributed to the chemistry of the extractives. Axial resistance is about half that of the transverse. Resistance increases with decreasing temperature; in oven-dry wood it doubles over a temperature drop of 12.5 °C (22.5 °F). Practical use of the relationship of wood's moisture content to its electric resistance is made in electric moisture meters. Important also are the dielectric, or poor-conductor, properties of wood. These properties – dielectric constant and power factor – assume a practical importance in drying wood with electric current (a theoretical possibility, although not presently a reality), gluing wood with high-frequency electric current, or making electric meters (capacity and radio-frequency power-loss type) for measuring its moisture content. Wood exhibits the piezoelectric effect – that is, electric polarization (the appearance of opposite electric charges on opposite sides of a piece) occurs under mechanical stress. Conversely, when subjected to an electric field, wood exhibits mechanical deformation (changes in size). Acoustic Properties:- wood can produce sound (by direct striking) and can amplify or absorb sound waves originating from other bodies. For these reasons, it is a unique material for musical instruments and other acoustic applications. The pitch of sound produced depends on the frequency of vibration, which is affected by the dimensions, density, moisture content, and modulus of elasticity of the wood. Smaller dimensions, lower moisture content, and higher density and elasticity produce sounds of higher pitch. When sound waves of extrinsic origin strike wood, they are partly absorbed and partly reflected, and the wood is set in vibration. The sound can be amplified, as in violins, guitars, organ pipes, and other musical instruments, or it can be absorbed, as in wooden partitions. Normally, wood absorbs a very small portion of acoustic energy (3–5 percent), but special constructions incorporating empty spaces and porous insulation boards can increase absorption to as high as 90 percent. The speed of sound in wood is about 3 500–5 000 meters (about 11 500–16 400 feet) per second axially and 1 000–1 500 meters (3 300–4 900 feet) per second transversely; the axial value approaches the speed of sound in iron and is 10 times higher than that in air. The velocity of sound in wood is reduced by moisture, which therefore contributes to faster damping of sound. For musical instruments, a preference exists for selected spruce wood, but fir, pine, maple, and tropical woods also are used. Abnormalities such as decay affect acoustic properties; use of this fact is made in nondestructive testing of wood. Degradation:- wood is subject to degradation by bacteria, fungi, insects, marine borers, and climatic, mechanical, chemical, and thermal factors. Degradation can affect wood of living trees, logs, or products, causing changes in appearance, structure, or chemical composition; these changes range from simple discoloration to alterations that render wood completely useless. It should be noted that wood can last for hundreds or thousands of years, as demonstrated, for example, by furniture and other wooden items found in excellent condition in the tombs of ancient Egyptian pharaohs (see Egyptian Art). Wood is degraded or destroyed not with the passage of time but only under the action of external factors. Bacteria are considered to be the cause of discolorations in the form of darker-colored heartwood in living trees (a phenomenon called wetwood in fir and black heartwood in hybrid poplars). The color lightens on exposure to air, and the properties of the wood are not seriously affected. Bacteria also appear during prolonged storage of wood in water, including seawater (e.g., in the case of old sunken ships). Acting in combination with physical and chemical factors related to submersion, they can cause considerable structural changes, leading to breakdown of the wood after exposure to air. Fungi that attack wood are responsible for discoloration (stain) or decay. Blue stain (sap stain) of pines is the most common and serious consequence of attack by stain Fungi. The sapwood becomes bluish or blackish, usually in wedge-shaped patches. Blue stain may appear very quickly in warm weather, sometimes within hours or days after the tree is felled or the green wood is sawed or otherwise processed. The degradation is mainly aesthetic (with a large reduction in the market value of the wood); among properties, only toughness appears to be affected. Decay fungi are, by far, the most important cause of wood loss. Decay is not an innate property of wood, however; it takes place only if the conditions of exposure – namely, moisture, air, and temperature – are suitable for growth and activity of fungi. A moisture content below 20 percent inhibits growth of fungi, as do temperatures lower than 10 °C (50 °F) and higher than 30 °C (86 °F). If wood is kept under water, it cannot be attacked by fungi, because of insufficient oxygen. Toxic extractives contained in wood are a delaying factor and are the main reason for differences in resistance to decay among species, but no wood is immune. Insects, like fungi, can attack the wood of living trees, logs, or products. Once trees are felled, the region between wood and bark (rich in nutrients) is especially vulnerable to insect attack, and for this reason prompt debarking is a protective measure. Insects bore holes and tunnels, and some reduce the interior of wood to dust, leaving only a thin outer layer. Conditions of exposure are the same as for fungi – suitable temperature, moisture, and air. Infested wood can be rendered free of insects at temperatures of 50–60 °C (122–140 °F), by the introduction of insecticides, or by exposure to toxic gases. Surface coatings of paint or varnish also offer some protection, reducing egg-laying sites. Marine borers (certain species of mollusks and crustaceans) attack wooden structures in seawater (wharf pilings, boats, and other submerged wood) and cause severe damage. All wood species are vulnerable, but toxic extractives (as in certain tropical woods) provide some temporary protection. Preservative treatment imparts considerable resistance to these organisms. Wood is also subject to degradation by changing climatic conditions (e.g., by rain and sunlight causing repeated wetting and drying), mechanical stresses (e.g., imposed on railroad ties), and exposure to chemicals (e.g., acids and alkalies). Furthermore, wood is destroyed by fire. Large-dimension timbers (such as glued laminated beams) offer more resistance for a certain time, and fire-retardant treatments are also available. Bark And Bark Products:- bark constitutes, on the average, about 10 percent of the volume of a tree, but the figure varies depending on tree species and age. Although inner and

outer bark can be distinguished by eye, growth rings are not macroscopically distinct. The cellular composition of bark has certain similarities to that of wood but also important differences. Nutrient-conducting cells – sieve cells and sieve tube members (which in wood correspond to the axial tracheids of softwoods and the vessel members of hardwoods, respectively) – are thin-walled and nonlignified, serving usually only one season of growth. Fibers and parenchyma cells also are contained in bark, as well as some specialized cells, and the bark of some softwood species possesses resin canals. Annual growth increments are very thin, and cells are deformed a short distance from the cambium, because of the pressure exercised by the growing wood. Consequently, growth rings are generally difficult to distinguish even under a microscope. Content of cellulose and hemicelluloses is lower in bark than in wood, and the properties of lignin are different. Differences also exist in physical and mechanical properties – density, hygroscopicity, dimensional stability (shrinkage and swelling), and others. Like wood, bark is anisotropic with regard to dimensional stability and strength. Thermal properties and heating value are similar to those of wood. Bark can be used in products such as particleboard and fiberboard, and small amounts are tolerated in semichemical and kraft pulping processes. Bark also has utility as a source of adhesives and other chemicals (e.g., tannins, dyes, and waxes), in environmental protection applications (e.g., absorption of spilled oil, industrial wastes, and sewage effluents), and as a fuel. Nevertheless, differences in the structure and chemical composition of different barks, difficulties of separating bark from wood when in the form of particles, and differences in the properties of inner and outer bark have impeded fuller utilization. Cork is also bark – the outer bark of a western Mediterranean Oak, Quercus suber. It is stripped without adverse effects to the trees and grows again; it can be collected every 8–10 years. Aside from its use as bottle stoppers, cork is incorporated in life preservers and fishing equipment. As a reconstituted material (after chipping, grinding, and gluing), it finds uses as thermal and sound insulation, gaskets, flooring, bulletin boards, and various other products. / развод (или потёк (stain)). , ветви и корни деревьев, кустов и прочих Древесных Растений; . лес (forest). Под Древесиной понимается то же, что Ксилема (Xylem). Иногда древесиной называют только вторичную ксилему.

(2) Wood:- wood and wood products used as fuel, including round wood (cord wood), limb wood, wood chips, bark, sawdust, forest residues, charcoal, pulp waste, and spent pulping liquor. / Древесина:- древесина и древесные продукты используются в качестве топлива, включая .

WOOD AND WASTE = ДРЕСИНА И ОТХОДЫ – Wood And Waste (as used at electric utilities):- wood energy, garbage, bagasse (sugarcane residue), sewerage gas, and other industrial, agricultural, and urban refuse used to generate electricity for distribution.

WOOD AND WOOD–DERIVED FUELS = ДРЕВЕСНЫЕ И ПРОИЗВОДНЫЕ ОТ ДРЕВЕСИНЫ ВИДЫ ТОПЛИВА – Wood and Wood-Derived Fuels:- wood and products derived from wood that are used as fuel, including round wood (cord wood), limb wood, wood chips, bark, sawdust, forest residues, charcoal, paper pellets, railroad ties, utility poles, black liquor, red liquor, sludge wood, spent sulfite liquor, and other wood-based solids and liquids.

WOOD–BURNING STOVE POLLUTION = ЗАГРЯЗНЕНИЕ ОТ ПЕЧЕЙ, СЖИГАЮЩИХ ДРЕВЕСИНУ – Wood-Burning Stove Pollution is the air pollution caused by emissions of particulate matter, carbon monoxide, total suspended particulates, and polycyclic organic matter from wood burning stoves.

WOOD CELLS = ДРЕВЕСНЫЕ КЛЕТКИ – Wood Cells are the basic units comprising wood having open ends and set one above the other so as to form continuous tubes. The openings of the vessels on the surface of a piece of wood are usually referred to as Pores. Also known as Vessels. / обычно относятся к порам. Известны также как Сосуды (Vessels).

WOODCHUCK = САЛАГА (или ДЕРЕВЕНЩИНА, или СУРОК) – Woodchuck is a driver with low job seniority. / водитель с малым трудовым стажем.

WOOD CONVERSION TO BTU = КОНВЕРСИЯ (или ПЕРЕСЧЁТ) ДРЕВЕСИНЫ В БТЕ – Wood Conversion To Btu:- converting cords of wood into a Btu equivalent is an imprecise procedure. The number of cords each household reports having burned is inexact, even with the more precise drawings provided, because the estimate requires the respondent to add up the use of wood over a 12-month period during which wood may have been added to the supply as well as removed. Besides errors of memory inherent in this task, the estimates are subject to problems in definition and perception of what a cord is. The nominal cord as delivered to a suburban residential buyer may differ from the dimensions of the standard cord. This difference is possible because wood is most often cut in lengths that are longer than what makes a third of a cord (16 inches) and shorter than what makes a half cord (24 inches). In other cases, wood is bought or cut in unusual units (for example, pickup-truck load, or trunk load). Finally, volume estimates are difficult to make when the wood is left in a pile instead of being stacked. Other factors that make it difficult to estimate the Btu value of the wood burned is that the amount of empty space between the stacked logs may vary from 12 to 40 percent of the volume. Moisture content may vary from 20 percent in dried wood to 50 percent in green wood. (Moisture reduces the useful Btu output because energy is used in driving off the moisture). Finally, some tree species contain twice the Btu content of species with the lowest Btu value. Generally, hard woods have greater Btu value than soft woods. Wood is converted to Btu at the rate of 20 million Btu per cord, which is a rough average that takes all these factors into account. Also see Btu Conversion Factors.

WOOD DECAY = ГНИЕНИЕ ДРЕВЕСИНЫ (или ЗАГНИВАНИЕ ДРЕВЕСИНЫ, или РАЗЛОЖЕНИЕ ДРЕВЕСИНЫ) – Wood Decay is a deterioration of wood by primarily enzymatic activities of microorganisms. For practical purposes, fungi are the only agents of wood decay. There are other kinds of deterioration, by insects, marine animals, UV, but this is not decay, nor is it quantitatively as important as decay. There are three types of decay:- (i) Brown Rot (color:- ± brown), (ii) Soft Rot (color:- bleached or brown), and (iii) White Rot (color:- ± bleached). / Гниение Древесины – порча древесины посредством преимущественно ферментативной деятельности микроорганизмов. На практике, только лишь грибы являются факторами гниения древесины. Существуют и иные виды порчи, насекомыми, морскими животными, ультрафиолетом (УФ (UV)), но это не относится к гниению, . При гниении или загнивании древесины вследствие воздействия дереворазрушающих грибов возникают гнили – ненормальные по цвету участки древесины с понижением твёрдости. Существуют четыре типа гниения:- (i) Белая Волокнистая Гниль, (ii) Бурая Трещиноватая Гниль, (iii) Заболонная Гниль, и (iv) Пёстрая Ситовая Гниль. Долю гнилой древесины определяют визуально.

WOODEN BARREL = ДЕРЕВЯННАЯ БОЧКА – Wooden Barrel is a packaging made of natural wood, of round cross-section, having convex walls, consisting of staves and heads and fitted with hoops. / Деревянная Бочка – упаковка, произведённая из натуральной древесины, круглого поперечного сечения, имеющая выпуклые стенки, состоящая из бочарных досок и heads и стянутых обручами.

WOOD BRICKS = ДРЕВЕСНЫЕ КИРПИЧИКИ – Wood Bricks:- dried and condensed sawdust and wood chips, formed into a block shape that burns as a highly efficient cord wood alternative. (We like to explain wood bricks as big pellets that can be burned in a wood stove or fireplace.) While bricks are great for wood stoves, they cannot be used in pellet stoves. Also known as Biomass Bricks.

WOODED LAND = ЗЕМЛЯ, ПОКРЫТАЯ ДЕРЕВЬЯМИ – Wooded Land:- the sum of forested and other wooded land.

WOODED LAND AND ASSOCIATED SURFACE WATER = ЗЕМЛЯ, ПОКРЫТАЯ ДЕРЕВЬЯМИ, И АССОЦИИРОВАННАЯ ПОВЕРХНОСТНАЯ ВОДА – Wooded Land And Associated Surface Water:- forested land and other wooded land. Forested land is defined as land under cultivated or non-cultivated stands of trees of a size of more than 0.5 hectares with crown cover of more than 10 per cent and on which trees are able to grow to a height of 5 meters or more at maturity. Other wooded land is defined as land either with a tree crown cover of 5–10 per cent of trees able to reach a minimum height of 5 meters or with a crown cover of more than 10 per cent of trees not able to reach a height of 5 meters.

WOOD ENERGY = ДРЕВЕСНАЯ ЭНЕРГИЯ – Wood Energy:- wood and wood products used as fuel, including round wood (cord wood), limb wood, wood chips, bark, sawdust, forest residues, charcoal, pulp waste, and spent pulping liquor.

WOODEN TICKET = ДЕРЕВЯННЫЙ БИЛЕТ – Wooden Ticket:- a confirmation, sent in violation of MSRB (short for the US Municipal Securities Rulemaking Board) and SEC (short for the US Securities and Exchange Commission) rules, 'confirming' the terms of a transaction with a customer which, in fact, did not take place. An unscrupulous dealer might send these fraudulent confiramtions to unsophisticated investors on the chance that some investors might mistakenly honor the transactions. The practice of sending wooden tickets is a violation of MSRB fair dealing and SEC anti-fraud rules. / 'Деревянная Квитанция' (Wooden Ticket):- неэтичная практика подтверждения исполнения приказа клиенту, когда на самом деле он не выполнен.

WOOD GRAIN = ДРЕВЕСНОЕ ЗЕРНО – (1) Wood Grain is a texture produced by the fibers in wood.

(2) Wood Grain is a fabric defect that consists of fillingwise streaks resembling the irregular appearance of wood grain in lumber. Wood grain is usually caused by strained filling in quilling, the tension being more pronounced near the butt of the quill. / Порок или дефект ткани, который . уточина в .

WOOD GUM = ДРЕВЕСНАЯ РЕЗИНА (или ДРЕВЕСНАЯ КАМЕДЬ, или ДРЕВЕСНАЯ ГУММИ) – Wood Gum:- xylan. Note:- the name 'gum' alone is not actually correct for this wood, but the 'two' woods represented here are the sapwood (sweet gum) and heartwood (red gum) of the same tree. / Древесная Резина – ксилан.

WOOD HULL = ДЕРЕВЯННЫЙ КОРПУС – Wood Hull:- hulls of plywood, molded plywood molded planking, or any other wood fiber in its natural consistency including those of wooden construction that have been 'sheathed' with fiberglass or sheet metal.

WOOD LAMINATE = ДРЕВЕСНЫЙ ЛАМИНАТ (или ДРЕВЕСНЫЙ ЛИСТ, или ДРЕВЕСНЫЙ СЛОИСТЫЙ ПЛАСТИК) – A Wood Laminate is a thin sheet of material used to cover the core of a wood project in order to change the appearance of the material. Laminates may be any material, but typically they are made veneers, which are thin sheets of wood. The advantage to a laminate is that they help to lower the overall construction cost of kitchen cabinets while still providing the same sort of aesthetic beauty as solid hardwood cabinets. A disadvantage is that a laminated cabinet is slightly more difficult to refinish in the future and the overall cabinet lacks the strength of the hardwood it is being made to resemble. Special care should be taken when maintaining and caring for laminate cabinets. Unlike that used on countertop laminates, the material used to laminate is thinner on cabinets. They can be maintained with regular soap and water, but one should exercise caution to prevent any water from sitting on the cabinet as this can lead to a softening of the glue used to attach the laminate. The laminate used on countertops is designed to handle prolonged exposure to moisture, but the laminate on cabinets is not. Wood Laminate is a product made by bonding layers of wood or other material to a wood substrate. / Под Древесными Пластиками понимают материалы, вырабатываемые из лущёного шпона, древесной крошки или опилок, пропитанных синтетическими смолами и склеенных под высоким давлением и температурой. Древесные пластики подразделяют на древесные слоистые пластики (ДСП), армированные, спрессованные и склеенные из шпона и ткани, усиленные металлической сеткой. Древесные пластики из измельчённой древесины – изделия, полученные из древесной крошки или опилок прессованием в обогреваемых пресс-формах.

WOODLANDS = ЛЕСНЫЕ МАССИВЫ (или ЛЕСИСТЫЕ ЗЕМЛИ) – Woodlands:- includes natural or planted woodlots or timber tract, cutover and deforested land with young growth that have or will have value for wood products, land planted for Christmas tree production, and pastured woodland.

WOOD PACKAGING MATERIAL = ДРЕВЕСНЫЙ УПАКОВОЧНЫЙ МАТЕРИАЛ – Wood Packaging Material is a wood or wood products (excluding paper products) used in supporting, protecting or carrying a commodity (includes dunnage). Formerly known as Solid Wood Packing Material. / Древесный Упаковочный Материал – древесина или древесные изделия (за исключением бумажных изделий), используемые для поддержки, защиты или упаковки товара (включая крепёжную древесину).

WOOD PELLETS = ДРЕВЕСНЫЕ ПЭЛЕТЫ (или ДРЕВЕСНЫЕ ПЕЛЛЕТЫ, или ДРЕВЕСНЫЕ ГРАНУЛЫ) – Wood Pellet:- highly efficient heating fuel composed of dried and compressed sawdust. Wood pellets are burned in a wood pellet stove, fireplace insert, boiler, or furnace. Wood Pellets and briquettes are made by compressing dry sawdust or wood shreds under extremely high pressure until the lignin softens and binds the material together. The combination of low moisture content (typically below 10%) and highly compressed material gives pellets a very high volume energy density, typically three to four times that of wood chips. They are also clean, consistent and flow easily, making them particularly attractive in domestic applications. The significantly lower storage requirements compared with wood chips also make them attractive to urban applications such as city schools. Pellets for domestic and small scale applications are typically 6–8 mm diameter, while those for industrial applications may be 10–12 mm. Above 25 mm diameter they are known as Briquettes and can resemble a firelog in appearance and function, though with improved storage, handling and combustion properties. Poor quality pellets can crumble to sawdust, or produce more ash, so it is important that pellets have been manufactured to a recognized standard. The EU-wide CEN standard for solid biofuels, which includes wood pellets, is the CEN/TC EN 335 biomass standard. Wood Pellets:- sawdust compressed into uniform diameter pellets to be burned in a heating stove. Wood Pellets are made from dry sawdust compressed under high pressure and extruded through a die. They may include a low level of added binder, such as starch, but many use nothing other than steam. They come in a range of sizes:- for domestic and relatively small scale systems 6 or 8 mm is typical, while for larger systems 10 or 12 mm are common. Wood pellets should be dry, clean, mechanically robust and have an ash content defined by the appropriate standard (see below) to which they have been made, which may also define other contaminants such as chlorine content. They should also flow freely and can be delivered via a pneumatic system. Briquettes are similar to wood pellets, but physically larger. Sizes vary but briquettes can vary in diameter from around 50 mm to 100 mm +. Briquettes are usually between 60 mm and 150 mm in length. They can offer a cleaner, more consistent alternative to firewood logs, offering higher energy density and steady combustion. Energy density:- the combination of low moisture content (8–10%) with a compressed, dense pellet (typically >1 000 kg/m^3, i.e. greater than the original wood) and the ability to flow and pack closely, gives a fuel with a high bulk energy density. This then requires less storage space than lower density fuels such as wood chips. Using as a biofuel:- wood pellets are also a pleasant, clean, consistent fuel, and modern pellet boilers are highly sophisticated, featuring all the facilities available on modern gas boilers. When combined with a reliable supply, infrastructure wood pellets have proved to be a very popular renewable alternative to fossil fuel based domestic, and small to medium scale district and site heating in several European countries. Using as an alternative to coal:- wood pellets also provide an alternative, renewable and low carbon

alternative to fuel old coal boilers. Commercial conversion kits are available, but some systems are being run with few modifications other than to the fuel feed which needs to be higher owing to the lower energy density of wood pellets. Where coal is in use storage and handling infrastructure for a solid fuel will already be in place. Wood pellets provide a fuel that, in addition to its environmental benefits, is cleaner, more pleasant to handle, is less aggressive to fuel handling components such as augers, and produces considerably less ash. A coal storage bunker will hold enough pellets for operation for around one half to a third of the time possible with the same volume of coal. Standards:- wood pellets are only as good as the standard to which they are manufactured. Poor quality pellets may display inferior mechanical robustness, and will tend to disintegrate into sawdust more readily than those of better quality. They may also have lower energy density, higher levels of ash or contaminants such as heavy metals, chlorides or sulphur or higher moisture content. There are a number of established standards in the EU:- (i) ÖNORM M1735 in Austria; and (ii) SS 187120 and SS 187121 in Sweden and DIN 51731. The EU-wide CEN standard EN 335 for solid biofuels is in preparation, which includes wood pellets. Wood pellets have a higher embedded energy than woodchips, owing to the energy needed to grind the wood to fine sawdust (typically in a hammer mill) and press it through a die at high pressure. The energy (and financial) cost of active drying is not usually justified. However a very low moisture content (typically <10%) is required of the sawdust, so many pellet production facilities are established where there is an existing supply of very dry material, such as were processing of wood that is already kiln dried takes place. For example:- (i) Joinery workshops; (ii) Wood recycling sites; and (iii) Sawmills processing dried wood. This also removes the need to transport the very low density sawdust. Where a supply of bone dry sawdust is available, this may be supplemented with sawdust of higher moisture content provided the overall moisture content does not become too high. The precise embedded energy figure for a batch of pellets will depend on the details of production (plus that of the feedstock), transport etc.

WOOD PRESERVATIVE = ЗАЩИТНОЕ СРЕДСТВО ДЛЯ ДРЕВЕСИНЫ (или СРЕДСТВО ЗАЩИТЫ ДЛЯ ДРЕВЕСИНЫ) – Wood Preservative is any suitable substance that is toxic to fungi, insects, borers, and other living wood-destroying organisms. Wood Preservative is a coating applied to timber as a protection against decay, insects, eather, etc. / Под Защитным Средством Для Древесины понимается соответствующее вещество, которое является токсичным для грибов (грибков), насекомых, точильщиков и прочих живых организмов, разрушающих древесину.

WOOD PULP = ДРЕВЕСНАЯ ПУЛЬПА (или ДРЕВЕСНАЯ ЦЕЛЛЮЛОЗА) – Wood Pulp is the term used to describe a range of products that are derived from treatment of plant materials taken from trees. Trees are stripped of bark and then subjected to chemical or mechanical treatments that separate the cellulose fibers. The dominant method is the chemical sulfate (kraft) process. The pulp is then usually bleached, dried and baled for sale on the market. Global wood pulp production of 175 million metric tons (MMt) is composed of several different types:- northern bleached softwood kraft pulps (including NBSKP), bleached hardwood kraft (BHK) pulps, unbleached kraft pulps, sulfite pulps as well as semi-chemical and mechanical pulps. There is a high degree of positive price correlation among these different types. Northern bleached softwood kraft (NBSK) pulp is produced from coniferous trees growing in colder climates. The principal growing areas for these trees are Canada, the northern and western United States, Scandinavia, parts of Central Europe and northern Russia. The fiber in this pulp is long and narrow with a thin wall, providing excellent raw material for many paper products. NBSK pulp is the benchmark grade for pricing market pulp around the world. BHK pulp, although it is produced from a variety of hardwoods, has become predominantly produced from eucalyptus due to lower production costs. The principal growing areas for these trees are in Latin America and Asia. About 70 percent of global pulp production is integrated with paper production; about 30 percent of pulp or about 50 MMt is sold on the market. NBSK and BHK pulps each have about 40 percent of the market share. Canada is the largest supplier and produces about 11 MMt of market pulp annually, most of it NBSKP, while US market pulp production is about 9 MMt. Together, they account for about 40 percent or 20 MMt of global market pulp production, but only about 10 MMt or 20 percent of global market pulp production is consumed within North America. At USD750 per ton, North American production is valued at USD15 billion. The United States has a largely balanced export-import trade while Canada has net exports of almost 10 MMt yearly, about 30 percent to the United States and 20 percent to Europe. Brazil is the largest supplier of BHK pulp, about 6 MMt. Europe is a major source of demand for global market pulp with about 20 MMt, or 40 percent of the world production, consumed annually. Pulp is used to produce numerous products. Printing/writing papers (55 percent), towels/tissues (15 percent), packaging (13 percent) and sanitary goods (9 percent) are the main product areas consuming market pulp. Large consumergoods firms are prominent participants in all four of these product areas. The specialty paper and paperboard segments are made up of mostly smaller paper mills. Wood Pulp is the cellulosic raw material for viscose rayon and for acetate. Wood Pulp is a fiber from wood with varying degrees of purification that is used for the production of paper, paper board, and chemical products.

WOOD RESIDUES = ДРЕВЕСНЫЕ ОСТАТКИ – Wood Residues are the sawdust, chips, bark, and shavings.

WOOD SUGAR = ДРЕВЕСНЫЙ САХАР – Wood Sugar is a sugar extracted from wood or straw; used in foods for diabetics. Wood Sugar is another name for xylose. Wood Sugar is a white, crystalline, water-soluble powder, $C_5H_{10}O_5$, the dextrorotatory form of xylose: used chiefly in dyeing and tanning. / Древесный Сахар, то же самое, что Ксилоза.

WOOD TAR = ДРЕВЕСНАЯ СМОЛА – Wood Tar:- liquid obtained as one of the products of the carbonization, or destructive distillation, of wood. There are two types:- hardwood tars, derived from such woods as oak and beech; and resinous tars, derived from pine wood, particularly from resinous stumps and roots. Crude wood tar may be used as fuel or for preserving rope and wood and for caulking. The tar may be fractionated to yield creosote, oils, and pitch. Hardwood tars are obtained from pyroligneous acid, either as a deposit from the acid or as a residue from the distillation of the acid. Crude pyroligneous acid is the condensed, volatile product of wood distillation. Resinous wood tars differ from hardwood tar in containing the pleasant-smelling mixture of terpenes known as Turpentine. Pine-wood tar, commonly called Stockholm, or Archangel, Tar, is made extensively in the forests of Russia, Sweden, and Finland. It is the residue after the turpentine has been distilled, usually with the aid of steam. It is widely used in manufacturing tarred ropes and twine and in impregnating hemp fiber for oakum. In pharmacy, it has some slight use as a component of some ointments and antiseptics. Distillates of pine-wood tar, particularly the creosote fraction, are used in metallurgy in the froth flotation processes. / Древесная Смола – вязкая маслянистая жидкость от тёмно-бурого до чёрного цвета с резким запахом, получаемая при пиролизе древесины. Сложная смесь органических веществ. Применяется для получения понизителей вязкости глинистых растворов и литейных крепителей, в качестве консерванта древесины. Из древесной смолы получают также ингибиторы окисления топлив и масел, флотореагенты и другие. Древесная Смола или Древесный Дёготь – продукт сухой перегонки древесины или газификации древесины. Различают:- (i) отстойную смолу, отстаивающуюся от водного дистиллята термической переработки древесины; (ii) растворимую, находящуюся в этом дистилляте в растворённом виде, а также (iii) экстракционную, получаемую экстракцией из водного дистиллята. Отстойная смола – вязкая маслянистая жидкость от тёмно-бурого до чёрного цвета, с резким запахом; плотность от 1 000 до 1 150 кг/м^3. Представляет собой сложную смесь органических веществ:- фенолов (10–25%), кислот (10–30%) и нейтральных веществ (40–55%). В состав фенолов входят фенол, крезолы, ксиленолы, о-этилфенол, псевдокуменолы, пирокатехин, гваякол, метиловые эфиры пирогаллола и другие. Из кислот присутствуют представители жирного ряда от муравьиной до каприловой, пальмитиновая, арахиновая, бегеновая и другие, а также ненасыщенные кислоты этого ряда и смоляные (абиетиновая и другие). В состав нейтральных соединений

входят кетоны, альдегиды, спирты, углеводороды различных классов и другие. При дистилляции отстойной смолы получают различные фракции масел (55–60%) и пек с $t_{пл}$ 70–80 °С (40–45%). Среднюю фракцию масел (240–310 °С) используют как ингибитор для топлив и масел. Из масел получают также флотореагенты, мягчители для резиновой промышленности и другие ценные продукты. Из пека получают литейные крепители. Кроме того, отстойную смолу используют как консервант древесины. Растворимая смола содержит фенолы, углеводы, лактоны и применяется для получения понизителей вязкости глинистых растворов и литейных крепителей. Экстракционную смолу, содержащую 30% и больше фенолов, также применяют для получения понизителей вязкости.

WOOD TREATMENT CERTIFICATE = СЕРТИФИКАТ ОБРАБОТКИ ДРЕВЕСИНЫ – Wood Treatment Certificate is a certificate of treatment against insect infestation.

WOOD WAFER = ДРЕВЕСНАЯ СТРУЖКА – Wood Wafers are produced by feeding logs to a rotary cutter head drum with the longitudinal axis of the logs disposed substantially parallel to the rotational axis of the drum. The drum mounts a plurality of wafer cutting head units arranged in a V-shaped pattern with the apex of the V trailing the base thereof and with the cutting blades defining the ends of the base positioned at the opposite ends of the operative length of the drum. Each wafer cutting blade having a cutting edge disposed substantially parallel to the axis of the drum and offset circumferentially parallel to the axis of the drum and offset circumferentially and axially from an adjacent cutting blade so that the cut produced by a cutting blade overlaps the cut produced by the next adjacent preceding cutting blade. / Древесные Стружки образуются при подаче брёвен на режущее лезвие. Под Стружкой понимается тонкий, узкий, обычно свернувшийся в завиток, слой дерева, срезанный острым инструментом при обработке.

WOODY = ДЕРЕВЯННОЕ (или ДЕРЕВЯНИСТОЕ, или ОДРЕВЕСНЕВШЕЕ) – Woody:- made of or resembling wood. Of plant tissues hardened by accumulation of lignin. Woody:- hard in texture. (1) Woody (plants):- with an aboveground shoot composed of relatively hard tissue that persists from one growing season to the next. Compare with Herbaceous. (2) Woody (seed cone scales):- of or resembling wood, and thus relatively hard and dry. Compare with Fleshy and Leathery. / .

WOODY = СТОЯК (или ХХ) – Woody:- a slang to describe a market moving strongly upward, as in, ‘This market has a woody’. / жаргонный термин для описания рынка, двигающегося строго вверх, как во фразе ‘У рынка стояк’ (‘This market has a woody’).

WOODY; WOODY PLANTS; WOODY CROPS = ДРЕВЕСНЫЕ; ДРЕВЕСНЫЕ РАСТЕНИЯ; ДРЕВЕСНЫЕ (СЕЛЬСКОХОЗЯЙСТВЕННЫЕ) КУЛЬТУРЫ – Woody; Woody Plants; Woody Crops:- plants with stems and limbs containing lignin, the chief noncarbohydrate constituent of wood, and a polymer that functions as a natural binder and support for the cellulose fibers. A Woody Plant is a plant that produces wood as its structural tissue. Woody plants are usually either trees, shrubs, or lianas. These are usually perennial plants whose stems and larger roots are reinforced with wood produced from secondary xylem. The main stem, larger branches, and roots of these plants are usually covered by a layer of bark. Wood is a structural cellular adaptation that allows woody plants to grow from above ground stems year after year, thus making some woody plants the largest and tallest terrestrial plants. Wood is primarily composed of xylem cells with cell walls made of cellulose and lignin. Xylem is a vascular tissue which moves water and nutrients from the roots to the leaves. Most woody plants form new layers of woody tissue each year, and so increase their stem diameter from year to year, with new wood deposited on the inner side of a vascular cambium layer located immediately beneath the bark. However, in some monocotyledons such as Palms and Dracaenas, the wood is formed in bundles scattered through the interior of the trunk. Woody herbs are Herbaceous Plants that develop hard woody stems. They include such Plants as Uraria Picta and certain Species in Family Polygonaceae. These herbs are not truly woody but have hard densely packed stem tissue. Other Herbaceous Plants have woody stems called a Caudex, which is a thickened stem base often found in plants that grow in alpine or dry environments. Under specific conditions, woody plants may decay or may in time become petrified wood. The symbol for a woody plant, based on Species Plantarum by Linnaeus is ϧ, which is also the astronomical symbol for the planet Saturn.

WOOF = УТОЧИНА (или УТОК) – The term Woof comes from the Anglo-Saxon Owef. It is another name for the warp or warp yarn. Sometimes in advertising textiles, the word has been used to imply filling yarn, and made to interchange with the other term, weft. Woof is an old term for Weft. Woof is another name for Filling, the crosswise thread that interlaces with the warp threads on a woven fabric. Other names are Weft, Shoot, and Shute. See also Filling, and Weft. / Смотрите также Уточина (Filling), и Уток (Weft).

WOOL = ВАТА – Wool:- xxxxx. Cotton Wool is a soft mass of cotton, used especially for applying liquids or creams to your skin. Cotton Wool is bleached and sterilized cotton from which the gross impurities, such as the seeds and waxy matter, have been removed:- used for surgical dressings, tampons, etc. / Под Ватой, от Немецкого слова Watte, понимается пушистая масса волокон, слабо переплетённых между собой в различных направлениях. По способу получения различают:- естественную вату – шерстяную, шёлковую, пуховую, хлопковую, льняную, пеньковую, сосновую, асбестовую, и искусственную вату – целлюлозную, стеклянную, металлическую, шлаковую, базальтовую. Естественная вата по назначению разделяется на одёжную, мебельную, техническую (термоизоляционная, огнестойкая и другие), прокладочную, листовую клеёную и медицинскую. При изготовлении ваты сырьё расщипывается, разрыхляется и очищается от примесей, полученная волокнистая масса формируется в так называемые Холсты на машинах разрыхлительно-трёпального агрегата; бесформенная масса волокна, составляющая холст, на чёсальной машине превращается в съём ваты определённой толщины. При производстве медицинской ваты сырьё подвергается варке в щёлочи под давлением и затем обрабатывается гипосульфитом натрия. В результате волокно приобретает белизну и характерные свойства – способность быстро смачиваться и поглощать жидкости. Различают гигроскопическую и компрессную медицинскую вату. Гигроскопическая Вата белая, легко расслаивается, употребляется как материал, впитывающий жидкие выделения (гной, сукровицу) при перевязке ран поверх слоёв перевязочной марли. Компрессная Вата служит для отепления завязанной или забинтованной части тела (например, при согревающих компрессах), а также мягкой подкладкой при наложении шин иммобилизующих повязок (например, гипсовых). Искусственная Вата широко применяется в строительстве в качестве тепло- и звукоизоляционного материала; в химической промышленности – для фильтрации жидкостей и газов. Особый вид ваты – так называемый Ватилин, то есть вата, проклеенная с одной или с двух сторон клеевой эмульсией. Ватилин – заменитель ваты при шитье одежды, прокладочный материал и другое.

WOOL = ШЕРСТЬ – Wool:- the most important animal fiber, yielded by the sheep and consisting of the medulla (which contains the color pigments), the cortical layer and the outer layer which under microscope appears composed of numerous small scales. The finer the wool the larger the number of the scales which give the felting property to the wool. Anther characteristic of the wool is the waviness and elasticity of the fiber, both existing in a greater degree in fine than in coarse wools. The various properties of wool (as length, fineness, felting, strength, thickness, etc), are subject to the climate and the breed of the sheep, which are being classified into 32 principal varieties and a large number of sub and crossbred varieties. On the average about 5 000 wool fibers are found on one square inch of the sheep’s skin. The US wools are classed mainly as territory wools (from Arizona, Idaho, Montana, Utah, and a few other Western States), bright and braid wools (or quarter-blood or three-eighths blood, from Indiana, Kentucky, Missouri, and New England, used for serges, braid, etc), and Ohio fleeces (from Michigan, Ohio and Pennsylvania, the finest American staple). English

wools are classified as long wools (Lincoln, Notts, Leicester, Cotswold, Hampton, Romney Marsh, Devon, Roscommon, Wensleydale), short wools (called Downs, containing Exmoors, Shropshire, Suffolk, Southdown, Oxford, Dorset, Wiltshire, Hampshire), special wools (middle length wools, as Cheviot, blackfaced, Herdwick, Shetland, Welsh). Other important wools in the trade are:- Silesian merino (from Germany, yields the finest wool), the Rambouillet wool (France), the Donskoi (or washed coarse wool from South Russia), Awassi, Bussora and Karadi (carpet wools from Mesopotamia), Bagdad (merino strain from Mesopotamia), Georgian (wools for the finest carpets), Indian (coarse crossbred wools), Persian (white or colored carpet wools), Chinese (various carpet wools), Cape (fine, silky, short wool from South Africa), River Plate (crossbred from Argentine), Montevideo (Rambouillet and other merino strain from Uruguay), Punta Arenas (very spongy wool for knit goods from South Argentine), Falkland Islands (springy cheviot), Australia (merinos and crossbreds), New Zealand (crossbreds). Irrespective of the breed wool is divided into two classes:- tops and noils, according to the length of the fiber. It shows a great variety according to the breed, measuring up to 10 inches or more in length, while the weigth of a fleece is ranging from three pounds (fine English), to 30 pounds or more (as in some South American varieties). For the commerce wool is put up in bales, the weight of which varies according to the countries. All kinds and classes of wool of commercial importance in Europe and mostly in America and Australia have sprung from the original Spanish merino. The amount of this strain is expressed in the United States as:- full blood, three-quarter blood, three-eighths blood, half-blood, one-quarter blood. Wool in the grease, or as it comes from the sheep's back, contains from 20 to 80 per cent animal grease, dirt, etc, which is removed by washing and scouring before the fiber is spun and woven. The largest quota of the wool on the market is shorn from the live sheep. The skin wools and slipes are removed from the skin of the dead animal and each such fiber has a root. Lamb's wool and hogget has one pointed and one cut end while wether has two cut ends. In its properties wool is highly hygroscopic and has a great affinity for dyestuffs (except when kempy). When set afire it gives an ammoniacal odor and leaves black crinkled ashes behind. Diluted acids have no appreciable effect on wool, but alkalies produce remarkable change. Concentrated alkalies produce a high luster, a scroop and increase considerably its tensile strength. On the other hand a 5 per cent solution of caustic soda will completely dissolve wool in a few minutes at a boiling point. Weak solutions of chlorine will give the wool a scroop and increase its affinity for dyestuffs, but destroys its felting property. When treated with nitric acid the fiber usually becomes yellow. Concentrated mineral acids completely destroy the wool fiber while it readily absorbs organic acids. The loss in the weight of wool in the grease through scouring and after the wool is permitted to assimilate the legal regain of 16 per cent of moisture is called Shrinkage and is expressed in percentage. Shrinkage shows a great deal of difference according to the kind of wool and the country the wool comes from. Test reported by the US National Association of Wool Manufacturers show that to produce one pound of woolen cloth an average of 3.73 pounds of grease wool or 1.37 pounds of scoured wool were required. For one pound of worsted cloth an average of 3.66 pounds of grease wool or 1.55 pounds of scoured wool are required. Wool was used in ancient times among the various people living not only under cold but also hot climates. In ancient Egypt it was used chiefly by the lower classes, priests being forbidden to wear next to the skin any garment of wool (as being 'unclean') and as a rule no one was buried in it. Its importance among the ancient Jews is shown by the fact that it is specified among the first fruits to be offered to the priests. The wool of Miletus was famous for its fineness, as mentioned by Pliny (I century AD), as well as the wool of Damascus; white wool was considered as the image of purity (Is. I, 18). In the British Isles wool was known long before the Romans' arrival although the latter opened the first factory of woolen fabrics there to supply their armies with clothes. Since the Conquest many Flemish wool weavers settled in England and the industry was greatly encouraged especially under Edward III, who, however, prohibited the export of English wool in order to further stimulate the industry. With various degrees of enforcement this prohibition was in existence until the reign of Queen Elizabeth, but in 1660 the prohibition was again invoked and abolished only at the beginning of the XIX century. Until a comparatively late date, for centuries wool and manufactures thereof were the main source of income for England. The full characteristics of the present day Leicester wool were developed around 1750 by Bakewell and the Lincoln wool was developed around 1760 or later. Merino sheep were introduced into Saxony in 1765 and soon, through crossing with native stock, a very superior grade of wool, called Saxony Merino, was developed. In 1786 the importation of merino sheep to Rambouillet by Daubenton started the famous Rambouillet breed. The first sheep in the United States were imported in 1609 at Jamestown, and at Boston, in 1633; the first fulling mill in the New World was erected at Rowley, State of Massachusetts, in 1643. The first importations of pure merinos were made in 1802 and 1809. In South America the wool trade begins perhaps with Henri Solanet, around 1840 in Buenos Ayres, and soon, by importing Rambouillet rams and later Lincoln rams the present characteristics of the South American sheep (large carcass combined with long wool) were developed by the middle of the 1880s. Sheep were introduced to Falkland Islands about 1867 and to Punta Arenas in the 1880s. In Australia the wool industry began with the XIX century, first centering on pure merino; later as the development of the meat industry, crossbreds with large carcass and long coarse wool were begun to be developed (toward the middle of the 1880s), in New Zealand and even in Australia. Still later, with the extension of the grazing area, pure merino was bred in the interior (having only meager salty grass), by introducing the Vermont bred merino. (1924). Wool is the fine, soft, curly hair that forms the fleece of sheep and certain other animals, characterized by minute, overlapping surface 'scales' which give it its felting property. Characteristics:- strong and resilient, soft and warm, wicks away moisture and dyes well for rich coloration. Strictly speaking, the fibers that grow on the sheep fleece. In the United States the Wool Products Labeling Act of 1939, however, decreed that wool 'means the fiber from the fleece of the sheep or lamb, or the hair of the Angora or Cashmere goat (and may include the so-called specialty fibers from the hair of the Camel, Alpaca, Llama, and Vicuna) which has never been reclaimed from any woven or felted wool product'. This law also defines the following:- (1) Reprocessed Wool – the resulting fiber when wool has been woven or felted into a wool product which, without ever having been utilized in any way by the ultimate consumer, subsequently has been made into the fibrous state. (2) Reused Wool – the resulting fiber when wool or reprocessed wool has been spun, woven, knitted, or felted into a wool product which after having been used in any way by the ultimate consumer, subsequently has been made into the fibrous state. (3) Wool Product – any product, or any portion of a product, which contains, purports to contain, or in any way is represented as containing wool, reprocessed wool, or reused wool. Wool from sheep will readily felt, a highly desirable property. The fiber is made of overlapping scales or serrations which vary with the several breeds of sheep and the grades of wool; there are from 600 to about 3 000 to inch. The structure of the fiber is comparable with the scales on a fish or an asparagus tip. Wool is warm, springly, elastic; it may be either harsh or soft. There are five general types used in some classifications:- Fine Wools, Medium Wools, Crossbred Wools, Luster Wools, and Carpet Wools. On the four-point method of classifying wool the table lists Combing, Carding, Clothing, Carpet Wools. There are several types and varieties of wool used, and they are classified according to fineness, color, staple length, etc. Some few of these types include:- (1) Alpaca Wool – fine long-staple wooly hair of the alpaca, a South American goatlike animal. (2) Angora Wool – long, soft, hair-like wool from the Angora goat, native to Anatolia, the homeland of the Turks; now raised extensively in Texas with Kerrville as the center. Used in combination with wool, mohair, and mixture fabrics. (3) Botany Wool – very fine merino wool from Botany Bay area in Australia. Used only in the finest of woolen and worsted fabrics. (4) Cashmere Wool – very fine, soft wool found underneath the outer or harsh hair on goats raised chiefly in the Himalaya Mountain area. (5) Carding Wool – wool of irregular length and not of the quality that can withstand the combing operation in processing. Carded woolen yarn may be classed as a conglomerate mass of fibers when compared with a combed worsted yarn. (6) Combing Wool – wool fibers with a staple length from 1-1/2 inches up to 6 inches. Combed stock is known as Worsted in which the fibers are of the same staple length, such as a 3-inch, 4-1/2-inch staple, etc. Worsted top is used as the base for making worsted yarn. (7) Kempy Wool – harsh, irregular, rough wool used chiefly in carpets. Sick or diseased

sheep will often produce a type of wool that is known as Kempy. (8) Lamb's Wool – elastic, soft, resilient wool fibers obtained from lambs when they are seven to eight months old – the first or virgin clipping from the animal. This lofty stock is used in better grades of fabrics. (9) Merino Wool – the highest, finest and best quality wool fiber obtained from sheep and used in better-grade materials. Merino originated in Spain two thousand years ago and was developed under the aegis of Columella, the animal-husbandry expert in the time of Julius Caesar. Several types of Merino are raised in some wool centers throughout the world – Italian, Ohio, Rambouillet, Saxony, Silesia, South African, Spanish, etc. (10) Shetland Wool – rugged wool, ideal for Cheviots, Shetland, home-spuns and tweeds, raised chiefly in Scotland and the adjacent islands. Cheviot wool is comparable with Shetland wool. (11) Top Wool – worsted slubbing or sliver wound in a top form which resembles a cheese in size. Noil has been removed from these fibers in combing, and top stock contains fibers of the same staple length throughout. Used in making worsted yarn and fabric. (12) Virgin Wool – 'any wool that has never before been woven, knitted, felted, or otherwise processed into cloth or fabric, nor used for any other purpose'. Wool usually associated with fiber or fabric made from the fleece of sheep or lamb. However, the term 'Wool' can also apply to all animal hair fibers, including the hair of the Cashmere or Angora Goat or the specialty hair fibers of the Camel, Alpaca, Llama, or Vicuna. Commonly used in slacks and outerwear. Wool:- the term is usually used for the fleece of sheep, but according to the Textile Fiber Products Identification Act, Wool is defined for purposes of labeling as:- 'The fiber from the fleece of the sheep or lamb or hair of the Angora or Cashmere goat (and may include the socalled specialty fibers from the hair of the Camel, Alpaca, Llama, and Vicuna) which has never been reclaimed from any woven or felted wool product'. Wool is used in a variety of blends in which it is combined with nearly all natural or manufactured fibers. Wool fibers have scales that tend to interlock with each other, binding the fibers together. This process is called Felting. In blends, particularly those with manufactured fibers, wool is used to improve the feel or appearance of finished products. Manufactured fibers are sometimes blended with wool to enable the spinning of very fine or loosely twisted yarns with increased tensile strength or to produce ease-of-care properties. Wool can be treated to control shrinkage, to provide resistance to damage by moths, to impart stain-resistance, and to set permanent creases in fabrics. Wool:- usually associated with fiber or fabric made from the fleece of sheep or lamb. However, the term 'Wool' can also apply to all animal hair fibers, including the hair of the Cashmere or Angora Goat or the specialty hair fibers of the Camel, Alpaca, Llama, or Vicuna. Wool refers to fleece wool used for the first time in the complete manufacture of a wool product. Wool differs from hair and fur in that it has a natural felting ability. Wool:- animal fiber forming the protective covering, or fleece, of sheep or of other hairy mammals, such as goats and camels. Prehistoric man, clothing himself with sheepskins, eventually learned to make yarn and fabric from their fiber covering. Selective sheep breeding eliminated most of the long, coarse hairs forming a protective outer coat, leaving the insulating fleecy undercoat of soft, fine fiber. Wool is mainly obtained by shearing fleece from living animals, but pelts of slaughtered sheep are sometimes treated to loosen the fiber, yielding an inferior type called Pulled Wool. Cleaning the fleece removes 'wool grease', the fatty substance purified to make lanolin, a by-product employed in cosmetics and ointments. Wool fiber is chiefly composed of the animal protein keratin. Protein substances are more vulnerable to chemical damage and unfavorable environmental conditions than the cellulose material forming the plant fibers. Coarser than such textile fibers as cotton, linen, silk, and rayon, wool has diameters ranging from about 16 to 40 microns (a micron is about 0.000 04 inch). Length is greatest for the coarsest fibers. Fine wools are about 1.5 to 3 inches (4 to 7.5 centimeters) long; extremely coarse fibers may be as much as 14 inches in length. Wool is characterized by waviness with up to 30 waves per inch (12 per centimeter) in fine fibers and 5 per inch (2 per centimeter) or less in coarser fibers. Color, usually whitish, may be brown or black, especially in coarse types, and coarse wools have higher luster than fine types. Single wool fibers can resist breakage when subjected to weights of 0.5 to 1 ounce (15 to 30 grams) and when stretched as much as 25 to 30 percent of their length. Unlike vegetable fibers, wool has a lower breaking strength when wet. The resilient fiber can return to its original length after limited stretching or compression, thus imparting to fabrics and garments the ability to retain shape, drape well, and resist wrinkling. Because crimp encourages fibers to cling together, even loosely twisted yarns are strong, and both crimp and resilience allow manufacture of open-structured yarns and fabrics that trap and retain heat-insulating air. The low density of wool allows manufacture of lightweight fabrics. Wool fiber has good to excellent affinity for dyestuffs. Highly absorbent, retaining as much as 16 to 18 percent of its weight in moisture, wool becomes warmer to the wearer as it absorbs moisture from the air, thus adjusting its moisture content and, consequently, its weight, in response to atmospheric conditions. Because moisture absorption and release are gradual, wool is slow to feel damp and does not chill the wearer by too-rapid drying. Wool that has been stretched during yarn or fabric manufacture may undergo relaxation shrinkage in washing, with fibers resuming their normal shape. Felting shrinkage occurs when wet fibers, subjected to mechanical action, become matted into packed masses. Wool has good resistance to dry-cleaning solvents, but strong alkalies and high temperatures are harmful. Washing requires the use of mild reagents at temperatures below 20° C (68° F), with minimum mechanical action. The performance of wool has been improved by development of finishes imparting insect and mildew resistance, shrinkage control, improved fire resistance, and water repellency. Woolen yarns, usually made from shorter fibers, are thick and full and are used for such full-bodied items as tweed fabrics and blankets. Worsteds, usually made from longer fiber, are fine, smooth, firm, and durable. They are used for fine dress fabrics and suitings. Wool that has had no previous use is described as new wool, or, in the United States, as Virgin Wool. The limited world supply results in the use of recovered wools. In the United States, wool recovered from fabric never used by the consumer is called Reprocessed Wool; wool recovered from material that has had use is called Reused Wool. Recovered wools, employed mainly in woolens and blends, are often of inferior quality because of damage suffered during the recovery process. Australia, Russia, New Zealand, and Kazakhstan lead in fine-wool production, and India leads in the production of the coarser wools known as Carpet Wools. Leading consumers include the United Kingdom, the United States, and Japan. See also Virgin Wool. Wool is the fiber derived from the specialized skin cells of Sheep, Goats, Llamas or other Mammals. It is crimped, elastic and naturally stain-resistant and wrinkle-resistant. It is very absorbent and comes in many forms, including:- crêpe, challis, gabardine, merino, melton, Jersey and worsted wool suitings. Wool:- a woven fabric of wool, namely the soft wavy or curly hypertrophied undercoat of various hairy mammals and especially the Sheep made of a matrix of keratin fibers and covered with minute scales. A garment made of wool. The term 'Wool' refers to the fibers from the fleece of Lambs, Sheep, Cashmere Goats, Angora Goats, Camels, Llamas, Alpacas, and Vicunas. Wool from sheep is the most common, Lamb's wool is shorn from Sheep less than eight months old, and Merino wool is from a specific breed that yields the finest and softest sheep wool. Mohair is the wool of the Angora Goat. Sheep say baa, Goats say maa. Seriously, their voices are different. Wool(s):- traditionally, the fibers covering the skin of a sheep. According to the US Wool Products Labeling Act of 1939, the term includes the fleece of a Sheep, Angora Goat, undercoat of a Cashmere Goat, and specialty fibers of Alpaca, Llama, Vicuna, and Guanaco. The undercoat of mammals other than the Sheep, Goat, or Camel Families are referred to as Fur. Wool, a protein fiber, is the fourth most important natural fiber traded in the world. It accounts for over 6% of total natural fiber production grease. The four main sources of wool are Sheep, Goats, Camels and Rabbits. The wool from diverse sources has different fiber diameters and, therefore, huge differences in quality. Wool fiber can be as fine as Cashmere/Merino (diameter about 15 microns) to make expensive garments or it can be coarse enough (diameter about 40 microns) to make carpets. A single Sheep can produce up to 11 kilograms of wool a year (clean basis). It is estimated that half of all wool production goes into the garment industry and the other half is used to make blankets, carpets and other goods. The flameretardant and heat-resistant qualities of wool make it one of the safest of all household textiles. Technical textile uses include police uniforms, military uniforms, thermal insulation, billiard cloths and automotive composites. Wool is produced in about 100 countries, but Australia, China and New Zealand account for half of the world's

production. Wool is the term used for the fleece of Lambs and Sheep, but also applies to similar fibers from such animals as the Angora and Cashmere Goats, the Llama, and other animals used for clothing. It is un like carpet wool, which is much coarser and unsuitable for clothing. Wool refers to fleece wool used for the first time in the complete manufacture of a wool product. Wool differs from hair and fur in that it has a natural felting ability. See also Felt, Woolen, and Worsted. Wool:- The Animal:- Sheep (Ovis Aries) were first domesticated 10 000 years ago. They currently number about 1 billion head, in 200 breeds, worldwide. Sheep are shorn of their wool usually once a year. After scouring to remove grease and dirt, wool is carded and combed, then spun into yarn for fabrics or knitted garments. Merino sheep produce up to 18 kg of greasy wool a year. The Fiber:- Wool has natural crimpiness and scale patterns that make it easy to spin. Fabrics made from wool have greater bulk than other textiles, provide better insulation and are resilient, elastic and durable. Fiber diameter ranges from 16 microns in superfine Merino wool (similar to Cashmere) to more than 40 microns in coarse hairy wools. Wool:- Limited supply and exceptional characteristics have made wool the world's premier textile fiber. Uses Of Wool:- Wool is a multifunctional fiber with a range of diameters that make it suitable for clothing, household fabrics and technical textiles. Its ability to absorb and release moisture makes woollen garments comfortable as well as warm. Two thirds of wool is used in the manufacture of garments, including sweaters, dresses, coats, suits and 'active sportswear'. Blended with other natural or synthetic fibers, wool adds drape and crease resistance. Slightly less than a third of wool goes into the manufacture of blankets anti-static and noise-absorbing carpets, and durable upholstery (wool's inherent resistance to flame and heat makes it one of the safest of all household textiles). Industrial uses of wool include sheets of bonded coarse wool used for thermal and acoustic insulation in home construction, as well pads for soaking up oil spills. Producers:- The world's leading animal fiber, wool is produced in about 100 countries on half a million farms. Major producers are Australia, Argentina, China, the Islamic Republic of Iran, New Zealand, Russia, the United Kingdom and Uruguay. Depending on the country and region, wool producers range from small farmers to large scale commercial grazing operations. Production And Trade:- Annual wool production is around 2.1 million tons. Australia produces one fifth, while China, New Zealand, Iran, Argentina and the UK each produce more than 50 000 tons. An estimated 50% of wool, both raw and partially processed, is exported to major textile centers in other countries to be spun and woven. China is the No. 1 importer of raw wool (310 000 tons in 2007), followed by Italy. The retail value of sales of wool products is around USD80 billion a year. / привоз (importation). Шэвьё (Cheviot). Щёлочь (Alkali). Сродство (Affinity). каустическая сода или едкий натр (caustic soda). Регенерированная Шерсть получается при расщипывании шерстяного лоскута. Верблюд, Альпака, Лама и Викунья (Вигонь). (1) Шерсть Альпаки – . Жиропот, мушки. В процессе первичной переработки шерсть подвергается следующим технологическим процессам:- трепание, обезрепеивание, крашение, промывка (washing), отжим, сушка, расщипывание, эмульсирование и смешивание (blending). К отходам в прядении шерсти относятся:- ровничный лом, крутые концы, аппаратный сдир и аппаратный очёс. Под Шерстью понимается:- (1) волосяной покров млекопитающих, обладающий прядильными качествами или свойлачиваемостью; (2) одно из основных натуральных текстильных волокон, сырьё шерстеперерабатывающей промышленности. Основную массу шерсти, перерабатываемой промышленностью, составляет овечья шерсть; значительно меньшее количество её получают с Коз, Верблюдов, Яков (сарлычья шерсть), Лошадей, Коров, Оленей, Собак и других животных. Ценные свойства шерсти (низкая теплопроводность, большая влагопоглощаемость и другие) обусловили её использование как материала для изготовления тканей, трикотажа, ковров, одеял, обуви, технических сукон, войлока, фетра и других изделий. Мировое производство овечьей шерсти в 1976 составило 2.6 миллиона тонн (т). Наибольшее её количество производили Австралия (747 000 т), Новая Зеландия (311 000 т), Аргентина (160 000 т). В бывшем Союзе Советских Социалистических Республик (СССР) в 1976 было получено шерсти 432 800 т. Шерсть, состригаемую с животных (овечья, козья, сарлычья и другая), вычёсываемую (верблюжья, сарлычья, собачья, козий и кроличий пух) или собираемую при линьке (коровья, конская, сарлычья), называют Натуральной Шерстью, снимаемую со шкур убитых животных – Заводской Шерстью. Шёрстные волокна представляют собой производные кожи (смотрите Волосы). Шерсть состоит из покровного волоса и подпуши (подшёрстка). У Овец покровный волос составляют:- ость, переходный и кроющий волос; подпушь – пух. Покровный волос имеет чешуйчатый (кутикула), корковый и, как правило, сердцевинный слои; подпушь – чешуйчатый и корковый. Чешуйчатый слой – тонкая (0.5–2 мкм) защитная оболочка волокна; наличие его обусловливает прядильные качества и валкоспособность шерсти, повреждение способствует разрушению коркового слоя и снижению технологических свойств шерсти. От состояния коркового слоя, расположенного под чешуйчатым, зависят прочность, упругость, растяжимость и другие свойства шерсти. Сердцевинный слой – сплошной или пористый (с воздушными полостями), расположен в осевой части волокна; чем сильнее развит этот слой, тем ниже технологические свойства шерсти. Ость – грубые, мало извитые, покрытые некольцевидными чешуйками, как правило, наиболее длинные волокна. По технологическим свойствам уступают пуховым и переходным волокнам. Переходный волос по длине, тонине и строению – промежуточный между остью и пухом. Сердцевинный слой у него слабо развит или отсутствует. Обладает лучшими технологическими свойствами, чем ость. Пух – самые тонкие, как правило, менее длинные, чем остевые и переходные, волокна. Овечья шерсть, в зависимости от типа составляющих её волокон, делится на:- (i) однородную шерсть, представленную волокнами одного типа, и (ii) неоднородную шерсть, состоящую из волокон разных типов. В однородной шерсти пуховые волокна, соединяясь в группы, образуют штапели (переходные волокна шерсти овец длинношёрстных пород – однородные косицы). В неоднородной шерсти пуховые, переходные и остевые волокна соединяются в косички. Штапели или косички являются элементами руна – шёрстного покрова Овцы, снятого при стрижке в виде целого пласта. Физические свойства шерсти, определяющие её технологические и товарные качества:- тонина, длина, извитость, прочность, упругость, гигроскопичность, цвет, блеск и другие. Средняя тонина (мкм):- пуха 10–25, переходного волоса 30–50, ости 50 и более. По Советской шкале однородную шерсть подразделяли на 13 классов тонины:- от 32 (средняя тонина 55.1–67 мкм) до 80 (14.5–18.0 мкм). Ость чаще всего имеет слабую извитость, пух однородной шерсти – нормальную, переходный волос однородной шерсти – плоскую. Извитость придаёт волокнам дополнительную упругость. Самая длинная шерсть у Овец длинношёрстных мясных (Линкольн и другие) и некоторых грубошёрстных (Горнокарпатская и другие) пород –до 40 сантиметров (см) и более; короткая – у тонкорунных и некоторых грубошёрстных (Гиссарская и другие) – 4–7 см (смотрите также Текстильные Волокна). Цвет шерсти определяется наличием в короковом слое пигмента меланина, содержащегося по всей длине или в части волокна, и его окраской (коричнево-чёрной или жёлто-красной). Основные цвета шерсти – белый, чёрный и рыжий (или коричневый). Для технологического использования наиболее ценна белая шерсть, пригодная для окраски в любой цвет. Особенно сильный (люстровый) блеск характерен для шерсти Овец породы Линкольн, Коз Ангорской породы, матовый – для большинства грубошёрстных Овец. От блеска зависит в некоторой степени производственное назначение шерсти, так как он влияет на внешний вид изделия. Жиропот и минеральные примеси, находящиеся в шёрстном покрове Овец, покрывают волокна и соединяют их в общую массу. Жиропот защищает шерсть от действия факторов внешней среды и соединяет волокна в общую массу. Для промышленной переработки, исключая некоторые виды валяльно-войлочного производства, используют в основном чистую (мытую) шерсть, процентное отношение массы которой, с поправкой на кондиционную влажность, к первоначальной массе грязной (немытой) шерсти называется Выходом Чистой Шерсти или Выходом Мытой Шерсти. Производственное использование шерсти определяется комплексом свойств, присущих каждому её виду. Тонкая Шерсть – однородная, состоит из пуховых волокон средней тонины (18–25 мкм) или тонких. Характеризуется уравнённостью волокон по

тонине и длине в штапеле, равномерной извитостью по длине волокна, высокими физическими и технологическими свойствами. Цвет преимущественно белый. Полутонкая Шерсть – однородная, состоит из огрублённых пуховых волокон или переходного волоса (средняя тонина до 25–40 мкм). Имеет более крупную, но менее равномерную извилистость волокна в штапеле и косице, а иногда и меньшую уравнённость их по длине. Цвет преимущественно белый. К этой же группе относятся кроссбредная шерсть и шерсть кроссбредного типа, характеризующиеся высокими технологическими свойствами, а также цигайская шерсть – малой валкоспособностью и хорошей упругостью. Полугрубая Шерсть – неоднородная, состоит из пуховых волокон, переходного волоса и небольшого количества тонкой ости. Отличается неуравнённостью волокон по тонине и длине. Цвет от белого до чёрного. Грубая Шерсть – неоднородная, состоит из пуховых волокон, переходного волоса, ости, часто содержит сухой и мёртвый волос. Отличается большей, чем полугрубая шерсть, неуравнённостью волокон по тонине и длине. Используют овечью шерсть для производства различных тканей, трикотажа, ковров, валяльно-войлочных изделий. Козья Шерсть – однородная (белая) и неоднородная (от белого до чёрного цвета). Характеризуется низкими технологическими качествами, плохой прядомостью и валкостью; вследствие этого у Коз с неоднородной шерстью используется преимущественно пух, из которого изготовляют вязаные изделия. Козы Ангорской и Советской шёрстной пород дают однородную полутонкую шерсть (могер), состоящую из переходного волоса, отличающуюся люстровым блеском и прочностью. Верблюжья Шерсть – неоднородная, цвет – от белого до тёмно-коричневого, в основном коричневый. Отличается высокой прочностью и упругостью, хорошим блеском и малой свойлачиваемостью. Используется для изготовления высококачественного бобрика, одеял, пледов, трикотажа; из грив изготовляют приводные ремни, салфетки для маслобойной промышленности. Шерсть Яков неоднородная, используется в производстве сукон. Шерсть Кроликов и Зайцев, отличающаяся тониной, хорошей эластичностью и свойлачиваемостью, – ценное сырьё для фетровой промышленности. Из пуха Кроликов пуховых пород изготовляют трикотаж и фетр. Конская шерсть – сырьё низкого качества, идёт для производства грубых войлоков. Коровья шерсть обладает хорошей свойлачиваемостью, используется в основном в валяльно-войлочном производстве. Оленья шерсть содержит большое количество мёртвого волоса, используется в седельном, матрацном, мебельном производстве и как изоляционный материал. Из шерсти некоторых пород Собак изготавливают кустарные вязаные изделия. В небольшом количестве используют шерсть Лам, Гуанако, Альпака и других животных. Шерсть, текстильное волокно из волосяного покрова животных (Верблюдов, Коз, Овец и других), которое поддаётся переработке в пряжу или в войлок. Шерсть отличается низкой теплопроводностью, большой влагопоглощаемостью и износостойкостью. Основную массу перерабатываемой в промышленности шерсти составляет овечья. Шерсть широко используется в чистом виде или в смеси с другими волокнами (хлопок, химическое волокно). Видами шерстяных волокон являются:- (i) ‘мёртвый волос’, малопрочный и жёсткий; (ii) ость, более толстое, жёсткое и менее извитое, чем пух волокно; (iii) переходный волос; и (iv) пух, наиболее ценное тонкое, мягкое извитое волокно. Шерсть состоит в основном из белкового вещества – кератина. Из шерсти вырабатывают пряжу, ткани, трикотаж, валяльно-войлочные изделия и другое. Шерсть – волокно волосяного покрова Верблюдов, Коз, Овец и других животных – ценное текстильное волокно, обладающее высокими эластичностью, гигроскопичностью и теплозащитными свойствами. Из шерсти в основном вырабатывают пряжу для костюмных, платьевых, пальтовых, технических тканей и верхнего трикотажа. Шерсть обладает способностью свойлачиваться, благодаря чему её применяют при выработке валяльно-войлочных изделий (войлоков, валенок, шляп и другого). В небольших количествах используют ‘Заводскую’ Шерсть, получаемую со шкур убитых животных, и ‘Утильную’ Шерсть, изготовляемую расщипыванием лоскута, рвани пряжи и тому подобного. Шерсть – натуральное волокно, сырьё для изготовления валяных изделий, пряжи для вязания и ткачества. Состриженную весной и осенью шерсть моют, просушивают, сортируют, чешут и прядут в нить. Обработка шерсти была известна самым древним цивилизациям Передней Азии, откуда это искусство проникло в Грецию и остальную Европу. Первые тонкорунные породистые Овцы выводились в Милете (Древняя Греция), откуда завозились на Пиренеи, где была приручена порода Мериносов, затем во Францию (порода Рамбулье, получившая название по фамилии помещика, занимавшегося разведением тайно вывезенных из Испании Овец), в Англию (порода Шевиот), Австралию. Уже в античное время производились шерстяные ткани, например, Коптские, служившие для изготовления одежды, в средние века во всей Европе широко развилось производство сукон разного качества и цвета. Различия шерстяной пряжи обусловлены большей частью различиями в сортах шерсти. Наиболее часто используются:- (i) шерсть Альпака – шерсть млекопитающего из Рода Лам Альпака, чуть волнистая, шелковисто-блестящая; (ii) шерсть Ангора – шерсть Ангорского Кролика, в пряже её соединяют с шерстяной, хлопчатобумажной, шёлковой нитью; (iii) шерсть верблюжья – шерсть от светло- до тёмно-коричневого цвета, как тонкая, так и грубая, цвет и толщина её зависят от возраста Верблюда. Как правило, верблюжью шерсть не окрашивают; (iv) шерсть кашмир – шерсть Индийских и Иранских Кашмирских Коз, очень тонкая, длинная, с шелковистым блеском; (v) шерсть Ламы – шерсть Южноамериканской Ламы, прочная, длинная, естественный цвет варьируется от светло- до тёмно-коричневого; (vi) шерсть мериносовая – красивая пушистая тонкая шерсть Овцы Мериноса; (vii) шерсть мохер – шерсть Ангорских Коз, которых разводят в Испании, Малой Азии, Южной Америке, пушистая, длинная, мягкая, тонкая, с шелковистым блеском, пышнозавитая, естественный цвет – белый. Под Пороками Шерсти понимаются дефекты, снижающие технические свойства шерсти. В зависимости от характера и происхождения их делят на две группы:- (i) пороки шерсти, обусловленные породными и индивидуальными особенностями овец; и (ii) пороки шерсти, являющиеся следствием нарушения кормления и содержания (ослабленная крепость волокон, переслед, или ‘голодная тонина’, засорённость посторонними примесями, потеря натурального цвета, следы чесотки и поражения клещами, дефекты стрижки и другие). Пороки шерсти первой группы устраняют целенаправленной племенной работой – отбором и подбором животных с ценными качествами шерсти. Ослабление крепости шерсти и замедление её роста вызвано обычно неудовлетворительным кормлением или резкими перебоями в кормлении. Засорённость шерсти различна в зависимости от способов содержания животных и типов пастбищ. Шерсть, засорённую растительными примесями, делят на:- (i) Сорную Шерсть (с легкоотделимым растительным сором – обломками сена, соломы и другими кормовыми остатками) и (ii) Репейную Шерсть (с колючими – Крымским репьём, тырсой, которые прочно удерживаются в шерсти). Репейную шерсть подвергают механической или химической очистке, после которой волокна в значительной степени утрачивают многие технологические свойства – крепость, эластичность, упругость и другие. Песок, засоряющий шерсть, разрушает верхний чешуйчатый слой волокон, снижает их прочность. При совместном содержании или стрижке тонкорунных и полутонкорунных овец с грубошёрстными и полугрубошёрстными тонкая и полутонкая шерсть засоряется цветными, остевыми и мёртвыми волокнами. Отделить эти волокна от белой однородной шерсти сложно, поэтому такая шерсть непригодна для выработки светлых тканей. При содержании в сырых и тесных помещениях и на базах шерсть загрязняется экскрементами (так называемая Кизячная Шерсть), впитывает влагу, подпаривается, приобретает желтоватый или буроватый оттенок, утрачивает крепость, упругость и эластичность, сваливается. Шерсть теряет натуральный цвет, а иногда и крепость при купании овец в противочесоточных растворах, поэтому обработку ими рекомендуют проводить после стрижки. Снижают качество шерсти следы чесотки и поражения клещом, травление несмывающимися красками. Основной дефект стрижки – Перестрига. Нестандартной считают также шерсть, полученную при двукратной стрижке (весной и осенью) тонкорунных и полутонкорунных овец. Предприятия шерстяной отрасли вырабатывают пряжу, разнообразные обычные, технические и специальные ткани и валяльно-войлочные и фетровые изделия, нетканые материалы как из чистой

шерсти, так и из смесей шерсти с химическими волокнами. Поступающая на предприятия шерсть часто бывает засорена цепкими растительными примесями – репьём. Наличие таких примесей, трудно удаляемых на трёпальных машинах, значительно снижает качество пряжи и ткани. Для устранения растительных примесей шерсть обрабатывают на карбонизационных установках непрерывного действия. Сущность карбонизации заключается в том, что шерсть, пропитанную 4–5%-ным раствором серной кислоты, высушивают при температуре 105–110 °С. Кислота концентрируется и разрушает целлюлозу, из которой состоят растительные примеси. Целлюлоза превращается в гидроцеллюлозу, представляющую собой хрупкий продукт, легко удаляемый механическим воздействием рабочих органов. Карбонизации подвергаются и гребенные очёсы, используемые в смесях. Шерстяную пряжу вырабатывают по трём системам прядения:- аппаратной (или суконной), гребенной (камвольной) и кардной. В аппаратной (или суконной) системе прядения шерсти чесание волокон смеси осуществляется на кардочёсальной машине, а утонение продукта в основном процессе деления на ровничной каретке и частично в процессе вытягивания в вытяжном приборе прядильной машины. Особенностями аппаратной пряжи являются её пушистость, высокая ворсистость, малая крутка, слабая ориентация волокон вдоль оси пряжи, достаточно высокая упругость. Такая пряжа используется для выработки суконных пальтовых, костюмных и платьевых тканей, а также одеял, технических сукон и платков. В гребенной системе прядения шерсти чесание осуществляется на кардочёсальных и гребнечёсальных машинах, а утонение продукта – в вытяжных приборах. В зависимости от тонины шерсти гребенная система прядения делится на (i) тонкогребенную для переработки тонкой и относительно короткой полутонкой шерсти длиной от 55 до 110 миллиметров и (ii) грубогребенную систему для переработки длинной полутонкой, полугрубой и грубой шерсти длиной более 130 миллиметров. Из гребенной пряжи вырабатывется широкий ассортимент платьевых и костюмных тканей, платков, трикотажных полотен и изделий. Ткани из гребенной пряжи отличаются большой плотностью, низкой теплопроводностью и хорошей воздухопроницаемостью. Эти ткани имеют гладкую или рисунчатую поверхность, поэтому одним из основных требований к качеству пряжи является высокая равномерность по линейной плотности, отсутствие на поверхности соринок, узелков, шишек и других пороков. Для переработки длинной шерсти типа кроссбредной и восточно-полугрубой шерсти в смеси с химическими волокнами используется кардная система прядения. По этой системе вырабатывается пряжа большой линейной плотности (от 50 до 500 текс) для технических тканей и ковровых изделий. В этой системе прядения чесание шерсти осуществляется на кардочёсальных машинах, утонение продукта в вытяжных приборах ленточных, ровничных и кольцевых прядильных машин. Непрядомые Отходы (красильный и ворсовальный сбой, стригальный кноп и другие) прядильного производства используют для выработки нетканых, строительных и других материалов. Суконное Прядение – получение шерстяной пряжи для выработки суконных тканей по аппаратной системе прядения. Сукно – ткань из шерстяной или полушерстяной пряжи аппаратного прядения, на лицевой стороне которой в результате валки образован войлокообразный застил (фильц), скрывающий рисунок переплетения нитей (саржевого или полотняного). Сукно применяют в технике в качестве фильтров, прокладок и тому подобного. Сукно – ткань из шерстяной или полушерстяной пряжи аппаратного прядения, на лицевой поверхности которой в результате валки образован войлокообразный застил, скрывающий рисунок переплетения нитей. Сукно обычно вырабатывают полотняным или саржевым переплетением. В результате усиленной валки происходит усадка неотделанного (сурового) сукна по длине и особенно по ширине (до 50%), что придаёт сукну большую плотность. В зависимости от вида и толщины пряжи сукно подразделяется на:- тонкое, полугрубое и грубое; в зависимости от отделки на:- безворсовое и ворсованное. Сукно используется главным образом для зимних пальто, костюмов, форменной одежды, а также как технические ткани, применяемые в качестве фильтров, прокладок, для обивки автомобилей, мебели и прочего. Сукном называют также хлопчатобумажную ворсованную меланжевую или гладкокрашеную ткань, напоминающую внешним видом сукно, заменителем которого она является. Используется главным образом для школьной формы, ватных пальто, лыжных костюмов и прочего. Следует отличать собственно сукно от суконных тканей вообще, к которым, кроме сукна, относятся все ткани из пряжи аппаратного прядения, подвергающиеся валке (шевиот, трико, драп, бобрик, байка и другие).

WOOL ACT = АКТ О ШЕРСТИ – Wool Act was enacted to reduce dependency on foreign wool imports and increase domestic production by providing a subsidy for wool and mohair producers in the United States. See also National Wool Act Of 1954.

WOOL AND MOHAIR MARKET LOSS ASSISTANCE PROGRAM = ПРОГРАММА ПОМОЩИ ПО УБЫТКАМ НА РЫНКАХ ШЕРСИ И МОХЕРА – The US Wool and Mohair Market Loss Assistance Program (WAMLAP and WAMLAP II):- Section 204(d) of the Agricultural Risk Protection Act of 2000 provided for payments to domestic wool and mohair producers who produced and sheared wool or mohair from January 01, 1999, through December 31, 1999. The program was extended to producers who suffered economic loss due to low prices in the 2000 marketing year.

WOOL CLASSER = КЛАССИФИКАТОР ПО ШЕРСТИ (или КЛАССЁР ПО ШЕРСТИ) – Wool Classer is the person who sorts the 'Wool Clip' into the appropriate 'Grades'. / Классификатор по Шерсти – лицо, умеющее правильно произвести классировку и сортировку шерсти.

WOOL CLIP = НАСТРИГ ШЕРСТИ (или ШЕРСТЯНОЕ РУНО) – Wool Clip is the total yield of wool short during one season from the sheep of a particular region.

WOOL COMBS = ШЕРСТОГРЕБНЕЧЁСАЛЬНЫЕ СТАНКИ (или ГРЕБНИ ПО ШЕРСТИ) – Wool Combs:- a variety of combs used to produce fibers for worsted spinning. The single-pitch and 2-pitch combs are what I call the peasant combs and are great for producing semi-worsted yarns. English combs are the multi-pitch combs (4- to 5-pitch) used to prepare a true worsted prep.

WOOL CRÊPE = ШЕРСТЯНОЙ КРЕП – Wool Crêpe is made of woolen or worsted yarns. The crêpe texture is achieved by keeping the warp yarns loose.

WOOL–DYED = ВЫКРАШЕННАЯ В ШЕРСТИ – Wool-Dyed:- a term applied to yarns where the fibers were dyed prior to spinning; either in the loose fibers or as top or roving. See also Yarn-Dyed.

WOOL DYEING = КРАШЕНИЕ ШЕРСТИ – Wool Dyeing:- wool can be dyed with the following dyestuffs:- (i) acid (metal-free) dyes; (ii) chrome dyes; (iii) 1:1 and 1:2 metal complex dyes; and (iv) reactive dyes.

WOOLEN = ШЕРСТЯНОЕ (или СУКОННОЕ, или АППАРАТНОЕ) – Woolen:- yarns made from shorter fibers of 1 to 3 inches, which stick out in all directions, giving the yarn its characteristic fuzziness. They are often singles yarns, and are thicker and more loosely twisted than worsted yarns. The outer layer of each yarn has a typical fuzzy appearance. The split web is known as a Slubbing. Fabrics made from woolen yarns are warm and fuzzy, such as flannels, tweeds and sweaters. Woolen is a wool fabric made of short-staple carded yarns. Woolens normally have a blurry surface and are not shiny. Woolen:- a fabric made of wool and especially of woolen yarns having a fuzzy or napped face (as for use in clothing or blankets) - compare worsted. Garments of woolen fabric, namely a fabric made of wool. / Шерстяные Ткани подразделяются на:- (i) Камвольные:- вырабатываются из тонкой гладкой, так называемой гребенной пряжи, для пошива платьев, костюмов, пальто и тому подобного; (ii) Тонкосуконные:- из более толстой, так

называемой аппаратной пряжи, для пальто и костюмов; и (iii) Грубосуконные:- из самой грубой, толстой аппаратной пряжи, для пальто, одеял и другого.

WOOLEN CARD = ШЕРСТОКАРДОЧЁСАЛЬНЫЙ СТАНОК – Woolen Card is a type of roller card used in the woolen spinning system, usually consisting of three cards in tandem:- the breaker, intermediate, and finisher sections. / roller card = валичная чёсальная машина; роликовый картон.

WOOLEN COUNT = ШЕРСТЯНАЯ НУМЕРАЦИЯ (или НУМЕРАЦИЯ ШЕРСТИ) – Woolen Count:- the two systems used to determine woolen yarn counts in the United States are the run system and the cut system. The run system has a standard of 1 600 yards per hand, while the cut system is based on 300 yards per hank. The Woolen Count is based on 1 600 yards of yarn per pound. With woolen yarns, this is called a 'Run', so a '2 run' would refer to a 3 200 yards.

WOOLEN CUT = ШЕРСТЯНОЙ ОТРЕЗ – Woolen Cut is a woolen yarn measure. A 1-cut woolen yarn has 300 yards in one pound of yarn.

WOOLEN FABRIC = ШЕРСТЯНАЯ ТКАНЬ (или СУКНО, или СУКОННАЯ ТКАНЬ) – Woolen (American English) or Woollen (Commonwealth English) is a type of yarn made from carded wool. Woolen yarn is soft, light, stretchy, and full of air. It is thus a good insulator, and makes a good knitting yarn. Woolen yarn is in contrast to worsted yarn, in which the fibers are combed to lie parallel rather than carded, producing a hard, strong yarn. The woolen and worsted process both require that the wool (and other similar animal fibers, cashmere, camel, etc) be cleaned before mechanical processing. Woolen and worsted nomenclatures apply only to the textile processing of animal fibers, but it has become common to include fiber blends under these terms. The resultant fabrics will be classified as being either woolen or worsted, but this designation is assigned during fiber processing and yarn formation, not in the cloth or finished garment. A woven woolen fabric is one which is subjected to fabric finishing techniques designed to add a directional pile – in that the end consumer can 'stroke' the garment in a single direction (shoulder to cuff etc), such as a casual jacket. This feels like the fibers are directionally arranged. Woolen yarn formation is also very common for knitwear, where the resultant garment has some bulk and the requirement for visual aesthetics (of fiber alignment) is minimal. The worsted processing route is more complex and requires the removal of short fibers and the use of a focused mechanical process to make the individual fibers parallel to each other. The yarn formation process is significantly more comprehensive and results in a very sleek yarn which will offer a clean looking woven fabric, such as for suitings. The worsted process is significantly more expensive and is seldom used for knitwear. Woolen Fabrics:- complements worsted fabrics, the fibers of woolen fabrics are intentionally tangled to create a tufted surface yarn and fabric. Fabrics produced from woolen yarn are usually thick and fuzzy. Wool Fabric is usually made from the fleece of a sheep or lamb, but can come from a variety of animal hair fibres including Cashmere or Angora Goats, as well as the speciality hair fibers of the Camel, Alpaca, Llama or Vicuña. Wool fabric is most commonly used for jumpers, knitwear and suiting. / Шерстяная Ткань, текстильная ткань, выработанная из чисто-шерстяной пряжи или в сочетании её с другими видами нитей, а также из пряжи, полученной из шерсти в смеси с другими волокнами. Кустарное производство шерстяных тканей (сукон) имело место ещё в городах Древнего Востока – Сидоне, Вавилоне, Багдаде. Дальнейшее развитие сукноделие получило в средние века. Наиболее крупные суконные производства в этот период были сосредоточены во Фландрии, Голландии, Англии, Франции (Седан), Саксонии, а также во Флоренции, которая славилась производством тонких сортов сукон, составлявших наиболее важный предмет её торговли. Во 2-й половине XVIII века в связи с появлением совершенных кардочёсальных, ровничных и прядильных машин было начато машинное производство шерстяных тканей. В России кустарное производство шерстяных тканей существовало в Киеве и Новгороде уже в X веке. В 1650 в Москве была создана мануфактура по изготовлению тонких сукон, но выдержать конкуренцию с привозными товарами она не смогла и скоро закрылась. Петр I, заботясь о снабжении армии, поддерживал создание суконных фабрик. Первая фабрика армейского сукна была создана в 1698, а в 20-х годах XVIII века имелось уже около полутора десятков шерстоткацких предприятий. Однако производство камвольных шерстяных тканей было налажено только во 2-й половине XIX века. В бывшем Союзе Советских Социалистических Республик (СССР) объём производства шерстяных тканей составлял 800 миллионов квадратных метров ($м^2$) (в 1977), а их ассортимент насчитывает около 2 000 артикулов. В зависимости от вида сырья различают чисто-шерстяные ткани и полушерстяные ткани. Чисто-шерстяные могут содержать до 10% химических волокон, обычно вводимых с целью получения внешних эффектов. Полушерстяные могут иметь до 25% восстановленной (регенерированной) шерсти и от 10 до 80% волокон других видов. Если химические волокна вводят смешиванием их в пряже с шерстью, то полученные ткани называют Смешанными Тканями. Если ткань получают переплетением шерстяной пряжи с хлопчатобумажной пряжей или с химическими нитями, то её называют Неоднородной Тканью. В зависимости от вида используемой пряжи различают Камвольные, Тонкосуконные и Грубосуконные шерстяные ткани. Камвольные шерстяные ткани вырабатывают из сравнительно тонкой и гладкой одиночной или кручёной пряжи гребенного прядения. Они имеют гладкую поверхность с чётко выраженным ткацким рисунком. Тонкосуконные шерстяные ткани – получают из пушистой пряжи аппаратного прядения. Эти шерстяные ткани имеют на поверхности ворс, частично или полностью скрывающий ткацкий рисунок. Ворс может быть специально расчёсан, подстрижен или запрессован. Грубосуконные шерстяные ткани вырабатывают из грубошёрстной аппаратной пряжи и также уваливают и ворсуют. Шерстяные ткани обладают достаточной устойчивостью к истиранию, действию света и химической чистки, упругостью, гигроскопичностью, высоким тепловым сопротивлением. Добавление к шерсти синтетических волокон (полиамидных, полиэфирных и других) повышает износостойкость шерстяных тканей, но несколько снижает их гигроскопичность и увеличивает способность к пилингованию (образованию волокнистых комочков на поверхности ткани). Использование вискозного волокна и хлопчатобумажной пряжи удешевляет шерстяные ткани, но делает их более сминаемыми. Часть шерстяных тканей используется для технических целей, однако основную массу составляют одёжные:- платьевые, костюмные и пальтовые. Платьевые шерстяные ткани бывают камвольные и тонкосуконные. Вырабатываются саржевым, полотняным, мелкоузорчатым, комбинированным и крупноузорчатым переплетениями. Выпускаются отбелёнными, гладкокрашеными, пестротканными, меланжевыми и набивными. Камвольные платьевые ткани сравнительно тонкие и лёгкие (масса 1 $м^2$ 150–300 граммов (г)). Тонкосуконные платьевые ткани более рыхлые, мягкие, ворсистые и тяжёлые (масса 1 $м^2$ 200–350 г). Вырабатываются полушерстяными. Костюмные шерстяные ткани большей частью бывают камвольные (масса 1 $м^2$ 170–340 г). Чистошерстяными камвольными тканями являются бостон, креп, трико и другие. Полушерстяные камвольные костюмные ткани очень разнообразны (например, шевиот, диагональ). Распространены также костюмные ткани из смешанной двух- или трёхкомпонентной пряжи, которые чаще бывают пестротканными и по виду напоминают трико. Тонкосуконные костюмные ткани более тяжёлые (масса 1 $м^2$ 260–520 г), более рыхлые, иногда с ворсистой поверхностью. Обладают повышенной теплозащитностью и используются чаще для изготовления зимних повседневных костюмов и пиджаков. Пальтовые шерстяные ткани делятся на камвольные, тонкосуконные и грубосуконные. Камвольные (масса 1 $м^2$ 187–540 г) с открытым ткацким переплетением выпускаются гладкокрашеными. Ткани габардин и диагональ вырабатывают из гребенной пряжи саржевым переплетением, ткань букле – из фасонных нитей мелкоузорчатым переплетением. К тонкосуконным относятся сукна, драпы и так называемые пальтовые ткани. Последние обычно рыхлые и мягкие ткани, идущие в основном на

изготовление женских и детских пальто. Грубосуконные пальтовые ткани – это главным образом тяжёлые сукна из грубошёрстной смешанной пряжи, используемые для пошива ведомственной и воинской одежды. Шерстяные Ткани подразделяются на:- (i) Камвольные:- вырабатываются из тонкой гладкой, так называемой гребенной пряжи, для пошива платьев, костюмов, пальто и тому подобного; (ii) Тонкосуконные:- из более толстой, так называемой аппаратной пряжи, для пальто и костюмов; и () Грубосуконные:- из самой грубой, толстой аппаратной пряжи, для пальто, одеял и другого. Очень важный фактор – вес ткани, который может варьироваться от 700 граммов на погонный метр (г/пог.м) (тяжёлые пальтовые ткани) до 100 г/пог.м (лёгкие ткани для женских блузок). За много лет средний вес тканей постепенно уменьшался по мере появления более комфортных условий за счёт центрального отопления и бытовых кондиционеров. Австралийские производители Мериносовой шерсти ответили на эту тенденцию выращиванием более тонкого волокна, необходимого для создания более лёгких тканей. Типичный средний вес камвольных тканей для мужских костюмов – 350 г/пог.м. Костюмная ткань Мёрино Кул^{T3} (Merino Cool^{TM}) (по классификации компании Вулмарк (Woolmark), Австралия, из Прохладной Шерсти весит менее 250 г/пог.м. Шерстяные Ткани отличаются природной эластичностью:- они дают свободу движений и очень быстро восстанавливают свою исходную форму, создавая владельцам шерстяной одежды непревзойдённый комфорт и облегание. Дополнительная пластичность тканей может быть получена за счёт внедрения в ходе ткачества до 4% эластана, что даёт им возможность растягиваться без искажений на 15–20% и делает облегающую одежду ещё более комфортной. Швейный Процесс:- пошив одежды из шерстяных тканей – специализированный процесс, который соединяет до 25 деталей в единое изделие, например такое, как пиджак, причём все детали должны быть взаимно совместимыми между собой. Швейный процесс можно разделить на четыре стадии:- (1) Раскладка И Кройка:- обычно ведётся при свободном состоянии полотен, при этом несколько слоёв ткани раскраивают одновременно с помощью ленточных ножей. (2) Проклейка Прокладочными Материалами:- производится с помощью горячего пресса, который расплавляет клеевую пропитку прокладочных материалов и фиксирует их на шерстяных тканях. (3) Шитьё:- различные компоненты сшиваются вместе. Во избежание раздвижки шва нужно очень аккуратно подбирать строчку, нитку и шаг стежка так, чтобы при шитье они были совместимы с тканью изделия. (4) Прессование:- изделие прессуют на разных производственных стадиях, чтобы удалить складки и придать готовой одежде объёмную форму. Шерстяные ткани при шитье требуют особого обращения, поскольку они впитывают и испаряют влагу. Существует ряд рекомендаций:- (1) ткани следует хранить в условиях относительно высокой влажности; уровень относительной влажности швейного цеха должен составлять 65–75%, во избежание проблем со стягиванием строчки вследствие влажного расширения ткани. (2) Подушка пресса должна быть обтянута соответствующими мягкими и упругими материалами, такими как, силиконовая пена, во избежание нежелательных отпечатков от швов и карманов. (3) Шерстяные полотна зачастую имеют весьма разреженную структуру ткачества, что бывает причиной раздвижки шва. Чтобы предотвратить или уменьшить раздвижку шва, иногда следует увеличить плотность стежка, вести строчку по косой линии, ставить подкладку под шов, или применять цепной шов зигзаг. Можно избежать многих из этих потенциальных проблем, возникающих при шитье лёгких тканей, если швейное предприятие получает полотна с контрольной таблицей FAST – Контрольные Показатели Параметров Ткани (FAST – Fabric Assurance by Simple Testing), которая показывает, какие операции требуют к себе особого внимания.

WOOLEN RUN = ШЕРСТЯНОЙ СБЕГ – Woolen Run is a woolen yarn measure. A 1-run woolen yarn has 1 600 yards in one pound of yarn, a 2-run yarn has 3 200 yards, and so on. / Run – Английская линейная единица нумерации пряжи – число мотков по 1 600 ярдов каждый в 1 фунте веса.

WOOLEN SPINNING SYSTEM = СИСТЕМА АППАРАТНОГО ПРЯДЕНИЯ (или ШЕРСТОПРЯДИЛЬНАЯ СИСТЕМА) – Woolen Spinning System:- in this system, fiber is carded two or three times but not combed and goes directly from cards to the spinning process. Generally wool used for this system are shorter, have more crimp and better felting qualities. With this system it is possible to use wools of different types, lengths and character together in blends. Woolen Spinning System is a system in which fiber is carded two or three times but not combed, and goes directly from cards to the spinning process. Generally, wool used for this system is shorter with better felting qualities. With this system it is possible to use wools of different types, lengths, and character together in blends. See also Worsted Spinning System. / Шерстопрядение, совокупность технологических процессов, используемых для переработки в пряжу шерсти или в смеси с нею других волокон (химических, хлопка). Смешивание осуществляется для удешевления пряжи, улучшения её отдельных свойств (например, износостойкости), а также способствует нормализации технологических процессов. В зависимости от вида перерабатываемой шерсти, линейной плотности пряжи и её назначения в шерстопрядении используют тонкогребенную, грубогребенную, полугребенную и аппаратную системы прядения, которые отличаются главным образом видом чесания (смотрите Чесание Волокнистых Материалов). Тонкогребенная Система Прядения применяется для выработки пряжи линейной плотности 15.5–42 текс из чистой шерсти и смеси её с химическими волокнами. В этой системе сырьё после разрыхления и смешивания подвергается кардному чесанию. Полученная лента затем обрабатывается на нескольких переходах двухпольных ленточных машин для подготовки её к гребнечесанию, которое осуществляется на гребнечёсальной машине периодического действия. Лента с гребнечёсальной машины подвергается выравниванию на ленточных машинах. Для снятия напряжений в волокнах и фиксации волокон в распрямлённом состоянии ленту подвергают глажению на гладильной машине. Иногда глажению предшествует крашение. Подготовленная таким образом лента вылёживается в течение нескольких суток в помещении с повышенной влажностью, что способствует уменьшению электризации волокон, а затем поступает в ровничный отдел, где получают сучёную ровницу. Ровница вновь подвергается вылёживанию, после чего она поступает на кольцевые прядильные машины. Основными особенностями Грубогребенной Системы Прядения, по которой вырабатывают пряжу (обычно из грубой и полугрубой шерсти) линейной плотности 30–83 текс, является использование гребнечёсальных машин непрерывного действия и получение кручёной ровницы на рогульчатых ровничных машинах. Полугребенная Система Прядения применяется для выработки пряжи линейной плотности 42 текс и выше из полутонкой, полугрубой и грубой шерсти в смеси с химическими волокнами. В этой системе чёсаная лента обрабатывается на нескольких переходах ленточных машин, одна из которых оснащается авторегулятором толщины ленты, которая с последнего перехода ленточных машин поступает непосредственно на кольцевую прядильную машину. Аппаратная Система Прядения применяется для выработки пряжи линейной плотности 42–500 текс из натуральной шерсти, химических волокон, а также прядомых отходов аппаратного и гребенного прядения. Иногда используют также хлопковое волокно и восстановленную шерсть, полученную путём разработки шерстяного или полушерстяного лоскута. Компоненты смешиваются на смесовых машинах. Смесь подвергается замасливанию и расщипыванию на щипальной машине. Чесание смеси производится на чёсальных аппаратах, в состав которых входят 2–3 валичные чёсальные машины. На ровничной каретке аппарата прочёс разделяется в продольном направлении на отдельные ленточки, которые, ссучиваясь, превращаются в ровницу. Ровница поступает на прядильную машину. WOOLEN SYSTEM = ШЕРСТЯНАЯ СИСТЕМА – Woolen System is the fundamental system of making yarns for woolen fabrics. In yarns spun on the woolen system, the fibers are not parallel but are crossed in what appears to be a haphazard arrangement. After blending, fibers produced on the woolen system are evenly distributed in carding on two, three, or even four cards. From here, the split

web, called Roving, goes to the spinning frame. In addition to wool, manufactured fibers, cotton, wastes, and noils can be processed on the woolen system. In general, the fibers used are shorter and more highly crimped than those used on the worsted system and are of the type that can be fulled. Wollen System:- wools of short length are often used in the wollen system. In this system the wool is not combed, but rather carded. As a result, the materials are thicker, and garments look bulky in appearance. Some examples of the wollen products include, sweaters, and carpets. / для шерстяных (или суконных) тканей (woolen fabrics).

WOOLEN YARN = ШЕРСТЯНАЯ ПРЯЖА (или АППАРАТНАЯ ПРЯЖА, или СУКОННАЯ ПРЯЖА) – Woolen Yarn is a type of carded yarn made of relatively short fibers of varying lengths. Manufacturing Woolen Yarns:- in the manufacture of woolen yarns, the fibers are passed through two stages such as:- (i) Carding; and (ii) Spinning. The objective of carding process is to disentangle the fibers. In this process the wool fibers are passed between rollers covered with thousands of fine wire teeth. The wool fibers are disentangled by the action of the wires and are arranged in parallel fashion. This makes the woolen yarns smooth. Since the production of woolen yarns is intended to be rough or fuzzy, it is not desirable to have the fibers too parallel. By use of an oscillating device, one thin film, or sliver, of wool is placed diagonally and overlapping another sliver to give a crisscross effect to the fibers. This process helps in obtaining a fuzzy surface on the yarn. The next stage is spinning which is similar to that of worsted production process. / тип кардной пряжи, выработанной из относительно коротких волокон различной длины.

WOOL GREASE = ШЕРСТЯНОЙ ЖИРОПОТ – Wool Grease is secreted by the sebaceous glands in sheep skin, making it a naturally occurring substance from a renewable source. Its prime function is to coat and soften the wool fibers, protecting both skin and fleece against exposure to the elements. Wool grease is referred to as Neutral Wool Grease, Centrifuged Wool Grease, Crude Wool Grease, (Crude) Wool Wax, (Crude) Wool Fat, Lanolin Industrial. While chemically a wax, the term Wool Grease is most commonly used, which is why it has been chosen for this website, too. It's recovered from the liquids resulting from scouring sheep wool. Firstly, heavy impurities such as sand and dirt are removed by gravity settlement. The wax is then obtained using either centrifugal separation or solvent extraction. The crude product is a dark, highly viscous paste with a distinct sheep-like odour. Wool scouring and treatment is performed in factories around the world, and the quality of the resulting crude wool wax is affected by plant conditions and local regulations. However, wool wax grades according to standardised specifications are available. Wool Grease is a natural oil covering the wool fibers sheared off sheep; when purified the resulting lanolin is mixed into cosmetics. Wool Grease is a fatty slightly sticky wax coating the surface of the fibers of sheep's wool. Compare with Wool Fat. / Под Жиропотом шерсти понимается смесь выделений сальных и потовых желёз кожи овец. Количество жира в шерсти мериносовых овец 30–40%, полутонкорунных – 12–20%, грубошёрстных – около 4%. Жиропот смазывает и защищает шерсть от дейстия влаги, механических загрязнений и других внешних факторов, способствует лучшему сохранению физико-механических свойств шёрстных волокон. При недостатке жиропота шерсть делается сухой, теряет блеск; при избытке жиропота уменьшается выход чистой шерсти. Жиропот используют для получения ланолина.

WOOL IN THE GREASE = ШЕРСТЬ В ЖИРОПОТУ – Wool in the Grease is a wool in its natural condition as it is shorn from the sheep. / Шерсть в Жиропоту или Немытая Шерсть или Оригинальная Шерсть – шерсть в том состоянии, в каком она была снята с овцы.

WOOLLY = ШЕРСТИСТОЕ (или ШЁРСТНОЕ, или МОХНАТОЕ) – Wooly:- clothed with long and entangled soft hairs. Woolly:- thickly covered with long hairs. Woolly:- a garment made from wool, especially underclothing of knitted wool (usually used in plural).

WOOL PRODUCTION SEQUENCE = ПОСЛЕДОВАТЕЛЬНОСТЬ ПРОИЗВОДСТВА ШЕРСТИ – Wool Production Sequence:- the manufacturing process:- the major steps necessary to process wool from the sheep to the fabric are: shearing, cleaning and scouring, grading and sorting, carding, spinning, weaving, and finishing. (1) Shearing:- sheep are sheared once a year – usually in the springtime. A veteran shearer can shear up to two hundred sheep per day. The fleece recovered from a sheep can weigh between 6 and 18 pounds (2.7 and 8.1 kilograms); as much as possible, the fleece is kept in one piece. While most sheep are still sheared by hand, new technologies have been developed that use computers and sensitive, robot-controlled arms to do the clipping. (2) Grading and Sorting:- grading is the breaking up of the fleece based on overall quality. In sorting, the wool is broken up into sections of different quality fibers, from different parts of the body. The best quality of wool comes from the shoulders and sides of the sheep and is used for clothing; the lesser quality comes from the lower legs and is used to make rugs. In wool grading, high quality does not always mean high durability. (3) Cleaning and Scouring:- wool taken directly from the sheep is called 'Raw' or 'Grease Wool'. It contains sand, dirt, grease, and dried sweat (called Suint); the weight of contaminants accounts for about 30 to 70 percent of the fleece's total weight. To remove these contaminants, the wool is scoured in a series of alkaline baths containing water, soap, and soda ash or a similar alkali. The byproducts from this process (such as lanolin) are saved and used in a variety of household products. Rollers in the scouring machines squeeze excess water from the fleece, but the fleece is not allowed to dry completely. Following this process, the wool is often treated with oil to give it increased manageability. After being carded, the wool fibers are spun into yarn. Spinning for woolen yarns is typically done on a mule spinning machine, while worsted yarns can be spun on any number of spinning machines. After the yarn is spun, it is wrapped around bobbins, cones, or commercial drums. (4) Carding:- next, the fibers are passed through a series of metal teeth that straighten and blend them into slivers. Carding also removes residual dirt and other matter left in the fibers. Carded wool intended for worsted yarn is put through gilling and combing, two procedures that remove short fibers and place the longer fibers parallel to each other. From there, the sleeker slivers are compacted and thinned through a process called Drawing. Carded wool to be used for woolen yarn is sent directly for spinning. (5) Spinning:- thread is formed by spinning the fibers together to form one strand of yarn; the strand is spun with two, three, or four other strands. Since the fibers cling and stick to one another, it is fairly easy to join, extend, and spin wool into yarn. Spinning for woolen yarns is typically done on a mule spinning machine, while worsted yarns can be spun on any number of spinning machines. After the yarn is spun, it is wrapped around bobbins, cones, or commercial drums. (6) Weaving:- next, the wool yarn is woven into fabric. Wool manufacturers use two basic weaves:- the plain weave and the twill. Woolen yarns are made into fabric using a plain weave (rarely a twill), which produces a fabric of a somewhat looser weave and a soft surface (due to napping) with little or no luster. The napping often conceals flaws in construction. Worsted yarns can create fine fabrics with exquisite patterns using a twill weave. The result is a more tightly woven, smooth fabric. Better constructed, worsteds are more durable than woolens and therefore more costly. (7) Finishing:- after weaving, both worsteds and woolens undergo a series of finishing procedures including: fulling (immersing the fabric in water to make the fibers interlock); crabbing (permanently setting the interlock); decating (shrink-proofing); and, occasionally, dyeing. Although wool fibers can be dyed before the carding process, dyeing can also be done after the wool has been woven into fabric. Byproducts:- the use of waste is very important to the wool industry. Attention to this aspect of the business has a direct impact on profits. These wastes are grouped into four classes:- (i) Noils:- these are the short fibers that are separated from the long wool in the combing process. Because of their excellent condition, they are equal in quality to virgin wool. They constitute one of the major sources of waste in the industry and are reused in high-quality products. (ii) Soft Waste:- this is also high-quality material that falls out during the spinning and carding stages of production. This material is usually reintroduced into the process from which it came. (iii) Hard Waste:- these wastes are generated by spinning, twisting, winding, and warping. This material requires much re-processing and is therefore considered to be of lesser value. (iv) Finishing Waste:- this category includes a

wide variety of clippings, short ends, sample runs, and defects. Since this material is so varied, it requires a great deal of sorting and cleaning to retrieve that which is usable. Consequently, this material is the lowest grade of waste. The spun wool yarn is woven into fabric using two basic weaves:- the plain weave and the twill weave. Woolen yarns are made into fabric using a plain weave (rarely a twill), which produces a fabric of a somewhat looser weave and a soft surface (due to napping) with little or no luster. The napping often conceals flaws in construction. Worsted yarns can create fine fabrics with exquisite patterns using a twill weave. The result is a more tightly woven, smooth fabric. Better constructed, worsteds are more durable than woolens and therefore more costly. See also Production Sequence (wool). Wool Processing:- Shearing; Washing; Blending; Carding; Spinning; Weaving; Fulling & Finishing; and Chemical Finishes. As with many discoveries of early man, anthropologists believe the use of wool came out of the challenge to survive. In seeking means of protection and warmth, humans in the Neolithic Age wore animal pelts as clothing. Finding the pelts not only warm and comfortable but also durable, they soon began to develop the basic processes and primitive tools for making wool. By 4000 BC, Babylonians were wearing clothing of crudely woven fabric. People soon began to develop and maintain herds of wool-bearing animals. The wool of sheep was soon recognized as one of the most practical to use. During the XI and XII centuries, wool trade prospered. The English had become proficient in the raising of sheep, while the Flemish had developed the skills for processing. As a result, the British began to sell their wool to the Flemish, who processed the raw material and then sold it back to the English. The ambitious British soon realized the advantages of both producing and processing their own wool. As Britain began to prosper, it sought to enhance its position by enacting laws and embargoes that would stimulate its domestic production. Some laws, for example, required that judges, professors, and students wear robes made of English wool. Another law required that the dead be buried in native wool. When the American colonies began to compete with the motherland, the English passed a series of laws in an attempt to protect their ‘golden fleece’. One law even threatened the amputation of the hand of any colonist caught trying to improve the blood line of American sheep. Today, wool is a global industry, with Australia, Argentina, the United States, and New Zealand serving as the major suppliers of raw wool. While the United States is the largest consumer of wool fabric, Australia is the leading supplier. Australian wool accounts for approximately one-fourth of the world’s production. What for centuries was a small home-based craft has grown into a major industry. The annual global output is now estimated at 5.5 billion pounds. Though cotton is the number one plant used for fabrics and the number one fiber overall, the number one source for animal fiber is still wool. / :- стрижка, промывка, смешивание, кардочесание, прядение, ткачество, валяние (или валка или уваливание) и заключительная отделка; и . Производственная Цепочка:- первый шаг в производстве пряжи – шерстомойный процесс, или промывка шерсти в тёплой воде с целью удаления их неё жира и грязи. Промытая и высушенная шерсть готова к дальнейшей переработке по одному из двух основных производственных направлений:- (1) Аппаратное Производство:- более короткое, для выработки более низких номеров пряж. Волокна в аппаратных пряжах имеют произвольное распределение и меньшую длину, чем волокна в гребенных пряжах. Мытую шерсть смешивают и распутывают на кардочёсальных машинах, волокна разделяют на порядке игольчатых валов, вращающихся с различными скоростями относительно друг друга. С последнего вала снимают прочёсанную шерсть в виде тонкого слоя волокнистой ватки. Далее ватку делят на тонкие полоски с помощью системы разделительных ремешков. Полоски с ремешков поступают в конденсор, на сучильные рукава, откуда они выходят в виде рыхлого сученого жгута без крутки, или аппаратной ровницы, которая приобретает прочность при дальнейшем прядении. Прядильный процесс вытягивает и скручивает шерсть, в результате чего образуется пряжа. Эту однониточную пряжу можно использовать в качестве утка, однако для основы обычно требуется двухниточная пряжа. Для этого в процессе сложения скручивают воедино две нити, применяя противоположную крутку. (2) Гребенное Производство:- обычно применяется для выработки пряж более высоких номеров. Волокна в гребенных пряжах лежат параллельно друг другу. Гребенное производство имеет много общего с аппаратным, однако технологическая цепочка отличается большей протяженностью. Мытую шерсть обрабатывают на кардочёсальной машине так же, как и при аппаратной технологии, однако снимают её с машины не в виде отдельных жгутов без крутки, но в форме единого толстого сливера из параллельных волокон. На следующей стадии шерсть несколько раз проводят через ленточные машины, на которых отдельные ленты складываются и протягиваются вместе для повышения регулярности волокон. Далее идёт процесс гребенного чесания, где из ленты удаляются короткие волокна, которые перерабатываются отдельно как гребенной очёс. Полученная гребенная лента называется топсом. Финальная стадия перед прядением вытягивает топс в тонкий жгут, или ровницу. Гребенная ровница аналогична аппаратной, однако её выработка требует большего числа переходов. В процессе прядения ровница вытягивается примерно в двадцать раз относительно своей первоначальной длины и получает крутку, за счёт чего образуется тонкая гребенная пряжа. Далее из пряжи удаляют все крупные узлы или утолщения и сращивают концы тонкими соединениями, прежде чем намотать её на крупные паковки. Подобно аппаратным пряжам, гребенные пряжи, идущие в основу ткани, должны быть, как правило, двухниточными. Тканые полотна, как и шерстяные пряжи, делятся на две группы:- суконную (из аппаратных пряж) и камвольную (из гребенных пряж). Независимо от группы, физические свойства готовой ткани зависят от четырёх основных параметров пряжи (номер или толщина; уровень крутки (число кручений на метр); гребенная или аппаратная; и сложение (одинарная или двуниточная пряжа)).

WOOL PRODUCTS LABELING ACT OF 1939 = АКТ ОБ ЭТИКЕТИРОВАНИИ ПРОДУКТОВ ИЗ ШЕРСТИ ОТ 1939 – The US Wool Products Labeling Act of 1939 (PL 76-850) (15 USC §§ 68 et seq.):- signed into law October 14, 1940. The Act, as amended, requires that all wool products bear a label indicating the percentage of the total wool fiber weight of the wool product, recycled wool, each fiber other than wool, and the aggregate of all other fibers of the product. Also, the label must identify the manufacturer and include the country where the wool product was processed or manufactured.

WOOL ROLLER = СВЁРТЩИК ШЕРСТИ – Wool Roller is the person in a shearing shed who skirts the fleece, then rolls it. The fleece is then classed.

WOOL RUG = ГРУБЫЙ ШЕРСТЯНОЙ КОВРИК – A Wool Rug is a wool floor covering made of carded yarn.

WOOL TOP = ШЕРСТЯНАЯ ГРЕБЕННАЯ ЛЕНТА (или ШЕРСТЯНАЯ МЫЧКА, или ШЕРСТЯНОЙ ЖГУТ, или ШЕРСТЯНОЙ ХОЛСТ, или ШЕРСТЯНОЙ ВЕРХ, или ШЕРСТЯНОЙ ТОП, или ШЕРСТЯНАЯ ВАТКА) – Topmaking mills make Wool Top, a semi-processed product from raw wool. The process requires that the wool be scoured (washed) and combed and sorted. The longer fibers resulting from the process are called Tops, and are in a form ready for spinning. To be closer to customers, much of the industry has moved from Australia, Europe and the USA to China. Many British companies produce high quality wool top in Britain from British wool and fibre; most work with the fleece from cleaning it to hand dying. A Topmaker is an old term for a person engaged in the process. Wool Top is a strand of longer wool fibers that have been straightened, made parallel, and separated from the shorter fibers by combing. Wool Top:- also referred to as Worsted Top, it is a continuous sliver from long, choice woolen fibers which are to be manufactured ultimately into worsted yarn. The combing operation takes out the short fibers from the desired, choice stock.

WOR = WATER OIL RATIO

WORD = СЛОВО – Word:- a fundamental unit of storage in a computer. The size of a word in a particular computer architecture is one of its chief distinguishing characteristics. The size of a word is usually the same as the width of the computer's data bus so it is possible to read or write a word in a single operation. An instruction is usually one or more words long and a word can be used to hold a whole number of characters. These days, this nearly always means a whole number of bytes (eight bits), most often 32 or 64 bits. In the past when six bit character sets were used, a word might be a multiple of six bits, e.g., 24 bits (four characters) in the ICL 1900 series (International Computers Limited (ICL) was a large British computer hardware). Word is a set of bits that is of a fixed size and is typically operated on by a computer's processor. Word is a computing a set of bits used to store, transmit, or operate upon an item of information in a computer, such as a program instruction. / Слово:- в компьютерной технологии, группа двоичных чисел (битов (binary digits)), рассматриваемая как единое целое и хранимая в компьютерной памяти отдельно от других групп. Обычно слово состоит из 16 или 32 битов (2 или 4 байтов (bytes)).

WORD–OF–MOUTH ADVERTISING = УСТНАЯ РЕКЛАМА (или СЛОВЕСНАЯ РЕКЛАМА) – Word-Of-Mouth Advertising is an unpaid form of promotion in which satisfied customers tell other people how much they like a business, product or service . Word-of-mouth advertising is important for every business, as each happy customer can steer dozens of new ones your way. And it's one of the most credible forms of advertising because a person puts their reputation on the line every time they make a recommendation and that person has nothing to gain but the appreciation of those who are listening. What are you doing to make sure your potential ambassadors feel confident enough in your business to recommend it? What are you doing to trigger word-of-mouth? Here are some tips to help you generate word-of-mouth:- Word-of-mouth is triggered when a customer experiences something far beyond what was expected. Slightly exceeding their expectations just won't do it. You've got to go above and beyond the call of duty if you want your customers to talk about you. Don't depend on your staff to trigger word-of-mouth by delivering 'exceptional customer experience'. Good customer service is sporadic, even in the best establishments. The customer who receives exceptional service today can't be sure their friends will receive the same tomorrow, so even the most well-served are unlikely to put their necks on the line and make a recommendation. Deep down, customers know service comes from an individual, not from an establishment. And even the best people have bad days. Physical, nonverbal statements are the most dependable in triggering word-of-mouth. These statements can be architectural, kinetic or generous, but they must go far beyond the boundaries of what's normal. If you don't want to be average, why do you insist on being normal? Here are some examples of these statements:- (i) Architectural:- the piano store that looks like a huge piano, with black and white keys forming the long awning over the long front porch. The erupting volcano outside the Mirage in Las Vegas. A glass-bottom floor that allows customers to see what's happening on the floor below them. Do you remember when McDonalds began building attached playgrounds to all their restaurants? It's worked like magic for more than 20 years. (ii) Kinetic:- the tossing of fresh fish from one employee to another at Pike Place Market in Seattle. The magical, twirling knives of the tableside chefs at Benihana. Kissing the codfish when you get 'screeched in' at any pub in Newfoundland. (A screech is a loud and funny ceremony during which non-Newfoundlanders down a shot of cheap rum, repeat some phrases in the local dialect and kiss a codfish. Everyone who visits that wonderful island returns home with a story of being 'screeched in'.) While it may at first seem like a kinetic word-of-mouth trigger is a violation of #2 above, 'Don't depend on your staff...', it's really not. A kinetic word-of-mouth trigger is constantly observable by management. It isn't a 'customer service' experience delivered privately, one on one. (iii) Generous:- are you willing to become known as the restaurant that allows its guests to select – at no charge – their choice of desserts from an expensive dessert menu? You can cover the hard cost of it in the prices of your entrees and drinks. Flour, butter and sugar are cheap advertising. Are you the jewelry store that's willing to become known for replacing watch batteries at no charge, even when the customer hasn't purchased anything and didn't buy the watch from your store? Word will spread. And watch batteries cost less than any type of advertising. Architectural, kinetic, generous:- these are the flour, butter and sugar of effective word-of-mouth. Will you put these rich ingredients into the mouths of your potential word-of-mouth ambassadors? Budget to deliver the experience that will trigger word-of-mouth. Sometimes your word-of-mouth budget will be incremental, so that its cost is tied to your customer count. Other times it'll require a capital investment, so that repayment will have to be withheld from your advertising budget over a period of years. The greatest danger isn't in overspending but in under spending. Under spending on a word-of-mouth trigger is like buying a ticket that only takes you halfway to Europe. Don't promise it in your ads. Although it's tempting to promise the thing you're counting on to trigger word-of-mouth, these promises will only eliminate the possibility of your customers becoming your ambassadors. Why would a customer repeat what you say about yourself in your ads? You must allow your customers to deliver the good news. Don't rob your ambassadors of their moment in the sun. Xxxxx. Word Of Mouth Advertising (WOM) is the unpaid spread of a positive marketing message from person to person. It can take place directly using the human voice, or can be transmitted via any communicative means such as through the internet or via text message. WOM is a powerful promotional tool and should be considered as part of almost every business marketing strategy. The least powerful WOM message is neutral – these tend not to travel very far and are not strong influencing factors. 'Did you know there is a new restaurant in town'? Positive WOM usually results for a good brand experience and is spread by 'brand ambassadors'. 'Did you know there's a new restaurant in town? The food and service are great'! Negative messages are spread by 'saboteurs' or 'detractors'. 'Don't go to that new restaurant – I got food poisoning and had to take two days off work'. Word of mouth is difficult to control and measure but can spread quickly and be highly influential in purchase decisions, Think about the last film you went to see, the last car you bought or the area you live in. Chances are you arrived at those choices due to a personal recommendation from a friend or trusted acquaintance. Types of worth of mouth advertising media:- the major methods of human to human communication can be summarised as follows:- (1) Personal:- personal communication is conversation based. It is difficult to ignore and a powerful influencing tool. (i) Face to face personal conversations:- face to face communications remain the most powerful way of transmitting a message from one person to another. Human conversations involve much more than simply words – cues such as voice tone and body language also convey information such as enthusiasm, sadness, emotion and truthfulness. (ii) Voice only conversations:- voice only conversations are a close second. Live voice-based communication holds the attention of the listener and allows for the transmission of important tonal cues. (2) Digital:- digital communication can involve conversations or one way electronic communication. Although less powerful than personal communications, they allow a message to travel quickly over long distances. (i) Multimedia based digital messages and conversations:- image and audio based messages come third in terms of message strength. If text-based digital conversation can be supported by images and audio it adds power to the message. Examples include Facebook, Email, MMS and YouTube. (ii) Text based digital messages and conversations:- text only messages are the least powerful, but the easiest to transmit via digital means. There are countless methods of transmitting a text based messages from one person to another, including SMS messages, Twitter, text only emails, RSS feeds and instant messaging services. (3) Viral advertising:- Viral advertising is a method of advertising which relies on digital transmission, but doesn't necessarily require any first hand brand experience for it to be passed on. The reason viral advertising is important is because of the potentially massive exposure a successful viral can provide. Viral ads generally take the form of some impressive video footage or something 'chat-worthy' which is designed to be passed through the population via email or a similar tool. Many people tend to send viral ads to a large group of friends which is why virals can spread quickly and effectively across the world. The influencing strength of the message versus transmission speed and distance is summarised in the diagram below. How do people influence how a message spreads? The transmission of a word of mouth message through the population is a fairly complex process to model. If everyone passes a message to just two people via a conversation, you

get exponential growth as shown below. However, humans aren't that predictable which has lead us to develop two different models which explain how a message spreads... 'Limited communication' model:- unfortunately, not everyone who has a good experience or hears good things about a brand will pass on the message. Some people will be pleased with a product or service or read an interesting recommendation from a friend, but may just keep it to themselves or forget about the whole experience all together – this can leave a WOM message dead in its tracks. Certain individuals, however, are much more likely to post customer reviews and chat to people over dinner about a product, so maybe it's more important to try and influence these special people… 'Certain people are more influential than others' model:- according to the social researcher Malcolm Gladwell there are two types of special individuals which help spread WOM. Tap into these individuals and your message can spread much more quickly than via the general population. Connectors:- most people know a connector – these people get a real buzz out of meeting people and are genuinely interested in them. Their motivation is the joy of being social and talking about interesting conversation points. They aren't as persuasive as a 'Maven' (below), but have a large social group. Recommenders or 'Mavens':- these people are motivated by the joy of giving good advice. They are not as sociable as the Connectors, but they get a kick out of giving advice and enjoy finding the best deal on everything. They are persuasive talkers and can be influential when it comes to a customer's product decision. How does word of mouth spread through a population? (i) A positive (or negative) personal experience makes an impression at the individual level. (ii) The individual decides to pass on the message and spread the word to others (the message is seeded). (iii) The message is sent or discussed using the available communications methods. (iv) Some people will be influenced to experience the source of the story for themselves, others will simply pass the message on. The conversion rate depends on the power of the message, the method of communication and the personalities involved (see next section). (v) The message is re-seeded and the cycle continues. What makes a message spread successfully? Word of mouth messages can be positive, neutral or negative and the degree and speed of transmission depends on:- The strength of the message:- for a marketing message to spread successfully through the population, the message needs to be strong enough that it warrants passing on, whereas a weak message can be forgotten about if not deemed 'chat-worthy'. Strong positive conversational WOM almost always results from a good customer experience or convincing message. The method of communication used:- the method of communication greatly influences the speed of spread, the 'transmission reach' and also contributes to the strength of the message. A carefully constructed viral YouTube video can spread through a population at epidemic speeds, but face to face communications spread much more slowly. The latter is much more likely to influence purchase intent on an individual level but is not as useful for raising awareness. The personalities involved:- people's personalities affect the spread of a message depending on how persuasive, social and internet savvy they are. It's difficult to predict how well a message will spread, some people simply ignore viral advertising emails, while others will talk to anyone and everyone about the surprisingly good meal they had the new restaurant in town. The quality of the viral:- if you're intentionally creating a viral message, it stands a greater chance of success if it uses the following criteria among others. Making sure you have a great creative team behind you will help! (i) Entertainment/awe-inspiring; (ii) Cringe worthiness; (iii) Extreme/shock value; (iv) Terrible/embarrassing. Using WOM to promote your business:- so, how can you harness the power of word of mouth marketing to promote your business? There is an active and a passive approach. Active WOM – encouraging and influencing the message:- if you intend WOM to form a major part of your promotional investment, you can't just sit back and hope that it will happen. Use the tools at your disposal to encourage word positive of mouth. Determine your objectives and ensure your message, the means of communication and the people you target work together in order to promote your business. Provide access to the communications tools:- develop both message based and conversational methods of communication whether this is a Twitter account, a social bookmarking tool or a chat room, and encourage your customers to use this tool to discuss your brand. Consider the communication medium and which is most relevant to your target audience, don't just open a Twitter account because everyone else is doing it. Determine your message and seed it at the community level:- target specific communities which could include a particular interest group, location or demographic and seed your message using honest means. A great way to seed a message in a community to provide people with an excellent customer experience. Recruit brand ambassadors:- actively encourage certain key individuals to generate stories for you and actively engage with your customers. Use PR to generate a story:- use the press as a catalyst to start a discussion. The more news worthy your story the better. Make the message memorable and exciting and 'sticky'. Ensure the message is worth passing on – motivate people to discuss your brand and spread the word. Create viral ads:- these should be interesting, useful, funny, shocking, exciting, emotional, dramatic, awe-inspiring or controversial. Most of all they need to be 'chat-worthy' and easy to pass on. Be honest:- if you lie about anything, people will find out and now they'll have the perfect medium to show you up. Get lucky:- only a few WOM ideas go 'epidemic' but even without a wildfire approach, personal communication can lead to tangible marketing results. Use opinion formers and influencers:- if possible, find and enthuse the opinion formers, blog owners, and social media connectors. According to Keller, author of 'The Influential' these people also tend to adopt new products and technology earlier. Passive WOM – doing a great job:- Use the marketing mix to create a customer focus:- ensure all elements of your business are ticking over like a well oiled machine. From the people you use to the way you sell and deliver your product. Satisfy and exceed customer expectations:- add excitement, value, or great customer service to your brand. Never let a customer go without engaging and enthusing them. Use 'surprise and delight':- add little unexpected touches which are there simply to give the customer 'a little extra'. Sometimes these aspects of a brand, however insignificant can generate a large amount of WOM advertising. Manage unhappy customers well:- avoiding negative WOM can be as valuable as generating positive. In addition, a well handled complaint can sometimes create a brand ambassador. Remember WOM can be bad as well as good:- there's no quicker way to destroy a brand than by negative word of mouth advertising. Dissatisfied customers are much more likely to post public warnings about a bad product on their blog than a satisfied customer is to recommend it to a friend. Upset people at your peril! When people talk about word of mouth advertising this is the model that is normally quoted and leads to huge volumes of noise in a very short period of time. This model is great in practice, but as usual the real world isn't quite as simple as this. (i) Experiential marketing; (ii) Building a brand; (iii) Writing a marketing plan. / МэкДонэлдз (McDonalds). Устная Реклама – рекламирование нового товара или услуги покупателем, который рассказывает своим друзьям, соседям и знакомым о достоинствах товара, особенно если это происходит до того, как начнётся реклама товара или услуги в средствах массовой информации.

WORDSMITHING = ЧЕКАНКА СЛОВ (или СЛОВОТВОРЧЕСТВО, или СЛОВОБЛУДСТВО) – Wordsmithing is the art of inventing new words by modfying existing ones or creating entirely new words. Werid means weirdness in a good way is an example of fine wordsmithing. Wordsmithing is a verb meaning to create clever and funny words. Wordsmithing is the making of changes to a text to improve clarity and style, as opposed to content. For example, we've drafted an agreement, but there's still a bit of wordsmithing left to do. / Термин Чеканка Слов или Словотворчество характеризует выдумывание слов и манипулирование терминами в ходе переговоров; часто используется в качестве маневра в международной торговле. Он получил распространение благодаря преподавателям экономических университетов, которые прибегают к этому вместо использования стандартной терминологии.

WORK = РАБОТА – (1) Work:- in physics, measure of energy transfer that occurs when an object is moved over a distance by an external force at least part of which is applied in the direction of the displacement. If the force is constant, work may be computed by multiplying the length of the path by the component of the force acting along the path. Work done on a body is accomplished not only

by a displacement of the body as a whole from one place to another but also, for example, by compressing a gas, by rotating a shaft, and even by causing invisible motions of the particles within a body by an external magnetic force. No work, as understood in this context, is done unless the object is displaced in some way and there is a component of the force along the path over which the object is moved. Holding a heavy object stationary does not transfer energy to it, because there is no displacement. Holding the end of a rope on which a heavy object is being swung around at constant speed in a circle does not transfer energy to the object, because the force is toward the centre of the circle at a right angle to the displacement. No work is done in either case. The mathematical expression for work depends upon the particular circumstances. Work done in compressing a gas at constant temperature may be expressed as the product of pressure times the change in volume. Work done by a torque in rotating a shaft may be expressed as the product of the torque times the angular displacement. Work done on a body is equal to the increase in the energy of the body, for work transfers energy to the body. If, however, the applied force is opposite to the motion of the object, the work is considered to be negative, implying that energy is taken from the object. The units in which work is expressed are the same as those for energy, for example, in the metre-kilogram-second system, Joule (Newton-metre); in the centimetre-gram-second system, erg (dyne-centimetre); and in the English system, foot-pound.

(2) Work is any activity which contributes to the production of goods or services within the production boundary. Work:- in economics and sociology, the activities and labor necessary to the survival of society. The major activity of early humans was hunting and gathering food. As early as 40 000 BC, hunters began to work in groups to track and kill animals. Younger or weaker members of the tribe were more naturally suited to gathering food. It seems likely that women, because of the requirements of pregnancy and nursing, did not generally participate in hunting. Some primitive peoples demonstrated an aptitude for making weapons, thus providing an early instance of the division of labor. When agricultural cultivation replaced simple gathering, the resulting modest surplus of food freed some members of the tribe to pursue crafts such as pottery making, textiles, and metallurgy. A sufficient food supply and the development of copper and bronze tools laid the groundwork for more complex societies that could support larger populations; as towns were established, new specialized occupations developed in commerce, law, medicine, and defense. The increasing complexity of these economies required permanent records; thus, writing and bookkeeping evolved. These civilizations, and the later societies of Greece and Rome, were characterized by rigid, hereditary, hierarchical class structures. Kings and nobles ruled, supported by warriors; priests served as government officials; merchants dealt in the products of artisans and craftsmen; peasants worked family farms; and slaves worked in mines and craft workshops. These craft workshops were prototypes of the modern factory, producing metal weapons and tools with fewer than a dozen workers under the direction of a master craftsman. Larger projects, such as pyramids and aqueducts, were directed by master builders, who were assisted by foremen and scribes. The work required laborers of varying degrees of skill ranging from craftsmen to slaves. Some of this organizational sophistication was lost in Europe immediately after the disintegration of the Roman Empire, as social life contracted into smaller, self-enclosed spheres. Nobles owned tracts of land that were farmed by peasants, who were bound to their plots by inheritance. The peasants turned over much of their produce to the nobles in return for military protection. The church was also an important feature of the medieval economy, offering work to masons, carvers, and glaziers. As town life grew more vigorous, craft guilds assumed greater importance, reaching their peak in the XIV century. Their purpose was to limit the supply of labor in a profession and to control production. Guild members were ranked according to experience:- masters, journeymen, and apprentices. Strains developed within the guilds as some masters discovered that trading in raw materials and finished products held greater rewards than craftsmanship; others discovered that they could secure greater profits by excluding journeymen from promotion to the master class. Thus, apprentices and journeymen became a class of free laborers, and the employer-employee relationship was established. Beginning about AD 1000, wind and water power began to replace or assist human laborers in tanning, grain processing, olive pressing, and the operation of bellows in mines and blast furnaces. Mechanization had little effect on large construction projects, however:- churches and castles were built by strongly individualistic craftsmen under the direction of a master mason who not only designed the building but handled accounts and bought raw materials. Technological advances, combined with worldwide exploration and colonization by European powers, did eventually change economic life profoundly. Some guild masters were able to accumulate large amounts of capital, forcing less-successful masters to become wage laborers. This transition was most pronounced in England, where it was encouraged through the granting of monopolistic charters, the evolution of finance and trade, and the development of machinery, particularly steam power, in the XVIII century. Early factories divided the work previously done by a single craftsman into a number of distinct tasks, each performed by low-paid unskilled or semiskilled workers with the assistance of machinery. This new organization shortened the time required to produce an item, lowered its cost, and often improved its quality. Workers, however, who previously had controlled production, rebelled at the discipline required in such factories, and it became necessary to install a supervisory hierarchy far more complex than that required for preindustrial management. The factory system both encouraged and required the growth of large cities. Urbanization demanded greater agricultural productivity, which was achieved through the use of fertilizers, scientific breeding practices, and mechanization. The colonies of the New World provided Europe's cities with agricultural products, often produced by slaves. The production of large quantities of goods at low cost through the use of standardized parts and extensive division of labor was made possible by the development of machine tools (lathe-like machines for shaping metals) in the XIX century. Mass production encouraged manufacturing firms to grow much larger, demanding ever more specialized positions for managers, supervisors, accountants, scientists, engineers, technicians, salesmen, and others. Clerical work in some cases came to be organized according to principles similar to those of the industrial assembly line. Continuing trends toward specialization and professionalization of work gave rise in industrial nations in the XX century to a number of disciplines concerned with various aspects of work, including personal comfort and motivation of workers, efficiency of technology, efficiency of entire systems, productivity, and the application of science to industry. Among these disciplines, some of whose functions overlap, are production management, industrial relations, personnel administration, research and development, human-factors engineering, operations research, and systems engineering.

WORK AT HOME = РАБОТА НА ДОМУ – Work At Home includes those economic activities that are conducted from units or offices within the home. This category includes farmers who work and live on their farms, persons working and living at work camps, and those engaged in own- account production of goods.

WORKABILITY = ОБРАБАТЫВАЕМОСТЬ – Workability is the degree of ease and smoothness with which wood can be worked. / Под Обрабатываемостью понимается способность материала поддаваться обработке.

WORKABLE COMPETITION = РАБОТАЕМАЯ КОНКУРЕНЦИЯ – Workable Competition is a notion which arises from the observation that since perfect competition does not exist, theories based on it do not provide reliable guides for competition policy. The idea was first enunciated by the American economist John Maurice Clark (1884–1963) in 1940. He argued that the goal of policy should be to make competition 'workable', not necessarily perfect. He proposed criteria for judging whether competition was workable, and this provoked a series of revisions and counter- proposals. The criteria put forward are wide ranging, e.g., the number of firms should be at least large as economies of scale permit, promotional expenses should not be excessive and advertising should be

informative. No consensus has arisen over what might constitute workable competition but all bodies which administer competition policy in effect employ some version of it. / Дьжон Морис Кларк (John Maurice Clark (1884–1963)).

WORK BARGE = РАБОЧАЯ БАРЖА – Work Barge is a barge equipped with aids to navigation material pushed ahead of the tender and containing storage space for lumber, sinkers, buoys, an aids to navigation workshop, and a boom for hoisting buoys on board.

WORK CENTER = РАБОЧИЙ ЦЕНТР – Work Center is a section of a production facility where all tasks associated with a particular process (such as assembling, painting, welding) are performed. Work Center, normally, is an individual production area or sub-process of an overall manufacturing process.

WORKED OFF = ОТРАБОТАННОЕ (или СВЕДЁННОЕ НА НЕТ, или СНИЗИВШЕЕСЯ) – Worked Off:- xxxxx. / Выпало Из Работы (Worked Off):- минутное падение цены на ценную бумагу или товар.

WORK ENVIRONMENT = РАБОЧАЯ СРЕДА – The term Work Environment is used to describe the surrounding conditions in which an employee operates. The work environment can be composed of physical conditions, such as office temperature, or equipment, such as personal computers. It can also be related to factors such as work processes or procedures. The work environment can involve the social interactions at the workplace, including interactions with peers, subordinates, and managers. Generally, and within limits, employees are entitled to a work environment that is free from harassment. A hostile work environment exists when unwelcome sexual conduct interferes with an employee's job performance, or creates a hostile, intimidating, or offensive work environment. The term Work Environment can also be associated with the physical condition of the building. Healthy work environments will be free from problems associated with sick building syndrome, which is often due to poor ventilation or off-gassing of chemicals used during construction. The accumulation of molds and mildew may also lead to sick building syndrome. The Work Environment is comprised of the physical location, equipment, materials processed or used, and the activities of an employee while engaged in the performance of his work, whether on or off the railroads property. There are no stated exclusions of place or circumstance. Work Environment is location where a task is completed. When pertaining to a place of employment, the work environment involves the physical geographical location as well as the immediate surroundings of the workplace, such as a construction site or office building. Typically involves other factors relating to the place of employment, such as the quality of the air, noise level, and additional perks and benefits of employment such as free child care or unlimited coffee, or adequate parking. / Рабочая Среда – это совокупность всех внутренних переменных, в процессе управления модифицированных и приспособленных к потребностям организации. Огромное количество факторов, бесконечное число потенциальных вариаций каждой переменной и тот факт, что все эти факторы взаимосвязаны между собой и постоянно меняются, чрезвычайно повышают сложность организационной рабочей среды. На сегодняшний день исследователи пока совсем не готовы объяснить и научно спрогнозировать влияние рабочей среды на поведение работников. Поскольку это действительно очень сложный вопрос. Но есть два аспекта рабочей среды, которые настолько сильно влияют на индивидуальное поведение, что мы не можем не упомянуть о них:- это группы и лидерство. Рабочая Среда (или Производственная Среда) – это физические, химические, биологические, социальные и культурные факторы, совокупность которых составляет среду на рабочем месте.

WORK EQUIPMENT = РАБОЧЕЕ ОБОРУДОВАНИЕ – Work Equipment is an equipment which can be coupled in a train for movement over the carrier's tracks, and which is used in the carrier's work service. Includes such equipment as ballast cars, business cars, company cars, derrick cars, ditching cars, outfit cars, pile drivers, snow dozers, tool cars, wrecking cars, and others.

WORKER = РАБОТНИК – Worker is any railroad employee assigned to inspect, test, repair, or service railroad rolling equipment, or their components, including brake systems. Members of train and yard crews are excluded except when assigned such work on railroad rolling equipment that is not part of the train or yard movement they have been called to operate (or been assigned to as 'Utility Employees'). Utility employees assigned to and functioning as temporary members of a specific train or yard crew (subject to the conditions set forth in 49 CFR 218.22), are excluded only when so assigned and functioning. Worker is a person who does a particular job to earn money. Worker is a person whose job does not involve managing other people. Worker is a person who is actively involved in a particular activity. Worker is a person who works in a (specified) industry or place or with (specified) materials or equipment:- dockworker or steelworker. Worker is a someone who works for a company or organization but does not have a powerful position. / Работник – физическое лицо, вступившее в трудовые отношения с работодателем (Статья 21 Трудовой Кодекс Российской Федерации). Работником может быть лицо, обладающее трудовой право- и дееспособностью или правосубъектностью. Способность лица приобретать в сфере труда права и обязанности, осуществлять и выполнять их и нести ответственность за их неисполнение связана с его возрастом, физическими и интеллектуальными способностями и другими его свойствами. Работник:- в трудовом праве РФ лицо, выполняющее трудовые функции на основе трудового договора (контракта) с работодателем, обладающее трудовыми правами и несущее трудовые обязанности в соответствии с законодательством и условиями контракта. Лицо, выполняющее работу на основе не трудового, а гражданско-правового договора (подряда, поручения, авторского договора, договора на выполнение НИР и другого), трудовым законодательством РФ не рассматривается в качестве работника. В соответствии со Статьёй 37 Конституции РФ каждый имеет право свободно распоряжаться своими способностями к труду, выбирать род деятельности и профессию. Принудительный труд в РФ запрещён. По общему правилу, гражданин может заключить трудовой договор с работодателем с 16-летнего возраста. В порядке исключения стороной такого договора может быть и лицо, достигшее 15 и даже 14 лет (Статья 173 КЗоТ). Работник имеет право на труд в условиях, отвечающих требованиям безопасности и гигиены, на вознаграждение за труд без какой бы то ни было дискриминации и не ниже установленного федеральным законом минимального размера оплаты труда, а также право на защиту от безработицы. Признаётся право работника на индивидуальные и коллективные трудовые споры с использованием установленных федеральным законом способов их разрешения, включая право на забастовку. Работник имеет право на отдых. Каждому лицу, работающему по трудовому договору, гарантируются установленные федеральным законом продолжительность рабочего времени, выходные и праздничные дни, оплачиваемый ежегодный отпуск. Иные трудовые права аботника (на возмещение ущерба, причинённого трудовым увечьем, на объединение в профсоюзы, на социальное обеспечение, на судебную защиту своих прав и другое) предусмотрены КЗоТ, в частности Статья 2. Трудовые обязанности работника состоят в добросовестном отношении к выполнению возложенных на него трудовых функций, соблюдении трудовой дисциплины, выполнении правил внутреннего трудового распорядка, бережном отношении к имуществу работодателя, выполнении установленных норм труда.

WORKER COMPENSATION INSURANCE EXPENSE = РАСХОД НА СТРАХОВАНИЕ КОМПЕНСАЦИЙ РАБОТНИКАМ – Worker Compensation Insurance Expense:- under the accrual method of accounting, this account reports the amount of worker compensation insurance expense that pertains to the period indicated in the heading of the income statement, whether or not the company has paid the insurance premiums within this time period. The worker compensation insurance expense associated with the selling and administrative functions of the business will appear as on operating expense on the company's income statement. Worker compensation insurance cost associated with employees in the manufacturing function of the business will be an integral part of the

cost of the products manufactured. If all of the products are sold, the worker compensation insurance cost will be included in the cost of the goods that were sold. If some of the products manufactured are in inventory, then some of the worker compensation insurance costs will be included in the costs of the products that are held in inventory. Worker Compensation Insurance Expense is the amount a company allocates to cover costs associated with claims related to an employee's injury.

WORKER COMPENSATION INSURANCE PAYABLE = К ОПЛАТЕ ЗА СТРАХОВАНИЕ КОМПЕНСАЦИЙ РАБОТНИКАМ – Worker Compensation Insurance Payable:- this current liability account reports the amount a company owes as of the balance sheet date for its worker compensation insurance policy premiums. The amounts owed are usually based on the policy's rates for the various work classifications of the company's employees. Worker Compensation Insurance Payable is an account that holds the amounts paid for an employee's work related injury.

WORKER PROTECTION = ЗАЩИТА ТРУДЯЩИХСЯ (или ЗАЩИТА РАБОЧИХ) – Worker Protection:- the United States has free trade agreements (FTAs) with 19 countries that include provisions to protect worker rights and facilitate cooperation among labor ministries. These labor provisions establish official processes for receiving complaints, or 'submissions' from interested organizations that believe a trading partner is not fulfilling the labor commitments it made. In the United States, the US Department of Labor, specifically the Office of Trade and Labor Affairs (OTLA), receives and reviews submissions made under the North American Agreement on Labor Cooperation (NAALC) and the FTA Labor Chapters. / В США под Защитой Трудящихся понимаются временные меры защиты, введённые для обеспечения плавного перехода в отраслях, которые сталкиваются с возросшей конкуренцией в результате заключения торговых соглашений. Например, для защиты от возросшей конкуренции со стороны Мексики и Канады NAFTA предусматривает:- (i) продолжительные переходные периоды (до 15 лет) для отмены пошлин США на наиболее 'чувствительные' для США продукты, например, изделия из стекла, обувь, некоторые фрукты и овощи; (ii) положения, допускающие временное повышение тарифных ставок до уровня, предшествовавшего NAFTA, для защиты Американских трудящихся и фермеров в случае угрозы со стороны возросшего привоза (или импорта) из Мексики; и (iii) жёсткие правила в отношении происхождения товара, которые гарантировали бы выгоды от снижения пошлин, согласно NAFTA, только на товары, произведённые в Северной Америке.

WORKER PROTECTION STANDARDS = СТАНДАРТЫ ЗАЩИТЫ ТРУДЯЩИХСЯ (или СТАНДАРТЫ ЗАЩИТЫ РАБОЧИХ) – Worker Protection Standards (WPD) are the US Environmental Protection Agency (EPA) standards for agricultural employers requiring them to maintain daily records of all chemicals applied to farm fields, including brand name and active ingredients and the method and rate of application. The employer must provide training and protective clothing for workers if they apply farm chemicals. The worker must also know what to do in an emergency, and the name, telephone number, and address of the nearest emergency medical facility. Workers must be restricted from entering treated farm fields for a prescribed period of time, and treated fields must be posted.

WORKERS' COMPENSATION = КОМПЕНСАЦИЯ РАБОТНИКАМ – Workers' Compensation:- financial support system established under law to provide income, medical care, and rehabilitation to employees for illness, injury, or death arising out of, and in the course of, their employment whether or not the employee was at fault. These benefits are claimed by the employees (or their dependents) as a matter of right and the employer cannot resort to any legal defense. Amount paid as compensation is based on the salary of the employee (also on the number of his or her dependents in some jurisdictions) and is usually subject to a specified maximum. In most countries, this system is compulsory although agricultural and domestic workers are generally excluded. Also called Workmen's Compensation. Worker's Compensation is, usually, a state or privately managed insurance fund in the United States that reimburses employees for injuries suffered on the job.

WORKERS' COMPENSATION INSURANCE = СТРАХОВАНИЕ КОМПЕНСАЦИЙ РАБОТНИКАМ – Workers' Compensation Insurance or Workers' Comp, also known as Workman's Compensation Insurance, provides for your employees' medical expenses and some portion of their wages if they are injured on the job. All accidental injuries, occupational diseases and even death arising from the subject's employment are covered by Workers' Comp. In most industries, if you have four or more employees, you are required to provide Workers' Compensation, however, the statutory requirements for contractors is significantly more strict. The Longshore Harbor Worker's Compensation Act, often referred to as USL&H (United States Longshore & Harbor), provides benefits similar to Workers' Compensation to employees working in the maritime industry. USL&H covers employees if any injury or death occurs while working on navigable waters, on a dock, during a dry dock or other areas commonly used by vessels. Workers' Compensation policies can be endorsed to offer coverage for the employee while working on land as well as for USL&H exposures. The Merchant Marine Act of 1920, otherwise known as the Jones Act, is a federal act which provides benefits similar to Workers' Compensation to masters and crew of vessels. An employee working on a vessel in the capacity of an engine repairman, for example, may be covered by USL&H law while working on a ship while docked or navigating US waterways. However, that same employee doing the same job may become a 'crew member' and therefore fall under Jones Act coverage while the ship is sailing. Workers Compensation Insurance is an insurance that pays benefits on behalf of an insured employer to employees or their families in the case of injury, disability, or death resulting from occupational hazards. Workers' Compensation is a form of insurance providing wage replacement and medical benefits to employees injured in the course of employment in exchange for mandatory relinquishment of the employee's right to sue his or her employer for the tort of negligence. The tradeoff between assured, limited coverage and lack of recourse outside the worker compensation system is known as 'The Compensation Bargain'. While plans differ among jurisdictions, provision can be made for weekly payments in place of wages (functioning in this case as a form of disability insurance), compensation for economic loss (past and future), reimbursement or payment of medical and like expenses (functioning in this case as a form of health insurance), and benefits payable to the dependents of workers killed during employment (functioning in this case as a form of life insurance). General damages for pain and suffering, and punitive damages for employer negligence, are generally not available in workers' compensation plans, and negligence is generally not an issue in the case. These laws were first enacted in Europe and Oceania, with the United States following shortly thereafter. Statutory compensation law provides advantages to employees and employers. A schedule is drawn out to state the amount and forms of compensation to which an employee is entitled, if he/she has sustained the stipulated kinds of injuries. Employers can buy insurance against such occurrences. However, the specific form of the statutory compensation scheme may provide detriments. Statutes often award a set amount based on the types of injury. These payments are based on the ability of the worker to find employment in a partial capacity:- a worker who has lost an arm can still find work as a proportion of a fully able person. This does not account for the difficulty in finding work suiting disability. When employers are required to put injured staff on 'light-duties' the employer may simply state that no light duty work exists, and sack the worker as unable to fulfill specified duties. When new forms of workplace injury are discovered, for instance:- stress, repetitive strain injury, silicosis; the law often lags behind actual injury and offers no suitable compensation, forcing the employer and employee back to the courts (although in common-law jurisdictions these are usually one-off instances). Finally, caps on the value of disabilities may not reflect the total cost of providing for a disabled worker. The government may legislate the value of total spinal incapacity at far below the amount required to keep a worker in reasonable living conditions for the remainder of his life. A related issue is that the same physical loss can have a markedly different impact on the earning capacity of individuals in different professions. For instance, the loss of a finger could modestly reduce a banker's professional facilities but ruin a pianist. Workers'

Compensation Insurance provides your employees' medical expenses and some of their wages if they are injured on the job. Workers Compensation Insurance and related services can help manage worker injuries and stay on top of the factors that drive up costs. Cover your company's risk now! / хозяевам (или капитанам) и . Вокёз Комп. (Workers' Comp.). Акт Дьжонза (Jones Act). Компенсационное Страхование Рабочих или Страхование Компенсаций Работникам – страхование, оплачиваемое работодателем, по которому производятся выплаты рабочим и их семьям в случае получения производственных травм, инвалидности или смерти от несчастного случая на работе.

WORKERS IN SEASONAL EMPLOYMENT = РАБОТНИКИ В СЕЗОННОЙ ЗАНЯТОСТИ – Workers In Seasonal Employment are workers who hold implicit or explicit contracts of employment where the timing and duration of the contract is significantly influenced by seasonal factors such as the climatic cycle, public holidays and/or agricultural harvests. These workers may be classified as employees or own-account workers according to the specific characteristics of the employment contract.

WORKERS IN SHORT–TERM EMPLOYMENT = РАБОТНИКИ В КРАТКОСРОЧНОЙ ЗАНЯТОСТИ – Workers In Short-Term Employment are workers who hold explicit or implicit contracts of employment which are expected to last longer than the period used to define casual workers, but shorter than the one used to define regular employees. These workers may be classified as employees or own-account workers according to the specific characteristics of the employment contract.

WORKERS INVOLVED IN A LOCKOUT = РАБОТНИКИ, ВОВЛЕЧЁННЫЕ В ЛОКАУТ – Workers Involved In A Lockout comprise:- (i) workers directly involved in a lockout are those employees of the establishments involved who were directly concerned by the labor dispute and who were prevented from working by the lockout; (ii) workers indirectly involved in a lockout are those employees of the establishments involved who were not directly concerned by the labor dispute but who were prevented from working by the lockout.

WORKERS INVOLVED IN A STRIKE = РАБОТНИКИ, ВОВЛЕЧЁННЫЕ В СТАЧКУ – Workers Involved In A Strike comprise:- (i) workers directly involved in a strike are those who participated directly by stopping work; (ii) workers indirectly involved in a strike are those employees of the establishments involved, or self-employed workers in the group involved, who did not participate directly by stopping work but who were prevented from working because of the strike.

WORKERS INVOLVED IN OTHER ACTION = РАБОТНИКИ, ВОВЛЕЧЁННЫЕ В ПРОЧЕЕ ДЕЙСТВИЕ – Workers Involved In Other Action comprise:- (i) workers directly involved in other action are those who participated directly in the action; (ii) workers indirectly involved in other action are those employees of the establishments involved or self-employed workers in the groups involved who did not participate directly in the action but who were unable to perform their work in the usual manner or prevented from working as a result of it.

WORKERS NOT CLASSIFIABLE BY STATUS = РАБОТНИКИ, НЕ КЛАССИФИЦИРУЕМЫЕ ПО СТАТУСУ – Workers Not Classifiable By Status include those for whom insufficient relevant information is available, and/or who cannot be included in any of the preceding categories.

WORKERS' PARTICIPATION = УЧАСТИЕ РАБОТНИКОВ – Workers' Participation may broadly be taken to cover all terms of association of workers and their representatives with the decision-making process, ranging from exchange of information, consultations, decisions and negotiations, to more institutionalized forms such as the presence of workers' member on management or supervisory boards or even management by workers themselves (as practiced in Yugoslavia). The main implications of workers' participation in management as summarized by the International Labour Organization (ILO):- (i) workers have ideas which can be useful; and (ii) workers may work more intelligently if they are informed about the reasons for and then intention of decisions that are taken in a participative atmosphere. According to Keith Davis, Participation refers to the mental and emotional involvement of a person in a group situation which encourages him to contribute to group goals and share the responsibility of achievement. According to Walpole, Participation in Management gives the worker a sense of importance, pride and accomplishment; it gives him the freedom of opportunity for self-expression; a feeling of belongingness with the place of work and a sense of workmanship and creativity. Clegg says, 'It implies a situation where workers representatives are, to some extent, involved in the process of management decision making, but where the ultimate power is in the hands of the management'. According to Dr. Davis, 'it is a mental and emotional involvement of a person in a group situation which encourages him to contribute to goals and share responsibilities in them'. See also Industrial Democracy. Workers' Participation is generally indirect, i.e. through representatives and also restricted to certain aspects of management particularly those that are directly related to workers. Worker's Participation in management means giving scope for workers to influence the managerial decision making process at different levels by various forms in the organisation. Objectives of Workers' Participation In Management:- (i) Increasing productivity for the general benefit of the enterprise, the employee and the community; (ii) Giving employees a better understanding of their role in the working of the industry and of the process of production; (iii) Satisfying the workers' urge for self-expression; (iv) Achieving industrial peace, better relations and increased cooperation in industry; (v) Development of Human Personality; and (vi) Development of leaders from within the industry. Importance of Workers' Participation:- (i) Reduced Industrial Unrest:- tries to remove or at least minimise the diverse and conflicting interests between the parties by substituting in their place cooperation, homogeneity of objectives and common interests; (ii) Reduced Misunderstanding:- participation helps dispelling the employee's misunderstanding about the outlook of management in industry. This misconceptions would otherwise die hard; (iii) Increased Organisation Balance:- if workers are invited to share in organisational problems and to work towards common solutions, a greater degree of organisational balance occurs because of decreased misunderstanding and individual and group conflicts; (iv) Improved Communication:- because of the existence of barriers to the upward flow of information in most enterprises much valuable information possessed by subordinates never reaches their managers. Participation tends to make information available which alters the decisions and the quality of decisions thus improved; (v) Higher Productivity:- it has been empirically tested that poor labour management relations do not encourage the workers to contribute anything more than the minimum desirable to retain their jobs; (vi) Increased Commitment:- if the individual knows that he can express his opinion and ideas, a personal sense of gratification and involvement takes place within him which in turn fortifies his identification with the organisation resulting in greater commitment; (vii) Industrial democracy:- based on the principle of recognition of the human factor, it tends to reduce class conflict between capital and labour; (viii) Development of Individuals:- the employees natural ingenuity and ability are allowed expression. Individuals thus direct their initiative and creativity towards the objective of the group; (ix) Less Resistance to Change:- participation in the decision making process give them opportunity of being heard. They know what to expect and why, resulting in reduced resistance. / Смотрите также Промышленная Демократия (Industrial Democracy).

WORKER'S RIGHTS = ПРАВА ТРУДЯЩЕГОСЯ (или ПРАВА РАБОЧЕГО) – Worker's Rights:- under the North American Free Trade Agreement (NAFTA) workers have virtually no rights to complain of problems such as exposure to toxic materials, lack of safety gear, training in use of dangerous chemicals, etc. In contrast, investors do have considerable rights under one of the eleven (11) typical free trade agreements the United States has with several countries throughout the world. Under NAFTA for example, a company that feels threatened by regulations it feels will be costly can file claims under the Chapter 11. The Investments chapter in NAFTA imposes obligations toward foreign investing companies from other NAFTA countries, and also secures rights for investors to seek

compensation through international arbitration for violation of their rights under this chapter. The Chapter 11 investor rights have been described as a dream for multinational corporations and a nightmare for citizens. In 2005 for example, California state was sued under NAFTA for USD50 million for enacting a law that protected Indian sacred lands and put an end to open metal mining in a southern desert. Workers' rights under NAFTA are virtually nonexistent. At best workers have rights under the North American Agreement on Labor Cooperation (NAALC). One of the first claims filed under NAALC involved current and former workers at the Custom Trim/Auto Trim Breed-Mexicana factory in Matamoros on July 03, 2000. NAALC is a side agreement to NAFTA. Therefore if a worker is having a problem with her employer who happens to be a US company investing at the border she must direct her action not in a court against the company, but rather before the National Administration Office (NAO) against Mexico for its failure in enforcing its own labor, health or safety laws or some other international norms that govern the workplace for free trade! This indirect and cumbersome procedure is designed intentionally to favor investor's needs for smooth, uninterrupted production in the free trade market. Not surprisingly NAALC has been criticized as being weak and ineffective for securing workers' rights. In the case of Mexican workers any problems arising in the workplace are reviewed either under Mexican labor law or Mexican health and safety laws and thus a complaint raised under the North American Agreement on Labor Cooperation is directed against Mexico in front a board known as the National Administration Office. The NAO has been renamed as The Office of Trade Agreement and Technical Cooperation (TAATC) is located in Washington, DC, the United States. / Права Трудящегося или Права Рабочего:- в США некоторые профсоюзы и группы граждан считают, что NAFTA должно предусматривать положения, гарантирующие уважение международно признанных прав трудящихся и обеспечивающие наличие у трудящихся инструментов, необходимых для того, чтобы добиваться приличной заработной платы и достойных условий труда. Подобно экологическим стандартам нарушение таких прав трудящихся должно служить юридическим основанием для иска о нечестной практике. Некоторые же полагают, что текст NAFTA подрывает нормы, существующие в торговом законодательстве США в отношении прав трудящихся, так как делает для Мексики и других стран, присоединившихся к соглашению, изъятия из трудовых стандартов, которые требуются в настоящее время от стран, добивающихся привилегированного доступа на рынки США.

WORK EXPERIENCE = СТАЖ РАБОТЫ – Work Experience refers to the past work experience of the person classified as unemployed. It establishes whether the person worked before or is seeking or available for work for the first time. Work Experience is a short unpaid period of time at a workplace, to gain experience of a working environment. Work Experience (in the United Kingdom) is a far more flexible term but normally refers to some form of temporary work placement within a company where you will work on junior-level tasks for the purpose of gaining experience and insight into the industry. The work can vary hugely, from making the tea to offering administrative support or working on projects. If you prepare well and are proactive, you may be able to make shape the placement to suit you and gain fantastic insight into an industry or role and a set of valuable contacts for the future. Work experience is far more common in smaller firms, charities, media, marketing and PR (where it's the accepted first step on the ladder). Placements are often a short-term, lasting from several days to several weeks, but work is normally full time. UK law states that employers must pay the national minimum wage for any work undertaken by students that is not part of your course of study. However, the line between voluntary placements, which can be unpaid, and work experience can be difficult to define. If you are in doubt, contact the Careers Service for further advice. Where do I look? Work experience opportunities are seldom advertised; you will need to create a placement for yourself through well targeted, speculative applications and persistence. More Types of Work Experience:- (1) Summer Jobs:- casual, paid work during the summer vacation; (2) Part-Time Jobs:- paid work for up to 15 hours per week during term-time, which can sometimes continue over the holidays; (3) Work Shadowing:- a day or more observing a person in their role to gain real insight into the work. These positions are unpaid and unadvertised, so you'll need to create the opportunity by approaching someone directly. (4) Industry Placements (Sandwich Placements):- a year long placement in industry during your degree. Some universities have sandwich courses where students have to take a placement as part of their study. (5) Volunteering:- working with a charity or organisation on a voluntary, unpaid basis. Voluntary positions can vary widely, but the LSE Volunteer Centre advertises a range of opportunities and offers advice on how to find a position and how to use the experience to develop employable skills. Work Experience is defined as a period of work that is designed to encourage reflection on the experience and to identify the learning that comes from working. Work Experience (mainly British) is a short period spent in a workplace, usually by young people, to learn what it is like to do that kind of work. For example, I'm going to do work experience in a factory.

WORKFLOW = РАБОЧИЙ ПОТОК (или РУТИНА) – Workflow is the 'flow of work'. Workflow diagrams are a formal way to identify procedural steps and the logic employed in a process used to complete a task or job. Workflow diagrams include each interim step and product(s); the direction of movement through the process (indicated by arrows); decision points, alternative processes and repeated steps, and dependencies (steps or processes that must be completed before, during or after completion of a particular step); and can include the estimated time required for each step, who performs or reviews each step, and resource requirements. Depending on the type of workflow diagramming method used, the start and end points of each interim step may be listed separately or the entire process step can be indicated by a single notation. Workflow is the definition of the series of tasks within a business process. Includes rules, roles, and routing of work to appropriate people inside or outside of the agency or the State of Florida. Some examples of workflow:- approving requisitions; placing orders; receiving reports; requesting payment; and approving payment. / Рабочий Поток или Управление Потоком Документов – полная или частичная автоматизация бизнес-процессов, при которой документы (сообщения) передаются от одного участника другому для выполнения определённых действий согласно своду процедурных правил.

WORKFLOW INCOMING AMENDMENT IMAGE FILE WRAPPER = ОБЁРТКА ФАЙЛА ИЗОБРАЖЕНИЯ ПОТОКОВОЙ ВХОДЯЩЕЙ ПОПРАВКИ – Workflow Incoming Amendment IFW (short for the Image File Wrapper):- from Public PAIR/IFW (short for the Public Patent Application Information Retrieval/Image File Wrapper) – designates the point in time when an amendment is received in the office (the United States Patent and Trademark Office (USPTO)) and the paper scanning process may be started at the United States Patent and Trademark Office (USPTO); does not indicate whether scanning has actually started.

WORKFLOW MARKETPLACE = РЫНОЧНАЯ ПЛОЩАДКА РАБОЧЕГО ПОТОКА – Workflow Marketplace provides project tracking or collaboration services for complex, iterative, multiparty projects in construction, syndicated bank debt, or licensed trademarks. Charge subscriptions but add transaction fees, such as Bidcom.com charging a contractor to print project blueprints. Create an information-sharing network that gives all parties an appropriate view of the project. Examples:- Bidcom (construction), Hurricane (intellectual property). Also, many Net markets incorporate workflow to hold onto users. Once a Net market becomes part of everyday business processes, the switching to another Net market becomes much harder.

WORK FOR THE DISABLED = ДОБИВАТЬСЯ НЕТРУДОСПОСОБНОСТИ (или ХХ) – Work For The Disabled in the context of labor market programs comprises sheltered work and subsidies to regular employment.

WORK HARDENING = УПРОЧНЕНИЕ (или НАКЛЁП, или НАГАРТОВКА) – Work Hardening:- in metallurgy, increase in hardness of a metal induced, deliberately or accidentally, by hammering, rolling, drawing, or other physical processes. Although the first few

deformations imposed on metal by such treatment weaken it, its strength is increased by continued deformations. The reason for this seeming paradox lies in the crystalline structure of metal. As stresses are exerted, the crystals slip against each other; but, because of the complexity of the crystal structure, the more such slips are multiplied, the more they tend to place obstacles in the way of further slippage, because the various dislocation lines crisscross each other. See also Tempering. / Наклёп – изменение структуры и свойств металлов и сплавов в результате пластической деформации. При наклёпе уменьшаются пластичность и ударная вязкость, но повышаются твёрдость и прочность. Используется для поверхностного упрочнения деталей. Наклёп металлов и сплавов, изменение структуры и соответственно свойств металлов и сплавов, вызванное пластической деформацией при температуре ниже температуры рекристаллизации. Наклёпом называется также технологический процесс создания упрочнённого состояния материала холодной поверхностной пластической деформацией. Явление наклёпа объясняется накапливанием в металле части энергии деформации, которая расходуется на искажение кристаллической решётки, образование преимущественно ориентированных кристаллов (текстур), изменение дислокационной структуры, а также на увеличение удельного объёма металла в слое. Наклёп может быть результатом действия внешних деформирующих сил (Деформационный Наклёп) или, реже, фазовых превращений (Фазовый Наклёп). Наклёп сопровождается увеличением прочности и твёрдости и снижением пластичности материала. В технике наклёп используется для поверхностного упрочнения деталей. Кроме того наклёп приводит к возникновению в поверхностном слое детали благоприятной системы остаточных напряжений, влияние которых главным образом и определяет высокий упрочняющий эффект поверхностной пластической деформации, выражающийся в повышении усталостной прочности, а иногда и износостойкости. Наклёп осуществляют специальными способами и на специальном оборудовании, например, производят обкатку цилиндрических поверхностей роликами, зубьев зубчатых колёс роликами или зубчатыми накатниками, дробеструйную обработку фасонных поверхностей, обработку ударными инструментами и другое. Упрочнение в технологии металлов, повышение сопротивляемости материала заготовки или изделия разрушению или остаточной деформации. Упрочнение характеризуется степенью упрочнения – показателем относительного повышения значения заданного параметра сопротивляемости материала разрушению или остаточной деформации по сравнению с его исходным значением в результате упрочняющей обработки, а также (в ряде случаев) глубиной упрочнения (толщиной упрочнённого слоя). Упрочнение обычно сопровождается снижением пластичности. Поэтому практически выбор способа и оптимального режима упрочняющей обработки определяется максимальным повышением прочности материала при допустимом снижении пластичности, что обеспечивает наибольшую конструкционную прочность. Упрочнение материала в процессе его получения может быть вызвано термическими, радиационными воздействиями, легированием и введением в металлическую или неметаллическую матрицу (основу) упрочнителей – волокон, дисперсных частиц и другого (смотрите Композиционные Материалы). Упрочнение материала заготовок и изделий достигается механическими, термическими, химическими и другими воздействиями, а также комбинированными способами (химико-термическими, термомеханическими и другими). Наиболее распространённый вид упрочняющей обработки – поверхностное пластическое деформирование (ППД) – простой и эффективный способ повышения несущей способности и долговечности деталей машин и частей сооружений, в особенности работающих в условиях знакопеременных нагрузок (оси, валы, зубчатые колёса, подшипники, поршни, цилиндры, сварные конструкции, инструменты и тому подобное). В зависимости от конструкции, свойств материала, размеров и характера эксплуатационных нагрузок деталей применяются различные виды ППД:- накатка и раскатка роликами и шариками, обкатка зубчатыми валками, алмазное выглаживание, дорнование, гидроабразивная, вибрационная, дробеструйная и другие способы обработки. Часто ППД, кроме упрочнения, значительно уменьшает шероховатость поверхности, повышает износостойкость деталей, улучшает их внешний вид (упрочняюще-отделочная обработка). Упрочнение при термической обработке металлов обеспечивается, в частности, при закалке с последующим отпуском. Улучшению прочностных свойств значительно способствуют и определённые виды термо-механической обработки (в том числе горячий и холодный наклёп). Упрочнение химико-термическим воздействием может осуществляться путём азотирования, цианирования, цементации, диффузионной металлизации (насыщением поверхности детали алюминием, хромом и другими металлами). Упрочнение обеспечивается также применением электрофизических и электрохимических методов обработки, ультразвуковой, электроэрозионной, магнитоимпульсной, электрогидравлической, электроннолучевой, фотоннолучевой, анодно-химической, электроискровой, а также воздействием взрывной волны, лазера и другими. Упрочняющая обработка может быть поверхностной (например, пластическое деформирование с возникновением поверхностного наклёпа), объёмной (например, изотермическая закалка) и комбинированной (например, термическая обработка с последующим ППД). Объёмная и поверхностная упрочняющая обработки могут вестись последовательно несколькими методами.

WORKING = ПРОРАБОТКА (или ХХ) – Working:- attempting to complete the remaining part of a trade, by finding either buyers or sellers for the rest.

WORKING ASSET = РАБОЧИЙ АКТИВ (или ОБОРОТНЫЙ АКТИВ) – Working Asset is the current asset such as cash in hand (and in bank), accounts receivable, finished goods inventory, raw materials inventory, and work in process, that continually flows in and out of a firm during the course of its business cycle. Also called Circulating Asset or Floating Asset. Working Asset is an asset other than a capital asset. Working Asset is the invested capital that is comparatively liquid. / Оборотный Актив:- те инвестированные в ценные бумаги активы, от которых ожидают, что они будут колебаться более или менее в унисон с ценами на обыкновенные акции. Могут быть сделаны корректировки для устранения имеющихся во владении инвестиционной компании наличных и пакетов первоклассных ценных бумаг с более высоким приоритетом и для повышения веса пакетов эмиссий, не имеющих приоритета.

WORKING ASSET STATEMENT = ОТЧЁТ ПО РАБОЧИМ АКТИВАМ (или ОТЧЁТ ПО ОБОРОТНЫМ СРЕДСТВАМ, или ХХ) – Working Asset Statement is a net worth statement minus any personal assets, the car, house, boat, etc. A working asset statement will give a clear picture of an individual's invested assets.

WORKING AWAY = ОТРАБОТКА (или ХХ) – Working Away:- transacting with another broker/dealer.

WORKING CAPITAL = РАБОЧИЙ КАПИТАЛ (или (СОБСТВЕННЫЕ) ОБОРОТНЫЕ СРЕДСТВА, или ОБОРОТНЫЙ КАПИТАЛ) – Working Capital is the Working Capital Ratio. Working capital is the amount of money that a company has tied up in funding its day to day operations. A company has to tie up money to fund its stocks, credit sales and other current assets, but this is offset by its ability to fund this from current liabilities liabilities such as purchases on credit. If a company buys on credit it does not have to tie up (as much) money in its stocks. In some businesses (such as grocery retail) working capital can even be negative. A business that buys on credit and sells for cash is being partly funded by its suppliers. The most common definitions of working capital are:- (i) Current Assets – Current Liabilities; and (ii) Stocks + Trade Debtors – Trade Creditors. The advantage of the second definition is that it focuses on the most important parts of working capital from the point of view of judging the efficiency of a business's operations. It avoids some short term liabilities (such as overdrafts) which reflect the financing of the business rather than the capital requirements of its operations. It is worth looking at trends in working capital, and in particular the reasons for increases or decreases. For example, if

working capital is growing faster than sales it could mean that the company is offering over generous credit terms to get sales, or that it is over-stocking. These are just two of many possibilities. Either of these would also slow the conversion of profits into cashflow. Working capital, particularly when defined as current assets minus current liabilities, is closely related to key measures of financial stability such as the current assets ratio and the quick assets ratio. In accounting terms, Working Capital is the difference between an organization's assets that can be converted to cash within one year. Working Capital is essential to the operation of any business, and having an adequate amount of working capital available is crucial to the success of the business. When working capital is too low, the liquidity of the business, and the ability to meet its short-term commitments, and payments on long-term liabilities is jeopardized. And too much working capital may mean that assets are not being efficiently used to their full potential and benefit. As mentioned above, working capital is defined as current assets minus current liabilities. Current assets include cash on hand; amounts held in bank accounts; marketable securities; accounts receivable from customers, clients, and other parties; inventories; and prepaid expenses. These are all assets that are generally turned over during the normal business cycle. Current liabilities include short-term bank loans payable; lines of credit; accounts payable to vendors, suppliers, contractors, and other providers of materials and supplies or services; accrued expenses; taxes payable; and the current portion of long-term debt – the installments that are due within one year. Provided current assets exceed current liabilities, the business has positive working capital. If current liabilities exceed current assets, working capital is negative, resulting in a potential liquidity problem. There will not be enough current assets to be converted to cash during the normal business cycle to meet the obligations falling due within that period. But, just having a positive balance in working capital may not be sufficient. The actual amount of working capital on hand should be compared with the amount of working capital needed. If working capital on hand is less than what is required, there is a deficit in working capital. On the other hand, if working capital on hand is greater than what is needed, there is a surplus of working capital. For a business just starting up, the estimated working capital that is needed should form part of the financial analysis and projections done in preparing a business plan, strategy, and budget. For an ongoing business, working capital requirements may be based on experience, in addition to taking into account the plan, strategy and budget. An aspect to keep in mind in determining working capital requirements, for both a start-up business, and an ongoing business, is to have sufficient working capital to be able to confront unforeseen difficulties, and to take advantage of opportunities that arise, such as cash discounts on early payments to suppliers, thereby lowering the cost of goods sold and expenses. Also, working capital may be needed to expand sales, finance the development of new products or services, to replace machinery, equipment and other fixed assets as they wear out or become obsolete, to finance advertising or marketing campaigns, and to do research and development. Comprises current assets less current liabilities. A measure of the long-term investment required to finance the day-to-day operations at a given level of activity. In finance and accounting, excess of a company's current assets over current liabilities (cash + accounts receivable + inventory, less accounts payable + accrued liabilities + short-term loans). The amount of working capital available to a firm is an indication of its ability to meet its obligations, to expand and to take advantage of business opportunities. Also used to denote the amount of cash required by a business to carry out its operations. Also known as Net Current Assets. The assets a company has that can be poured into the company's operations. Working Capital is a measure of both a company's efficiency and its short-term financial health. The Working Capital Ratio is calculated as:- Working Capital = Current Assets – Current Liabilities. This ratio indicates whether a company has enough short term assets to cover its short term debt. Anything below 1 indicates negative W/C (working capital). While anything over 2 means that the company is not investing excess assets. Most believe that a ratio between 1.2 and 2.0 is sufficient. Also known as Net Working Capital, or the Working Capital Ratio. If a company's current assets do not exceed its current liabilities, then it may run into trouble paying back creditors in the short term. The worst-case scenario is bankruptcy. A declining working capital ratio over a longer time period could also be a red flag that warrants further analysis. For example, it could be that the company's sales volumes are decreasing and, as a result, its accounts receivables number continues to get smaller and smaller. Working capital also gives investors an idea of the company's underlying operational efficiency. Money that is tied up in inventory or money that customers still owe to the company cannot be used to pay off any of the company's obligations. So, if a company is not operating in the most efficient manner (slow collection), it will show up as an increase in the working capital. This can be seen by comparing the working capital from one period to another; slow collection may signal an underlying problem in the company's operations. Things to Remember:- (i) if the ratio is less than one then they have negative working capital; and (ii) a high working capital ratio isn't always a good thing, it could indicate that they have too much inventory or they are not investing their excess cash. Working Capital is the difference between current assets and current liabilities, excluding short-term debt. Current assets may or may not include cash and cash equivalents, depending on the company. Working Capital is the excess of total current assets over total current liabilities. This excess is sometimes called Net Working Capital, with current assets and current liabilities being the components of working capital. Current assets and current liabilities consist of items that will be converted into cash or paid within a year or the operating cycle, whichever is longer. The working capital components are the financial resources utilized by an enterprise in its operating cycle. Working Capital is an excess of current assets over current liabilities. Working Capital is funds invested in a company's cash, accounts receivable, inventory, and other current assets (gross working capital); usually refers to net working capital – that is, current assets minus current liabilities. Working capital finances the cash conversion cycle of a business – the time required to convert raw materials into finished goods, finished goods into sales, and accounts receivable into cash. These factors vary with the type of industry and the scale of production, which varies in turn with seasonality and with sales expansion and contraction. Internal sources of working capital include retained earnings, savings achieved through operating efficiencies and the allocation of cash flow from sources like depreciation or deferred taxes to working capital. External sources include bank and other short-term borrowings, trade credit, and term debt and equity financing not channeled into long-term assets. See also Current Ratio, and Net Current Assets. Capital required for the day to day running of the business. It is calculated by deducting current liabilities from current assets. Working Capital is:- (1) the cash available for day-to-day operations of an organization. Strictly speaking, one borrows cash (and not working capital) to be able to buy assets or to pay for obligations. Also called Current Capital. (2) In accounting:- net liquid assets computed by deducting current liabilities from current assets. The amount of available working capital is a measure of a firm's ability to meet its short-term obligations. Sources of working capital are:- (i) net income, (ii) long-term loans, (iii) sale of capital assets, and (iv) injection of funds by stockholders. Ample working capital allows management to take advantage of unexpected opportunities, and to qualify for bank loans and favorable trade credit terms. In the normal trade cycle of a company, working capital equals working assets. Working Capital:- net current assets. A ratio used in static balance sheet analysis designed to track changes in a company's liquidity. It shows the difference between current assets and short and medium-term debt. In cash flow accounting, changes in working capital are used to assess a company's liquidity and financial situation. A valuation metric that is calculated as current assets minus current liabilities. If a company's current assets do not exceed its current liabilities, then it may run into trouble paying back creditors that want their money quickly. The working capital ratio, which measures this ability to pay back creditors, is calculated as current assets divided by current liabilities. Also known as Operating Assets. Working Capital is the net amount of money that is used to fund the short-term operation of the business. It is the Current Assets less the Current Liabilities. Working Capital (WC) is current assets minus current liabilities. Also called Net Current Assets or Current Capital. It measures the margin of protection for current creditors. It reflects the ability to finance current operations. Working Capital:- the assets a company has that can be poured into the company's operations. Working Capital is the amount of an entity's current assets minus its current liabilities. The result is considered a prime measure of the short-term liquidity of an

organization. A strongly positive working capital balance indicates robust financial strength, while negative working capital is considered an indicator of impending bankruptcy. A 2:1 ratio of current assets to current liabilities is considered healthy, though the ratio can vary by industry. The ratio may also be reviewed on a trend line, with the intent of spotting any declines or sudden drops that could indicate liquidity problems. As an example of the calculation of working capital, a business has USD100 000 of accounts receivable, USD40 000 of inventory, and USD35 000 of accounts payable. Its working capital is:- USD140 000 Current Assets – USD35 000 Current Liabilities = USD105 000 Working Capital. / строка баланса (item). Оборотные Средства – это средства, используемые предприятием для осуществления своей постоянной деятельности, оборотные средства включают в себя производственные запасы предприятия (основные и вспомогательные материалы, топливо), полуфабрикаты, незавершённое производство, запасы готовой и отгруженной продукции, дебиторскую задолженности, а также наличные деньги в кассе и денежные средства на счетах предприятия. Оборотные средства являются непременным условием для осуществления предприятием хозяйственной деятельности. По сути, оборотные средства – это денежные средства, авансированные в оборотные производственные фонды и фонды обращения, не стоит путать их с денежными средствами, вложенными в основные фонды. Сущность оборотных средств определяется их экономической ролью, необходимостью обеспечения воспроизводственного процесса, включающего как процесс производства, так и процесс обращения. В отличие от основных фондов, неоднократно участвующих в процессе производства, оборотные средства функционируют только в одном производственном цикле и независимо от способа производственного потребления полностью переносят свою стоимость на готовый продукт. Основные средства бывают собственными и заёмными. Под Оборотным Капиталом понимаются собственные оборотные средства. Представляет собой разницу между текущими активами и такущими обязательствами. Является одной из основных мер ликвидности предприятия. Называется также как Чистые Текущие Активы (Net Current Assets). Под Оборотным Капиталом понимается часть капитала компании, который задействован в её повседневной коммерческой деятельности. Он состоит из текущих активов (current assets) (главным образом это товарно-материальные запасы, дебиторская задолженность и наличные деньги) за вычетом из них текущих обязательств (в основном кредиторской задолженности). При нормальном производственно-торговом цикле – поставка поставщиком товара, продажа товарного запаса без предоплаты, оплата товара наличными, использование поступившей наличности на оплату поставщиков – оборотный капитал представляет собой показатель чистых активов в обороте, иногда называемых оборотными активами (working assets). Оборотные Средства или Рабочий Капитал – средства, инвестированные в наличность компании, дебиторская задолженность (accounts receivable), товарный запас (inventory) и краткосрочные активы (current assets); их также называют совокупные оборотные средства (gross working capital). Обычно этот термин используется по отношению к чистым оборотным средствам (net working capital), то есть краткосрочным активам за вычетом краткосрочных обязательств (current liabilities). С помощью оборотных средств финансируется цикл движения наличных средств (cash conversion cycle) коммерческого предприятия – период, необходимый для преобразования сырья в готовую продукцию, готовой продукции – в продажи, а дебиторской задолженности – в наличные средства. Конкретные факторы затрат зависят от типа промышленности и объёмов производства, а также от сезонной динамики продаж. Внутренние источники оборотного капитала включают удержанные (нереализационные) доходы (retained earnings), сбережения, полученные в результате увеличения эффективности производства и перераспределения наличности (cash flow) из таких источников, как амортизация (depreciation) или отсроченные платежи налогов за оборотные средства. Внешние источники включают банковские и иные краткосрочные займы, торговый кредит (trade credit), а также срочные кредиты и финансирование из собственных средств (equity financing). Смотрите также Current Ratio и Net Current Assets. Оборотный (Рабочий) Капитал (Working Capital):- сумма, на которую текущие активы превышают текущие обязательства.

WORKING–CAPITAL ACCOUNT = СЧЁТ ОБОРОТНОГО КАПИТАЛА – Working-Capital Account (WCA):- xxxxx. / Счёт Оборотного Капитала:- . Смотрите также Счёт Управления Наличностью (Cash Management Account).

WORKING CAPITAL CREDIT = КРЕДИТ НА ОБОРОТНЫЙ КАПИТАЛ (или КРЕДИТ НА РАБОЧИЙ КАПИТАЛ) – Working Capital Credit is a loan granted to temporarily strengthen the working capital of companies and self-employed persons. Examples:- seasonal loans, interim or bridging loans. Such investments are financed with capital investment loans.

WORKING CAPITAL DAYS OF NET SALES = ДНИ ЧИСТЫХ ПРОДАЖ ПО ОБОРОТНОМУ КАПИТАЛУ – Working Capital Days Of Net Sales measures how many days of net revenue are tied up in working capital. It is calculated:- Working Capital Days of Net Sales = Working Capital / Net Revenue * 365. Low values tend to show problems in ability to support sales while high values may indicate under-capitalization problems.

WORKING CAPITAL DEFICIT = ДЕФИЦИТ ОБОРОТНОГО КАПИТАЛА (или ДЕФИЦИТ РАБОЧЕГО КАПИТАЛА) – Working Capital Deficit:- when there is a working capital deficit, some of the following measures, or a combination of them, may need to be taken:- (i) attempt to have your suppliers store your raw materials and supplies, thereby reducing the amount of cash you have tied up in inventory, and the expenses that result from having to maintain inventory on site; (ii) reduce the number of days in the production cycle, that is, the days from the first receipt of raw materials through the completion of the final product; this may mean better planning and scheduling of orders for materials, better use of available resources and manpower, and looking for efficiencies that can be gained in the production process; (iii) sell scrap materials and obsolete inventory items that are taking up space and generating additional inventory maintenance expense; (iv) bill customers and clients earlier; coordinate the shipping and billing processes; incorporate the use of any information systems that will facilitate the billing process; (v) speed up collections from customers and clients; maintain a close follow-up process on outstanding accounts, send statements, and make collection calls regularly; (vi) pay invoices when they are due, and not before, unless you can take advantage of cash discounts for prompt payment; (vii) if possible, negotiate longer payment terms with vendors and suppliers; (viii) increase owner's equity or long-term financing, in order to decrease the use of short-term debt to finance operations; (ix) refinance long-term debt at more favorable rates, in order to reduce current installments (and also reduce the total interest cost of the debt); and (x) sell off fixed assets, preferably those that are worn-out, obsolete, or that are not serving to generate income.

WORKING CAPITAL FUND = ФОНД (СОБСТВЕННЫХ) ОБОРОТНЫХ СРЕДСТВ (или ФОНД ОБОРОТНОГО КАПИТАЛА, или ФОНД РАБОЧЕГО КАПИТАЛА) – Working Capital Fund:- an account under Title I, Agricultural Programs, of agricultural appropriations. It was created for certain central services in the USDA including duplicating and other visual information services, art and graphics, video services, supply, the centralized accounting system, voucher payments services, data processing, telecommunications systems, and the centralized automated data processing system for payroll, personnel, and related services. Working Capital Fund is a revolving fund established to finance inventories of supplies and other stores, or to provide working capital for industrial-type activities. / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо).

WORKING CAPITAL MANAGEMENT = УПРАВЛЕНИЕ РАБОЧИМ КАПИТАЛОМ – Working Capital Management is the process of managing activities and processes related to working capital. This level of management serves as a check and balances system to ensure that the amount of cash flowing into the business is enough to sustain the company's operations. This is an ongoing process that must be evaluated using the current level of assets and liabilities. Working capital management may involve implementing short-term decisions that may or may not carry over from one earnings period to the next. Working Capital Management involves the relationship between a firm's short-term assets and its short-term liabilities. The goal of working capital management is to ensure that a firm is able to continue its operations and that it has sufficient ability to satisfy both maturing short-term debt and upcoming operational expenses. The management of working capital involves managing inventories, accounts receivable and payable, and cash. Working Capital Management is a managerial accounting strategy focusing on maintaining efficient levels of both components of working capital, current assets and current liabilities, in respect to each other. Working capital management ensures a company has sufficient cash flow in order to meet its short-term debt obligations and operating expenses. Implementing an effective working capital management system is an excellent way for many companies to improve their earnings. The two main aspects of working capital management are ratio analysis and management of individual components of working capital. A few key performance ratios of a working capital management system are the working capital ratio, inventory turnover and the collection ratio. Ratio analysis will lead management to identify areas of focus such as inventory management, cash management, accounts receivable and payable management. Working Capital Management is the deployment of current assets and current liabilities so as to maximize short-term liquidity. Working Capital Management is a tactical focus on maintaining a sufficient amount of working capital to support a business, while minimizing the investment in this area. The core goal in working capital management is to ensure that there is always sufficient cash on hand to pay for liabilities as they come due for payment. Since there can be a high cost associated with the funding of working capital, there is an offsetting pressure to keep funding levels low. This latter goal is achieved by closely monitoring the turnover levels for accounts receivable, inventory, and accounts payable, and taking action when the turnover levels vary from expectations. An additional tool used to monitor working capital levels is the short-term and medium-term cash forecast, which tells management when unusually high or low cash levels are expected.

WORKING CAPITAL RATIO = СООТНОШЕНИЕ С РАБОЧИМ КАПИТАЛОМ – Working Capital Ratio:- to figure out how much working capital a company needs to stay in business, the ratio is computed by taking the value of assets minus the value of liabilities. The Working Capital Ratio is the same as the current ratio. It is the relative proportion of an entity's current assets to its current liabilities, and is intended to show the ability of a business to pay for its current liabilities with its current assets. A working capital ratio of less than 1.0 is a strong indicator that there will be liquidity problems in the future, while a ratio in the vicinity of 2.0 is considered to represent good short-term liquidity. To calculate the working capital ratio, divide all current assets by all current liabilities. The formula is:- Current Assets / Current Liabilities. The rapid increase in the amount of current assets indicates that the retail chain has probably gone through a rapid expansion over the past few years and added both receivables and inventory. The sudden jump in current liabilities in the last year is particularly disturbing, and is indicative of the company suddenly being unable to pay its accounts payable, which have correspondingly ballooned. The acquirer elects to greatly reduce her offer for the company, in light of the likely prospect of an additional cash infusion in order to bring its operations onto an even keel. Problems with the Working Capital Ratio:- the working capital ratio can be misleading if a company's current assets are heavily weighted in favor of inventories, since this current asset can be difficult to liquidate in the short term. This problem is most obvious if there is a low inventory turnover ratio. A similar problem can arise if accounts receivable payment terms are quite lengthy (which may be indicative of unrecognized bad debts). The working capital ratio will look abnormally low for those entities that are drawing down cash from a line of credit, since they will tend to keep cash balances at a minimum, and only replenish their cash when it is absolutely required to pay for liabilities. In these cases, a working capital ratio of 1:1 or less is common, even though the presence of the line of credit makes it very unlikely that there will be a problem with the payment of liabilities. Working Capital Ratio is working capital expressed as a percentage of sales. Working Capital is a measure of both a company's efficiency and its short-term financial health. The Working Capital Ratio is calculated as:- Working Capital = Current Assets – Current Liabilities. This ratio indicates whether a company has enough short term assets to cover its short term debt. Anything below 1 indicates negative W/C (working capital). While anything over 2 means that the company is not investing excess assets. Most believe that a ratio between 1.2 and 2.0 is sufficient. Also known as Net Working Capital, or the Working Capital Ratio. If a company's current assets do not exceed its current liabilities, then it may run into trouble paying back creditors in the short term. The worst-case scenario is bankruptcy. A declining working capital ratio over a longer time period could also be a red flag that warrants further analysis. For example, it could be that the company's sales volumes are decreasing and, as a result, its accounts receivables number continues to get smaller and smaller. Working capital also gives investors an idea of the company's underlying operational efficiency. Money that is tied up in inventory or money that customers still owe to the company cannot be used to pay off any of the company's obligations. So, if a company is not operating in the most efficient manner (slow collection), it will show up as an increase in the working capital. This can be seen by comparing the working capital from one period to another; slow collection may signal an underlying problem in the company's operations. Things to Remember:- (i) if the ratio is less than one then they have negative working capital; and (ii) a high working capital ratio isn't always a good thing, it could indicate that they have too much inventory or they are not investing their excess cash. See also Current Ratio, and Working Capital.

WORKING CAPITAL REQUIREMENTS = ТРЕБОВАНИЯ К ОБОРОТНОМУ (или РАБОЧЕМУ) КАПИТАЛУ (или ТРЕБОВАНИЯ К ИЗЛИШКАМ ОБОРОТНЫХ СРЕДСТВ) – Working Capital Requirement is the amount of working capital a company determines it must maintain in order to continue to meet its costs and expenses. The working capital requirement will be different for each company, depending upon many factors such as how frequently the company receives earnings and how high their expenses are. Working Capital Requirements:- funds needed for day-to-day operations of a non-financial enterprise. Working capital requirements are determined by the difference between inventories plus accounts receivable, less accounts payable. The Working Capital Requirement is the minimum amount of resources that a company requires to effectively cover the usual costs and expenses necessary to operate the business. Since the capital needs of each company will be a little different, there is no ideal amount of working capital that is universally applicable to all businesses, or even to companies engaged in the same industry. Even so, new companies can develop an idea of what type of requirement they will need to operate at given levels by researching the cost and expenses associated with other corporations engaged in similar operations. The basic formula for determining working capital involves only two factors. First, it is necessary to define the current liquid assets that the company has. This may be somewhat different from general assets, since the focus is on those resources that can be converted into cash quickly and easily. Liquid assets may be such resources as the outstanding current accounts receivable balance, property that is not directly used in the operation of the business, and balances in various operating accounts. The current liabilities of the corporation must also be determined. This includes both short-term liabilities, such as the usual and general monthly operating expenses, as well as any long-term debt. By deducting the liabilities from the liquid assets, it is possible to determine the current working capital requirement. The general idea is to ensure there is enough revenue generated to cover the essential operations of the corporation and allow for additional revenue to be generated in the future. Companies may operate with a negative working capital, based on some long-term debt, and this is not necessarily a sign that the

company is in financial trouble. Calculating the current working capital requirement at least once a quarter, however, will allow the company to spot trends that may indicate problems. For example, if the requirement reveals a higher negative ratio from previous periods even though long-term debt was reduced, this may indicate an issue with decreased sales, lower earnings, or other factors. / Фонды, необходимые для ежедневных операций не финансового предприятия. Требования к оборотному капиталу определяются исходя из разницы между стоимостью материально-производственных запасов плюс дебиторской задолженности минус кредиторская задолженность.

WORKING CAPITAL STATEMENT = ОТЧЁТ ПО ОБОРОТНОМУ КАПИТАЛУ (или ХХ) – Working Capital Statement (WCS) is part of the financial statements' 'Statements of Cash Flows or Changes in Financial Position'. The WCS normally includes sections covering:- Sources of Working Capital, Uses of Working Capital, and Working Capital Changes.

WORKING CAPITAL SURPLUS = ИЗЛИШКИ ОБОРОТНОГО (или РАБОЧЕГО) КАПИТАЛА (или ИЗЛИШКИ ОБОРОТНЫХ СРЕДСТВ) – Working Capital Surplus:- when there is a working capital surplus, it may be advisable to take some of the following measures:- (i) maximize the use of cash; invest idle cash in marketable securities in order to earn a return, or take advantage of purchase discounts for prompt payment; (ii) use surplus cash to pay down long-term debt and thereby reduce the interest cost over the life of a loan; (iii) make capital expenditures, such as purchases of property, plant and equipment, that will increase your business's productivity and profitability; and (iv) use surplus working capital to help the business grow and expand. Expenditures may be needed to increase market share or to develop and promote new products and services. And investments, such as in research and development, can be made that will benefit the business in the future. Working Capital Surplus:- undistributed corporate profits resulting from regular business operations. Also known as Operating Surplus in the United Kingdom. See also Retained Earnings. / Нераспределённая прибыль корпорации, образовавшаяся в результате осуществления операций, связанных с проведением собственной повседневной деятельности. Известны в Соединённом Королевстве как Операционные Излишки (Operating Surplus). Смотрите также Нераспределённые Заработки (Retained Earnings).

WORKING CAPITAL TO SALES RATIO = СООТНОШЕНИЕ РАБОЧЕГО КАПИТАЛА С ПРОДАЖАМИ – Working Capital To Sales Ratio:- the higher a company's working capital as compared to sales, the better off and more stable the company is financially. When sales increase but working capital falls, the company may have difficulty sustaining operations and purchasing inventory to fulfill new orders, and it may also experience other financial problems. Working Capital:- working capital is calculated using the equation of a company's current assets minus current liabilities. Observing a company's existing working capital balance is the easiest way for investors to judge the amount of a company's assets that are easily liquidated. Liquid assets must be available on an ongoing basis to invest in building the company's business, funding future growth and increasing value for its shareholders. Working Capital to Sales:- the working capital to sales ratio shows a company's ability to pay costs related to generating new sales without the need to take on additional debt. Although borrowing money to finance new equipment or other initiatives to help increase sales is not bad on its own, a company must still be able to easily pay down its debt and maintain enough liquid assets to finance the ongoing operations of the company. Conversely, if a company maintains an exceedingly high working capital to sales ratio, it may be holding on to too many assets that would be better used to finance new growth or additional sales. Cost of Goods:- the costs a company needs to cover in order to generate goods for sale are captured in the cost of goods sold – or COGS – line item on the income statement. This does not include general and administrative costs required to keep the company running. COGS is matched with sales in a given time period on the income statement. COGS includes the cost of raw inventory inputs to the manufacturing process, and may also contain wages for employees specific to the manufacturing process. Negative Working Capital:- financial statements that show negative working capital may be a sign of problems to come. Negative working capital means the company's liabilities exceed its assets, providing the company with very limited ability to spend as much on current operations and future growth as its peers who have positive working capital. When working capital continues to drop as a percentage of sales, the company may not have enough cash to pay its vendors or cover its debts. Working Capital To Sales Ratio indicates the firm's ability to finance additional sales without incurring additional debt. Formula:- Working Capital / Sales Revenue.

WORKING CAPITAL TURNOVER = ОБОРОТ РАБОЧЕГО КАПИТАЛА – Working Capital Turnover is a measurement comparing the depletion of working capital to the generation of sales over a given period. This provides some useful information as to how effectively a company is using its working capital to generate sales. Formula:- Working Capital Turnover = Sales / Working Capital. A company uses working capital (Current Assets – Current Liabilities) to fund operations and purchase inventory. These operations and inventory are then converted into sales revenue for the company. The working capital turnover ratio is used to analyze the relationship between the money used to fund operations and the sales generated from these operations. In a general sense, the higher the working capital turnover, the better because it means that the company is generating a lot of sales compared to the money it uses to fund the sales. For example, if a company has current assets of USD10 million and current liabilities of USD9 million, its working capital is USD1 million. When compared to sales of USD15 million, the working capital turnover ratio for the period is 15 (USD15M/USD1M). When used in fundamental analysis, this ratio can be compared to that of similar companies or to the company's own historical working capital turnovers. Working Capital Turnover:- a ratio that shows the number of times the working capital is converted into revenue in an accounting period, or how efficient the management is in using its working capital to generate sales revenue. Formula:- Sales Revenue / Average Working Capital. Working Capital Turnover (WCT) shows how efficiently Working Capital (WC) is employed, i.e. it measures how efficiently the business is using its available assets. WCT measures the amount of Net Revenue generated per monetary unit of Working Capital. It varies widely by industry; therefore it is best to compare WCT to industry averages. Formula:- Net Revenue / (Current Assets – Current Liabilities).

WORKING COLLECTION = РАБОЧАЯ КОЛЛЕКЦИЯ – Working Collection is a sizable number of evaluated accessions that is stored, documented, and frequently used in breeding research. / вычисляемых .

WORKING CONTROL = РАБОЧИЙ КОНТРОЛЬ – Theoretically, Working Control is an ownership of 51 percent of a company's voting stock is necessary to exercise control. In practice, and this is particularly true in the case of a large corporation, effective control sometimes can be exerted through ownership, individually or by a group acting in concert, of less than 50 percent. Working Control is an effective control of a corporation by a shareholder or shareholders with less than 51% voting interest. Working control by a minority holder, or by two or more minority holders working in concert, it possible when share ownership of a firm is otherwise widely dispersed. See also Minority Interest. Working Control:- when a minority shareholder (or shareholders) has enough voting power to influence or determine corporate policy. Working control exists particularly in corporations with widely dispersed share ownership where no shareholder has a majority interest. Working control exists when a minority shareholder or multiple minority shareholders unite to possess a controlling vote in a corporation. The opportunity for minority shareholders to gain this control is seen especially in corporations where there is no dominant majority (greater than 50%) shareholder. While there are no official benchmarks for defining working control, 20% ownership is often considered large enough to exhibit this level of influence. Working Control is a control of a corporation by a shareholder or shareholders having less than 51% voting interest because of the wide dispersion of share ownership. /

51% акций составляет контрольный пакет акций. Рабочий Контроль:- теоретически, для осуществления контроля необходимо обладание 51% акций, дающих владельцу право голоса. На практике – и это особенно верно в случае с крупной корпорацией – эффективный (то есть фактический) контроль достигается благодаря владению индивидуально или совместно действующей группой менее 50% акционерного капитала. Рабочий Контроль – фактический контроль над предприятием со стороны акционеров или акционеров, имеющих менее 51% акций с правом голоса. Рабочий контроль стороны, имеющей меньшую долю акций, или двумя или более такими сторонами, действующими совместно, возможен, когда остальные акции компании рассеяны. WORKING DAY = РАБОЧИЙ ДЕНЬ – Working Day is:- (1) in commerce:- any day (other than Sunday or legal holiday) on which legal business can be conducted. Whether Saturday is a working day or not depends on the custom or usage of the trade or jurisdiction. (2) In law:- any day other than Sunday or gazetted or statutory holiday. Also called Dies Juridicus, Latin for Judicial Day. Working Day is a day on which the banks in a currency's principal financial center are open for business. For FX transactions, a working day only occurs if the bank in both (all relevant currency centers in the case of a cross are open) currencies is working. The number of Working Days in a month is the total number of days less the number of weekend days and national holidays. In some countries, such as France, national holidays are fixed on a particular date rather than a day of the week and the holiday is lost if it occurs at the weekend (or on Sundays in Japan). In other countries, such as the United States or the United Kingdom, national holidays are fixed to a particular day in the month. Some national holidays, e.g., at Easter can occur in March or April, significantly affecting the annual change in total working days in these months. Working Days are the days on which work is normally done. This normally means Monday–Friday. / , например, . В коммерции Рабочие Дни:- все дни недели, кроме Воскресенья и – в отдельных случаях – Субботы (в зависимости от традиций). Общественные праздники и банковские праздники также не входят в число рабочих дней. В судоходстве и некоторых других отраслях принято особо выделять погожие рабочие дни (weather working days).

WORKING DAY OR TRADING DAY = РАБОЧИЙ ДЕНЬ ИЛИ ТОРГОВЫЙ ДЕНЬ – Working Day or Trading Day Adjustments refer to the correction for differences in the number of working or trading days in a given month or quarter which differ from year to year which will impact upon the level of activity in that month or quarter for flow series or the sort/type of day for stock series. In most countries working day adjustment and trading day adjustment are used as synonyms. The number of working or trading days in a given month or quarter can vary significantly for each statistical domain (e.g., production, merchandise trade) because of differing institutional arrangements, trade specific holidays, etc. Some countries also include bridging effects in working day adjustments. These result from people taking holidays, for example, on Mondays and Fridays when an official public holiday occurs on Tuesdays and Thursdays respectively. The type of working/trading day adjustment carried out needs to be tailored to the cultural and institutional environment operating within individual countries. In the United States, for example, working day adjustment classifies the days of the week into workdays (Monday through to Friday) and non-workdays (Saturday and Sunday) and thus the seasonal adjustment estimates two factors – workday and non-workday. Trading day adjustment (as performed in the US at least) allows for a different effect for each day of the week and computes seven factors – a Monday factor, a Tuesday factor and so on. Essentially, trading day adjustment is a more fine tuned seasonal adjustment method to account for calendar variation. In other countries there may be very distinct differences between workdays and non-workdays in the amount of business conducted, but not so much difference between Mondays, Tuesdays, through the Fridays. The US on the other hand, has distinctly different patterns of activity each day of the week and methods used in that country try to account for that difference.

WORKING DIRECTOR = РАБОТАЮЩИЙ ДИРЕКТОР – Working Director is a Company Director who works for the company in a full or part-time capacity. This term is mainly used for taxation purposes.

WORKING FAMILIES TAX CREDIT = НАЛОГОВЫЙ КРЕДИТ ДЛЯ РАБОТАЮЩИХ СЕМЕЙ – Working Families Tax Credit (WFTC) is a form of social security family income supplement, payable to families where one or more persons are in employment and have a PAYE code. The benefit is normally awarded for a period of twenty six weeks. From October 1999 payments were made directly by the Inland Revenue but from April 2000 employers of claimants will be instructed to make payments of WFTC along with salary or wages, on behalf of the Government. The employer does not know on what basis the benefit entitlement or amount has been worked out. The WFTC paid out (as far as the employer is concerned) can be is met out of the total tax and NIC which is deducted through the payroll and which the employer would normally hand over to the Inland Revenue. For this reason the payment is called a Tax Credit. However it is not a true tax credit in the hands of the recipient and does not require to be reported on your tax return. Nor should it enter into any calculations you or the Inland Revenue may make of your outstanding tax liability or rebate due at the end of the tax year.

WORKING GAS = АКТИВНЫЙ ГАЗ – Working Gas (in the United States) is the amount of gas in a storage facility above the amount needed to maintain a constant reservoir pressure (the latter is known as Cushion Gas). Working (top storage) Gas:- the volume of gas in a reservoir that is in addition to the base gas. It may or may not be completely withdrawn during any particular withdrawal season. Conditions permitting, the total working capacity could be used more than once during any season. / Объём газа в резервуаре, который закачивается в него в дополнение к буферному или, как его ещё называют, технологическому газу. Активный газ может быть выбран из резервуара частично или полностью в течение любого конкретного сезона отбора. Если позволяют условия, полный рабочий объём газа может быть использован в течение любого сезона неоднократно.

WORKING GROUP = РАБОЧАЯ ГРУППА – Working Group is a group of statisticians chaired by Eurostat and composed of delegates from all EU Member States. It deals with particular subject matter – normally meets once a year and works in at least EN/FR/DE languages. Working Group is a group that meets regularly to consider a particular issue.

WORKING GROUP III = III РАБОЧАЯ ГРУППА – Working Group III (WG III) is a subcommittee of the Central Balance Sheet Data Offices (CBSO) dealing with the International Accounting Standards (IAS) issues.

WORKING GROUP ON FINANCIAL MARKETS = РАБОЧАЯ ГРУППА ПО ФИНАНСОВЫМ РЫНКАМ – The Working Group on Financial Markets is also known as The President's Working Group on Financial Markets and colloquially as the Plunge Protection Team (PPT). This is a group the was created by executive order by United States President Ronald Reagan on the 18 March 1988, five months after the Black Monday meltdown of the financial markets on 19 October 1987. The working group consists of:- The Secretary of the Treasury, The Chairman of the Board of Governors of the Federal Reserve System, The Chairman of the Securities and Exchange Commission, The Chairman of the Commodity Futures Trading Commission or their designees. On 06 October 2008, the working group stated that it was taking multiple actions available to it in order to attempt to stabilize the financial system. The purchase of stock shares was not part of the statement, however, the government may end up owning shares in the firms to which it has provided loans, as they will receive warrants as collateral for these loans. / Президент США Ранэлд Вилсэн Рэйген (Ronald Wilson Reagan; 1911–2004).

WORKING INTEREST = РАБОЧИЙ ИНТЕРЕС (или РАБОЧИЙ ПРОЦЕНТ) – (1) A term Working Interests refers to a form of investment in oil and gas drilling operations in which the investor is directly liable for a portion of the ongoing costs associated with exploration, drilling and production. In a similar fashion, working interest owners also fully participate in the profits of any successful wells. This stands in contrast to royalty interests, in which an investor's cost is usually limited to their initial investment, also resulting in a lower potential for large profits. While the idea of earning unlimited profits from owning a working interest in a well might sound wonderful, the downside can wipe out unsuspecting investors. It's generally recommended that investors without deep pockets and a solid working knowledge of oil and gas exploration stick with limited liability royalty interests. A Working Interest generally paid in consideration for work related to the prospect. This interest is paid, or carried, for the drilling and or completion costs as specified in the contract between the parties, by another working interest owner typically until casing point is reached, or through the tanks, meaning through completion of the well, as agreed upon contractually. Working Interest is an interest in a mineral property that entitles the owner of that interest to all of share of the mineral production from the property, usually subject to a royalty. A working interest permits the owner to explore, develop, and operate the property. The working-interest owner bears the costs of exploration, development, and operation of the property and, in return, is entitled to a share of the mineral production from the property or to a share of the proceeds therefrom. It may be assigned to another party in whole or in part, or it may be divided into other special property interests. Working Interest is an interest in an natural gas and oil lease that gives the owner of the interest the right to drill for and produce natural gas and oil on the leased acreage and requires the owner to pay a share of the costs of drilling and production operations. The share of production to which a working interest is entitled will be smaller than the share of costs that the working interest owner is required to bear to the extent of any royalty burden. Working Interest is a percentage of ownership in an oil and gas lease granting its owner the right to explore, drill and produce oil and gas from a tract of property. Working interest owners are obligated to pay a corresponding percentage of the cost of leasing, drilling, producing and operating a well or unit. After royalties are paid, the working interest also entitles its owner to share in production revenues with other working interest owners, based on the percentage of working interest owned. / Рабочий Процент (РП; Working Interest (WI)):- (1) Деятельное (активное) долевое участие на основе аренды; рабочий процент. Непосредственное участие арендатора в расходах на добычу минерального сырья и доходах от его реализации, а также доля такого участия в добыче. Устанавливается как доля в валовом доходе до вычета процента за роялти. (2) Смотрите также Net Interest (1).

(2) Working Interest:- direct participation with unlimited liability, as distinguished from passive limited partnership shares. The US Tax Reform Act of 1986 let investors with working interests in drilling ventures, such as general partners, offset losses against all types of income. / Рабочее Участие (Working Interest) в товариществе – прямое участие в товариществе с неограниченной ответственностью – в отличие от пассивной доли участия в товариществе с ограниченной ответственностью (limited partnership). Американский Акт О Налоговой Реформе от 1986 (Tax Reform Act of 1986) позволяет инвесторам с рабочим участием в предприятиях по добыче полезных ископаемых, например генеральным партнерам (general partners), компенсировать убытки всех видов полученными ими доходами.

WORKING LAND CONSERVATION PROGRAMS = ПРОГРАММЫ СОХРАНЕНИЯ РАБОЧИХ ЗЕМЕЛЬ – Working Land Conservation Programs are the conservation programs under the US Farm Security and Rural Investment Act of 2002 that support the adoption and maintenance of structural practices and land management practices on agricultural land including cropland, grazing land, and in some cases, forest land. Such programs include the Environmental Quality Incentives Program, Conservation Security Program, and Wildlife Habitat Incentives Program.

WORKING LAYER = РАБОЧИЙ СЛОЙ – In reinsurance, Working Layer is the first layer above the cedant's retention wherein moderate to heavy loss activity is expected by the cedant and reinsurer. Working layer reinsurance agreements often include adjustable features to reflect actual underwriting results. Working Layer is a layer of excess of loss reinsurance in which frequent claims are likely to arise.

WORKING LEVEL = РАБОЧИЙ УРОВЕНЬ – Working Level (WL) is a unit of measure for documenting exposure to radon decay products. One working level is equal to approximately 200 picoCuries per liter.

WORKING LEVEL MONTH = МЕСЯЦ РАБОЧЕГО УРОВНЯ – Working Level Month (WLM) is a unit of measure used to determine cumulative exposure to radon.

WORKING LIFE OF AN ADHESIVE = ЭКСПЛУАТАЦИОННАЯ ДОЛГОВЕЧНОСТЬ СВЯЗУЮЩЕГО (или СРОК ГОДНОСТИ СВЯЗУЮЩЕГО) – Working Life Of An Adhesive is the period of time during which an adhesive, after mixing with catalyst, solvent, or other compounding ingredients, remains suitable for use. Also known as Pot Life Of An Adhesive. / Working – эксплуатация/действие; Life – долговечность/стойкость/срок службы; Pot – посадка/прокладка/подкладка/консервирование. Под Долговечностью понимается свойство изделия (технического устройства) сохранять работоспособность (при установленной системе технического обслуживания и ремонтов) до наступления предельного состояния. Количественно оценивается, например, техническим ресурсом.

WORKING LOSS = РАБОЧАЯ ПОТЕРЯ – Working Loss is the irrecoverable loss of weight or yardage of a textile material that occurs during a textile process.

WORKING MEMBER = РАБОТАЮЩИЙ ЧЛЕН – Working Member is a member who occupies himself principally with the conduct of business at Lloyd's by a Lloyd's broker or underwriting agent, or a member who has retired but who immediately before his retirement occupied himself in this way.

WORKING ORDER = РАБОТАЮЩЕЕ РАСПОРЯЖЕНИЕ – Working Order is the standing order in the marketplace, through which a broker bids or offers to fill the order in a series of lots at opportune times in hopes of obtaining the best price.

WORKING PAPERS = РАБОЧИЕ БУМАГИ – (1) In accounting, Working Papers are the documents required on an audit of a company's financial statements. The working papers are the property of the accounting firm conducting the audit. These papers are formally referred to as Audit Documentation or sometimes as the Audit File. The documents serve as proof of audit procedures performed, evidence obtained and the conclusion or opinion the auditor reached. Working Papers, in accounting, are papers that document the evidence gathered by auditors to show the work they have done, the methods and procedures they have followed, and the conclusions they have developed in an audit of financial statements or other type of engagement. / Под Рабочими Бумагами понимаются различные внутренние документы, таблицы, расчёты, используемые бухгалтерами для облегчения организации своей работы по подготовке финансовой отчётности. Рабочие Бумаги или Рабочие Документы (Working papers):- материалы, подготовленные аудитором или для него, или полученные и сохранённые аудитором в связи с проведением аудита. Рабочие документы могут храниться в форме данных на бумажных носителях, ксерокопиях, в электронном формате или других носителях информации.

(2) Sometimes the term Working Paper is used synonymously as technical report. Working papers are typically hosted on websites, belonging either to the author or the author's affiliated institution. The United Nations uses the term 'Working Paper' in approximately this sense for the draft of a resolution.

WORKING POOR = РАБОТАЮЩАЯ БЕДНОТА – The Working Poor are defined as the proportion of employed persons living below the poverty line. Working Poor is a term used to describe individuals and families who remain as poor even though they have regular employment. The working poor are distinct from paupers, poor who are supported by government aid or charity. In the United States (US), a person is recognized as being working poor depending on their revenues compared to an absolute poverty level. In the US working poor are defined as persons who spent at least 27 weeks in the labor force during the year but whose incomes falls below the official poverty level. Often, those defined as 'Working Poor' have debts and they lack the ability to escape personal and economic contingencies.

WORKING PROPRIETORS = РАБОТАЮЩИЕ СОБСТВЕННИКИ – Working Proprietors (in an establishment) include all individual proprietors and partners actively engaged in the work of the establishment, excluding silent or inactive partners whose principal activity is outside of the establishment.

WORKING RESERVES = РАБОЧИЕ РЕЗЕРВЫ – Working Reserves are the reserves held by banks above the required minimum level – or cash reserve ratio – mandated by regulations and laws. Working reserves are normally in the form of vault currency, deposits at other banks, cash being collected and excess reserves held as deposits at the Federal Reserve bank. Banks typically hold a buffer of working reserves to avoid their reserves falling below the minimum required level due to large net withdrawals. Banks hold an optimum level of working reserves since inadequate working reserves would lead to avoidable interest penalties on borrowed reserves. On the other hand, an excessively high level of working reserves would mean foregoing substantial interest income on customer loans. Working Reserves are those maintained by a certain bank which is beyond what is required of them. Also known as Cash Reserve Ratio, working reserves are mandated by applicable laws. Usually, working reserves come in the form of deposits made to other banks or vault currencies. Working Reserves are the amount of capital a bank holds on reserve in the form of currency or deposits at other banks that are in excess of the minimum reserve requirement dictated by the Federal Reserve Bank. Banks seek to maintain enough working reserves to provide a margin of safety over minimum reserve requirements while optimizing its interest earning opportunity. / Текущие Резервы .

WORKING SAMPLE = РАБОЧАЯ ПРОБА – A Working Sample of grain is usually around 1 000 grams. It may be more or less, at the discretion of the inspector. / Рабочая Проба зерна обычно составляет приблизительно 1 000 грамм. Она может быть немного больше или немного меньше, по усмотрению инспектора.

WORKING STANDARD = РАБОЧИЙ СТАНДАРТ (или РАБОТАЮЩИЙ СТАНДАРТ, или ОБЩЕПРИНЯТЫЙ СТАНДАРТ, или РАБОЧИЙ ОБРАЗЕЦ) – Working Standard is:- (1) an instrument standard or laboratory standard in routine use; and (2) a standard that is almost identical to the laboratory standard and the color difference is exaclty known from the laboratory standard. Working Standard is a standard of unit measurement calibrated from either a primary or secondary standard which is used to calibrate other devices or make comparison measurements. Working Standards are the standards used for practical measurements in scientific research, production, commerce, and other fields. They differ from base standards, which are only used to calibrate other standards. Working standards are classified as measures, measuring instruments, measuring transducers, measuring assemblies, and measuring systems. The last two categories represent various combinations of the first three categories with additional auxiliary equipment needed for measuring, including current sources, switching and control devices, communications lines, stabilizers, thermostats, and specialized computing systems.

WORKING STORAGE CAPACITY = РАБОЧАЯ ЁМКОСТЬ ХРАНЕНИЯ (или РАБОЧИЙ ЗАПАС ХРАНЕНИЯ) – In the US oil and gas industries, Working Storage Capacity is the difference in volume between the maximum safe fill capacity and the quantity below which pump suction is ineffective (bottoms).

WORKING–TIME ARRANGEMENTS = ДОГОВОРЁННОСТИ О ВРЕМЕНИ РАБОТЫ – Working-Time Arrangements comprise different elements:- normal and maximum number of hours per working day or week; overtime provisions; rest periods; the distribution of working-time during the day, week or year and the associated flexible time arrangements. These elements are regarded as a fundamental dimension of international labor standards.

WORKING TIME IN SCHOOL = РАБОЧЕЕ ВРЕМЯ В ШКОЛЕ – Working Time In School refers to the working time teachers are supposed to be at school including teaching time and non-teaching time.

WORKING (TOP STORAGE) GAS (NATURAL GAS) = АКТИВНЫЙ (ХХ) ГАЗ (ПРИРОДНЫЙ ГАЗ) – Working (Top Storage) Gas (Natural Gas) is the volume of gas in an underground storage reservoir above the designed level of the base. It may or may not be completely withdrawn during any particular withdrawal season. Conditions permitting, the total working capacity could be used more than once during any season. See also Working Gas.

WORKING TRIAL BALANCE = РАБОЧИЙ ПРОБНЫЙ БАЛАНС (или ХХ) – A Working Trial Balance is a trial balance that is in the process of being adjusted. In concept, it is an unadjusted trial balance, to which you pencil in any adjusting entries needed to close a reporting period (such as for the monthly, quarterly, or annual financial statements). These additional entries are then entered in the general ledger, resulting in a completed trial balance. The working trial balance is useful for testing a complete set of adjusting entries to determine their impact on the financial statements, before actually making the entries in the general ledger. The steps required to use a working trial balance (assuming the existence of an accounting software package) are:- (i) Print the current version of the ending trial balance, or (better yet) convert the report to an electronic spreadsheet; (ii) Enter all adjusting entries needed to close the month; (iii) Note the descriptions and calculations for each adjusting entry at the bottom of the report; (iv) Carry forward the adjusted account balances to the right side of the report and manually translate them into the income statement and balance sheet; (v) Revise the adjusting entries as needed, based on the preliminary financial statement results; (vi) Create journal entries for each entry made in the working trial balance, and enter them in the general ledger, along with explanations; and (vii) Print the trial balance again, and verify that all entries were made to the correct accounts and in the correct amounts. The columns used in a working trial balance (in order from left to right) are:- (i) Account number; (ii) Account name; (iii) Ending debit total; (iv) Ending credit total; (v) For manual entries:- blank space for debit entries; (vi) For manual entries:- blank space for credit entries; and (vii) For financial statements:- blank space to enter income statement and balance sheet totals. The working trial balance is part of the documentation required to prepare the financial statements; it is not part of the financial statement reporting package. It is not possible to construct a balanced working trial balance in a single entry system; the report is designed for use only with a double entry bookkeeping system. Working Trial Balance is similar to the trial balance. Additionally, it contains columns for adjusting entries and the adjusted balance. This report is typically used at year-end to assist in making adjusting entries. Working Trial Balance is similar to the trial balance. Additionally, it contains columns for adjusting entries and the adjusted balance. This report is used at year-end to assist in making adjusting entries. A trial balance is a

list of all the nominal ledger accounts contained in the ledger of a business. This list will contain the name of the nominal ledger account and the value of that nominal ledger account. The value of the nominal ledger will hold either a debit balance value or a credit value balance.

WORK IN PROCESS = РАБОТА В ПРОЦЕССЕ (или НЕЗАВЕРШЁНКА, или НЕЗАВЕРШЁННАЯ РАБОТА) – A term Work In Process is:- (1) in contracting:- partly completed jobs valued at total cost up to the stated period and including, in case of long-term contracts, a percentage of the profit. (2) In manufacturing:- partially completed goods, parts, or subassemblies that are no longer part of the raw materials inventory and not yet part of the finished products inventory. Work in process inventory forms a part of the working or current assets of a firm and is valued usually at lower of cost and realizable value. Also called Work In Progress, and Goods In Process. Work In Process is parts and subassemblies in the process of becoming completed finished goods. Work In Progress (WIP):- parts and subassemblies in the process of becoming completed assembly components. These items, no longer part of the raw materials inventory and not yet part of the finished goods inventory, may constitute a large inventory by themselves and create extra expense for the firm.

WORK–IN–PROCESS INVENTORY = ИНВЕНТАРЬ РАБОТЫ–В–ПРОЦЕССЕ (или ИНВЕНТАРЬ НЕЗАВЕРШЁННОГО ПРОИЗВОДСТВА) – In the official statistics of US Census Bureau, Work-In-Process (WIP) Inventory:- accumulated costs of all commodities undergoing fabrication within your plants and long-term contracts where the inventory costs are for undelivered items and the value of work done that has not been reported in sales. See also Inventory. WIP Inventories (short for the Work in Progress Inventories) is the total value of the work-in-progress inventories on hand at the end of the period. Therefore it is the value of inventories that are in the process of being converted into finished product. WIP is an acronym for Work in Process/Progress. Usually refers to inventory that has value added from labor or additional processing. When considered for inventory value, the value of the raw material plus the value added component is accounted for in determining the value of that inventory at that point in the process. / Запасы Незавершённого Производства:- счёт запасов, используемый обрабатывающими и производственными предприятиями, на котором накапливаются все производственные затраты за отчётный период. Конечное сальдо на этом счёте составляет незавершённое производство на конец отчётного периода, то есть все затраты, отнесённые на незаконченную на данный момент продукцию. Назвается также как (Goods In Process) и (Work In Progress). В США под Незавершённым Производством понимаются частично произведённые товары или частично выполненные договоры. В отчётности и учёте незавершённое производство обычно оценивается по его стоимости путём учёта издержек на сырьё и материалы и рабочую силу, уже вложенные в него, и некоторой величины распределённых накладных расходов. Если речь идёт о долгосрочных контрактах, в стоимость незавершённого производства может включаться и элемент прибыли.

WORK IN PROGRESS = РАБОТА–В–ПРОЦЕССЕ (или НЕЗАВЕРШЁНКА, или НЕЗАВЕРШЁННОЕ ПРОИЗВОДСТВО) – Work In Progress (WIP) is the part of stocks that is currently being worked on. WIP is no longer raw materials because it has undergone some processing. It is also not yet finished goods because more work has to be done to put it into the state in which it would normally be sold. Like any other stock, WIP is valued at the lower of:- (i) Cost:- this is the cost of the raw materials and the processing. This could be any of FIFO (First In First Out), LIFO (Last In First Out), replacement cost, average cost or specific cost. (ii) Net Realisable Value:- the price for which it could be sold less costs involved in selling. The value of WIP includes the cost of processing in order to match costs with revenues in accordance with the accrual principle. If the value of stocks falls, an unrealized loss has been made and this needs to be reflected in the accounts. The valuation of work in progress does depend on the methods of costing employed by a company:- companies have a lot of discretion about which costs are allocated to the cost of goods they make, and which are simply taken as expenses in the period. The rules for calculating WIP for tax purposes are (for obvious reasons) more rigid than those for financial reporting purposes. A term Work In Progress is:- (1) a continuation of a partly-completed work towards its conclusion; and (2) alternative term for Work In Process. Work In Progress:- partially manufactured stock you have on hand, or partially completed work on contracts under which you provide your service. Work In Progress a piece of work that is not yet finished. / Незавершённое Производство:- частично произведённые товары или частично выполненные договоры. В отчётности и учёте незавершённое производство обычно оценивается по его стоимости путём учёта издержек на сырьё и материалы и рабочую силу, уже вложенные в него, и некоторой величины, распределённых накладных расходов. Если речь идёт о долгосрочных контрактах, в стоимость незавершённого производства может включаться и элемент прибыли. В США незавершённое производство называют обычно Незавершённая Работа (Work In Process).

WORK LOAD = РАБОЧАЯ НАГРУЗКА – Work Load is the quantity of work ahead assigned to a certain facility such as a work station, capacity group or a department respectively staff-member.

WORK–OF–ART = ПРОИЗВЕДЕНИЕ ИСКУССТВА – Work-Of-Art is a product of one of the fine arts; especially a painting or sculpture of artistic merit.

WORK ORDER = РАБОЧИЙ ЗАКАЗ – Work Order is:- (1) in contracting:- written order from the customer providing specific or blanket authorization to the contractor to proceed with the performance of the contract without further instructions. Work orders differ from job orders in the breadth of the scope. (2) In manufacturing:- internal authorization to incur costs in the design, development, and production of a specific product.

WORKOUT = ОТРАБОТКА – Workout is a situation, such as a bad loan or troubled firm, where remedial measures are being taken. Workout:- informal repayment or loan forgiveness arrangement between a borrower and creditors. / Workout:- урегулирование сложной ситуации. Это может быть, например, невыплаченный заём; компания может испытывать трудности, и тогда необходимо принять корректирующие меры.

WORKOUT AGREEMENT = СОГЛАШЕНИЕ ОБ ОТРАБОТКЕ (или СОГЛАШЕНИЕ О РЕСТРУКТУРИЗАЦИИ) – Workout Agreement is a mutual agreement entered into by a borrower and a lender to reschedule loan payments. Loan payment can be modified by extending the original maturity date. Foreclosure and bankruptcy proceeding can be avoided through a workout agreement. Loans which are written off as bad debt are negotiated in new terms and the lender expects to collect from recoveries. Debt service burden will be reduced in a workout agreement. Workout Agreement is an agreement to restructure a loan. This is done to avoid default or foreclosure. Refer to nonperforming loan and slow loan. Workout Agreement is a mutual agreement between a lender and borrower to renegotiate terms on a loan that is technically in default, so as to avoid foreclosure or liquidation. The renegotiated terms will generally provide some measure of relief to the borrower in terms of reducing the debt-servicing burden through accommodative measures provided by the lender, such as extending the term of the loan, rescheduling repayments and so on. A workout agreement is only possible if it is in the interest of both the borrower and the lender to work things out. While the benefits to the borrower of a workout agreement are obvious, the advantage to the lender is that it avoids the expense and effort of recovery efforts such as foreclosure. / Соглашение О Реструктуризации – соглашение между кредитором и должником о продлении срока кредита, изменении других условий в случае неспособности заёмщика выполнять обязательства.

WORKOUT DATE = ДАТА ОТРАБОТКИ – Workout Date:- when Bridge LP (company) applications calculate yields, the date selected as the yield-to date. The workout date varies by option (call, put, sinking fund) and the user-selected yield type. For yields to maturity, for example, the workout date is always the maturity date. For yields to best put, the workout date is the put date with the highest yield. For yields to worst call, the workout date is the call date with the lowest yield. Also known as Effective Redemption Date. Workout Date:- based on the current price and call schedule for a bond, this is the date when the bond is most likely to be called or redeemed. / Бридьж Эл.Пи. (Bridge LP).

WORKOUT LOANS = ОТРАБОТАННЫЕ ССУДЫ – Workout Loans, or Workout Agreements, are mutual agreements between lenders and borrowers intended to renegotiate the terms and conditions of a loan to meet the borrower's current financial condition. They are meant to be a temporary solution to a temporary problem, such as unemployment, decrease of income of 25% or greater, major medical expenses, divorce situations and natural disaster. So instead of a borrower falling behind on their payments, the lender will work with them to offer some form of financial relief that can help them keep current. While the prospect of defaulting on a loan may seem scary to borrowers, it's far from ideal for lenders as well. The financial losses and expenses of payment recovery involved in a default do nothing to help a lender's bottom line, meaning many lenders will do what they can to help a borrower get back on track. Types of Workout Loans:- the type of workout agreement a lender and borrower can come to varies, but the following are some common examples:- (i) Term Extension:- term extension will increase the lifespan of a loan, reducing monthly payments; (ii) Payment Deferment:- payment deferment allows borrowers to play catch up on missed payments by extending their loan; (iii) Repayment Plan:- repayment plans are special programs lenders may use to help borrowers begin to pay down their debt; (iv) Loan Modification:- loan modification changes the terms of a loan, often featuring more cost-effective concessions that can help borrowers stay up to date on their payments. This is usually a temporary change to help the borrower through their hardship. (v) Payment Forgiveness:- payment forgiveness involves a lender agreeing to waive payment obligation for a missed payment. It's important to note that this option is not always available. First Steps:- the most important thing a borrower facing financial difficulties should do is contact the lender. The sooner they know about the situation, the sooner the two parties can start working toward a solution. Additionally, waiting to request assistance will put the borrower ever further behind on payments. See also Workout Agreement. / Просроченные Ссуды С Перспективой Погашения.

WORKOUT MARKET = РЫНОК ОТРАБОТКИ – Workout Market refers to a prediction indicating the trading price range that a security will occupy within a reasonable period of time. It is made by a market maker. These predictions will vary depending upon market conditions, and the price given in a prediction will not always be available for trading. Workout Market is a market indicating prices at which it is believed a security can be bought or sold within a reasonable length of time. Workout Market is a market maker prediction as to the trading price range that a security will occupy within a reasonable period of time. The characteristics of a workout market are seen prevalently in thin markets. Prices quoted by the market maker are subject to the availability of a matching order. Also, there are usually significant mark-ups on the security being traded. / 'Оценочный' Рынок (Workout Market):- цена, установленная для акций, являющаяся скорее не твёрдой ценой, а наилучшей оценкой для данного момента.

WORKOUT PERIOD = ПЕРИОД УРЕГУЛИРОВАНИЯ ПРОБЛЕМ – Workout Period:- realignment of a temporarily misaligned yield relationship that sometimes occurs in fixed income markets. Workout Period is the period of time when temporary yield discrepancies between fixed income securities are adjusted. A workout period can be viewed as a sort of reset period, in which bond issuers and credit rating agencies review outstanding fixed income issues and adjust any discrepancies in price/yield, in order to correct any inefficiencies in the market. Investors typically take advantage of this period by participating in a bond or sector swap. For example, if an investor believes that the yield spread between two bonds is too wide, their investment would be moved from the higher yielding bond to the lower yielding bond. If the investor has guessed the expected workout period correctly, the investor will gain from the yield adjustment. / Период Урегулирования Проблем – период урегулирования временных проблем в отношениях сторон, связанных с доходностью, которые иногда возникают на рынках с фиксированным доходом.

WORKOVER = РАЗРАБОТКА (или ОПЕРАЦИИ ПО УВЕЛИЧЕНИЮ ДЕБИТА СКВАЖИНЫ, или КАПИТАЛЬНЫЙ РЕМОНТ СКВАЖИНЫ) – (1) Workover is an operation on a producing well to restore or increase production. Tubing may be pulled out and the casing at the bottom of the well pumped or washed free of accumulated sand. Well bores may be fractured or redrilled, gravel packing may be used, or pumps may be replaced. The repair or stimulation of an existing production well for the purpose of restoring, prolonging or enhancing the production of hydrocarbons. Workover operations are major remedial operations sometimes required to maintain maximum oil producing rates. If, for example, a well begins to produce an excessive amount of salt water, a service rig is moved onto the well, and operations to reduce the saltwater production are begun.

(2) Workover is the process of performing major maintenance or remedial treatments on an oil or gas well. In many cases, workover implies the removal and replacement of the production tubing string after the well has been killed and a workover rig has been placed on location. Through-tubing workover operations, using coiled tubing, snubbing or slickline equipment, are routinely conducted to complete treatments or well service activities that avoid a full workover where the tubing is removed. This operation saves considerable time and expense.

WORK PENETRATION = РАБОЧЕЕ ПРОНИКНОВЕНИЕ (или ХХ) – Work Penetration is the penetration of a sample of lubricating grease immediately after it has been brought to 77F and then subjected to 60 Stokes in a standard grease worker. This procedure and the standard grease worker are described in ASTM Method D 217. American Society for Testing and Materials (ASTM). / Американское Общество по Испытаниям и Материалам (АОИМ).

WORKPLAN = РАБОЧИЙ ПЛАН (или ПЛАН РАБОТ) – Workplan is an official document specifying the phytosanitary measures agreed to by the National Plant Protection Organizations of both importing and exporting countries, intended to prevent the movement of regulated pests while facilitating trade of plants and plant products.

WORK PRODUCT = РАБОЧИЙ ПРОДУКТ (или ПРОДУКТ РАБОТЫ) – Work Product:- the totality of the professional services provided by an actuary to a principal including any opinion or report, as well as any supporting calculations and documentation produced by the actuary rendering professional services under an International Actuarial Standard of Practice (IASP). Work Product:- material prepared in anticipation of litigation. Generally, work product is privileged, meaning it is exempt from discovery. However, there are exceptions. Work product is divided into two categories:- ordinary and opinion. Ordinary work product is the result of gathering basic facts or conducting interviews with witnesses, and is discoverable if there is a showing of substantial need, like a witness that becomes unavailable. Opinion work product is the record of an attorney's mental impressions, ideas or strategies, and is almost never subject to discovery. Work Product is that work done for a client by an attorney representing the client and generally considered protected from discovery. It includes statements written and spoken, as well as tactics, opinions, and thoughts that are protected by the attorney-client privilege. Work Product refers to the writings, notes, memoranda, reports on conversations with the client or witness, research and confidential materials that reflect an attorney's impressions, conclusions, opinions, or legal research or theories. Work product materials are confidential and are not required to be submitted in answer to discovery requests or subpoenae. The privilege

against disclosure belongs to the attorney. Courts generally hold that there is no protection for work done prior to attorney involvement. For example, work of an investigator hired by an insurance company prior to hiring of attorney or filing of suit is not protected. To be afforded protection under the work-product immunity doctrine, the material in question must have been prepared in anticipation of litigation or for trial. Work Product:- deliverable or outcome (such as a training course or a building) that must be produced to complete a project and achieve its objectives. Work Product is the writings, notes, memoranda, reports on conversations with the client or witness, research, and confidential materials which an attorney has developed while representing a client, particularly in preparation for trial. A 'Work Product' may not be demanded or subpoenaed by the opposing party, as are documents, letters by and from third parties and other evidence, since the work product reflects the confidential strategy, tactics and theories to be employed by the attorney.

WORK RECOVERY = ВОССТАНОВЛЕНИЕ РАБОТЫ – Work Recovery is the ratio of recoverable work to the total work required to strain a fiber a specified amount under a given program of strain rate.

WORK–RELATED = СВЯЗАННОЕ С РАБОТОЙ – Work-Related:- any event, exposure, activity, etc, occurring within the work environment resulting in death, injury, illness to an employee is generally considered to be work-related, regardless who was responsible or at fault.

WORK RELATED EXPENSES = СВЯЗАННЫЕ С РАБОТОЙ ИЗДЕРЖКИ – Work Related Expenses are the expenses which you incur in carrying out your employment.

WORKSHEET = РАБОЧИЙ ЛИСТОК – Worksheet is the computerized page allowing the user to manipulate many columns and rows of number. The worksheet can contain formulas so that if one number is changed, the entire worksheet is automatically updated, based on those formulas. Analysts, investors, and accountants track a company's financial statements, balance sheets, and other data on worksheets. A Worksheet is a single page or sheet in a spreadsheet program such as Excel. By default, in Excel there are three worksheets per file. Switching between worksheets is done by clicking on the sheet tab at the bottom of the screen. Also known as Sheet. Common misspellings:- Work Sheet. A Worksheet is a sheet of paper, or on a computer, on which problems are worked. A worksheet generator is a software program that generates problems, particularly in mathematics or numeracy. Such software is often used by teachers to make classroom materials and tests. In accounting a Worksheet often refers to a loose leaf piece of stationery from a columnar pad, as opposed to one that has been bound into a physical ledger book. From this, the term was extended to designate a single, two-dimensional array of data within a computerized spreadsheet program. Common types of worksheets used in business include financial statements, such as profit and loss reports. Analysts, investors, and accountants track a company's financial statements, balance sheets, and other data on worksheets. In the Microsoft spreadsheet program Excel, a single document is known as a 'Workbook' and by default each workbook contains three arrays or 'worksheets'. One advantage of such programs is that they can contain formulae so that if one cell value is changed, the entire document is automatically updated, based on those formulae. In accounting worksheet, you have to take one sheet and make its column for showing unadjusted trial balance, adjusted trial balance, income statement and balance sheet together. Worksheet:- informal document in which an accountant or auditor records the information for (1) adjusting trial balances prior to preparing financial statements, or to (2) substantiate his or her opinion regarding an account balance or a transaction. Work Sheet is a document or schedule in which an accountant or auditor gathers information to substantiate an opinion concerning an account balance or 'test of transaction'. / Рабочий Листок или Рабочая Таблица – один из видов рабочих документов, используемый как основное средство, облегчающее подготовку финансовых отчётов. Рабочая Страница (Worksheet):- табличный файл. Компьютерная страница, позволяющая пользователю манипулировать большим числом столбцов и строк. В неё можно закладывать формулы так, что если одна цифра в ячейке изменится, то все параметры рабочей страницы автоматически преобразуются. С помощью рабочих страниц аналитики, инвесторы и бухгалтеры отслеживают финансовое положение компании, её балансовые и другие данные.

WORK STANDARD = СТАНДАРТ РАБОТЫ (или РАБОЧИЙ СТАНДАРТ) – Work Standard is a number of manhours allocated for the completion of a specific task.

WORKSTATION = РАБОЧАЯ СТАНЦИЯ – The Workstation is the means through which sensitive information and instructions get passed to online services. It is therefore very important that workstations are free from compromises. You should:- (i) transact only from workstations that are known to be secured. Avoid using shared or public workstations when accessing sensitive services. (ii) Make sure the workstations used are strengthened and protected by:- (a) keeping anti-virus and anti-Trojan software up-to-date with the latest virus and Trojan signatures; (b) keeping operating system and browser software up-to-date, including security patches; (c) periodically updating all installed software; (d) if possible, disabling or removing services that are not needed; and (e) installing a personal firewall if transactions are to be made using workstations that are outside the company firewall. (iii) Practice safe computing:- (a) do not allow unauthorized people to have physical access to the workstation; (b) do not run unknown software on the workstation; (c) do not leave the workstation unattended when you are logged into any services; (d) always log out from online sessions when no longer required; (e) close browser sessions or clear browser cache immediately after logging out of online sessions; (f) check that the bank's website address changes from http:// to the secure mode of https:// and that a security icon that looks like a lock or key appears on the bottom of the web page after logging on and before making sensitive transactions; (g) use a browser that supports the SSL 128 bit or higher encryption standard; (h) use the latest browser supported by the online applications; and (i) choose appropriate browser settings, e.g., disable Active-X control and/or allow Java-Applets only after additional confirmation. Workstation is a single terminal or personal computer that may or may not be connected to a larger network. Workstation:- a high-performance computer system that is basically designed for a single user and has advanced graphics capabilities, large storage capacity, and a powerful microprocessor (central processing unit). A workstation is more capable than a personal computer (PC) but is less advanced than a midrange computer (which can manage a large network of peripheral PCs or workstations and handle immense data-processing and reporting tasks). The term Workstation is also sometimes ascribed to dumb terminals (i.e. without any processing capacity) that are connected to mainframe computers. Most workstation microprocessors employ reduced instruction set computing (RISC) architecture, as opposed to the complex instruction set computing (CISC) used in most PCs. Because it reduces the number of instructions permanently stored in the microprocessor, RISC architecture streamlines and accelerates data processing. A corollary of that feature is that applications software run by workstations must include more instructions and complexity than CISC-architecture applications. Workstation microprocessors typically offer 32-bit addressing (indicative of data-processing speed), compared to the exponentially slower 16-bit systems found in most PCs. Some advanced workstations employ 64-bit processors, which possess four billion times the data-addressing capacity of 32-bit machines. Their raw processing power allows high-end workstations to accommodate high-resolution or three-dimensional graphic interfaces, sophisticated multitask software, and advanced abilities to communicate with other computers. Workstations are used primarily to perform computationally intensive scientific and engineering tasks. They have also found favor in some complex financial and business applications. In addition, high-end workstations often serve a network of attached 'client' PCs, which use resident tools and applications to access and manipulate data stored on the workstation. The workstation was developed in the United States in 1981 by the National Aeronautics and Space Administration for its Apollo space program and was introduced commercially in

1983. The chief delineation between PCs and workstations has traditionally been the latter's advanced graphics and data-processing capabilities. But advanced graphic interfaces, powerful microprocessors, and the integration of RISC technology into high-end PCs makes them barely distinguishable from low-end workstations. Likewise, high-end, 64-bit workstations closely mimic the processing prowess of some midrange computer systems. Workstation, in a manufacturing environment, is an area with equipment for the performance of a specialized task usually by a single individual. In a computer environment, it is:- (a) an intelligent terminal or personal computer usually connected to a computer network or (b) a powerful microcomputer used especially for scientific or engineering work. / Отдельный терминал или персональный компьютер, который может или не может быть подключён к более крупной сети.

WORK STUDY = ИЗУЧЕНИЕ РАБОЧЕГО ВРЕМЕНИ – Work Study:- the pioneering technique of improving value for money and productivity. Work study, under the major discipline of industrial engineering, emerged as the earliest effectiveness and efficiency technique that even to date remains the basic to all other techniques that developed later. Work study was the sequel to Taylor's famous scientific management. Work Study is defined as the systematic examination of the methods of carrying on activities so as to improve the effective use of resources and to set up standards of performance for the activities being carried out. Work study has two major branches:- (i) Method Study; and (ii) Work Measurement. Work Study is a study concerned with improving work methods and deciding how long particular jobs should take. Its aim is to reduce effort involved in avrious operations, to organize labour in the most economical manner and to provide data for planning, estimating and finacial incentive schemes. / Изучение Рабочего Времени:- поиск путей выполнения определённой работы более эффективно и с меньшими затратами. Анализ рабочего времени состоит из изучения методов работы (method study), сравнения существующих методов с предлагаемыми и хронометража (или нормативами) работы (work measurement), необходимого для определения времени, которое квалифицированный рабочий затрачивает на выполнение работы, после чего устанавливается определённый стандарт времени.

WORK–STUDY PROGRAMS = ПРОГРАММЫ РАБОТА–УЧЁБА – Work-Study Programs are combinations of work and education in which periods of both form part of an integrated, formal education or training activity. Examples of such programs include the 'dual system' in Germany; 'apprentissage' or 'formation en alternance' in France and Belgium; internship or co-operative education in Canada; apprenticeship in Ireland; and 'youth training' in the United Kingdom. / ; апрэтисаж (apprentissage) или формасьён он альтэрнас (formation en alternance) во Франции и Бельгии; .

WORK TIME = РАБОЧЕЕ ВРЕМЯ (или ВРЕМЯ РАБОТЫ) – Work Time is the paid time that starts when temporary workers are engaged at a worksite, and stops when they are released.

WORK–TO–BREAK = РАБОТА–НА–РАЗРЫВ – Work-To-Break:- the total area under the force extension curve up to the breaking force. See also Energy-To-Break.

WORK–TO–RULE = РАБОТА ПО ПРАВИЛАМ – Work-To-Rule:- industrial action where, in contrast to a strike, workers do not withdraw their labor. Instead, they stay on their jobs but drastically slow down the operations by punctilious adherence to a narrow interpretation of work rules included in the collective bargaining agreement. Work-To-Rule:- the practice of working to the strictest interpretation of the rules as a job action. Work-To-Rule:- a job action in which employees do no more than the minimum required by the rules of a workplace in order to cause a slowdown. Work-To-Rule:- to decrease the rate of working by this means. Work-To-Rule:- a form of industrial action in which employees adhere strictly to all the working rules laid down by their employers, with the deliberate intention of reducing the rate of working. Work-To-Rule:- the practice by workers of refusing to do any work that is not strictly required as a part of their jobs in order to protest something (such as unfair working conditions). / Работа По Правилам:- разновидность действий против предпринимателей или управляющих (industrial action), которые состоят в строгом выполнении рабочими всех правил, для того чтобы расстроить производственный процесс, не прибегая к забастовке (strike). Работа по правилам обычно включает в себя запрет на сверхурочную работу (overtime ban).

WORK TRAIN = РАБОЧИЙ ПОЕЗД – Work Trains are non-revenue trains used for the administration and upkeep service of the railroad. Examples are:- official trains; inspection trains; special trains running with company fire apparatus to save the railroad's property from destruction; trains that transport the railroad's employees to and from work when no transportation charge is made; construction and upkeep trains run in connection with maintenance and improvement work; and material and supply trains run in connection with operations.

WORLD AERONAUTICAL CHARTS = АЭРОНАВИГАЦИОННАЯ КАРТА МИРА – World Aeronautical Charts (WAC):- provide a standard series of aeronautical charts covering land areas of the world at a size and scale convenient for navigation by moderate speed aircraft. Topographic information includes cities and towns, principal roads, railroads, distinctive landmarks, drainage and relief. Aeronautical information includes visual and radio aids to navigation, airports, airways, restricted areas, obstructions, and other pertinent data.

WORLD AGRICULTURAL OUTLOOK BOARD = ПАЛАТА ПО ВСЕМИРНОМУ СЕЛЬСКОХОЗЯЙСТВЕННОМУ ОБОЗРЕНИЮ – The World Agricultural Outlook Board (WAOB) was created in 1977 by the US Department of Agriculture (USDA) in order to review and approve the Department's commodity and farm sector forecasts. It is now part of the Office of the Chief Economist. The Board utilises information from several USDA agencies in order to prepare its reports, which focus on both domestic and global agricultural supply and demand forecasts. This site provides information on the WAOB, its organisation, aims and activities. Details of WAOB supply and demand estimates are available, as is WAOB climate and weather data, and remote sensing information. Proceedings of the annual USDA Agricultural Outlook Forum can be viewed online from 1997 onwards. World Agricultural Outlook Board (WAOB):- as part of the Office of the Chief Economist, the WAOB coordinates the commodity forecasting program; monitors global weather and analyzes its impact on agriculture; and coordinates USDA's weather, climate and remote sensing work. The World Agricultural Outlook Board (WAOB) serves as USDA's focal point for economic intelligence and the commodity outlook for US and world agriculture. The Board coordinates, reviews, and approves the monthly World Agricultural Supply and Demand Estimates (WASDE) report, houses OCE's Joint Agricultural Weather Facility, and coordinates USDA's Agricultural Outlook Forum. Annually, the Forum attracts 1 500 attendees, including producers, policymakers, business leaders, and government and industry analysts. World Agricultural Outlook Board (WAOB) is a USDA agency created in 1977 to provide timely and improved forecasts of domestic and international agricultural production and trade. The agency oversees commodity estimates committees made up of members from different USDA agencies who reconcile estimates and arrive at the official USDA outlook for crop and livestock production, demand, prices, and stocks.

THE WORLD BANK = ВСЕМИРНЫЙ БАНК – The World Bank is a vital source of financial and technical assistance to developing countries around the world. Our mission is to fight poverty with passion and professionalism for lasting results and to help people help themselves and their environment by providing resources, sharing knowledge, building capacity and forging partnerships in the public and private sectors. We are not a bank in the common sense; we are made up of two unique development institutions owned by 187 member countries:- the International Bank for Reconstruction and Development (IBRD) and the International Development Association (IDA). Each institution plays a different but collaborative role in advancing the vision of inclusive and sustainable globalization. The

IBRD aims to reduce poverty in middle-income and creditworthy poorer countries, while IDA focuses on the world's poorest countries. Their work is complemented by that of the International Finance Corporation (IFC), Multilateral Investment Guarantee Agency (MIGA) and the International Centre for the Settlement of Investment Disputes (ICSID). Together, we provide low-interest loans, interest-free credits and grants to developing countries for a wide array of purposes that include investments in education, health, public administration, infrastructure, financial and private sector development, agriculture and environmental and natural resource management. The World Bank, established in 1944, is headquartered in Washington, DC, the United States. We have more than 10 000 employees in more than 100 offices worldwide (in 2011). The name World Bank was adopted for the International Bank For Reconstruction And Development (IBRD) in the 1970s. World Bank is headquartered in Washington, DC, USA. International organization affiliated with the United Nations and organized at the Bretton Woods Conference in 1944, whose chief purpose is to assist in the development of its members by facilitating capital investment, making loans out of its own funds, and promoting foreign investment by guaranteeing and participating in private loans and private investment. The World Bank finances projects primarily geared to developing the industrial infrastructure projects needed by its member nations for their economic development. All loans must be guaranteed by the government of the recipient countries. Also known as International Bank For Reconstruction And Development (IBRD). See also International Bank For Reconstruction And Development (IBRD), International Development Association (IDA), and International Finance Corporation (IFC). The World Bank is a multilateral development finance agency created by the 1944 Bretton Woods, (New Hampshire) negotiations. It makes loans to developing countries for social overhead capital projects that are guaranteed by the recipient country. See also International Bank for Reconstruction and Development. The World Bank Group is made up of five organizations, the:- (i) International Bank for Reconstruction and Development (IRBD); (ii) International Development Organisation (IDA); (iii) International Finance Corporation (IDC); (iv) Multilateral Investment Guarantee Agency (MIGA); and (v) the International Centre for Settlement of Investment Disputes (ICSID). Established in 1944 at a conference of world leaders in Bretton Woods, New Hampshire, United States, the World Bank is a lending institution whose aim is to help integrate developing and transition economies with the global economy, and reduce poverty by promoting economic growth. The Bank lends for policy reforms and development projects and policy advice, and offers technical assistance and non-lending services to its 181 member countries. World Bank:- the International Bank for Reconstruction and Development, commonly referred to as the World Bank, is an intergovernmental financial institution located in Washington, DC. Its objectives are to help raise productivity and incomes and reduce poverty in developing countries. Established in 1945, it loans financial resources to credit-worthy developing countries. It raises most of its funds by selling bonds in the world's major capital markets. The World Bank earns a profit that is plowed back into its capital. The World Bank:- in full World Bank Group international organization affiliated with the United Nations (UN) and designed to finance projects that enhance the economic development of member states. Headquartered in Washington, DC, the bank is the largest source of financial assistance to developing countries. It also provides technical assistance and policy advice and supervises – on behalf of international creditors – the implementation of free-market reforms. Together with the International Monetary Fund (IMF) and the World Trade Organization, it plays a central role in overseeing economic policy and reforming public institutions in developing countries and defining the global macroeconomic agenda. Origins:- founded in 1944 at the UN Monetary and Financial Conference (commonly known as the Bretton Woods Conference), which was convened to establish a new, post-World War II international economic system, the World Bank officially began operations in June 1946. Its first loans were geared toward the postwar reconstruction of western Europe. Beginning in the mid-1950s, it played a major role in financing investments in infrastructural projects in developing countries, including roads, hydroelectric dams, water and sewage facilities, maritime ports, and airports. The World Bank Group comprises five constituent institutions:- the International Bank for Reconstruction and Development (IBRD), the International Development Association (IDA), the International Finance Corporation (IFC), the Multilateral Investment Guarantee Agency (MIGA), and the International Centre for Settlement of Investment Disputes (ICSID). The IBRD provides loans at market rates of interest to middle-income developing countries and creditworthy lower-income countries. The IDA, founded in 1960, provides interest-free long-term loans, technical assistance, and policy advice to low-income developing countries in areas such as health, education, and rural development. Whereas the IBRD raises most of its funds on the world's capital markets, the IDA's lending operations are financed through contributions from developed countries. The IFC, operating in partnership with private investors, provides loans and loan guarantees and equity financing to business undertakings in developing countries. Loan guarantees and insurance to foreign investors against loss caused by noncommercial risks in developing countries are provided by the MIGA. Finally, the ICSID, which operates independently of the IBRD, is responsible for the settlement by conciliation or arbitration of investment disputes between foreign investors and their host developing countries. From 1968 to 1981 the president of the World Bank was former US Secretary of Defense Robert S. McNamara. Under his leadership the bank formulated the concept of 'sustainable development', which attempted to reconcile economic growth and environmental protection in developing countries. Another feature of the concept was its use of capital flows (in the form of development assistance and foreign investment) to developing countries as a means of narrowing the income gap between rich and poor countries. The bank has expanded its lending activities and, with its numerous research and policy divisions, has developed into a powerful and authoritative intergovernmental body. Organization:- The World Bank is related to the UN, though it is not accountable either to the General Assembly or to the Security Council. Each of the bank's more than 180 member states are represented on the board of governors, which meets once a year. The governors are usually their countries' finance ministers or central bank governors. Although the board of governors has some influence on IBRD policies, actual decision-making power is wielded largely by the bank's 24 executive directors. Five major countries – the United States, Japan, Germany, the United Kingdom, and France – appoint their own executive directors. The other countries are grouped into regions, each of which elects one executive director. Throughout the World Bank's history, the bank president, who serves as chairman of the Executive Board, has been an American citizen. Voting power is based on a country's capital subscription, which is based in turn on its economic resources. The wealthier and more developed countries constitute the bank's major shareholders and thus exercise greater power and influence. For example, at the beginning of the XXI century the United States exercised more than one-sixth of the votes, more than double that of Japan, the second largest contributor. Because developing countries hold only a small number of votes – e.g., in the late 1990s approximately 2 percent of the votes were held by 25 African countries combined – the system does not provide a significant voice for these countries, which are the primary recipients of World Bank loans and policy advice. The bank obtains its funds from the capital subscriptions of member countries, bond flotations on the world's capital markets, and net earnings accrued from interest payments on IBRD and IFC loans. Approximately one-tenth of the subscribed capital is paid directly to the bank, with the remainder subject to call if required to meet obligations. The World Bank is staffed by more than 10 000 people, roughly one-fourth of whom are posted in developing countries. The bank has offices in about 70 countries, and in many countries staff members serve directly as policy advisers to the ministry of finance and other ministries. The bank has consultative as well as informal ties with the world's financial markets and institutions and maintains links with nongovernmental organizations in both developed and developing countries. Debt And Policy Reform:- the debt crisis of the early 1980s – during which many developing countries were unable to service their external debt to multilateral lending institutions, because of a slowdown in the world economy, high interest rates, a decline in commodity prices, and wide fluctuations in oil prices, among other factors – played a crucial role in the evolution of World Bank operations. The bank had become increasingly involved in shaping economic and social policies in indebted developing countries. As a condition of receiving loans, borrowing countries were required to

implement stringent 'structural adjustment programs', which typically included severe cuts in spending for health and education, the elimination of price controls, the liberalization of trade, the deregulation of the financial sector, and the privatization of state-run enterprises. Although intended to restore economic stability, these programs, which were applied in a large number of countries throughout the developing world, frequently resulted in increased levels of poverty, mounting unemployment, and a spiraling external debt. In the wake of the debt crisis, the World Bank focused its efforts on providing financial assistance in the form of balance-of-payments support and loans for infrastructural projects such as roads, port facilities, schools, and hospitals. Although emphasizing poverty alleviation and debt relief for the world's least developed countries, the bank has retained its commitment to economic stabilization policies that require the implementation of austerity measures by recipient countries. The World Bank and the IMF played central roles in overseeing free-market reforms in eastern and central Europe after the fall of communism there in the 1980s and '90s. The reforms, which included the creation of bankruptcy and privatization programs, were controversial because they frequently led to the closure of state-run industrial enterprises. 'Exit mechanisms' to allow for the liquidation of so-called 'Problem Enterprises' were put into place, and labor laws were modified to enable enterprises to lay off unneeded workers. The larger state enterprises often were sold to foreign investors or divided into smaller, privately owned companies. In Hungary, for example, some 17 000 businesses were liquidated and 5 000 reorganized in 1992–93, leading to a substantial increase in unemployment. The World Bank also provided reconstruction loans to countries that suffered internal conflicts or other crises (e.g., the successor republics of former Yugoslavia in the late 1990s). This financial assistance did not succeed in rehabilitating productive infrastructure, however. In several countries the macroeconomic reforms resulted in increased inflation and a marked decline in the standard of living. The World Bank is the world's largest multilateral creditor institution, and as such many of the world's poorest countries owe it large sums of money. Indeed, for dozens of the most heavily indebted poor countries, the largest part of their external debt – in some cases constituting more than 50 percent – is owed to the World Bank and the multilateral regional development banks. According to some analysts, the burden of these debts – which according to the bank's statutes cannot be canceled or rescheduled – has perpetuated economic stagnation throughout the developing world. The World Bank is a name commonly used for the International Bank for Reconstruction and Development (IBRD) which, like the International Monetary Fund, was established in 1944 at Bretton Wodds (USA) and is headquartered in Washington, DC. It has 181 member countries (status in 1997/98). Switzerland only became a member in May 1992, but collaborated with the World Bank for many years prior to this, in particular through capital exports in the form of World Bank issues. It mainly grants long-term investment loans to developing countries. The International Development Association (IDA) and the International Finance Corporation (IFC) are affiliated with the World Bank. Together the three organizations form the so-called World Bank Group. The World Bank is a financial body part of the United Nations system. The World Bank was created in 1944 at the outlet of the Bretton Woods financial and monetary conference. First loans helped finance reconstruction of Western Europe and Japan following World War II, but today the World Bank has considerably broadened its presence throughout the globe, lending to countries of Africa, Asia, Central Europe, Latin America, the Middle East, and the former Soviet Union. Its priority is to lend capital to governments of developing countries to promote economic growth through the financing of large infrastructure projects, economic reform packages, and technical assistance. It thus has vested interests in a number of developing countries worldwide. Loans are also aimed at encouraging private sector development. Presently, the World Bank is composed of four main branches:- the International Bank for Reconstruction and Development (IBRD), the Multilateral Investment Guarantee Agency (MIGA), the International Development Agency (IDA), and the International Financial Society (IFS). Its headquarters are in Washington, DC. / ковка или штамповка (forging). В 1970-е название Всемирный Банк было адаптировано для обозначения Международного Банка Реконструкции и Развития (МБРР) (International Bank For Reconstruction And Development (IBRD)). Группа Всемирного Банка (World Bank Group) состоит из Всемирного Банка (Международного Банка Реконструкции и Развития (МБРР) (International Bank For Reconstruction And Development (IBRD))) и его филиалов, Международной Финансовой Корпорации (МФК) (International Finance Corporation (IFC)), Международной Ассоциации Развития (МАР) (International Development Association (IDA)) и Многостороннего Агентства Гарантирования Инвестиций (МАГИ) (Multilateral Investment Guarantee Agency (MIGA)). Всемирный Банк или Международный Банк Реконструкции и Развития (МБРР) – специализированное финансовое учреждение ООН со штабквартирой в Вашингтоне, США. МБРР часто именуют в правовой и научной литературе Всемирным Банком. Банк проводит множество проектов по внедрению мер, норм и стандартов по упрощению процедур торговли и транспорта в развивающихся странах, странах с экономиками перехода и соответствующих регионах. Всемирный Банк – международный институт, созданный в 1944 как часть Брэтон Вудзской системы и расположенный в Вашингтоне, Округ Колумбия, США. Начинал с предоставления кредитов для финансирования послевоенного восстановления. В настоящее время является важным источником финансирования развития, проводит экспертизы и осуществляет консультации по вопросам, связанным с проблемами экономического развития.

WORLD COLLECTION = ВСЕМИРНАЯ КОЛЛЕКЦИЯ (или МИРОВАЯ КОЛЛЕКЦИЯ) – World Collection is a comprehensive collection of samples from different geographic areas of the world which is documented and stored. These are kept in storage as a genetic stock, and available to all for breeding purposes or reestablishment of a variety in a given location. Only segments of the world collection are of immediate practical value and thus find their way into the working collection.

WORLD COMPARISONS OF REAL PRODUCT = МИРОВЫЕ СРАВНЕНИЯ РЕАЛЬНОГО ПРОДУКТА – World Comparisons Of Real Product:- xxxxx. The present publication provides the global results of phase V of the International Comparison Programme (ICP), which involved a total of 64 countries and areas with a reference year of 1985. The ICP is a complex world-wide statistical enterprise that began in 1967 and has gone through four previous phases with reference years 197, 1973, 1975 and 1980. The Programme aims at obtaining internationally comparable data on total and per capita gross domestic product (GDP) and its breakdown by type of expenditure. It also takes into consideration the purchasing power differences of the national currencies in which the national estimates were originally compiled. Thus the Programme provides insights into the price levels of different countries. / Мировые Сравнения Реального Продукта:- международное сопоставление, проводимое ООН на основе показателя ВВП (смотрите Gross Domestic Product Derivated From Net Material Product), используемого для сравнения уровня экономического развития стран мира. Объектом исследования Международной Программы Сравнений (International Comparison Programme (ICP)) ООН является валовой внутренний продукт (ВВП), исчисляемый методом конечного потребления. Его общая сумма рассматривается как сумма расходов нации на товары и услуги, используемые для индивидуального потребления (individual consumption of population); коллективного потребления; формирования основных фондов для их прироста и взамен изношенных; увеличения материальных оборотных средств; чистого вывоза (или чистого экспорта). Объём конечных расходов нации, исчисленный в международных ценах, называется реальной величиной ВВП, а их размер в национальной валюте – это его номинальная величина.

WORLD CONFEDERATION OF LABOUR = ВСЕМИРНАЯ КОНФЕДЕРАЦИЯ ТРУДА – World Confederation of Labour (WCL):- labor confederation founded as the International Federation of Christian Trade Unions in 1920 to represent the interests of Christian labor unions in western Europe and Latin America. It was reconstituted under its present name in 1968. Although the confederation seeks national, regional, and international economic integration, its influence is primarily limited to domestic policies and local affairs in

member countries. The WCL is the smallest international labor federation. / Всемирная Конфедерация Труда (ВКТ) была основана в 1920 при поддержке Ватикана под названием Международная Конфедерация Христианских Профсоюзов (МКХП). На Конгрессе 1968 переименована в ВКТ; из официальных документов организации были устранены отсылки к христианской доктрине. Занимая реформистские позиции, ВКТ поддерживает в то же время требования о повышении зарплаты, улучшении условий труда и жизни рабочих. Около 14 000 000 человек (в 1984). Штабквартира расположена в Брюсселе, Бельгия.

WORLD CONGRESS OF ACCOUNTANTS = ВСЕМИРНЫЙ КОНГРЕСС БУХГАЛТЕРОВ – World Congress Of Accountants (WCOA) is the leading international symposium for the accountancy profession. The World Congress of Accountants (WCOA) brings together leaders in accounting, business and regulation to explore current issues and innovations on an international and regional level. It is organized by the International Federation of Accountants (IFAC), in collaboration with the national accounting organization of the host country and other sponsors. Dubbed as the 'Olympics of the accountancy profession', the congress was first held in St. Louis, the United States in 1904. It was held in a different city every five years, but as of 2000 it has been held every four years. The 18th World Congress of Accountants, held in Kuala Lumpur, Malaysia, in November 2010, attracted 6 000 delegates from 134 countries. The Congress has accelerated the development of international standards in accounting and auditing. World Congress Of Accountants (WCOA):- an event held every four years, organized by the International Federation of Accountants, which gathers accounting professionals from around the globe to discuss practices, policy and regulatory issues, and financial accounting standards. WCOA is held every four years. It has sponsored and organised by various national accounting organisations, and today is organized by the International Federation of Accountants (IFAC), the worldwide organization for the accountancy profession. The Congress gives accounting professionals the opportunity to share their views on the current issues and trends in the profession.

WORLD CONSERVATION STRATEGY = ВСЕМИРНАЯ СТРАТЕГИЯ ОХРАНЫ – The World Conservation Strategy is a strategy published by the International Union for Conservation of Nature and Natural Resources (IUCN) (currently the World Conservation Union), United Nations Environment Program (UNEP) and the World Wide Fund for Nature (WWF) in 1980 with the objectives of:- (a) maintaining essential ecological processes and life support systems, (b) preserving genetic diversity, and (c) ensuring the sustainable utilization of species and ecosystems. An updated version entitled Caring for the Earth:- A Strategy for Sustainable Living (IUCN/WWF, 1991) was published in 1991.

WORLD CONSERVATION UNION = ВСЕМИРНЫЙ СОЮЗ ОХРАНЫ – The World Conservation Union (WCU) supports and develops cutting-edge conservation science; implements this research in field projects around the world; and then links both research and results to local, national, regional and global policy by convening dialogues between governments, civil society and the private sector. The Union's databases, assessments, guidelines and case studies, prepared by its global membership, Commissions and Secretariat, are among the world's most respected and frequently cited sources of information and reference on the environment. As the world's largest environmental knowledge network, the Union has helped over 75 countries to prepare and implement national conservation and biodiversity strategies. See also International Union for Conservation of Nature (IUCN). IUCN was established in 1948. It was previously called the International Union for Protection of Nature (1948–56) and the World Conservation Union (1990–2008). Its full legal name is International Union for Conservation of Nature and Natural Resources.

WORLD CUSTOMS ORGANIZATION = ВСЕМИРНАЯ ОРГАНИЗАЦИЯ ТАМОЖЕН – The World Customs Organization (WCO) is the only intergovernmental organization competent on Customs Issues. It is particularly noted for its work in areas covering the development of global Customs Standards, the simplification and harmonization of Customs procedures, the security and facilitation of the trade supply chain, trade facilitation and Sustainable Customs capacity building initiatives. The World Customs Organization promotes the national economic and social well being of its Members by promoting an honest, transparent and predictable Customs environment. This helps licit international trade to flourish, while at the same time making it possible to take effective action against fraudulent activities. In 1952 the Convention formally establishing the Customs Cooperation Council (CCC) came into force. In 1994, after years of membership growth, the Council adopted the working name 'World Customs Organization', to more clearly reflect its transition to a truly global intergovernmental institution. It is now the voice of 171 Customs administrations on all continents at all stages of economic development. Today, WCO Members are responsible for processing more than 98% of all international trade. The WCO is directed by the Council which is assisted by the Policy Commission. Financial advice is provided by the Finance Committee. The Council operates essentially through its Secretariat, and various high level strategic groups, technical committees and working groups, to complete its mission. The WCO ensures the effectiveness and the efficiency of Customs administrations across the globe. The WCO fulfils its mission by:- (i) Developing and administering various international instruments for the harmonization and uniform application of simplified and effective Customs systems and procedures governing the cross-border movement of commodities, people and goods:- (a) The Harmonized Commodity Description and Coding System contributes to the facilitation of international trade by providing a common basis for the classification of goods and the collection of Customs duties; (b) The revised Kyoto Convention, a key instrument covering Customs procedures, provides customs administrations with a modern set of uniform principles for simple, effective and predictable Customs procedures that facilitate effective Customs control; (c) The Istanbul Convention on temporary admission combines in one legal instrument all existing agreements covering temporary admission of goods exempted from the payment of duties and taxes in a state or customs union; and (d) The WCO ensures the interpretation and uniform application of the WTO Valuation Agreement, and has developed Harmonized Rules of Origin which are currently being examined by the WTO (Geneva) with a view to their implementation by its Members. (ii) Developing international standards to secure the movement of goods:- The SAFE Framework of Standards lists the minimum level of measures that WCO Members and economic operators should implement in order to secure the international trade supply chain. Its application is enhanced through sustainable customs capacity building conducted under the guise of the 'WCO Columbus programme'. (iii) Assisting its Members in their effort to modernise via its capacity building programme. In this regard, the WCO has developed various tools that will assist Customs in their modernisation efforts (for example, the WCO Diagnostic Framework, a guide to the organization and functionning of a XXI century Customs administration, training to facilitate the implementation of strategies imposed by the new international Customs environment, the Arusha Declaration on Customs Integrity, etc). It also provides a forum for international cooperation at global and regional levels, delivers technical assitance, and designs new learning and training methods. (iv) Encouraging cooperation between Customs administrations and between Customs administrations and the trading community to improve communication and facilitation notably with respect to trade security and the fight against fraud. (v) Training the private sector:- the World Customs Centre of Learning organizes training sessions that empower participants to deal with technical and operational problems generated by current and new strategies that must be implemented to respond to the many challenges raised by the international customs environment. World Customs Organization (WCO) or, in French, Organisation Mondiale Des Douanes (OMD) is an intergovernmental organization that helps member states communicate and cooperate on customs issues. It was established in 1952 as the Customs Co-operation Council (Conseil de Coopération Douanière); it adopted its current name in 1994. Headquarters are in Brussels, Belgium. Established in 1952 as the Customs Co-operation Council, the WCO is an independent intergovernmental body whose mission is to enhance the effectiveness and efficiency of Customs administrations. With 169 Member Governments, it is the only intergovernmental worldwide organization competent in Customs

matters. In order to fulfil this mission, the World Customs Organization:- (i) establishes, maintains, supports and promotes international instruments for the harmonization and uniform application of simplified and effective Customs systems and procedures governing the movement of commodities, people and conveyances across Customs frontiers; (ii) reinforces Members' efforts to secure compliance with their legislation, by endeavouring to maximize the level of effectiveness of Members' co-operation with each other and with international organizations in order to combat Customs and other transnational offences; and (iii) assists Members in their efforts to meet the challenges of the modern business environment and adapt to changing circumstances, by promoting communication and co-operation among Members and with other international organizations, and by fostering integrity, human resource development, transparency, improvements in the management and working methods of Customs administrations and the sharing of best practices. The history of the WCO began in 1947 when the thirteen European Governments represented in the Committee for European Economic Co-operation agreed to set up a Study Group. This Group examined the possibility of establishing one or more inter-European Customs Unions based on the principles of the General Agreement on Tariffs and Trade (GATT). In 1948, the Study Group set up two committees – an Economic Committee and a Customs Committee. The Economic Committee was the predecessor of the Organization for Economic Co-operation and Development (OECD), the Customs Committee became the Customs Co-operation Council (CCC). In 1952, the Convention formally establishing the CCC came into force. The Council is the governing body of the CCC and the inaugural Session of the Council was held in Brussels, Belgium on 1953-January-26. Representatives of seventeen European countries attended the first Council Session of the CCC. After years of membership growth, in 1994 the Council adopted the working name World Customs Organization, to more clearly reflect its transition to a truly global intergovernmental institution. It is now the voice of 169 Customs administrations which operate on all continents and represent all stages of economic development. Today, WCO Members are responsible for processing more than 98% of all international trade. The CCC is an international organization consisting of representatives of about 150 countries. The Council serve as a technical body which studies and seeks to resolve the various countries' customs problems in an attempt to harmonize customs operations and promote trade. One hundred sixty nine member states (2007), including Canada, Mexico and the US, with the goal of promoting international cooperation in customs matter. See also Customs Cooperation Council. WORLD ECONOMIC FORUM = ВСЕМИРНЫЙ ЭКОНОМИЧЕСКИЙ ФОРУМ – World Economic Forum (WEF):- (i) is an International Institution committed to improving the state of the world through public-private cooperation; (ii) engages political, business, academic and other leaders of society in collaborative efforts to shape global, regional and industry agendas. Together with other stakeholders, it works to define challenges, solutions and actions, always in the spirit of global citizenship. (iii) serves and builds sustained communities through an integrated concept of high-level meetings, research networks, task forces and digital collaboration; (iv) delivers unique value to its Partners, Members and Constituents through its Annual and Regional Meetings, its Centres dedicated to global, regional, and industry issues, its future-oriented communities of New Champions, its expert networks of Global Agenda Councils, its TopLink knowledge and interaction platform and the Forum Academy; (v) was established in 1971 as a not-for-profit Foundation and is headquartered in Geneva, Switzerland. It is independent, impartial and not tied to any special interests, working in close cooperation with all major international organisations; and (vi) strives in all its efforts to demonstrate entrepreneurship in the global public interest while upholding the highest standards of governance. Moral and intellectual integrity is at the heart of everything it does. http://www.weforum.org. Headquartered in:- (i) Cologny/Geneva, Switzerland; (ii) New York, The United States of America; (iii) Beijing, The People Republic of China; and in (iv) Tokyo, Japan. History:- The World Economic Forum was founded in January 1971 when a group of European business leaders met under the patronage of the European Commission and European industrial associations. German-born Klaus Schwab, then Professor of Business Policy at the University of Geneva, chaired the gathering, which took place in Davos, Switzerland. The organization was subsequently incorporated as a not-for-profit Foundation. Professor Schwab's inspiration for creating the Foundation was his book – Moderne Unternehmensführung im Maschinenbau – in which the stakeholder principle was first defined. This concept states that the management of an enterprise is not only accountable to its shareholders but must also serve the interests of all stakeholders, including employees, customers, suppliers and, more broadly, government, civil society and any others who may be affected or concerned by its operations. The Forum was called the European Management Forum until 1987, when it was renamed the World Economic Forum to reflect its expanding scope and transformation from a European to truly global organization. From the beginning, the Forum had considerable impact in improving political, economic and social awareness, acting as a catalyst for major bridge-building efforts. The Forum has provided a critical platform for furthering peace and reconciliation in many parts of the world, promoting understanding between East and West before and after the fall of the Berlin Wall, introducing emerging economies such as China and India to the international community, and bringing to the fore the latest trends and developments in many fields. The Forum has also been the catalyst for a number of significant global initiatives, such as the Global Compact (developed jointly with the UN); the GAVI Alliance (initially the Global Alliance for Vaccines and Immunization); the Global Fund to Fight AIDS, Tuberculosis and Malaria; the expansion of the OECD; and the development of the G20 concept. Over the last 20 years, the Forum has also evolved the stakeholder principle beyond the corporate level to a truly global sphere, stipulating that political, business and civil society leaders must work together to address the challenges of a globally interconnected world. This enhanced dimension has led to the notion of corporate global citizenship, as outlined by Professor Schwab in a Foreign Affairs article published in 2008. What has remained unchanged since its founding is the Forum's dedication to collaboration among stakeholders, its steadfast adherence to the high-level participation of leaders sharing the Forum's commitment to improving the state of the world, and the Forum's trust in the power of dialogue and exchange based on mutual respect and civility to bridge divides and shape effective solutions to global challenges. The

World Economic Forum has evolved from a modest yet ground-breaking attempt to convene European corporate stakeholders to discuss business strategies into an organization that today is widely regarded as the world's foremost multistakeholder platform for public-private partnership. The story of four decades of the World Economic Forum, as seen through the eyes of its members, leaders and the outside world. The Forum is perhaps most widely known for its Annual Meeting in Davos-Klosters. Through the years, numerous business, government and civil society leaders have made their way to the Swiss Alpine resort to consider the major global issues of the day and to brainstorm on solutions to address these challenges. While many global institutions are notable for the breadth of nations or the powerful political leaders attending their gatherings, the World Economic Forum Annual Meeting and indeed all the activities and initiatives of the Forum around the world are distinguished by the active participation of government, business and civil society figures, both the most experienced and the most promising, all working together in the collaborative and collegial Spirit of Davos. Professor Schwab then founded the European Management Forum as a non-profit organization based in Geneva, Switzerland, and drew European business leaders to Davos for their Annual Meeting each January. Initially, Professor Schwab focused the meetings on how European firms could catch up with US management practices. He also developed and promoted the 'stakeholder' management approach, which based corporate success on managers taking account of all interests:- not merely shareholders, clients and customers, but employees and the communities within which they operate, including government. Professor Schwab's vision for what would become the World Economic Forum grew steadilly as a result of achieving 'milestones'. Events in 1973, namely the collapse of the Bretton Woods fixed exchange rate mechanism and the Arab-Israeli War, saw the Annual Meeting expand its focus from management to economic and social issues, and political leaders were invited for the first time to Davos in January 1974. Two years later, the organization introduced a system of membership, which were 'the 1 000 leading companies of the world'. The European Management Forum was the first non-governmental institution to initiate a partnership with China's economic development commissions, spurring economic reform policies in China. Regional meetings around the globe were also added to the year's activities, while the publication of the Global Competitiveness Report in 1979 saw the organization expand to become a knowledge hub as well. The European Management Forum changed its name to the World Economic Forum in 1987 and sought to broaden its vision to include providing a platform for resolving international conflicts. World Economic Forum Annual Meeting milestones during this time include the Davos Declaration signed in 1988 by Greece and Turkey, which saw them turn back from the brink of war, while in 1989, North and South Korea held their first ministerial-level meetings in Davos. At the same Meeting, East German Prime Minister Hans Modrow and German Chancellor Helmut Kohl met to discuss German reunification. In 1992, South African President Frederik Willem de Klerk met Nelson Mandela and Chief Mangosuthu Buthelezi at the Annual Meeting, their first joint appearance outside South Africa and a milestone in the country's political transition. The Forum has since expanded its activities to include a Centre for Public-Private Partnerships, which engages businesses, civil society and political authorities in initiatives ranging from health in India to alliances combating chronic hunger in Africa. The Forum's knowledge center has expanded to include several other competitive reports, including the Global Gender Gap Report, Global Risk reports and regional scenario reports. / Давос-Клюстэрс (Davos-Klosters). WORLD ENERGY CONFERENCE = ВСЕМИРНАЯ КОНФЕРЕНЦИЯ ПО ЭНЕРГЕТИКЕ – World Energy Conference (WEC):- at the suggestion of Great Britain 'The First World Energy Conference' was convened in July, 1924 in London at which 1 700 representatives took part from 40 countries. This conference discussed a number of issues connected with power and its application. By the way, the conference took a decision that National Committees should be founded in individual countries to study and develop the issues mentioned above. The specificity of the WEC may be summarized in the form of three major features, that is:- (i) it is a non-governmental organization and, consequently, submitted to less constraints than many other international organizations; (ii) it is not specialized, because its activities cover all forms of energy; and (iii) it is organized into 80 national committees, representing energy producers and consumers of North and South, West and East. / Всемирная Энергетическая Конференция (World Energy Conference (WEC)), МИРЭК – международный форум специалистов в области освоения и использования энергоресурсов. Объединяет около 80 национальных комитетов. Сессии проводятся с 1924 раз в 3 года.

WORLD EQUITY BENCHMARKS = МИРОВЫЕ (или ВСЕМИРНЫЕ) ОРИЕНТИРЫ АКЦИЙ – International World Equity Benchmarks (WEBs) are the equity securities that were designed to track the stock market performance of a specific country. In particular, they are designed to emulate the performance of a specific Morgan Stanley Capital International (MSCI) Index. The MSCI indices are not actively managed country funds, but rather baskets of stocks intended to correspond with the general performance of a country's stock market. For example, the Hong Kong WEB (EWH) is designed to correspond to the performance of the Hang Seng Index. The World Equity Benchmark Series (WEBS) are similar to SPDRs. WEBS trade on the AMEX®, and track the Morgan Stanley Capital International (MSCI) country indexes. WEBS are available for:- Australia, Austria, Belgium, Canada, France, Germany, Hong Kong, Italy, Japan, Malaysia Free, Mexico, the Netherlands, Singapore, Spain, Sweden, Switzerland, and the United Kingdom. / Индекса от Моргэн Стэнли Кэпитэл Интёнэшэнэл (Morgan Stanley Capital International). WORLD EXPORT/IMPORT VOLUMES = МИРОВЫЕ ОБЪЁМЫ ВЫВОЗА/ПРИВОЗА (или МИРОВЫЕ ОБЪЁМЫ ЭКСПОРТА/ИМПОРТА) – World Export/Import Volumes are constructed by aggregating measures of the volume of exports/imports of individual countries on a constant price basis.

WORLD FEDERATION OF DIAMOND BOURSES = ВСЕМИРНАЯ ФЕДЕРАЦИЯ БИРЖ АЛМАЗОВ – The World Federation Of Diamond Bourses (WFDB) was founded in 1947 to unite and to provide bourses trading in rough and polished diamonds and precious stones, with a common set of trading practice. The WFDB provides a legal framework and convenes to enact regulations for its 29 member diamond bourses. The seat of the Federation is in Belgium – Antwerp consisting of General Secretariat. The seat of the elected president is in the country where the elected president resides. The seat of the Secretariat and the offices of the Secretary-General is in the country where the Secretary-Genaral resides. The function of the WFDB is as diverse as the members who belong to it. Ethics, good business practice and morality are paramount and these are protected vigorously by the Constitution of the WFDB which provides for Arbitration and Disciplinary procedures against any bourse member who transgresses the code. The purpose of the WFDB is to promote understanding and closer co-operation between people all over the world who earn their livelihood in the diamond and precious stones trade. Furthermore, WFDB encourages the establishment of bourses with a view to eventual affiliation. Members of the Bourses affiliated to the World Federation of Diamond Bourses pledge themselves to uphold the traditions, principles of mutual trust, consideration and friendship which prevail among the members of the bourses world-wide. They pledge themselves to abide by and hand down these principles and to ensure that they will forever serve as a basis in business relations between members of the affiliated bourses world-wide. The regulations of WFDB aim to ensure diamond trade on fair trade and sustainable development of world diamond trade. Decisions are made by WFDB to set up and to sustain morality rules in diamond markets. In addition to regulation rules, decisions are made on synthetic and treated diamonds or arbitration of conflicts between the market participants and on forming uniform rules in diamond trading all over the world. In this manner, on the forming stage of an organized diamond market in Turkey, it is

vital to become member to WFDB, for getting integrated to the world diamond markets and to establish operational and ethic rules which are applicable in the world diamond markets. Each affiliated Bourse is represented at the Congress of the WFDB by a maximum of three members; The President of each Bourse is by right one of the three delegates. When a delegate is elected an Executive Officer of the World Federation of Diamond Bourses either as President, Vice-President, Secretary-General, Treasurer-General, his Bourse may appoint an additional delegate, in order to have the full complement of three delegates. The delegates of the Bourses affiliated to the WFDB shall meet every two years in a Congress under the direction of the President. The presidents meet at least once a year. The Executive Committee consists of the President, the Vice-President, the Secretary-General, the Treasurer-General and six additional executive members, all of whom are to be nominated at least three months before the date of Congress. The President, the Vice-President and the six additional executive members are to be Presidents of their own Bourses, and the Secretary-General and the Treasurer-General shall be members of the Board of Directors of their own Bourses. No country may have more than two seats on the Executive Committee. The President and the Vice-President cannot be elected for more than three consecutive terms of office. The three major manufacturing and trading centers:- Antwerp, Tel Aviv and New York, shall each nominate the President of one of its Bourses for membership in the Executive Committee at the next Congress. Each of these three designated centers is represented on the Executive Committee at all times. Bourses whose members deal in diamonds, precious stones or jewellery are entitled to apply for membership of the WFDB provided they have been established for at least one full year under a written Constitution, have a clearly designated and representative governing body, and are able to prove their means of subsistence. The Constitution of the applicant must contain the principal commercial and business rules and procedures in use in the diamond trade. Applications have to be submitted with a certified copy of the Constitution, translated into English and shall state readiness to accept the By-Laws and Inner Rules of the WFDB, and to comply with their provisions and with the resolutions of the Congresses of the WFDB. Applications shall be submitted for decision to the next Congress. Applications are to be sent to the Secretary-General of the WFDB, at least six months before the date of the Congress. They shall at once be communicated to each affiliated Bourse. The Bourse which makes the application for membership to the World Federation of Diamond Bourses shall commit itself and its members not to restrict any trade with the countries where the affiliated Bourses are situated. The Bourse which makes the application for membership to the World Federation of Diamond Bourses shall file with the WFDB a certified copy of its Regulations applicable to arbitrations. Changes to these Regulations should also be notified to the World Federation of Diamond Bourses. If the original texts are in a different language, English translations will be added. WORLD FEDERATION OF EXCHANGES = ВСЕМИРНАЯ ФЕДЕРАЦИЯ БИРЖ – Fédération Internationale des Bourses de Valeurs (FIBV):- the World Federation of Exchanges (WFE) was founded in London in 1961 as the International Federation of Stock Exchanges, changing to its current name in 2001 to reflect the admission of derivatives platforms and clearinghouses. The Federation traces its roots to the International Bureau of Stock Exchange, created in the 1930s in an initiative spearheaded by the International Chamber of Commerce. The board of directors approved three priorities for 2009. It will look to help the International Organization of Securities Commissions (IOSCO) set best practices for short selling and securities lending. It will try to clarify the use of circuit breakers in volatile markets, ensuring that they are predictable and temporary, and study the effects of fragmentation and its impact on market quality. In February of 2010, the WFE announced priorities for the year. Its board of directors pledged to:- (i) support reform in the regulation of OTC derivatives markets, which were a contributing factor in the recent financial crisis; (ii) continue to press for international cooperation and coordination among regulators and exchanges on intermarket mechanisms; and (iii) examine the structure of fixed income markets in order to evaluate how post-trade transparency, risk management and investor protection could help these markets recover from the drop in liquidity that they have experienced since the credit crisis. The World Federation Of Exchanges (WFE) is the association of 52 regulated exchanges around the world. We develop and promote standards in markets. We are the trade association of 52 publicly regulated stock, futures and options exchanges. Our market operators are responsible for the functioning of key components in the financial world. Exchanges across the globe saw the value of their indexes drop an average of 11.5% in USD terms in the first six months of 2010. Among the markets showing gains in the first half of 2010, most were from emerging economies. In addition, several European exchanges in the NASDAQ OMX family, notably Copenhagen, Iceland, and Stockholm, rallied despite an 18% fall in the European/Middle East/African zone. Emerging markets and exchanges for junior companies led fund raising activities. Shenzhen Stock Exchange, the mainland market for smaller companies, led all WFE members with USD22.6 billion raised for initial public offerings (IPOs). That was more than the combined totals for BME Spanish Exchanges, Korea Exchange and London Stock Exchange Group which placed respectively 3rd through 5th. Shanghai Stock Exchange, the second market for IPOs, raised USD8.9 billion. TSX Group was second to Shenzhen Stock Exchange in the number of IPOs with 137 new companies listed between January-June 2010. Compared with first half of 2009, the CBOE® replaced the International Securities Exchange as the leader in trading stock options, while BM&F BOVESPA placed second thanks to an 80% increase in volume. In stock index options, the National Stock Exchange of India took second place after Korea Exchange, with a 50% increase in volumes compared with the first half of 2009. Membership in WFE is considered by some governments and national associations of asset managers as a criteria for preferential investment policy and taxation for these markets. There are 6 Associates, 15 WFE Affiliates with separate professional relations, and 27 exchanges which are WFE Correspondents. The Secretariat is based in Paris, France. It is a not-for-profit association under French law. The WFE promotes regulated exchanges in four ways:- (i) Quality:- we promote market standards and reliable statistics; (ii) Advocacy:- we work with policy makers, regulators and government organizations for fair, transparent and efficient markets; (iii) Networking:- we bring together exchange experts to improve markets; and (iv) Development:- we help newer, smaller exchanges to meet WFE standards. WFE member exchanges are key national economic actors in their countries, with a few members now spanning several jurisdictions and time zones. Capital raising and secondary-market pricing remain the key function for the securities and securities options segments; standardized contracts for financial and raw materials products on futures markets provide essential pricing indicators for the world's economy, going well beyond the individual corporation. The WFE is a central reference point for the securities industry, and for exchanges themselves. We offer member guidance in their business strategies, and in the improvement and harmonization of their management practices. To meet the goals of the WFE mission, we focus on the following areas:- (i) We post over 10 years of market statistics, and business news in our monthly newsletter, Focus. Our Annual Reports and notes from public meetings are available online. We report business management surveys, and thematic studies. (ii) We hold public meetings (topical workshops, conferences …) and run private committees (to transfer know-how and share expertise). (iii) We sponsor research (such as Securities Lending Report ...). (iv) We provide professional relations with various expert bodies. (v) We promote standards for generally accepted principles of securities business conduct, e.g., corporate governance. / СИБО® (CBOE®). НЭЗДЭК® У.Эм.Экс. (NASDAQ® OMX).

WORLD FEDERATION OF INSURANCE INTERMEDIARIES = ВСЕМИРНАЯ ФЕДЕРАЦИЯ СТРАХОВЫХ ПОСРЕДНИКОВ – The World Federation of Insurance Intermediaries (WFII) was created to promote the increasingly vital role of insurance intermediaries in today's economy, providing a powerful voice to advance their interests, to provide innovative solutions at international level. WFII enables insurance intermediaries to speak with one voice to international institutions and regulators that affect their business throughout the world. It enables the exchange of information on global issues and goals that all national associations of intermediaries

have in common. WFII provides global leadership, develops solutions and co-ordinates actions to promote the insurance intermediary industry at international level. The World Federation of Insurance Intermediaries, represents insurance agents and brokers from over 100 national associations (in over 80 countries) across the world. WFII was formally launched in January 1999, in Washington, DC, the United States and represents over 400 000 professional intermediaries who handle the vast majority of insurance placements globally. WFII represents the interests of intermediaries with international institutions and works to deepen the understanding of the role played by insurance brokers and agents in global commerce. WFII is recognised by the international institutions that have influence on our sector (Organisation for Economic Co-operation and Development (OECD), the International Association of Insurance Supervisors (IAIS), World Trade Organiztion (WTO), United Nations (UN), The World Bank, International Monetary Fund (IMF)) as the single voice of insurance intermediaries in international Public Affairs. WFII has observer status in the OECD and the IAIS and is regularly consulted on current issues in the market. WFII members believe that further liberalization of insurance intermediary markets across the globe is in the best interest of consumers and helps strengthen the economies of all participating countries. They fully accept competition from all sources of insurance distribution, provided this competition is fair and operates on a level playing field. They work together to ensure that all regulation supports a level playing field at national, regional and international levels. WFII represents the interests of intermediaries with international institutions and works to deepen the understanding of the role played by insurance brokers and agents in global commerce.

WORLD FEDERATION OF TRADE UNIONS = ВСЕМИРНАЯ ФЕДЕРАЦИЯ ПРОФСОЮЗОВ – World Federation of Trade Unions (WFTU):- (in French Fédération Syndicale Mondiale (FSM)) leftist-oriented international labor organization founded in 1945 by the World Trade Union Congress. Its principal organizers were the British Trades Union Congress, the US Congress of Industrial Organizations, and the All-Union Central Congress of Trade Unions. The organization was initially oriented toward the Soviet Union. Despite vigorous attempts to reconcile the differences between communist and noncommunist factions within the WFTU, the intensification of the Cold War finally led to a split. The noncommunist elements withdrew from the WFTU and in 1949 formed the International Confederation of Free Trade Unions. The largest WFTU affiliates are now in the developing nations of Asia, Latin America, and Africa, although France and Italy also have sizable affiliates. The WFTU maintains its headquarters in Prague, Czech Republic. / Всемирная Федерация Профсоюзов (ВФП) была основана в 1945. Объединяет национальные профцентры 81 страны (в том числе бывший СССР и другие социалистические страны), общая численность свыше 200 000 000 человек (в 1984). Издаёт журнал Всемирное Профсоюзное Движение. Председатель (с 1978) – Ш. Гашпар (Венгрия), Генеральный Секретарь (с 1980) – И. Закария (Судан). Штабквартира в Праге, Чешская Республика.

WORLD FOOD PROGRAMME = ВСЕМИРНАЯ ПРОДОВОЛЬСТВЕННАЯ ПРОГРАММА (или ВСЕМИРНАЯ ПРОГРАММА ПО ПРОДОВОЛЬСТВИЮ) – The World Food Programme (WFP) is the world's largest humanitarian agency fighting hunger worldwide. In emergencies, we get food to where it is needed, saving the lives of victims of war, civil conflict and natural disasters. After the cause of an emergency has passed, we use food to help communities rebuild their shattered lives. WFP is part of the United Nations system and is voluntarily funded. Born in 1961, WFP pursues a vision of the world in which every man, woman and child has access at all times to the food needed for an active and healthy life. We work towards that vision with our sister UN agencies in Rome – the Food and Agriculture Organization (FAO) and the International Fund for Agricultural Development (IFAD) – as well as other government, UN and NGO partners. On average, WFP aim to reach more than 90 million people with food assistance in more than 70 countries. About 12 000 people work for the organization, most of them in remote areas, directly serving the hungry poor. To learn more, watch the video outlining our mission, read our Mission Statement or browse our Policy Resources section. WFP's five objectives:- (i) save lives and protect livelihoods in emergencies; (ii) prepare for emergencies; (iii) restore and rebuild lives after emergencies; (iv) reduce chronic hunger and undernutrition everywhere; and (v) strengthen the capacity of countries to reduce hunger. WFP headquartered in Rome, Italy. In December 1994, WFP's governing body adopted the WFP Mission Statement, the first for an United Nations organization. The Mission Statement was based on a fundamental review of WFP's policies, objectives and strategies that involved member states of WFP, non-governmental organizations, United Nations and other agencies, academics and staff members. The WFP Mission Statement is to be considered as a living document that will be reviewed periodically. WFP is the food aid arm of the United Nations system. Food aid is one of the many instruments that can help to promote food security, which is defined as access of all people at all times to the food needed for an active and healthy life. The policies governing the use of World Food Programme food aid must be oriented towards the objective of eradicating hunger and poverty. The ultimate objective of food aid should be the elimination of the need for food aid. Targeted interventions are needed to help to improve the lives of the poorest people - people who, either permanently or during crisis periods, are unable to produce enough food or do not have the resources to otherwise obtain the food that they and their households require for active and healthy lives. Consistent with its mandate, which also reflects the principle of universality, WFP will continue to:- (i) use food aid to support economic and social development; (ii) meet refugee and other emergency food needs, and the associated logistics support; and (iii) promote world food security in accordance with the recommendations of the United Nations and FAO. The core policies and strategies that govern WFP activities are to provide food aid:- (i) to save lives in refugee and other emergency situations; (ii) to improve the nutrition and quality of life of the most vulnerable people at critical times in their lives; and (iii) to help build assets and promote the self-reliance of poor people and communities, particularly through labor-intensive works programmes. In the first case, food aid is essential for social and humanitarian protection. It will be used in a way that is as developmental as possible, consistent with saving lives. To the extent possible, the provision of relief food aid will be coordinated with the relief assistance provided by other humanitarian organizations. In the second case, food aid is a pre-investment in human resources. In the third, it uses poor people's most abundant resource, their own labor, to create employment and income and to build the infrastructure necessary for sustained development. WFP is well placed to play a major role in the continuum from emergency relief to development. WFP will give priority to supporting disaster prevention, preparedness and mitigation and post-disaster rehabilitation activities as part of development programmes. Conversely, emergency assistance will be used to the extent possible to serve both relief and development purposes. In both cases the overall aim is to build self-reliance. In carrying out its mandate, WFP will concentrate on what it is best suited to do with the resources available as cost-effectively as possible. WFP will focus on those aspects of development where food-based interventions are most useful. It will make all necessary efforts to avoid negative effects on local food production, consumption patterns and dependency on food aid. WFP will continue to play a major and significant role in providing transport and logistics expertise and assistance to ensure rapid and efficient delivery of humanitarian aid. WFP's multilateral character is one of its greatest strengths. WFP will exploit its capability to operate virtually everywhere in the developing world, without regard to the political orientations of governments, and to provide a neutral conduit for assistance in situations where many donor countries could not directly provide assistance. WFP will provide services:- advice, good offices, logistic support and information; and support to countries in establishing and managing their own food assistance programmes. WFP, on request, will provide bilateral services to donors, UN agencies and NGOs on the basis of full cost recovery. These will be administered and accounted for separately. Such services will complement WFP's regular operations to the extent possible. WFP will concentrate its efforts and resources on the neediest people and countries in accordance with the CFA's decision to provide at least 90 percent of WFP's development assistance to low-income, food-deficit countries and at least 50 percent of its development assistance to the least developed countries by 1997.

WFP will ensure that its assistance programmes are designed and implemented on the basis of broad-based participation. Women in particular are key to change; providing food to women puts it in the hands of those who use it for the benefit of the entire household, especially the children. WFP assistance will aim to strengthen their coping ability and resilience. To be truly effective, food aid should be fully integrated into the development plans and priorities of recipient countries and coordinated with other forms of assistance. WFP's starting point is the national policies, plans and programmes of developing countries, including their food security plans. WFP will pull together its activities in an integrated way at the country level so that it can respond to urgent needs as they occur while retaining core development objectives. The country strategy note, where this exists, should provide the framework for an integrated response by the United Nations system. In some special cases WFP will adopt a multi-country or regional approach. particularly for the provision of humanitarian assistance. No single agency has either the resources or the capacity to deal with all the problems of hunger and underdevelopment. Hence the importance WFP attaches to collaboration with other agencies, particularly with its parent bodies, the United Nations and FAO. WFP will continue to work closely with the United Nations Department of Humanitarian Affairs, UNHCR, other relevant agencies and non-governmental organizations (NGOs) in the response to emergencies and humanitarian crises. WFP will also collaborate closely with the Rome-based United Nations food and agriculture agencies, FAO and IFAD, especially in using food aid for achieving household food security. WFP will continue to forge effective partnerships of action with the World Bank and the International Monetary Fund, regional bodies and institutions, bilateral donors and NGOs in support of economic and social development. WFP will play its part as an active member of the United Nations system to bring the issue of hunger to the centre of the international agenda. In its dialogue with recipient governments and the aid community, WFP will advocate policies, strategies and operations that directly benefit the poor and hungry. World Food Programme (WFP):- since 1963, the UN agency operating in 82 countries and specializing in food assistance and logistics for emergencies and the feeding of refugees and internally displaced persons. WFP is governed by the WFP Executive Board, which consists of 36 Member States. The organization is headed by an Executive Director, who is appointed jointly by the UN Secretary General and the Director-General of FAO (UN Food and Agriculture Organization). The Executive Director is appointed for fixed five-year terms. The current Executive Director is Ertharin Cousin, who was appointed in 2012. She is responsible for the administration of WFP as well as the implementation of its programmes, projects and other activities. WFP also has one Deputy Executive Director and two Assistant Executive Directors with specific briefs. The organization's strategic direction is mapped out in its Strategic Plan, which is renewed every four years. The latest Plan, approved by the board in 2008, marks a historic shift from WFP as a food aid agency to WFP as a food assistance agency, with a more nuanced set of tools to respond to critical hunger needs. WFP relies entirely on voluntary contributions for its funding. Its principal donors are governments, but we also receive donations from the private sector and individuals. Information disclosure:- WFP is committed to making information relating to its operations and programmes available to the public. We believe public access to information contributes to a better understanding of WFP's unique mission and enhances our stakeholders' participation in the fight against global hunger. WORLD GOLD COUNCIL = ВСЕМИРНЫЙ СОВЕТ ПО ЗОЛОТУ – Founded in 1987, the World Gold Council is an organization formed and funded by the world's leading gold mining companies with the aim of stimulating and maximising the demand for, and holding of, gold by consumers, investors, industry, and the official sector. As well as undertaking marketing initiatives to drive demand, the World Gold Council is also instrumental in working to lower regulatory barriers to the widespread ownership of gold products, helping to develop distribution systems and promoting the role of gold as a reserve asset in the official sector. 2007:- our members are leading gold mining companies with production in 22 countries. Headquarters are in London, the United Kingdom. The market development organization for the gold industry and the global authoritative voice for gold. The World Gold Council is the market development organization for the gold industry. Working within the investment, jewellery and technology sectors, as well as engaging in government affairs, our purpose is to provide industry leadership, whilst stimulating and sustaining demand for gold. We develop gold-backed solutions, services and markets, based on true market insight. As a result, we create structural shifts in demand for gold across key market sectors. We provide insights into the international gold markets, helping people to better understand the wealth preservation qualities of gold and its role in meeting the social and environmental needs of society. Based in the UK, with operations in India, the Far East, Turkey, Europe and the USA, the World Gold Council is an association whose members include the world's leading and most forward thinking gold mining companies. World Gold Council is an industry based organization sponsored by a number of gold mining companies who pay an annual fee based on their level of production. The role of the World Gold Council is to promote the use of gold around the world. The World Gold Council is the global authority on gold and its uses and the first source of informed opinion and advice for stakeholders and decision makers. We use this knowledge to develop insights into the future role that gold can play across a number of sectors and then, in collaboration with partners, intervene to deliver solutions and create new markets, and to increase and sustain the demand for gold. In the Investment sector we make gold fundamental to investment decision making. For Governments and Central Banks, we are a trusted advisor to policy makers and reserve asset managers on all matters related to the gold market. In the Jewellery sector, we create new insights and ideas which increase the allure and significance of gold when given or worn. In the Technology sector, we work to place gold at the heart of technological advancement, and we are the authority on innovative uses of gold in industry and society. As the global advocate for gold, we are committed to playing a key role in the development of a responsible gold mining industry. Our members, the leading gold mining companies, regard the management of the local environment and relationships with local communities as paramount considerations during the lifetime of any mine project. Together, we work to ensure the industry as a whole is striving to develop and integrate best practice. All our work is informed by a deep understanding of the wide role gold has in society and its potential both now and in the future. Through commercial partnerships and industry leading research, we develop a clear understanding of, and insight into, each of its key markets. Using this insight, we create new, relevant and innovative solutions that deliver against clearly identified market needs. Our insight adds value to our partners and stakeholders across all sectors, and informs each of our programmes and market interventions. At present the World Gold Council has 21 members who include the world's leading and most forward thinking gold mining companies, representing approximately 60% of global corporate gold production. They are headquartered across the globe and have mining operations that stretch to almost every inhabited continent. Members' active support of the World Gold Council represents their shared vision of ensuring a sustainable gold mining industry, based on a deeper understanding of gold's role in society, now and in the future. Members in 2011:- Agnico-Eagle Mines Ltd.; Alamos Gold Inc.; AngloGold Ashanti; Barrick Gold Corp.; Buenaventura; Coeur d'Alene Mines Corporation; Eldorado Gold Corporation; Franco-Nevada Corporation; Goldcorp Inc.; Golden Star Resources Ltd.; Gold Fields Limited; IAMGOLD Corporation; Kinross Gold Corporation; New Gold Inc.; Newmont Mining Corporation; Primero Mining Corporation; and Yamana Gold Inc. We also have Associate members who include the Hutti Gold Mines Co Ltd., Royal Gold Inc., China Gold Group Corporation and Mitsubishi Materials Corporation. / Всемирный Совет по Золоту (World Gold Council) был создан в 1987. Главной миссией совета является стимулирование и поддержка спроса на золото, стабилизация его рыночных позиций в мире. Организация представляет ведущие золотодобывающие компании, чей суммарный оборот составляет 60% от ежегодного мирового производства золота. Самыми известными среди них являются:- ЭнглоГолд Лтд. (AngloGold Ltd.; США), Барик Голд Корпорэйшэн (Barrick Gold Corporation; Канада), Ньюмонт Корпорэйшэн (Newmont Corporation; США). Исполнительные директора и президенты этих

предприятий формируют правление Совета. Совет сотрудничает с многочисленными партнёрами, занятыми в производстве и использовании золота. Цель этого взаимодействия – привнесение необходимых изменений в структуру отрасли и её функционирование, а также способствование применению золота в различных сферах:- (i) в сфере инвестиций – с помощью открытия новых каналов рынка и обеспечения понимания того, насколько важно сохранить уровень ценности золота; (ii) в сфере производства драгоценностей – с помощью развития ювелирного рынка премиум класса и защиты рынка массового спроса; (iii) в промышленности – с помощью развития рынка электроники и поддержки новых технологий; (iv) в государственных делах – с помощью участия в решении макрополитических вопросов, связанных со снижением регуляционных барьеров на право владения золотом, а также продвижения этого металла в качестве резервных активов. Всемирный Совет по Золоту (ВСЗ) – коммерческая организация, деятельность которой сосредоточена на создании золоту нового, выдающегося положения в разных сферах политики, экономики и жизни. У совета есть своя штабквартира, расположенная в Лондоне, Соединённое Королевство, а также отделы, находящиеся в ключевых центрах золотопромышленности:- в Северной и Южной Америке (региональный офис в Нью Йорке), на Дальнем Востоке (офисы в Сингапуре, Токио, Шанхае и Пекине), на Ближнем Востоке (офисы в Стамбуле и Дубае), Индии (офисы в Чинае и Мумбае). Совет является главным источником независимой информации, данных и исследований о международном рынке золота, а также роли жёлтого металла в социальной и экономической жизни общества. Деятельность ВСЗ посвящена защите всей золотопромышленной отрасли, а также привнесению в неё образовательных, социальных, экологических, человеческих и этических аспектов. ВСЗ действует как информационный источник для его членов и других предприятий, работающих в золотодобывающей и ювелирной промышленностях. В перечень информационных услуг входит обеспечение текущей информацией относительно рынка золота и обзор главных событий за предшествующие годы. Подборка данных (например, статистика по добыче золота и его запасам на территории 106 государств) производится информационными отделами совета в Лондоне и Нью Йорке, а также многочисленными офисами этой организации по всему миру. Информационный отдел также содержит исторический архив ежемесячной статистики, который специально подготавливается Международным Валютным Фондом (МВФ) для определения уровня развития государств и выявления степени независимости национальной валюты. И главная информация – котировки цен на золото в различных валютах (Доллар, Евро, Йена) и объём валового внутреннего продукта. К этому материалу прилагаются крупноформатные таблицы, которые можно посмотреть на сайте ВСЗ:- http://www.gold.org. Влияние совета, как главного представителя и защитника отрасли, благотворно сказывается на развитии по-настоящему устойчивой золотодобывающей промышленности. ВСЗ является инициатором различных конференций, на которых участники обмениваются опытом, знаниями, ведут успешный диалог. Всё это очень помогает в решении проблем, с которыми сталкивается индустрия в частности, и всё общество в целом. Председателем ВСЗ в Декабре 2009 был избран Иэн Тчэлфё (Ian Telfer), глава Голдкоп Инк. (Goldcorp Inc.), имеющий 25-летний стаж работы на руководящих должностях в золотодобывающей отрасли. За это время он занимался управлением, развитием и финансированием месторождений в 12 странах мира (среди них Австралия, некоторые страны Америки и Азии). Мистер Тчэлфё был директором и членом правления многих компаний, таких как Лыхиа Голд Лимитид (Lihir Gold Limited), Ти.Ви.Экс. Голд, Инк. (TVX Gold, Inc.), а также предшественника Голдкоп Инк. (Goldcorp Inc.) – Витэн Ривё Минерэлз (Wheaton River Minerals). Помимо этого, он является членом Канадской Ассоциации Дипломированных Бухгалтеров, имеет степень Бакалавра Университета Торонто, степень Магистра Делового Администрирования Университета Оттавы. В настоящее время членство в ВСЗ открыто только для крупных компаний, занимающихся золотодобычей, но не для организаций и людей, занимающихся бизнесом, связанным с золотом. Заявки на предоставление членства от индивидуальных предпринимателей, корпораций, партнёрств, совместных предприятий, ассоциаций, акционерных обществ, трестов, а также других организаций, правительств, агентств или политических подразделений, занятых в горнопромышленном бизнесе, могут быть допущены на обсуждение правлением совета. Условием является лишь то, что общее производство кандидата за последние четыре календарных квартала (годовое производство) должно составлять не менее 3.1 тонн. С помощью расширения состава своих участников совет способствует достижению большей открытости золотопромышленной индустрии, рынка и выработке общих решений, касающихся текущего положения в отрасли. На данный момент членами ВСЗ являются 15 компаний:- (i) Канада:- Анико-Игл (Agnico-Eagle), Аламос Голд (Alamos Gold), Барык Голд Корп. (Barrick Gold Corp.), Элдорэйдо Голд Корп. (Eldorado Gold Corp.), Голдкоп Инк. (Goldcorp Inc.), Ай.Эй.Эм.Голд Корпорэйшэн (IAMGold Corporation), Кинрос Голд Корпорэйшэн (Kinross Gold Corporation), Нью Голд Инк. (New Gold Inc.), Ямана Голд (Yamana Gold); (ii) США:- Кёр д'Алэнэ Майнз Корп. (Coeur d'Alene Mines Corp.), Ньюмонт Майнин Корп. (Newmont Mining Corp.); (iii) Перу:- Буэнавэнтура (Buenaventura), Минэра Янакоча (Minera Yanacocha); (iv) ЮАР:- ЭнглоГолдАшанти (AngloGoldAshanti), Голд Филдз Лтд. (Gold Fields Ltd.). Главные партнёры и компаньоны:- Чайна Голд Корп. (China Gold Corp.; Китай), Фрэнько Нэвэда Корп. (Franco Nevada Corp.; Канада), Хутти Голд Майнз (Hutti Gold Mines; Индия), Мицубищи Мэтириэлз (Mitsubishi Materials; Япония), а также Ройэл Голд Корп (Royal Gold Corp.; США). Российские предприятия в совете не представлены. Всемирный Совет по Золоту – активный член двух известных и авторитетных организаций:- Международного Совета по Горной Промышленности и Металлам (International Council on Mining & Metals (ICMM)) и Ответственного Совета по Драгоценностям (Responsible Jewellery Council (RJC)). В настоящее время Международный Совет по Горной Промышленности и Металлам занимается привлечением своих членов в программу Структура Устойчивого Развития, которая представляет собой квинтэссенцию передовых мировых стандартов, публичности, открытости обществу, независимых гарантий, а также обмена опытом и успешной практикой. Целью же Ответственного Совета по Драгоценностям является внедрение этических, социальных и экологических аспектов во всю цепочку создания алмазных и золотых драгоценностей:- начиная от добычи сырья, заканчивая продажей. Всемирный Совет по Золоту отмечает важность того факта, что расширение деятельности, связанной с золотом, приносит большую социальную и экономическую выгоду развивающимся странам. В докладе ВСЗ, представленном в 2005 и озаглавленном Прикосновение Золота, говорится о том, что жёлтый металл стал одной из важнейших статей вывоза (или экспорта) бедных стран с большими долгами, а также о выгоде его производства для прогрессирующих экономик. Совет имеет ряд основных инициатив, к реализации которых его члены подходят с наибольшим вниманием и участием. ВСЗ спонсирует и поддерживает ряд международных конференций, посвящённых вопросу поиска новых способов приложения золота в индустрии. К наиболее успешным примерам подобных мероприятий можно отнести форум Золото Как Катализатор, который прошёл в Кейптауне (ЮАР) в Апреле 2001, а также Новые Пути Индустриального Использования Золота в 2003 в Ванкувере (Канада) и в 2006 в Лимерике (Ирландия). Но особняком стоит генеральное собрание Прогресс в Науке и Технике Золота, которое состоялось в Июне 1996 в Ханау (Германия) и объединило в себе обсуждение всех направлений использования золота. К самым крупным мероприятиям последнего времени можно отнести конференцию Золото 2009. Она состоялась в Июле 2009 в городе Хайдельберг (Германия). Во время работы участники затронули все самые актуальные вопросы применения золота в сферах науки и технологий, касающиеся катализа, химии, сырья и нанотехнологий. В совете уверены, что научное и производственное сообщество нуждается в такого рода мероприятиях. Они дают отличную возможность обсудить последние направления и разработки в области добычи и использования золота, таким образом, поддерживая коммерческое его использование и принося пользу обществу. Следующей сферой интересов ВСЗ является поддержка инноваций. Эта организация даёт

уникальную возможность для облегчения и ускорения коммерциализации перспективных технологий и разработок. Процесс ведётся двумя способами:- через сотрудничество с компаниями, занятыми в сфере инноваций, и активную работу с небольшими, но быстро развивающимися предприятиями. В работе с компаниями ВСЗ опирается на свою новую программу Инновационных Партнёрств. Её целью является поддержка и развитие исследований в области новых практических методов применения золота, соответствующих коммерческим требованиям рынка. Организациями-партнёрами могут стать компании, которые занимаются драгоценными металлами, химией, биомедициной, электроникой (от совсем маленьких компаний до международных предприятий). С теми, кого заинтересовала эта деятельность, совет готов выйти на контакт для обсуждения дальнейших перспектив сотрудничества. В период 2009–10 Всемирный Совет по Золоту был особо заинтересован в предложениях, касающихся технологий индустриального катализа (включая катализаторы контроля за загрязнением и химической обработки), биомедицины (включая медицинскую диагностику, терапию и материалы), передовой электроники (включая любые технологии, нацеленные на их использование в устройствах следующего поколения), систем топливных элементов, оптики (включая нанотехнологии, химикаты и покрытия). Всемирный Совет по Золоту не обходит своим вниманием и компании, чьи разработки по применению золота открыты для лицензирования и коммерческого использования. В настоящее время в этом направлении ВСЗ работает с множеством организаций, например:- с Университетом Лихай (технология использования золото-ванадиевой окиси для микромеханических переключателей), Project AuTEK (золото как катализатор водородной очистки в системах топливных элементов), Union Chemical Laboratories (золотой нанокатализ) и так далее. И в заключение следует добавить, что Всемирный Совет по Золоту продолжает работу над реализацией своих старых инициатив и разработкой стратегий инвестирования капитала в сферу новых технологий. На сайте совета представлена полная информация обо всём, что касается его работы, последние новости рынка золота, разнообразные исследования, доклады, статистические данные, статьи информационного бюллетеня ‘Goldbulletin’ и многое другое. Всемирный Совет по Золоту (ВСЗ) представляет собой коммерческую организацию, основным направлением деятельности которой является стабилизация позиции золота на мировом рынке и создание условий, позволяющих стимулировать спрос на золото. ВСЗ был основан в 1987 в Лондоне, и с тех пор расширил своё влияние по всему миру. В совет входят представители (прежде всего, президенты и директора) крупнейших золотодобывающих компаний, поставляющих в сумме до 60% золота на мировой рынок. Среди них Американские компании Ньюмонт Корпорэйшэн (Newmont Corporation) и ЭнглоГолд Лтд. (AngloGold Ltd.), Канадская Барик Голд Корпорэйшэн (Barrick Gold Corporation), Арабская ЭнглоГолдАшанти (AngloGoldAshanti) и другие корпорации. Среди членов совета нет представителей Российских компаний. Вступить в совет могут все золотодобывающие корпорации, объём производства которых составляет не менее 3.1 тонны за последний год. Влияние ВСЗ распространено на Ближний Восток (Стамбул, Дубай), Дальний Восток (Токио, Пекин, Шанхай, Сингапур), Американские страны (с центром в Нью Йорке), Индии (Мумбай и Чинай). ВСЗ регулярно издаёт независимые исследования по международному рынку золота, публикует статьи о роли драгоценного металла в экономике мира. Всемирный Совет по Золоту работает со всеми направлениями инвестиций в золото (как спекулятивными, так и долгосрочными), развивает новые способы инвестирования в драгоценные металлы, защищает массовый рынок украшений из золота и развивает сегмент премиум класса. Отдельным направлением деятельности является и развитие рынка технологий, где используется золото. Официальный сайт и публикации ВСЗ могут стать бесценным источником информации для инвестора в золото. На сайте представлена статистика и информация о котировках драгоценного металла в разных валютах (в том числе, Йенах), объёмах ВВП в ведущих странах. Кроме того, здесь можно найти информацию о работе самого совета, последние новости с международного рынка золота, доклады и исследования. Совет выпускает и собственный бюллетень – Goldbulletin, где можно узнать важную информацию о том или ином событии в сфере золотых инвестиций. Всемирный Совет по Золоту (ВСЗ; World Gold Council (WGC)) – это коммерческая организация, деятельность которой сфокусирована на создании особых условий для золота с целью стимулирования и поддержки спроса на золото, стабилизация его рыночных позиций в мире. Совет был создан в 1987 со штаб-квартирой в Лондоне. Всемирный Совет по Золоту представляет интересы ведущих золотодобывающих компаний мира, чей суммарный оборот составляет 60% от ежегодного мирового производства золота. Самыми известными среди них являются:- ЭнглоГолд Лтд. (AngloGold Ltd.; США), Барик Голд Корпорэйшэн (Barrick Gold Corporation; Канада), Ньюмонт Корпорэйшэн (Newmont Corporation; США). Исполнительные директора и президенты этих компаний формируют правление Совета. Российские предприятия в Совете не представлены. Всемирный Совет по Золоту осуществляет свою деятельность в ключевых центрах с большим спросом на золото:- в Северной и Южной Америке (региональный офис в Нью Йорке), на Дальнем Востоке (офисы в Сингапуре, Токио, Шанхае и Пекине), на Ближнем Востоке (офисы в Стамбуле и Дубае), Индии (офисы в Чинае и Мумбае). Всемирный Совет по Золоту является ведущим источником независимых исследований и знаний по международному рынку золота и роли золота, которую оно играет в социальных и экономической сферах общества. Так как Всемирный Совет по Золоту является ключевой организацией по развитию рынка золота, он сотрудничает с разными партнёрами для создания многоуровнего спроса на золото, а также способствует использованию золота в его разных формах:- создание новых способов инвестирования в золото, разъяснение для лучшего понимания свойств золота с целью сохранения благосостояния, развитие сегмента премиум класса в ювелирной промышленности и защита массового рынка ювелирных изделий. В промышленности Всемирный Совет по Золоту способствует развитию рынка электронных приборов и поддерживает развивающиеся технологии. В правительственных делах Всемирный Совет по Золоту внедряет макроэкономические механизмы, снижающие регулирующие барьеры для владения золотом, а также позиционирует золото как резервный актив. WORLD HEALTH ORGANIZATION = ВСЕМИРНАЯ ОРГАНИЗАЦИЯ ЗДРАВООХРАНЕНИЯ – The World Health Organization (WHO) is the directing and coordinating authority on international health within the United Nations’ system. WHO experts produce health guidelines and standards, and help countries to address public health issues. WHO also supports and promotes health research. Through WHO, governments can jointly tackle global health problems and improve people’s well-being. 193 countries (in 2012) and two associate members are WHO’s membership. They meet every year at the World Health Assembly in Geneva to set policy for the Organization, approve the Organization’s budget, and every five years, to appoint the Director-General. Their work is supported by the 34-member Executive Board, which is elected by the Health Assembly. Six regional committees focus on health matters of a regional nature. Who are our partners in health? WHO and its Member States work with many partners, including UN agencies, donors, nongovernmental organizations, WHO collaborating centers and the private sector. Only through new ways of working and innovative partnerships can we make a difference and achieve our goals. Last but not least, WHO is people. Over 8 000 public health experts including doctors, epidemiologists, scientists, managers, administrators and other professionals from all over the world work for WHO in 147 country offices, six regional offices and at the headquarters in Geneva, Switzerland. When diplomats met in San Francisco to form the United Nations in 1945, one of the things they discussed was setting up a global health organization. WHO’s Constitution came into force on 07 April 1948 – a date we now celebrate every year as World Health Day. Delegates from 53 of WHO’s 55 original member states came to the first World Health Assembly in June 1948. They decided that WHO’s top priorities would be

malaria, women's and children's health, tuberculosis, venereal disease, nutrition and environmental sanitation – many of which we are still working on today. WHO's work has since grown to also cover health problems that were not even known in 1948, including relatively new diseases such as HIV/AIDS. 1948:- WHO took over the responsibility for the International Classification of Disease (ICD), which dates back to the 1850s and was first known as the International List of Causes of Death. The ICD is used to classify diseases and other health problems and has become the international standard used for clinical and epidemiological purposes. Country teams:- WHO has dedicated HIV/AIDS staff working in over 85 countries worldwide. They advise Ministries of Health on technical issues and provide assistance in scaling-up essential prevention, treatment and care services through the health sector. They work with other players including other UN agencies, nongovernmental organizations and affected communities to help plan, implement and monitor programmes. These country teams also help with advocacy and fundraising efforts in countries. Regional teams:- Regional HIV/AIDS teams in each of WHO's six regional offices are the first point of contact for country offices that need extra technical or financial help. Regional offices also give special attention to adapting global HIV/AIDS policies to fit specific needs in their regions. For example, the response to HIV/AIDS requires different interventions in sub-Saharan Africa, where the epidemic is largely spread by heterosexual sex, from those in eastern Europe, where injecting drug use is the primary mode of HIV transmission. Headquarters team:- The HIV team at WHO headquarters in Geneva supports and builds on all of these regional and local efforts. It sets global policies and standards, facilitates technical support to regions and countries, monitors and publicizes progress, and helps mobilize political and financial support. WHO is working to ensure that everyone has access to quality health care. In many countries, there is little money available to spend on health. This results in inadequate hospitals and clinics, a short supply of essential medicines and equipment, and a critical shortage of health workers. Worse, in some parts of the world, large numbers of health workers are dying from the very diseases which they are trying to prevent and treat. WHO works with countries to help them plan, educate and manage the health workforce, for example, by advising on policies to recruit and retain people working in health. World Health Organization (WHO) is the global agency linked with the United Nations (UN) and cooperating with other technical agencies relating to health matters at sea and on land. WHO is the directing and coordinating authority for health within the United Nations system. It is responsible for providing leadership on global health matters, shaping the health research agenda, setting norms and standards, articulating evidence-based policy options, providing technical support to countries and monitoring and assessing health trends. The role of WHO in public health:- WHO fulfils its objectives through its core functions:- (i) providing leadership on matters critical to health and engaging in partnerships where joint action is needed; (ii) shaping the research agenda and stimulating the generation, translation and dissemination of valuable knowledge; (iii) setting norms and standards and promoting and monitoring their implementation; (iv) articulating ethical and evidence-based policy options; (v) providing technical support, catalyzing change, and building sustainable institutional capacity; and (vi) monitoring the health situation and assessing health trends. These core functions are set out in the 11th General Programme of Work, which provides the framework for organization-wide programme of work, budget, resources and results. Entitled 'Engaging for health', it covers the 10-year period from 2006 to 2015. History of WHO:- when diplomats met to form the United Nations in 1945, one of the things they discussed was setting up a global health organization. WHO's Constitution came into force on 07 April 1948 – a date we now celebrate every year as World Health Day. Headquartered in Geneva, Switzerland. / Всемирная Организация Здравоохранения (ВОЗ) – международное специализированное учреждение системы Организации Объединенных Наций в области здравоохранения. Эксперты ВОЗ разрабатывают рекомендации и стандарты в области охраны здоровья и оказывают помощь странам в разрешении проблем общественного здравоохранения. ВОЗ также оказывает поддержку и способствует проведению научных исследований в области здравоохранения. С помощью ВОЗ национальные правительства могут совместно искать решения глобальных проблем здравоохранения и добиваться улучшения благополучия своих граждан. В состав (в 2012) ВОЗ входят 192 государства-члена и два ассоциированных члена. Ежегодно их представители собираются на Всемирную ассамблею здравоохранения, которая проходит в Женеве, и определяют общие программные направления деятельности ВОЗ, утверждают бюджет Организации и каждые пять лет назначают Генерального Директора. В работе им оказывает поддержку Исполнительный Комитет в составе 34 членов, которые избираются Ассамблеей здравоохранения. Вопросы здравоохранения регионального характера относятся к сфере компетенции шести региональных комитетов. Кто наши партнёры в области здравоохранения? ВОЗ и её государства-члены сотрудничают с многими партнёрами, в том числе с другими учреждениями ООН, донорами, неправительственными организациями, сотрудничающими центрами ВОЗ и частным сектором. Только прокладывая новые пути в нашей работе и создавая новаторские партнёрства, мы сможем изменить положение к лучшему и достичь наших целей. Люди:- и последнее по порядку, но не по значению:- в ВОЗ работают люди. Почти 8 000 специалистов в области здравоохранения, в том числе врачи, эпидемиологи, учёные, управляющие, администраторы и другие эксперты из всех стран мира, работают в системе ВОЗ в 147 страновых бюро, в шести региональных бюро и в штабквартире в Женеве, Швейцария. Когда в 1945 дипломаты собрались в Сан Франциско для создания Организации Объединённых Наций, они, в том числе, обсуждали и вопрос об образовании глобальной организации здравоохранения. Конституция (Устав) ВОЗ вступила в силу 07 Апреля 1948, в день, который с тех пор ежегодно отмечается как Всемирный день здоровья. Делегаты 53 стран из 55 первых государств-членов ВОЗ прибыли на первую Всемирную ассамблею здравоохранения в Июне 1948. Они приняли решение, определившее главные приоритеты их деятельности, которыми стали малярия, здоровье матери и ребёнка, туберкулез, венерические болезни, питание и обеспечение санитарного состояния окружающей среды, то есть те, которые во многих случаях и сегодня остаются в центре нашего внимания. Деятельность ВОЗ в настоящее время охватывает проблемы здравоохранения, которые не были даже известны в 1948, в том числе такие относительно новые болезни, как ВИЧ/СПИД. 1948:- Международная классификация болезней:- ВОЗ взял на себя ответственность за Международную Классификацию Болезней (МКБ), которая была составлена ещё в 1850-е и была известна как Международный перечень причин смерти. МКБ классифицирует болезни и другие проблемы здоровья, и является единым международным стандартом, который применяется для клинических и эпидемиологических целей. Страновые группы:- ВОЗ имеет профессиональных специалистов, работающих по проблеме ВИЧ/СПИДа более чем в 40 странах по всему миру. Эти эксперты консультируют министерства здравоохранения по организационно-техническим вопросам и оказывают помощь в расширении основных профилактических мероприятий, терапевтических процедур и медицинского ухода в учреждениях здравоохранения. Они работают совместно с другими участниками процесса, в том числе учреждениями ООН, неправительственными организациями и заинтересованными группами населения, и помогают планировать, осуществлять и контролировать выполнение соответствующих программ. Эти страновые группы также оказывают поддержку при проведении мероприятий просветительского характера и акций по сбору средств в этих странах. Региональные группы:- Региональные группы по ВИЧ/СПИДу в каждом из шести региональных бюро ВОЗ являются пунктами первого контакта для национальных правительственных органов, которые нуждаются в дополнительной технической или финансовой помощи. Региональные бюро также уделяют особое внимание вопросам адаптирования глобальных программ борьбы против ВИЧ/СПИДа с учётом специфических потребностей их регионов. Например, ответные действия по проблемам ВИЧ/СПИДа требуют иных форм вмешательства в странах Африки, расположенных к югу от Сахары, где эта эпидемия, главным образом, распространяется в результате гетеросексуальных половых связей, по сравнению со странами Восточной Европы, где передача ВИЧ, в основном, обусловлена инъекционным введением наркотиков. Группа штабквартиры:- Группа экспертов по ВИЧ, работающая в штабквартире ВОЗ в Женеве,

предоставляет поддержку региональным и страновым бюро и обобщает опыт их работы. Она разрабатывает глобальную политику и стандарты, организует техническую помощь регионам и странам, ведёт мониторинг и публикует доклады о ходе работ, а также помогает мобилизовать необходимую политическую и финансовую поддержку. ВОЗ прилагает много усилий к тому, чтобы обеспечить всем и каждому доступ к качественному медико-санитарному обслуживанию. Во многих странах не хватает денег на здравоохранение. Поэтому их больницы и клиники неадекватно оснащены, там недостаточно основных лекарственных средств и медицинского оборудования, и наблюдается острый дефицит медицинского персонала. И, что хуже всего, в некоторых странах мира многие медицинские работники гибнут от тех болезней, которые они пытаются предотвратить или излечить. ВОЗ работает в странах в порядке оказания помощи в составлении программ, обучении и управлении медицинским персоналом, например, предоставляя консультации по политике в области набора и закрепления кадров в сфере здравоохранения. ВОЗ является направляющей и координирующей инстанцией в области здравоохранения в рамках системы Объединённых Наций. Она несёт ответственность за обеспечение ведущей роли при решении проблем глобального здравоохранения, составление повестки дня для научных исследований в области здравоохранения, установление норм и стандартов, разработку политики на основе фактических данных, обеспечение технической поддержки странам, а также контроль за ситуацией в области здравоохранения и оценку динамики её изменения. Роль ВОЗ в общественном здравоохранении:- на пути достижения своих целей ВОЗ выполняет следующие основные функции:- (i) обеспечение ведущей роли в вопросах, имеющих исключительно важное значение для здоровья, и налаживание партнёрских отношений там, где необходимы совместные действия; (ii) разработка повестки дня в области научных исследований и стимулирование сбора, освоения и распространения ценных знаний; (iii) установление норм и стандартов, содействие в их соблюдении и соответствующий контроль; (iv) увязка концепции этических вопросов с концепцией разработки политики на основе фактических данных; (v) обеспечение технической поддержки, активизация изменений и создание устойчивого институционального потенциала; и (vi) контроль за ситуацией в области здравоохранения и оценка динамики её изменения. Эти основные функции изложены в 11-й Общей Программе Работы, в которой представлены структура программы работы в рамках всей организации, бюджет, ресурсы и результаты. Программа под названием ‘Работа во имя Здравоохранения’ охватывает 10-летний период с 2006 по 2015. История ВОЗ:- на состоявшейся в 1945 встрече по поводу создания Организации Объединённых Наций дипломаты, помимо прочего, обсудили также вопрос о создании глобальной организации здравоохранения. Устав ВОЗ вступил в силу 07 Апреля 1948 – отныне мы ежегодно отмечаем этот день как Всемирный день здоровья. Штабквартира организации расположена в Женеве, Швейцария. Под Всемирной Организацией Здравоохранения (ВОЗ) понимается международная межправительственная организация, специализированное учреждение ООН. Создана в 1946. Уставные задачи:- (i) борьба с особо опасными болезнями; (ii) разработка международных санитарных правил; (iii) улучшение санитарного состояния внешней среды и так далее. В 1985 членами ВОЗ состояло 164 государства. Всемирная Организация Здравоохранения (ВОЗ) - специализированное учреждение Организации Объединённых Наций (ООН) ставящее целью ‘достижение всеми народами возможно высшего уровня здоровья’ (Статья 1 Устава ВОЗ). Членами ВОЗ на 01 Января 1971 были 128 стран-членов и 3 страны-сотрудника. Основана 07 Апреля 1948, когда 26 государств-членов ООН ратифицировали Устав ВОЗ; этот день отмечается ежегодно как Всемирный День Здоровья. ВОЗ организует борьбу с болезнями, их ликвидацию (например, международные кампании ликвидации малярии и оспы; оказывает помощь различным странам в борьбе с инфекционными и неинфекционными болезнями, проводит международные работы в области карантина и эпидемиологического надзора, контроль за качеством лекарственных препаратов, контроль за наркотиками, разработку международных стандартов лекарств и так далее. Организует и проводит научные исследования и создание справочных центров ВОЗ на базе национальных научно-исследовательских учреждений, организацию научных конференций, совещаний и симпозиумов, подготовку и усовершенствование научных медицинских работников. Ведёт работу по укреплению в слаборазвитых странах служб здравоохранения, подготовке национальных кадров. По инициативе бывшего Союза Советских Социалистических Республик (СССР) были приняты резолюции о задачах ВОЗ в связи с принятием Декларации ООН О Предоставлении Независимости Колониальным Странам И Народам (1961), Резолюции О Защите Человечества От Опасности Атомной Радиации (1961), о задачах ВОЗ в связи с принятием Резолюции ООН О Всеобщем И Полном Разоружении (1960). Структура ВОЗ – региональная. В её состав входят 6 региональных организаций (исполнительные органы этих организаций – Региональные Бюро):- Европейская (бюро в Копенгагене, Дания), Африканская (бюро в Браззавиле, Народная Республика Конго), Восточного Средиземноморья (бюро в Александрии, ОАР), Юго-Восточной Азии (бюро в Нью Дели, Индия), Западной части Тихого Океана (бюро в Маниле, Филиппины) и Американская (бюро в Вашингтоне, США). Высший орган ВОЗ – Всемирная Ассамблея Здравоохранения, сессии которой созываются ежегодно. Ассамблея определяет направление деятельности ВОЗ, назначает Генерального Директора ВОЗ, рассматривает и утверждает перспективные и годовые планы работы, бюджет, вопросы приёма в ВОЗ и лишения права голоса, права на обслуживание, вопросы сотрудничества с другими организациями. Другим руководящим органом ВОЗ является Исполнительный Комитет, состоящий из 24 человек, назначаемых таким же числом стран-членов ВОЗ (страны избирает Ассамблея Здравоохранения); члены Исполкома назначаются на 3 года. Исполкому предоставлено право принимать чрезвычайные меры в случаях, не терпящих отлагательства (при возникновении эпидемий, стихийных бедствий и так далее). Центральный административный орган ВОЗ – Секретариат (штаб-квартира в Женеве, Швейцария), возглавляемый Генеральным Директором (с 1953 по 1973 – Доктор Марколино Гомес Кандау (Marcolino Gomes Candau), Бразилия). Общее количество персонала ВОЗ на 01 Января 1971, включая персонал, работающий на местах, достигало 4 750 человек. Основным источником средств ВОЗ, составляющих регулярный бюджет, являются взносы стран-членов. Деятельность ВОЗ финансируют также добровольный фонд укрепления здоровья (учреждённый в 1960), который складывается из добровольных пожертвований стран-членов ВОЗ, Фонд Программы Развития ООН и Детский Фонд ООН (ЮНИСЕФ). Общая сумма средств, находившихся в распоряжении ВОЗ в 1970, составила 112 миллионов Долларов США.

WORLD HERITAGE = ВСЕМИРНОЕ НАСЛЕДИЕ – World Heritage:- a World Heritage Site is an area or place of cultural or natural significance that is deemed to have outstanding universal value and is therefore worthy of protection. That protection is made possible through the inscription by the World Heritage Committee of such a place in the World Heritage List in terms of the World Heritage Convention established in 1972 by UNESCO (United Nations Educational, Scientific and Cultural Organisation). The mission of the World Heritage Convention is to encourage countries to nominate cultural and natural heritage sites for possible inclusion on the World Heritage List. It also offers assistance to countries with challenges of safeguarding their sites against threats of changing social and economic conditions and natural decay. Once a site is inscribed in the World Heritage List, it receives national and international recognition and the country is required to ensure that effective and active measures are taken for the protection, conservation and presentation of the site. UNESCO’S World Heritage Mission:- (i) encourage countries to sign the World Heritage Convention and to ensure the protection of their natural and cultural heritage; (ii) encourage countries party to the convention to nominate sites within their national territory for inclusion on the World Heritage List; (iii) encourage countries to establish management plans and set up reporting systems on the state of conservation of their World Heritage Sites; (iv) help countries safeguard World Heritage properties by providing technical assistance and professional training; (v) provide emergency assistance for World Heritage sites in immediate danger; (vi)

support countries' public awareness building activities for World Heritage conservation; (vii) encourage participation of the local population in the preservation of their cultural and natural heritage; and (viii) encourage international cooperation in the conservation of our world's cultural and natural heritage. One of the most important benefits of a World Heritage Listing is the protection of the site for future generations. Imagine never being able to stand at the foot of the ancient pyramids, to experience the crashing of water as it thunders down Victoria Falls, or to listen to the chiming clock on the Tower of London. Imagine not being able to walk through the pristine mountains of the uKhahlamba Drakensberg Park (word uKhahlamba means Barrier of Spears in Zulu) or never being able to stand on Robben Island in the prison cell, 46664, of South Africa's first democratically elected president, Nelson Mandela, and feel the weight of history. The World Heritage Convention was enacted to ensure that such places are conserved for prosperity. See also National Estate. / (uKhahlamba). Нэлсэн Мандэла (Nelson Mandela).

WORLD INTELLECTUAL PROPERTY ORGANIZATION = ВСЕМИРНАЯ ОРГАНИЗАЦИЯ ИНТЕЛЛЕКТУАЛЬНОЙ СОБСТВЕННОСТИ – The World Intellectual Property Organization (WIPO) is a specialized agency of the United Nations. It is dedicated to developing a balanced and accessible international intellectual property (IP) system, which rewards creativity, stimulates innovation and contributes to economic development while safeguarding the public interest. WIPO was established by the WIPO Convention in 1967 with a mandate from its Member States to promote the protection of IP throughout the world through cooperation among states and in collaboration with other international organizations. WIPO's revised and expanded strategic goals are part of a comprehensive process of strategic realignment taking place within the Organization. These new goals will enable WIPO to fulfill its mandate more effectively in response to a rapidly evolving external environment, and to the urgent challenges for intellectual property in the XXI century. The nine strategic goals were adopted by Member States in the Revised Program and Budget for the 2008/09 Biennium. They are:- (i) Balanced Evolution of the International Normative Framework for IP; (ii) Provision of Premier Global IP Services; (iii) Facilitating the Use of IP for Development; (iv) Coordination and Development of Global IP Infrastructure; (v) World Reference Source for IP Information and Analysis; (vi) International Cooperation on Building Respect for IP; (vii) Addressing IP in Relation to Global Policy Issues; (viii) a Responsive Communications Interface between WIPO, its Member States and All Stakeholders; and (ix) an Efficient Administrative and Financial Support Structure to Enable WIPO to Deliver its Programs. The Strategic Goals will provide the framework for WIPO's six year Medium Term Strategic Plan (2010–15). Its headquarters are in Geneva, Switzerland. World Intellectual Property Organization (WIPO) is an intergovernmental organization of the United Nations system. WIPO is responsible for the promotion of the protection of intellectual property throughout the world and for the administration of various multilateral treaties dealing with the legal and administrative aspects of intellectual property. The roots of the World Intellectual Property Organization go back to 1883, when Johannes Brahms was composing his third Symphony, Robert Louis Stevenson was writing Treasure Island, and John and Emily Roebling were completing construction of New York's Brooklyn Bridge. The need for international protection of intellectual property became evident when foreign exhibitors refused to attend the International Exhibition of Inventions in Vienna, Austria in 1873 because they were afraid their ideas would be stolen and exploited commercially in other countries. 1883 marked the birth of the Paris Convention for the Protection of Industrial Property, the first major international treaty designed to help the people of one country obtain protection in other countries for their intellectual creations in the form of industrial property rights, known as:- (i) inventions (patents); (ii) trademarks; and (iii) industrial designs. The Paris Convention entered into force in 1884 with 14 member States, which set up an International Bureau to carry out administrative tasks, such as organizing meetings of the member States. In 1886, copyright entered the international arena with the Berne Convention for the Protection of Literary and Artistic Works. The aim of this Convention was to help nationals of its member States obtain international protection of their right to control, and receive payment for, the use of their creative works such as:- (i) novels, short stories, poems, plays; (ii) songs, operas, musicals, sonatas; and (iii) drawings, paintings, sculptures, architectural works. Like the Paris Convention, the Berne Convention set up an International Bureau to carry out administrative tasks. In 1893, these two small bureaux united to form an international organization called the United International Bureaux for the Protection of Intellectual Property (best known by its French acronym BIRPI). Based in Berne, Switzerland, with a staff of seven, this small organization was the predecessor of the World Intellectual Property Organization of today – a dynamic entity with 184 member States (in 2011), a staff that now numbers some 938, from 95 countries around the world, and with a mission and a mandate that are constantly growing. As the importance of intellectual property grew, the structure and form of the Organization changed as well. In 1960, BIRPI moved from Berne to Geneva to be closer to the United Nations and other international organizations in that city. A decade later, following the entry into force of the Convention Establishing the World Intellectual Property Organization, BIRPI became WIPO, undergoing structural and administrative reforms and acquiring a secretariat answerable to the member States. In 1974, WIPO became a specialized agency of the United Nations system of organizations, with a mandate to administer intellectual property matters recognized by the member States of the UN. In 1978, the WIPO Secretariat moved into the headquarters building that has now become a Geneva landmark, with spectacular views of the surrounding Swiss and French countryside. WIPO expanded its role and further demonstrated the importance of intellectual property rights in the management of globalized trade in 1996 by entering into a cooperation agreement with the World Trade Organization (WTO). The impetus that led to the Paris and Berne Conventions – the desire to promote creativity by protecting the works of the mind – has continued to power the work of the Organization, and its predecessor, for some 120 years. But the scope of the protection and the services provided have developed and expanded radically during that time. In 1898, BIRPI administered only four international treaties. Today its successor, WIPO, administers 24 treaties (three of those jointly with other international organizations) and carries out a rich and varied program of work, through its member States and secretariat, that seeks to:- (i) harmonize national intellectual property legislation and procedures; (ii) provide services for international applications for industrial property rights; (iii) exchange intellectual property information; (iv) provide legal and technical assistance to developing and other countries; (v) facilitate the resolution of private intellectual property disputes; and (vi) marshal information technology as a tool for storing, accessing, and using valuable intellectual property information. WIPO, a specialized agency, is a part of the United Nations system of organizations. Headquartered in Geneva, Switzerland, WIPO promotes protection of intellectual property around the world through cooperation among states, and administers various Unions, each founded on a multilateral treaty and dealing with the legal and administrative aspects of intellectual property. The World Intellectual Property Organization (WIPO) is an international organization dedicated to ensuring that the rights of creators and owners of intellectual property are protected worldwide and that inventors and authors are thus recognized and rewarded for their ingenuity. As a specialized agency of the United Nations, WIPO exists as a forum for its Member States to create and harmonize rules and practices to protect intellectual property rights. Most industrialized nations have protection systems that are centuries old. Many new and developing countries, however, are now building up their patent, trademark and copyright laws and systems. With the rapid globalization of trade during the last decade, WIPO plays a key role in helping these new systems evolve through treaty negotiation, legal and technical assistance, and training in various forms, including in the area of enforcement of intellectual property rights. WIPO also provides international registration systems for patents, trademarks, appellations of origin and industrial designs. These greatly simplify the process for simultaneously seeking intellectual property protection in a large number of countries. Instead of having to file national applications in many languages, these systems enable applicants to file a single application, in one language, and to pay a single application fee. The WIPO-administered systems of international protection include four different mechanisms of protection for specific industrial property rights:- (i) The Patent Cooperation Treaty (PCT) for filing patent

applications in multiple countries. (ii) The Madrid System for the International Registration of Marks for trade and service marks. (iii) The Hague System for the International Deposit for Industrial Designs. (iv) The Lisbon System for the International Registration of Appellations of Origin. Anyone applying for a patent or registering a trademark or design, whether at the national or international level, needs to determine whether their creation is new or is owned or claimed by someone else. To make this determination, huge amounts of information must be searched. Four WIPO treaties have created classification systems, which organize information on different branches of industrial property into indexed, manageable structures for easy retrieval:- (i) Strasbourg Agreement Concerning the International Patent Classification. (ii) Nice Agreement Concerning the International Classification of Goods and Services for the Purposes of the Registration of Marks. (iii) Vienna Agreement Establishing an International Classification of the Figurative Elements of Marks. (iv) Locarno Agreement Establishing an International Classification for Industrial Designs. WIPO also provides an Arbitration and Mediation Center, which offers services for the resolution of international commercial disputes between private parties involving intellectual property. The subject matter of these proceedings includes both contractual disputes (such as patent and software licenses, trademark coexistence agreements, and research and development agreements) and non-contractual disputes (such as patent infringement). The Center is also now recognized as the leading dispute resolution service provider for disputes arising out of the abusive registration and use of Internet domain names. World Intellectual Property Organization (WIPO) is an intergovernmental organization based in Geneva, Switzerland responsible for the promotion of the protection of intellectual rights throughout the world. It is one of the 16 specialized agencies of the United Nations system of organizations. The World Intellectual Property Organization (WIPO) is an international organization dedicated to promoting the use and protection of works of the human spirit. These works – intellectual property – are expanding the bounds of science and technology and enriching the world of the arts. Through its work, WIPO plays an important role in enhancing the quality and enjoyment of life, as well as creating real wealth for nations. With headquarters in Geneva, Switzerland, WIPO is one of the 16 specialized agencies of the United Nations system of organizations. It administers 23 international treaties dealing with different aspects of intellectual property protection. The Organization counts 182 nations as member states. World Intellectual Property Organization (WIPO) is an intergovernmental organization of the United Nations system. WIPO is responsible for the promotion of the protection of intellectual property throughout the world and for the administration of various multilateral treaties dealing with the legal and administrative aspects of intellectual property. World Intellectual Property Organization:- international organization designed to promote the worldwide protection of both industrial property (inventions, trademarks, and designs) and copyrighted materials (literary, musical, photographic, and other artistic works). The organization, established by a convention signed in Stockholm in 1967, began operations in 1970 and became a specialized agency of the United Nations in December 1974. It is headquartered in Geneva, Switzerland. The origins of WIPO can be traced to 1883, when 14 countries signed the Paris Convention for the Protection of Industrial Property, which created intellectual-property protections for inventions, trademarks, and industrial designs. The convention helped inventors gain protection for their works outside their native countries. In 1886 the Berne Convention required member countries to provide automatic protection for works that were produced in other member countries. The two organizations, which had established separate secretariats to enforce their respective treaties, merged in 1893 to become the United International Bureau for the Protection of Intellectual Property (BIRPI), which was based in Bern, Switzerland. In 1960 BIRPI moved its headquarters to Geneva. The aims of WIPO are twofold. First, through international cooperation, WIPO promotes the protection of intellectual property. The organization now administers more than 20 intellectual-property treaties. Second, WIPO supervises administrative cooperation between the Paris, Berne, and other intellectual unions regarding agreements on trademarks, patents, and the protection of artistic and literary works. WIPO's role in enforcing intellectual-property protections increased in the mid 1990s, when it signed a cooperation agreement with the World Trade Organization. As electronic commerce grew through the development of the Internet, WIPO was charged with helping to resolve disputes over the use of Internet domain names. WIPO's membership consists of more than 175 countries. Its main policy-making body is the General Assembly, which convenes every two years. WIPO also holds a biennial conference, which determines the organization's budget and programs. More than 160 nongovernmental organizations maintain observer status. / Всемирная Организация Интеллектуальной Собственности (ВОИС) – межправительственная организация со штаб-квартирой в Женеве, Швейцария. Штабквартира ВОИС находится в Женеве, Швейцария. Стратегические цели:- пересмотренные и расширенные стратегические цели ВОИС являются частью комплексного процесса перестройки, проходящего в организации. Обновлённые цели помогут ВОИС более эффективно выполнять свой мандат с учётом быстро меняющейся внешней конъюнктуры и настоятельной потребности решения задач в области интеллектуальной собственности в XXI веке. Девять стратегических целей, поставленных в пересмотренных Программе и бюджете на 2008–09, включают:- (i) Сбалансированное развитие международной нормативной базы ИС; (ii) Предоставление высококачественных услуг в глобальных системах охраны ИС; (iii) Содействие использованию ИС в интересах развития; (iv) Координация и развитие глобальной инфраструктуры ИС; (v) Всемирный источник справочной информации и аналитических данных в области ИС; (vi) Международное сотрудничество, направленное на обеспечение уважения ИС; (vii) Решение вопросов ИС в контексте глобальных стратегических задач; (viii) Обеспечение оперативной связи между ВОИС, её государствами-членами и всеми заинтересованными сторонами; и (ix) Эффективную структуру административно-финансовой поддержки, позволяющую ВОИС выполнять свои программы. Всемирная Организация Интеллектуальной Собственности (ВОИС) является межправительственной организацией, входящей в систему Организации Объединённых Наций (ООН) в качестве специализированного агентства (с 1974). Штабквартира ВОИС расположена в Женеве, Швейцария. Была создана в соответствии с Международной Конвенцией об Учреждении Всемирной Организации Интеллектуальной Собственности, подписанной в 1967 с целью содействия охране произведений интеллектуального творчества. Всемирная Организация Интеллектуальной Собственности (ВОИС) является одним из 15 специализированных учреждений ООН. Расположена в Женеве. Ведает защитой интеллектуальной собственности (авторское право, товарные знаки, патенты) во всём мире путём сотрудничества между странами, а также различными союзами, образованными в рамках международных договоров и занимающихся правовыми и административными аспектами интеллектуальной собственности. Всемирная Организация Интеллектуальной Собственности (ВОИС) – международная организация, созданная на основании Конвенции, принятой на состоявшейся в 1967 в Стокгольме дипломатической конференции государств-членов Парижского Союза По Охране Промышленной Собственности, Бернского Союза По Охране Произведений Литературы И Искусства и других специальных союзов. Парижский и Бернский союзы полностью автономны в вопросах, относящихся к их компетенции. ВОИС провозгласила

своей задачей поощрение творческой деятельности человека, содействие охране интеллектуальной собственности во всём мире, а также модернизацию и повышение эффективной деятельности отдельных международных организаций и союзов в области промышленной собственности (Парижский Союз) и охраны произведений литературы и искусства (Бернский Союз). Деятельность ВОИС распространяется на все виды интеллектуальной собственности:- права на литературные, художественные и научные произведения, охрана исполнительской деятельности артистов, изобретений, научных открытий, промышленных образцов и так далее. Высший орган ВОИС – Генеральная Ассамблея, состоящая из государств-участников Конвенции, которые являются членами какого-либо союза. Кроме того, созывается конференция государств-участников Конвенции, независимо от их членства в том или ином союзе. Образуется Координационный Комитет, состоящий из государств-членов исполкомов Парижского и Бернского союзов. Административный орган ВОИС – Международное Бюро (в Женеве, Швейцария). Бывший Союз Советских Социалистических Республик (СССР) ратифицировал Конвенцию Об Образовании ВОИС 19 Сентября 1968; на 01 Января 1971 Конвенцию ратифицировали также Болгария, Белорусская Советская Социалистическая Республика (БССР), Великобритания, Венгрия, ГДР, Дания, Израиль, Ирландия, Испания, Канада, Малави, Румыния, Сенегал, США, Украинская Советская Социалистическая Республика (УССР), Финляндия, ФРГ, Швеция, Швейцария, Чад, Чехословакия. 29 государств присоединились к Конвенции на основе Статьи 21(2) на 5 лет.

WORLD INVESTIBLE WEALTH = МИРОВОЕ ИНВЕСТИРУЕМОЕ БОГАТСТВО – World Investible Wealth is the part of world wealth that is traded and is therefore accessible to investors. World Investible Wealth:- the percentage of the global GDP that is available for investment. The world investible wealth includes all things of value that may be bought and sold for investment purposes. Examples include securities, commodities, real estate, and others. / Мировое Инвестируемое Богатство – часть мирового богатства, становящаяся доступной инвесторам в процессе торгов.

WORLD MARK = ВСЕМИРНЫЙ ЗНАК (или МИРОВАЯ МАРКА) – How to Design a Wordmark? A Wordmark is a logo without pictures, and it's hard to believe it's so easy! A logo without symbols or pictures is called a Wordmark, and it is easier to make than any other kind. Wordmarks are the most widely used of all logos:- In fact, many of the largest companies use them. Like any logo, a wordmark is a symbol of something. Before you begin, take time to consider what that something is. What is the company you are trying to represent? Is it a thing or a person? Does it manufacture a product or provide a service? Who is its market? You want these answers because as you work, you'll find the lure of new and interesting graphics can lead you into blind alleys – it's easy to wind up with an enchanting logo that has little to do with the company's actual needs. The more you know about the company, therefore, the less likely you'll wander. Word Mark is a type of trademark comprised of text. A Wordmark, Word Mark or Logotype is usually a distinct text-only typographic treatment of the name of a company, institution, or product name used for purposes of identification and branding. Examples can be found in the graphic identities of the Government of Canada, FedEx, Google, and Wikipedia. The organization name is incorporated as a simple graphic treatment to create a clear, visually memorable identity. The representation of the word becomes a visual symbol of the organization or product. In the United States and European Union, a wordmark may be registered, making it a protected intellectual property. In the United States, the term wordmark may not only refer to the graphical representation, but the text itself may be a type of trademark. / ФэдЭкс (FedEx), Гугл (Google), и Википидиа (Wikipedia). Под Логотипом, от древне–Греческих слов Логос (Logos), означающее Значение или Слово или Смысл, и Типос (Typos), означающее Отпечаток, понимается элемент фирменного стиля, представляющий собой уникальное начертание полного или сокращённого наименования компании. В логотипе помимо самих букв могут использоваться дополнительные графические элементы, являющиеся частью надписи.

WORLD MARKET = МИРОВОЙ РЫНОК – World Market:- the aggregate of all national markets, seen as linked through mutual economic and trade relations. In its initial form, the world market was based on the capitalist mode of production and was the world capitalist market. At the present stage, the world market takes in the full international division of labor as practiced between the world's two socioeconomic systems. The world market has expanded in scale as social production has become increasingly internationalized. The victory of the Great October Socialist Revolution in Russia in 1917 and the formation of the world socialist economic system and of the world socialist market as components of the world market have curbed monopoly capital's formerly unchallenged power to dictate over the world market. New trends in trade relations, both between socialist states and between states with differing socioeconomic systems, can now develop and expand within the overall world economy. In the early 1970's, the socialist countries accounted for over 10 percent of world trade volume; of this amount, approximately two-thirds represented trade between socialist countries and one-third was trade involving nonsocialist countries. As the majority of the world's colonies achieved political independence after World War II, the quick development of firm and friendly trade and economic relations between these countries and the world socialist system created significant new possibilities for the success of an anti-imperialist policy of pursuing economic independence within the world market. The socialist countries, along with progressive forces throughout the world, are fighting for the establishment of stable, truly equitable relations within the world market. This would further the development of relationships of mutual advantage, both in foreign trade and in the sphere of comprehensive industrial, technological, and scientific cooperation among all countries. In today's scientific and technological revolution, this would allow maximum utilization of the international division of labor. Such cooperation also constitutes a reliable material factor in the strengthening of peaceful relations among states. A particular feature of the world market at its present stage of development is the trend toward comprehensive long-term cooperation between countries with differing social systems, established through major intergovernmental agreements. Such agreements have been concluded by the USSR and other socialist countries since the early 1970's with many of the developing countries, as well as with a number of advanced capitalist states. Further prospects for progressive development of the world market are necessarily linked with the creation of conditions within that market which will strengthen peaceful coexistence between countries with differing social and political systems and which will expand the opportunities for all countries to enjoy the benefits of a mutually advantageous international division of labor. / Мировой Рынок, совокупность национальных рынков отдельных стран, связанных друг с другом торгово-экономическими отношениями. Сформировался впервые на базе капиталистического способа производства как мировой капиталистический рынок. В современную эпоху охватывает все основные направления международного разделения труда двух мировых социально-экономических систем. Масштабы развития мирового рынка отражают степень развития процесса интернационализации общественного производства. Победа Великой Октябрьской Социалистической Революции в России в 1917, образование мировой социалистической системы хозяйства (смотрите Мировая Система Социализма) и мирового социалистического рынка как части мирового рынка способствовали ограничению прежнего всевластия и диктата монополистического капитала на мировой рынок, привели к возникновению и укреплению в рамках глобальной мировой экономики (смотрите Мировое Хозяйство) новых направлений международных торговых связей как на рынке социалистических стран, так и между государствами, относящимися к различным социально-экономическим системам. В начале 1970-х на социалистические страны приходилось свыше 10% мирового товарооборота, из них примерно 2/3 составляла взаимная торговля стран социализма, 1/3 – их торговля с несоциалистическими странами. Завоевание после 2-й Мировой Войны (1939–45) большинством стран колониального мира политической самостоятельности, быстрое развитие и упрочение их дружественных торгово-экономических связей с мировой социалистической системой открывают принципиально новые возможности для

успешной антиимпериалистической борьбы за проведение независимой экономической политики на мировом рынке. Страны социализма, все прогрессивные силы мира борются за установление на мировом рынке устойчивых, подлинно равноправных отношений. Они добиваются развития на этом рынке взаимовыгодных отношений как во внешней торговле, так и в сфере всестороннего промышленного, технического и научного сотрудничества всех стран мира, которое в условиях современной научно-технической революции позволяет в наибольшей мере использовать преимущества международного разделения труда. Такое сотрудничество представляет собой также фактор надёжного материального закрепления мирных отношений между государствами. Особенностью современной фазы развития мирового рынка является переход на основе межгосударственных соглашений к комплексному и долгосрочному сотрудничеству между странами, относящимися к различным общественным системам. Такого рода соглашения были заключены бывшим Союзом Советских Социалистических Республик (СССР) и другими социалистическими государствами со многими развивающимися странами, а в начале 1970-х и с рядом развитых капиталистических государств. Дальнейшие перспективы прогрессивного развития мирового рынка неразрывно связаны с созданием на нём условий, способствующих укреплению мирного сосуществования стран с различным общественно-политическим строем, улучшению возможности использования всеми странами преимуществ взаимовыгодного международного разделения труда. WORLD MARKET PRICE = МИРОВАЯ РЫНОЧНАЯ ЦЕНА – World Market Price:- such prices are indications and are offered for general guidance purposes only. See also Adjusted World Price (AWP), Market Price, and Prevailing World Market Price. The market price is the price at which a good or service is bought and sold most efficiently. / Мировая Рыночная Цена – денежное выражение международной стоимости товара, реализуемого на мировом рынке. Мировые Цены, денежное выражение интернациональной (мировой) цены производства, складывающейся на мировом рынке. Интернациональная цена производства определяется условиями производства преобладающей в мировой торговле массы товаров. В условиях современного капитализма по мировым ценам осуществляются крупные коммерческие экспортные или импортные операции, имеющие регулярный характер и предусматривающие платежи в свободно конвертируемой валюте. Переход капитализма свободной конкуренции к монополистическому и государственно-монополистическому капитализму углубил отделение внутренних цен капиталистических государств от их внешнеторговых цен. Для промышленно развитых стран капитализма характерен более высокий уровень внутренних цен по сравнению с мировыми ценами, что объясняется многочисленными причинами. Важнейшие из них – взвинчивание внутренних цен монополиями в условиях более монополизированного внутреннего рынка в сравнении с внешним и протекционистские мероприятия буржуазных правительств. Современное капиталистическое государство охраняет устанавливаемые монополиями на внутреннем рынке уровни и пропорции цен с помощью таможенных пошлин, ограничений импорта, демпинга, валютного режима, налогообложения и так далее. На мировом рынке воздействие монополий и вмешательство государства проявляются значительно слабее. В процессе формирования мировых цен, протекающем в условиях более острой конкурентной борьбы, чем на внутренних рынках, происходит ‘очищение’ внутренних цен от таможенных пошлин, налогов, различных субсидий и иных наращений. В развивающихся странах, ввиду их однобокой специализации на производстве нескольких товаров, внутренние цены ниже мировых цен, что даёт возможность монополиям присваивать значительную часть этой разницы. Практически мировые цены на готовые изделия – это экспортные цены фирм, являющихся основными поставщиками данного вида изделий. Мировой ценой на сырьё по одним товарам являются цены важнейших стран-экспортёров или стран-импортёров, по другим – цены бирж, аукционов и других крупных центров международной торговли. На современном этапе общего кризиса капитализма под влиянием как экономического, так и неэкономического факторов усиливается дифференциация цен в международной торговле. Активизация деятельности различных правительственных и полуправительственных организаций капиталистических стран после 2-й Мировой Войны (1939–45), влияние валютных факторов, повышение роли международных монополий в мировой капиталистической экономике привели к тому, что в международной торговле, помимо рыночных мировых цен, сложились следующие виды цен:- по обычным коммерческим сделкам с платежом в несвободно конвертируемой валюте; по клиринговым соглашениям; по программам помощи и другим специальным операциям; трансфертные цены, по которым осуществляются внутрикорпорационные операции. Создаваемые монополиями разных стран мощные международные финансовые промышленные комплексы превращают значительную часть экспорта и импорта товаров отдельных стран в планируемые внутрикорпорационные операции, а их экспортные и импортные цены – во внутренние расчётные цены, устанавливаемые концернами. Цены мирового социалистического рынка не могут формироваться в отрыве от мировых цен. По этим ценам осуществляется торговля социалистических стран с капиталистическими. Кроме того, они принимаются в качестве базы при формировании цен в торговле между социалистическими странами. В этом случае мировые цены корректируются таким образом, чтобы устранить, по возможности, воздействие долговременных факторов, обусловливающих отклонение их от мировой цены производства (например, разного рода монопольных сговоров), а также исключить влияние конъюнктурных и спекулятивных факторов.

WORLD PETROLEUM CONGRESS = ВСЕМИРНЫЙ НЕФТЯНОЙ КОНГРЕСС – World Petroleum Congress (WPC):- International efforts to standardize the definitions of petroleum resources and how they are estimated began in the 1930s. Early guidance focused on Proved Reserves. Building on work initiated by the Society of Petroleum Evaluation Engineers (SPEE), SPEE published definitions for all Reserves categories in 1987. In the same year, the World Petroleum Council (WPC, then known as the World Petroleum Congress), working independently, published Reserves definitions that were strikingly similar. In 1997, the two organizations jointly released a single set of definitions for Reserves that could be used worldwide. In 2000, the American Association of Petroleum Geologists (AAPG), SPEE, and WPC jointly developed a classification system for all petroleum resources. This was followed by additional supporting documents:- supplemental application evaluation guidelines (2001) and a glossary of terms utilized in resources definitions (2005). SPEE also published standards for estimating and auditing reserves information (revised 2007). The World Petroleum Council (WPC) is the only global organisation that represents all aspects of the petroleum industry, with the purpose of providing networking opportunities in a global forum; common understanding of issues and challenges; co-operation (partnerships) with other organizations; promotion of science/technology/social issues/economics/R&D/management and the environment; a showcase for the industry; a forum for developing business opportunities; and information dissemination (congresses, reports, regional meetings and workshops). The WPC is recognized by all stakeholders as a proactive leader for the petroleum industry that benefits society’s expectations for sustainable energy. / Всемирный Нефтяной Конгресс (ВНК; World Petroleum Congress (WPC)) – международный форум специалистов в области геологии нефти и газа, разведки и разработки их месторождений, переработки и транспортировки углеводородного сырья. Сессии проводятся с 1933 раз в 3 года.

WORLD PETROLEUM COUNCIL = ВСЕМИРНЫЙ НЕФТЯНОЙ СОВЕТ – In 1987, the World Petroleum Council (WPC, formerly World Petroleum Congresses) published its report ‘Classification and Nomenclature Systems for Petroleum and Petroleum Reserves’, which included definitions for all categories of resources. The WPC report, together with definitions by other industry organizations and recognition of current industry practice, provided the basis for the system outlined by the combined organizations. Nothing in the resource definitions should be construed as modifying the existing definitions for petroleum reserves as approved by the SPE/WPC in

March 1997. Petroleum Resources Management System:- approved by the Society of Petroleum Engineers (SPE) Board in March 2007, this system for defining reserves and resources was developed by an international group of reserves evaluation experts and endorsed by the World Petroleum Council, the American Association of Petroleum Geologists, the Society of Petroleum Evaluation Engineers, and the Society of Exploration Geophysicists. The WPC is dedicated to the promotion of sustainable management and use of the world's oil, gas and other energy resources for the benefit of all. WPC's 70 member countries represent over 96% of the world's oil and gas consumption and production. Headquartered in London, the United Kingdom. The intention of organising the World Petroleum Congress is not only to promote a sustainable energy future but to leave a positive effect on the local community of the host country and a long lasting legacy for its environment. The host country for a World Petroleum Congress gets selected by the WPC Council in a secret electronic ballot vote four years prior to the scheduled event. Each member country receives one vote and can cast it for one of the nominated candidate countries after their year-long campaign.The organisation and logistics for the next Congress then become the responsibility of the Host, with the World Petroleum Council retaining the final approval and the responsibility for the programme content. The WPC carries out its responsibilities via the permanent secretariat and its working committees. One of the principles of organising the World Petroleum Congress is not only to organize a world class event and then move on to the next venue, but to enrich the local host community and to leave an enduring legacy. The surplus of each event is designed to go towards funding the seeds of a country legacy project proposed by the Host and agreed with the WPC and the Council. The WPC cooperates closely with a wide range of stakeholders in the oil and gas sector, including industry associations, international institutions, petroleum institutes, non-governmental organizations (NGOs) and the United Nations (UN):- United Nations Framework Classification (UNFC), United Nations Economic Commission for Europe (UNECE), Global Compact; International Energy Agency (IEA); Organisation for Petroleum Exporting Countries (OPEC); Oil and Gas Producers Association (OGP); International Petroleum Industry Environmental Conservation Association (IPIECA); International Standards Organisation (ISO); International Gas Union (IGU); Associations and Institutions from WPC member countries; Society of Petroleum Engineers (SPE); American Association of Petroleum Geologists (AAPG); European Association of Geological Engineers (EAGE); The World Coal Institute (WCI); The World Energy Council (WEC); The World Bank/IMF; Columbia University – Earth Sciences; Asistencia Reciproca Petrolera Estatal Latinoamericana (ARPEL); Petrofed; Transparency International; and many others. The World Petroleum Council (WPC) was founded in London in 1933. It is an international, unbiased, non-political organisation that provides a forum for discussing world issues facing the oil and gas industry. The WPC is dedicated to scientific advances in the oil and gas industries, technology transfer and the promotion of the management of the world's petroleum resources for the benefit of mankind. Every three years, the World Petroleum Council hosts an international oil and gas congress hosted by one of its member countries. The 19th World Petroleum Congress will take place in Madrid in June 2008, 20th – in Doha in 2011, 21st – in Moscow in June 2014, 22nd – in Istanbul in July 2017. Trends and outlooks integral to the future success of the industry are the focus of discussions, forums and presentations. Delegates explore international business opportunities, exchange ideas on global issues, network and share the latest information on technology, business management and industry developments. High-level government delegations from member countries and thousands of delegates usually attend the congresses. WPC Vision, Mission, Values and Principles:- Vision:- an enhanced understanding and image of the oil and gas sector's contribution to sustainable development. Mission:- the World Petroleum Council (WPC) is the only organisation representing the global oil and gas community. WPC's core value and purpose centres on sustaining and improving the lives of people around the world, through:- (i) Enhanced understanding of issues and challenges; (ii) Networking opportunities in a global forum; (iii) Cooperation (partnerships) with other organisations; (iv) An opportunity to showcase the industry and demonstrate best practice; (v) A forum for developing business opportunities; (vi) Information dissemination via congresses, reports, regional meetings and workshops; (vii) Initiatives for recruiting and retaining expertise and skills to the industry; and (viii) Awareness of environmental issues, conservation of energy and sustainable solutions. Values:- WPC values strongly:- (i) Respect for individuals and cultures worldwide; (ii) Unbiased and objective views; (iii) Integrity; (iv) Transparency; (v) Good governance; (vi) A positive perception of energy from petroleum; (vii) Science and technology; (viii) The views of all stakeholders; and (ix) The management of the world's petroleum resources for the benefit of all. Principles:- WPC seeks to be identified with its mission and flexible enough so that it can embrace change and adapt to it. WPC has to be:- (i) Pro-active and responsive to changes and not merely led by them; (ii) Creative and visionary, so that we add value for all; (iii) Challenging, so that our goals require effort to attain but are realistic and achievable; (iv) Focused, so that our goals are clear and transparent; and (v) Understandable to all. Key strategic areas:- (i) World Class Congress to deliver a quality, premier world class oil and gas congress. (ii) Inter-Congress activities to organize forums for cooperation and other activities on specific topics; and to organise regional events of relevance to WPC members and all stakeholders. (iii) Cooperation with other stakeholders to add value by cooperating with other organisations to seek synergies and promote best practice. (iv) Communication to increase awareness, of WPC's activities, through enhanced communication, both internally and externally. (v) Global representation to attract and retain worldwide involvement in WPC. (vi) Youth and gender engagement to increase the participation of young people and women in oil and gas issues, including the establishment of a dedicated Youth Committee for the development of active networking opportunities with young people. (vii) Legacy to create a central WPC legacy fund to benefit communities and individuals around the world based on WPC's mission. / Асистэнсиа Рэсипрока Эстаталь Латиноамэрикана (Asistencia Reciproca Petrolera Estatal Latinoamericana (ARPEL)), Пэтчрофэд (Petrofed). Первый Всемирный Нефтяной Конгресс состоялся в Лондоне в 1933.

WORLD PRICE = МИРОВАЯ ЦЕНА – World Price is:- (1) the price at which commodities will move in international trade under existing marketing conditions. The concept 'world price' lacks precision unless quality, location, and other factors are specified. See also Adjusted World Price (AWP), and Prevailing World Market Price. (2) The Free on Board (FOB) price of an exported agricultural commodity, with specific characteristics, at the principal port of deportation of a major exporting country or area. See also Border Price, Domestic Price, and Reference (Border) Price. In agricultural business, World Price often refers to the CIF (Cost, Insurance, and Freight) price of an imported agricultural commodity at the principal port of importation of a major importing country or area. The World Price is set by the supply and demand for imports. With an optimal tariff, the world price falls because the higher domestic price due to the tariff causes consumers to purchase less. So, even though consumers are paying a higher price because of the tariff, the nation gains because it is able to purchase the product from other countries at a lower world price. Import quotas would cut imports first. The decrease in supply would raise the price causing domestic firms to increase production. / привоз (importation). В сельскохозяйственном бизнесе, часто относится к цене привозимого (или импортируемого) сельскохозяйственного сырья на условиях CIF (Цена, Страхование и Фрахт) ведущий порт ввоза главных стран-импортёров или региона привоза (или импорта). Под Мировыми Ценами понимается денежное выражение мировой цены производства, определяемой условиями производства основной массы товаров мирового рынка. В современных условиях по мировым ценам осуществляются вывозные (или экспортные) или привозные (или импортные) операции, имеющие регулярный характер и предусматривающие платежи в свободно конвертируемой (обратимой) валюте. Мировые цены принимаются также в качестве базовых при формировании цен мирового рынка. Под Мировой Ценой понимается цена, по которой данный товар продаётся в международной торговле в условиях наличия рыночных отношений в момент продажи. Мировая Цена служит для определения цен международных контрактов, по которым заключается большинство торговых сделок в мире. Мировые Цены (в международной торговле) – цены крупных, систематических и устойчивых вывозных (или экспортных) или привозных (или

импортных) сделок, совершаемых на обычных коммерческих условиях в основных центрах международной торговли известными фирмами-экспортёрами и импортёрами соответствующей продукции. Мировая Цена (в экономической теории) – международная цена на товар или услугу, определяемая на основе соотношения мирового спроса и предложения. Мировые Цены – цены, обслуживающие международный рынок в целом и наиболее полно отражающие конъюнктуру товаров и услуг в масштабе общего мирового рынка.

WORLD RESERVE = МИРОВОЙ РЕЗЕРВ (или ВСЕМИРНЫЙ РЕЗЕРВ) – World Reserve:- xxxxx. / Мировой Резерв:- на аукционе минимальная цена, которую комитент может установить за всю коллекцию, представляя аукционисту возможность отклонений по отдельным предметам. Следовательно, если один предмет привлекает цену предложения победителя выше суммы, необходимой для создания резерва, это превышение может использоваться по отношению к другому предмету, что позволяет его продать за меньшую сумму.

WORLDSCALE = ВОРЛДСКЭЙЛ (или МИРОВАЯ ШКАЛА) – Worldscale is a unified system of establishing payment of freight rate for a given oil tanker's cargo. Worldscale was established in November 1952 by London Tanker Brokers' Panel on the request of British Petroleum and Shell as an average total cost of shipping oil from one port to another by ship. A large table was created. The same scale is used today, although it was merged with the American Tanker Rate Schedule (ATRS) in 1969. By 2002, the table included the average cost of 320 000 voyages in permutations of from one load and one discharge port to five loads and ten discharge ports. Worldscale is produced by Worldscale Association (NYC) Inc. (New York, the United States of America) for the Americas and by Worldscale Association (London) Limited (London, the United Kingdom) for the rest of the world. The freight for a given ship and voyage is normally expressed in a percentage of the published rate and is supposed to reflect the freight market demand at the time of fixing. In negotiating a price to pay, each freight rate in USD/ton is referred to as WS100 or 100% of Worldscale. The actual price negotiated between shipowner and charterer can range from 1% to 1 000% and is referred to respectively as WS1 to WS1000, depending on how much loss the first is willing to take on that voyage and how much the latter is willing to pay. An index representing the cost of time chartering a tanker for a specific voyage at a given time. The index is given at Worldscale 100, which represents the price in Dollars per ton for carrying the oil at that rate. The negotiated rate will be some percentage of the index value. Worldscale (WS) is the standard system for assessing freight rates. Once a year, a set of base charter rates is published for a theoretical standard vessel plying its trade between each of the world's most common origins and destinations. Spot freight rates are commonly expressed as percentages of those theoretical rates. Thus, if very large crude carrier rates are said to be WS67, actual rates are two-thirds of the base or flat rates published at the beginning of the year. Worldscale Association. The concept of freight rate schedules is over 40 years old and originated during the 1939–45 war. Before the war, rates of freight for tanker voyage charters were expressed in Dollars or Shillings and Pence per long ton (there were twenty Shillings to a pound, 12 Pence in a Shilling) and this meant that when a charterer required wide loading or discharging options it was necessary to agree many rates of freight. During the war, first the British Government and later the US Government requisitioned shipping and Owners received compensation on the basis of a daily hire rate. However, from time to time, the Government were able to make requisitioned tankers available on a voyage basis to the major oil companies for their private use particularly during the period from the end of hostilities until control of shipping was relinquished. On such occasions, the oil companies paid freight to the government concerned and the rate of freight, which was dependent upon the voyage performed, was determined in accordance with a scale or schedule of rates laid down by that government. The rates were calculated so that, after allowing for port costs, bunker costs and canal expenses, the net daily revenue was the same for all voyages. Here then was the genesis of the principle for tanker rate schedules, namely the Owners should receive the same net daily revenue irrespective of the voyage performed. The last schedule of tanker voyage rates to be issued by the British Ministry of Transport gave rates effective 01 January 1946 and this schedule became known simply as 'MOT'. Similarly, the last rates to be issued by the United States Maritime Commission, which took effect from 01 February 1946, became known as 'USMC'. In fact, government control of shipping continued until 1948 and by that time the tanker trade had come to recognise the advantages of freight rate schedules and therefore, in the free market, the system evolved of negotiating in terms of MOT or USMC plus or minus a percentage as dictated by the demand/supply position in the market. Between 1952 and 1962 a number of different schedules were issued as a service to the tanker trade by non-governmental bodies; Scales Nos. 1, 2 and 3 and then Intascale in London, ATRS in New York. Then in 1969 there came the joint London/New York production issued to replace both Intascale and ATRS called the 'Worldwide Tanker Nominal Freight Scale', more usually know under its code name 'Worldscale'. The full name is mentioned because it provides the opportunity to stress the word 'nominal' and to emphasize that it was only during the period of government control that the schedule rates were intended to be used as actual rates. Subsequently, it has been freely negotiated percentage adjustments to the scale rates that has determined the actual rate used for the payment of freight. Incidentally, with the introduction of Worldscale, it became the custom to express market levels of freight in terms of a direct percentage of the scale rates instead of a plus or minus percentage. This method is known as 'Points of Scale' and thus Worldscale 100 means 100 points of 100 per cent of the published rate or, in other words, the published rate itself, sometimes referred to as Worldscale Flat, while Worldscale 250 means 250 points or 250 per cent of the published rate and Worldscale 30 means 30 points or 30 per cent of the published rate. Under the older method these would have been referred to as plus 150 per cent and minus 70 per cent respectively. During its life span, from September 1969 until the end of 1988, Worldscale was regularly revised for changes in bunker prices and port costs but the fixed daily hire element of USD1 800 remained constant. Finally, to bring the story up to date, 'New Worldscale' was introduced with effect from 01st January 1989. However, in deference to the custom that emerged in the trade, the epithet 'new' was soon dropped and now it is generally understood that 'Worldscale' refers to the new scale, while the previous scale is called 'Old Worldscale'. Until the introduction of Old Worldscale, the various scales issued in London were all based on the old MOT rate of 32/6d (thirty two shillings and six pence) for the voyages Curacao to London. Indeed, the daily hire element of USD1 800 used for Old Worldscale was indirectly related to that rate in so far as this, at the rate of exchange of £1/$2.40 (as applied in 1969), was close to the sterling hire rate for its immediate predecessor Intascale. It was only when a replacement for Old Worldscale was being considered that systematic attempt was made to establish, by a series of lengthy exercises, the size of standard vessel and the relevant daily hire element that would provide the best practicable basis for a scale. It was concluded, from the results of these exercises, that a standard vessel with a carrying capacity of 75 000 tons and a daily hire element of USD12 000 was likely to provide such a basis for a scale to be used during the 1990s. Both 'Worldscales' are the joint endeavour of two non-profit making organisations know as Worldscale Association (London) Limited and Worldscale Association (NYC) INC. NYC standing of course for New York City. Each company is under the control of a Management Committee, the members of which are senior brokers from leading tanker broking firms in London and New York respectively. Worldscale is available on a subscription basis and the annual fee entitles the subscriber not only to the Schedule itself but also to notices of all amendments and the right to request rates for any voyage not shown in the Schedule. International freight index for tankers. A method of calculation of payment for the transport of oil by ships, for a single or several consecutive voyages. Worldscale is a table giving the amount of USD per ton oil for a number of standard routes. The rates listed in the table, so called flat rates termed WS100, are revised annually. / Бритиш Пэтчролиэм (British Petroleum) и Щел (Shell). ВорлдСкэйл – международная фрахтовая шкала для нефтеналивных судов стандартного водоизмещения. Устанавливается один раз в год в Долларах США на одну тонну по определённому маршруту и

используется в процессе переговоров при заключении контракта на перевозку нефти (умножается на текущую котировку фрахта, выраженную в процентах). WS – это Worldscale – нечто вроде котировок нефти от Platt's, но для фрахта нефти. Их несколько в мире, самая употребимая – Лондонская. Родилась во времена Второй Мировой Войны, как способ дать по рукам воюющим правительствам, которые хотели все возить на халяву, а не за справедливый фрахт. Если не запамятовал, WS квотируется для сырой нефти на 75-тысячнике, но это можно уточнить. Применяются WS как правило при длительном контракте с целью избежать базара на каждый вояж. Применяется в виде например – 'freight rates:- WS130' – это значит, что вот для этого груза, вот для этого клиента и на вот этот срок мы договорились брать при оплате ставку WS и умножать её на 1.3. Worldscale – появился в результате особенностей торговли нефтью и нефтепродуктами, когда необходим широкий диапазон портов погрузки и выгрузки. Существует понятие Flat (Flat = WS100) на направлении, то есть скажем на направлении Приморск–Роттердам флэт равен 4.21 Доллара за тонну нефти, а на направлении Новороссийск–Марсель флэт равен, например, 5.55 Долларов за тонну. И тип судна не имеет влияния на значение флэта. Если говорят, что уровень ставок из Приморска на Роттердам равен WordlScale 300, это значит, что перевезти тонну нефти стоит 12.63 Доллара за тонну. Flat по направлениям корректируется по результатам года и издаётся ежегодно достаточно дорогой книгой. МироваяШкала (МШ) – шкала базисных ставок фрахта на перевозки нефтеналивных грузов. Международные перевозки ещё с 1940-х оплачиваются по международным тарифам. Содержание судна в пути в среднем обходится около USD1.5 тысяч в сутки (затраты на топливо, зарплату команды, смазочные материалы, расход воды, амортизацию), на стоянке – приблизительно в USD1 000 в сутки. Ни судовладельцы, ни грузовладельцы друг друга обычно не знают. Для того, чтобы свести их вместе, существуют фрахтовые конторы. Фрахтовому брокеру, комиссия которого составляет в среднем 2% от суммы сделки, предоставляются все необходимые полномочия на фрахтование судна. Ориентировочные ставки фрахта определяются по Worldscale, которая содержит средние ставки за каждый прошедший год по определённым направлениям. При заключении сделки на морскую перевозку в чарт (договор на морскую перевозку) вносится либо конкретная сумма фрахта в Долларах за тонну, либо процент к ставке Worldscale. На величину ставки фрахта оказывают влияние множество факторов, в том числе тоннаж груза, направления перевозок, сроки погрузки-выгрузки. Ставки по шкале Worldscale (Worldwide Tanker Nominal Freight Scale) отражают отношение цены на перевозку к базовому тарифу, устанавливаемому Worldscale Association раз в год. Шкала Worldscale, это номинальная ставка WS100 по нескольким базовым машрутам и обьёмам партий грузов. Эта ставка устанавливается каждый год Ассоциацией Worldscale в Лондоне, и расчитывается в Долларах за тонну. Ставка расчитывается не для различных типов танкеров, а для маршрутов и обьёмов. Например, существующая ставка WS100 на маршруте Басра – Сингапур, это 10 Долларов за перевозку 1 тонны нефти. Танкер класса VLCC берётся перевезти 270 000 тонн из Басры в Сингапур по WS70, и общая сумма фрахта составит 1 890 000 Долларов – 70% от 10 Долларов/тонна, умноженных на 270 000 тонн. Суэцмакс на том же маршруте берётся перевезти 150 000 тонн по WS155, фрахт составит 232 500 Долларов – 155% от 10 Долларов, умноженных на обьём партии 150 000. Среднесуточная ставка вычисляется делением общей суммы фрахта на количество дней рейса, включая время возвращения и балластного пробега, а также время в портах, то есть в вышеприведённых примерах время в пути Басра – Сингапур – Басра, плюс стоянки в этих портах под грузовыми операциями.

WORLD TRADE CENTER = ВСЕМИРНЫЙ ТОРГОВЫЙ ЦЕНТР – World Trade Center:- complex of several buildings around a central plaza in New York City that in 2001 was the site of the deadliest terrorist attack in American history. The complex – located at the Southwestern tip of Manhattan, near the shore of the Hudson River and a few blocks Northwest of Wall Street – was built by the Port Authority of New York and New Jersey as a central facility for businesses and government agencies involved in international trade. Until the 2001 attack, it was notable for its huge twin towers, each of which had 110 stories. The roof of One World Trade Center reached to 1 368 feet (417 meters), and Two World Trade Center was 1 362 feet (415 meters) tall. Designed by Minoru Yamasaki and officially opened in 1972, the towers were the world's tallest buildings until surpassed in 1973 by the Sears Tower in Chicago. (See Researcher's Note:- Heights of Buildings.) Each of the twin towers had 97 passenger elevators, 21 800 windows, and roughly an acre (0.4 hectare) of rentable space per floor. An observation deck was situated on the 107th floor of the South Tower (Two World Trade Center), and a television-broadcasting mast 360 feet (110 meters) high was attached to the North Tower (One World Trade Center). Prior to 2001 the complex had sustained a major terrorist attack. On February 26, 1993, a large bomb planted by terrorists exploded in the underground garage of Two World Trade Center, damaging the base of the building (subsequently repaired), killing 6 people, and injuring some 1 000. The attack that occurred on September 11, 2001, was much more destructive. Hijackers deliberately flew two commercial airliners into the towers, the first striking the north tower at 08:46 am (local time) and the second hitting the south tower at 09:03. Badly damaged and engulfed in flames, the weakened south tower collapsed at 09:59; the north tower fell about a half hour later. Debris from the towers also destroyed or damaged other buildings in and around the complex. Some 2 800 people were killed. / Река Хадсэн (Hudson River). Минорю Ямасаки (Minoru Yamasaki).

WORLD TRADE ORGANIZATION = ВСЕМИРНАЯ ОРГАНИЗАЦИЯ ТОРГОВЛИ – The World Trade Organization (WTO) is the only global international organization dealing with the rules of trade between nations. At its heart are the WTO agreements, negotiated and signed by the bulk of the world's trading nations and ratified in their parliaments. The goal is to help producers of goods and services, exporters, and importers conduct their business. Established:- 01 January 1995. Created by:- Uruguay Round negotiations (1986–94). Membership:- 159 countries on 02 March 2013 (162 countries on 30 November 2015). Budget:- 196 million Swiss Francs for 2011. Secretariat staff:- 640. Head:- Mr Pascal Lamy (Director-General). Functions:- (i) administering WTO trade agreements; (ii) forum for trade negotiations; (iii) handling trade disputes; (iv) monitoring national trade policies; (v) technical assistance and training for developing countries; and (vi) cooperation with other international organizations. The World Trade Organization (WTO) is the intergovernmental organisation regulating international trade, providing a framework for negotiating trade agreements, and acting as dispute resolution process. The WTO was created by the Uruguay Round agreement and officially commenced in 1995. World Trade Organization (WTO):- international organization established to supervise and liberalize world trade. The WTO is the successor to the General Agreement on Tariffs and Trade (GATT), which was created in 1947 in the expectation that it would soon be replaced by a specialized agency of the United Nations (UN) to be called the International Trade Organization (ITO). Although the ITO never materialized, the GATT proved remarkably successful in liberalizing world trade over the next five decades. By the late 1980s there were calls for a stronger multilateral organization to monitor trade and resolve trade disputes. Following the completion of the Uruguay Round (1986–94) of multilateral trade negotiations, the WTO began operations on January 01, 1995. Origins:- the ITO was initially envisaged, along with the International Monetary Fund (IMF) and the World Bank, as one of the key pillars of post-World War II reconstruction and economic development. In Havana in 1948, the UN Conference on Trade and Employment concluded a draft charter for the ITO, known as the Havana Charter, which would have created extensive rules governing trade, investment, services, and business and employment practices. However, the United States failed to ratify the agreement. Meanwhile, an agreement to phase out the use of import quotas and to reduce tariffs on merchandise trade, negotiated by 23 countries in Geneva in 1947, came into force as the GATT on January 01, 1948. Although the GATT was expected to be provisional, it was the only major agreement governing international trade until the creation of the WTO. The GATT system evolved over 47 years to become a de facto global trade organization that eventually involved approximately 130 countries. Through various negotiating rounds, the GATT was extended or

modified by numerous supplementary codes and arrangements, interpretations, waivers, reports by dispute-settlement panels, and decisions of its council. During negotiations ending in 1994, the original GATT and all changes to it introduced prior to the Uruguay Round were renamed GATT 1947. This set of agreements was distinguished from GATT 1994, which comprises the modifications and clarifications negotiated during the Uruguay Round (referred to as Understandings) plus a dozen other multilateral agreements on merchandise trade. GATT 1994 became an integral part of the agreement that established the WTO. Other core components include the General Agreement on Trade in Services (GATS), which attempted to supervise and liberalize trade; the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS), which sought to improve protection of intellectual property across borders; the Understanding on Rules and Procedures Governing the Settlement of Disputes, which established rules for resolving conflicts between members; the Trade Policy Review Mechanism, which documented national trade policies and assessed their conformity with WTO rules; and four plurilateral agreements, signed by only a subset of the WTO membership, on civil aircraft, government procurement, dairy products, and bovine meat (though the latter two were terminated at the end of 1997 with the creation of related WTO committees). These agreements were signed in Marrakech, Morocco, in April 1994, and, following their ratification, the contracting parties to the GATT treaty became charter members of the WTO. By the early XXI century the WTO had more than 140 members. Objectives And Operation:- the WTO has six key objectives:- (1) to set and enforce rules for international trade, (2) to provide a forum for negotiating and monitoring further trade liberalization, (3) to resolve trade disputes, (4) to increase the transparency of decision-making processes, (5) to cooperate with other major international economic institutions involved in global economic management, and (6) to help developing countries benefit fully from the global trading system. Although shared by the GATT, in practice these goals have been pursued more comprehensively by the WTO. For example, whereas the GATT focused almost exclusively on goods – though much of agriculture and textiles were excluded – the WTO encompasses all goods, services, and intellectual property, as well as some investment policies. In addition, the permanent WTO Secretariat, which replaced the interim GATT Secretariat, has strengthened and formalized mechanisms for reviewing trade policies and settling disputes. Because many more products are covered under the WTO than under the GATT and because the number of member countries and the extent of their participation has grown steadily – the combined share of international trade of WTO members now exceeds 90 percent of the global total – open access to markets has increased substantially. The rules embodied in both the GATT and the WTO serve at least three purposes. First, they attempt to protect the interests of small and weak countries against discriminatory trade practices of large and powerful countries. The WTO's most-favored-nation and national-treatment articles stipulate that each WTO member must grant equal market access to all other members and that both domestic and foreign suppliers must be treated equally. Second, the rules require members to limit trade only through tariffs and to provide market access not less favorable than that specified in their schedules (i.e. the commitments that they agreed to when they were granted WTO membership or subsequently). Third, the rules are designed to help governments resist lobbying efforts by domestic interest groups seeking special favors. Although some exceptions to the rules have been made, their presence and replication in the core WTO agreements were intended to ensure that the worst excesses would be avoided. By thus bringing greater certainty and predictability to international markets, it was thought, the WTO would enhance economic welfare and reduce political tensions. Resolution Of Trade Disputes:- the GATT provided an avenue for resolving trade disputes, a role that was strengthened substantially under the WTO. Members are committed not to take unilateral action against other members. Instead, they are expected to seek recourse through the WTO's dispute-settlement system and to abide by its rules and findings. The procedures for dispute resolution under the GATT have been automated and greatly streamlined, and the timetable has been tightened. Dispute resolution begins with bilateral consultations through the mediation, or 'good offices', of the director-general. If this fails, an independent panel is created to hear the dispute. The panel submits a private draft report to the parties for comment, after which it may revise the report before releasing it to the full WTO membership. Unlike the IMF and the World Bank, both of which use weighted voting, each WTO member has only one vote. As in the earlier GATT system, however, most decisions are made by consensus. Unless one or both of the parties files a notice of appeal or the WTO members reject the report, it is automatically adopted and legally binding after 60 days. The process is supposed to be completed within nine months, and, if an appeal is lodged, the WTO Appellate Body hears and rules on any claim of legal error within 60 days. Appellate rulings are automatically adopted unless a consensus exists among members against doing so. Trade-Policy Reviews:- the WTO also seeks to increase awareness of the extent and effects of trade-distorting policies, a goal that it accomplishes through annual notification requirements and through a policy-review mechanism. Notices of all changes in members' trade and trade-related policies must be published and made accessible to their trading partners. For many developing countries and countries whose economies were formerly centrally planned, this requirement was a major step toward more transparent governance. The WTO reviews the trade policies of the world's four largest traders (the European Union, the United States, Japan, and Canada) once every two years, the policies of the 16 next largest traders once every four years, and the policies of all other traders once every six or more years. After extensive consultations with the member country under review, the WTO Secretariat publishes its review together with a companion report by the country's government. The process thus monitors the extent to which members are meeting their commitments and provides information on newly opened markets. It also provides a firmer basis for subsequent trade negotiations and the resolution of trade disputes. Assessment:- the pace of international economic integration via the GATT and WTO rounds of multilateral trade negotiations has been slower and less comprehensive than some members would prefer. Some have suggested that there should be additional integration among subgroups of (often neighboring) member economies – e.g., those party to the European Union, the North American Free Trade Agreement, and the Asia-Pacific Economic Cooperation – for political, military, or other reasons. Notwithstanding the most-favored-nation clauses in the agreements establishing the WTO, the organization does allow such preferential integration under certain conditions. Even though many such integration agreements arguably do not involve 'substantially all trade' – the WTO's main condition – there has been little conflict over the formation of free-trade areas and customs unions. The most common omissions from such agreements are politically sensitive sectors such as agriculture. Beginning in the late 1990s, the WTO was the target of fierce criticism. Opponents of globalization, and in particular those opposed to the growing power of multinational corporations, argued that the WTO infringes upon national sovereignty and promotes the interests of large corporations at the expense of smaller local firms struggling to cope with import competition. Environmental and labor groups (especially those from wealthier countries) have claimed that trade liberalization leads to environmental damage and harms the interests of low-skilled unionized workers. Protests by these and other groups at WTO ministerial meetings – such as the 1999 demonstrations in Seattle, Washington, US, which involved approximately 50 000 people – became larger and more frequent, in part because the development of the Internet and e-mail made large-scale organizing and collective action easier. In response to such criticism, supporters of the WTO claimed that regulating trade is not an efficient way to protect the environment and labor rights. Meanwhile, some WTO members, especially developing countries, resisted attempts to adopt rules that would allow for sanctions against countries that failed to meet strict environmental and labor standards, arguing that they would amount to veiled protectionism. Despite these criticisms, however, WTO admission remained attractive for nonmembers, as evidenced by the increase in the number of members after 1995. Most significantly, China entered the WTO in 2001 after years of accession negotiations. The conditions for Chinese membership were in some ways more restrictive than those for developing countries, reflecting the concerns of some WTO members that the admission of such a large and still somewhat planned economy might have an overall negative effect on free trade. Uruguay Round is the multilateral trade negotiations launched at Punta del Este, Uruguay in September 1986 and concluded in Geneva in December 1993.

Signed by Ministers in Marrakesh, Morocco, on 1994-April-15. World Trade Organization (WTO):- established January 01, 1995, as a result of the Uruguay Round. The legal and institutional foundation of the worldwide multilateral trading system. The WTO is the successor to the General Agreement on Tariffs and Trade (GATT), and provides the contractual obligations that guide how governments implement trade policy. The WTO provides the framework in which trade relations are negotiated and disputes adjudicated. The WTO differs from GATT in that it is a permanent commitment among its signatories, with rules that apply to trade in services and intellectual property as well as goods. An amended version of GATT is an integral part of the WTO Agreement. The World Trade Organization (WTO) or, in French, Organisation Mondiale du Commerce (OMC) is the only global international organization dealing with the rules of trade between nations. At its heart are the WTO agreements, negotiated and signed by the bulk of the world's trading nations and ratified in their parliaments. The goal is to help producers of goods and services, exporters, and importers conduct their business. Headquartered in Geneva, Switzerland. Established on 1995-January-01. Created by Uruguay Round negotiations (1986–94). Membership:- 162 countries on 30 November 2015 (160 countries on 2014-June-26; 150 countries on 2007-January-11). Functions:- (i) implementing WTO trade agreements; (ii) forum for trade negotiations; (iii) handling trade disputes; (iv) monitoring national trade policies; (v) technical assistance and training for developing countries; and (vi) cooperation with other international organizations. The first step is to talk. Essentially, the WTO is a place where member governments go, to try to sort out the trade problems they face with each other. At its heart are WTO agreements, negotiated and signed by the bulk of the world's trading nations. But the WTO is not just about liberalizing trade, and in some circumstances its rules support maintaining trade barriers – for example to protect consumers, prevent the spread of disease or protect the environment. (1) What is the World Trade Organization? Simply put:- the World Trade Organization (WTO) deals with the rules of trade between nations at a global or near-global level. But there is more to it than that. Is it a bird, is it a plane? There are a number of ways of looking at the WTO. It's an organization for liberalizing trade. It's a forum for governments to negotiate trade agreements. It's a place for them to settle trade disputes. It operates a system of trade rules. (But it's not Superman, just in case anyone thought it could solve – or cause – all the world's problems!) Above all, it's a negotiating forum … Essentially, the WTO is a place where member governments go, to try to sort out the trade problems they face with each other. The first step is to talk. The WTO was born out of negotiations, and everything the WTO does is the result of negotiations. The bulk of the WTO's current work comes from the 1986–94 negotiations called the Uruguay Round and earlier negotiations under the General Agreement on Tariffs and Trade (GATT). The WTO is currently the host to new negotiations, under the 'Doha Development Agenda' launched in 2001. Where countries have faced trade barriers and wanted them lowered, the negotiations have helped to liberalize trade. But the WTO is not just about liberalizing trade, and in some circumstances its rules support maintaining trade barriers – for example to protect consumers or prevent the spread of disease. It's a set of rules … At its heart are the WTO agreements, negotiated and signed by the bulk of the world's trading nations. These documents provide the legal ground-rules for international commerce. They are essentially contracts, binding governments to keep their trade policies within agreed limits. Although negotiated and signed by governments, the goal is to help producers of goods and services, exporters, and importers conduct their business, while allowing governments to meet social and environmental objectives. The system's overriding purpose is to help trade flow as freely as possible – so long as there are no undesirable side-effects – because this is important for economic development and well-being. That partly means removing obstacles. It also means ensuring that individuals, companies and governments know what the trade rules are around the world, and giving them the confidence that there will be no sudden changes of policy. In other words, the rules have to be 'transparent' and predictable. And it helps to settle disputes … This is a third important side to the WTO's work. Trade relations often involve conflicting interests. Agreements, including those painstakingly negotiated in the WTO system, often need interpreting. The most harmonious way to settle these differences is through some neutral procedure based on an agreed legal foundation. That is the purpose behind the dispute settlement process written into the WTO agreements. Born in 1995, but not so young. The WTO began life on 01 January 1995, but its trading system is half a century older. Since 1948, the General Agreement on Tariffs and Trade (GATT) had provided the rules for the system. (The second WTO ministerial meeting, held in Geneva in May 1998, included a celebration of the 50th anniversary of the system.) It did not take long for the General Agreement to give birth to an unofficial, de facto international organization, also known informally as GATT. Over the years GATT evolved through several rounds of negotiations. The last and largest GATT round, was the Uruguay Round which lasted from 1986 to 1994 and led to the WTO's creation. Whereas GATT had mainly dealt with trade in goods, the WTO and its agreements now cover trade in services, and in traded inventions, creations and designs (intellectual property). (2) Principles of the trading system:- the WTO agreements are lengthy and complex because they are legal texts covering a wide range of activities. They deal with: agriculture, textiles and clothing, banking, telecommunications, government purchases, industrial standards and product safety, food sanitation regulations, intellectual property, and much more. But a number of simple, fundamental principles run throughout all of these documents. These principles are the foundation of the multilateral trading system. A closer look at these principles:- trade without discrimination:- (i) most-favoured-nation (MFN):- treating other people equally Under the WTO agreements, countries cannot normally discriminate between their trading partners. Grant someone a special favour (such as a lower customs duty rate for one of their products) and you have to do the same for all other WTO members. This principle is known as Most-Favoured-Nation (MFN) Treatment (see box). It is so important that it is the first article of the General Agreement on Tariffs and Trade (GATT), which governs trade in goods. MFN is also a priority in the General Agreement on Trade in Services (GATS) (Article 2) and the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) (Article 4), although in each agreement the principle is handled slightly differently. Together, those three agreements cover all three main areas of trade handled by the WTO. Some exceptions are allowed. For example, countries can set up a free trade agreement that applies only to goods traded within the group – discriminating against goods from outside. Or they can give developing countries special access to their markets. Or a country can raise barriers against products that are considered to be traded unfairly from specific countries. And in services, countries are allowed, in limited circumstances, to discriminate. But the agreements only permit these exceptions under strict conditions. In general, MFN means that every time a country lowers a trade barrier or opens up a market, it has to do so for the same goods or services from all its trading partners – whether rich or poor, weak or strong. (ii) National treatment:- treating foreigners and locals equally Imported and locallyproduced goods should be treated equally – at least after the foreign goods have entered the market. The same should apply to foreign and domestic services, and to foreign and local trademarks, copyrights and patents. This principle of 'national treatment' (giving others the same treatment as one's own nationals) is also found in all the three main WTO agreements (Article 3 of GATT, Article 17 of GATS and Article 3 of TRIPS), although once again the principle is handled slightly differently in each of these. National treatment only applies once a product, service or item of intellectual property has entered the market. Therefore, charging customs duty on an import is not a violation of national treatment even if locally-produced products are not charged an equivalent tax. Freer trade:- gradually, through negotiation:- lowering trade barriers is one of the most obvious means of encouraging trade. The barriers concerned include customs duties (or tariffs) and measures such as import bans or quotas that restrict quantities selectively. From time to time other issues such as red tape and exchange rate policies have also been discussed. Since GATT's creation in 1947–48 there have been eight rounds of trade negotiations. A ninth round, under the Doha Development Agenda, is now underway. At first these focused on lowering tariffs (customs duties) on imported goods. As a result of the negotiations, by the mid-1990s industrial countries' tariff rates on industrial goods had fallen steadily to less than 4% But by the 1980s, the negotiations had expanded to cover non-tariff barriers on goods, and to the new areas such as services and intellectual

property. Opening markets can be beneficial, but it also requires adjustment. The WTO agreements allow countries to introduce changes gradually, through 'progressive liberalization'. Developing countries are usually given longer to fulfil their obligations. Predictability:- through binding and transparency:- Sometimes, promising not to raise a trade barrier can be as important as lowering one, because the promise gives businesses a clearer view of their future opportunities. With stability and predictability, investment is encouraged, jobs are created and consumers can fully enjoy the benefits of competition – choice and lower prices. The multilateral trading system is an attempt by governments to make the business environment stable and predictable. In the WTO, when countries agree to open their markets for goods or services, they 'bind' their commitments. For goods, these bindings amount to ceilings on customs tariff rates. Sometimes countries tax imports at rates that are lower than the bound rates. Frequently this is the case in developing countries. In developed countries the rates actually charged and the bound rates tend to be the same. A country can change its bindings, but only after negotiating with its trading partners, which could mean compensating them for loss of trade. One of the achievements of the Uruguay Round of multilateral trade talks was to increase the amount of trade under binding commitments (see table). In agriculture, 100% of products now have bound tariffs. The result of all this:- a substantially higher degree of market security for traders and investors. The system tries to improve predictability and stability in other ways as well. One way is to discourage the use of quotas and other measures used to set limits on quantities of imports – administering quotas can lead to more red-tape and accusations of unfair play. Another is to make countries' trade rules as clear and public ('transparent') as possible. Many WTO agreements require governments to disclose their policies and practices publicly within the country or by notifying the WTO. The regular surveillance of national trade policies through the Trade Policy Review Mechanism provides a further means of encouraging transparency both domestically and at the multilateral level. Promoting fair competition:- The WTO is sometimes described as a 'free trade' institution, but that is not entirely accurate. The system does allow tariffs and, in limited circumstances, other forms of protection. More accurately, it is a system of rules dedicated to open, fair and undistorted competition. The rules on non-discrimination – MFN and national treatment – are designed to secure fair conditions of trade. So too are those on dumping (exporting at below cost to gain market share) and subsidies. The issues are complex, and the rules try to establish what is fair or unfair, and how governments can respond, in particular by charging additional import duties calculated to compensate for damage caused by unfair trade. Many of the other WTO agreements aim to support fair competition:- in agriculture, intellectual property, services, for example. The agreement on government procurement (a 'plurilateral' agreement because it is signed by only a few WTO members) extends competition rules to purchases by thousands of government entities in many countries. And so on. Encouraging Development And Economic Reform:- the WTO system contributes to development. On the other hand, developing countries need flexibility in the time they take to implement the system's agreements. And the agreements themselves inherit the earlier provisions of GATT that allow for special assistance and trade concessions for developing countries. Over three quarters of WTO members are developing countries and countries in transition to market economies. During the seven and a half years of the Uruguay Round, over 60 of these countries implemented trade liberalization programmes autonomously. At the same time, developing countries and transition economies were much more active and influential in the Uruguay Round negotiations than in any previous round, and they are even more so in the current Doha Development Agenda. At the end of the Uruguay Round, developing countries were prepared to take on most of the obligations that are required of developed countries. But the agreements did give them transition periods to adjust to the more unfamiliar and, perhaps, difficult WTO provisions – particularly so for the poorest, 'least-developed' countries. A ministerial decision adopted at the end of the round says better-off countries should accelerate implementing market access commitments on goods exported by the least-developed countries, and it seeks increased technical assistance for them. More recently, developed countries have started to allow duty-free and quota-free imports for almost all products from least-developed countries. On all of this, the WTO and its members are still going through a learning process. The current Doha Development Agenda includes developing countries' concerns about the difficulties they face in implementing the Uruguay Round agreements. (3) The case for open trade:- The economic case for an open trading system based on multilaterally agreed rules is simple enough and rests largely on commercial common sense. But it is also supported by evidence:- the experience of world trade and economic growth since the Second World War. Tariffs on industrial products have fallen steeply and now average less than 5% in industrial countries. During the first 25 years after the war, world economic growth averaged about 5% per year, a high rate that was partly the result of lower trade barriers. World trade grew even faster, averaging about 8% during the period. The data show a definite statistical link between freer trade and economic growth. Economic theory points to strong reasons for the link. All countries, including the poorest, have assets – human, industrial, natural, financial – which they can employ to produce goods and services for their domestic markets or to compete overseas. Economics tells us that we can benefit when these goods and services are traded. Simply put, the principle of 'comparative advantage' says that countries prosper first by taking advantage of their assets in order to concentrate on what they can produce best, and then by trading these products for products that other countries produce best. In other words, liberal trade policies – policies that allow the unrestricted flow of goods and services – sharpen competition, motivate innovation and breed success. They multiply the rewards that result from producing the best products, with the best design, at the best price. But success in trade is not static. The ability to compete well in particular products can shift from company to company when the market changes or new technologies make cheaper and better products possible. Producers are encouraged to adapt gradually and in a relatively painless way. They can focus on new products, find a new 'niche' in their current area or expand into new areas. Experience shows that competitiveness can also shift between whole countries. A country that may have enjoyed an advantage because of lower labour costs or because it had good supplies of some natural resources, could also become uncompetitive in some goods or services as its economy develops. However, with the stimulus of an open economy, the country can move on to become competitive in some other goods or services. This is normally a gradual process. Nevertheless, the temptation to ward off the challenge of competitive imports is always present. And richer governments are more likely to yield to the siren call of protectionism, for short term political gain – through subsidies, complicated red tape, and hiding behind legitimate policy objectives such as environmental preservation or consumer protection as an excuse to protect producers. Protection ultimately leads to bloated, inefficient producers supplying consumers with outdated, unattractive products. In the end, factories close and jobs are lost despite the protection and subsidies. If other governments around the world pursue the same policies, markets contract and world economic activity is reduced. One of the objectives that governments bring to WTO negotiations is to prevent such a self-defeating and destructive drift into protectionism. (4) The GATT years:- from Havana to Marrakesh:- The WTO's creation on 01 January 1995 marked the biggest reform of international trade since after the Second World War. It also brought to reality – in an updated form – the failed attempt in 1948 to create an International Trade Organization. Much of the history of those 47 years was written in Geneva. But it also traces a journey that spanned the continents, from that hesitant start in 1948 in Havana (Cuba), via Annecy (France), Torquay (UK), Tokyo (Japan), Punta del Este (Uruguay), Montreal (Canada), Brussels (Belgium) and finally to Marrakesh (Morocco) in 1994. During that period, the trading system came under GATT, salvaged from the aborted attempt to create the ITO. GATT helped establish a strong and prosperous multilateral trading system that became more and more liberal through rounds of trade negotiations. But by the 1980s the system needed a thorough overhaul. This led to the Uruguay Round, and ultimately to the WTO. GATT:- 'provisional' for almost half a century:- from 1948 to 1994, the General Agreement on Tariffs and Trade (GATT) provided the rules for much of world trade and presided over periods that saw some of the highest growth rates in international commerce. It seemed well-established, but throughout those 47 years, it was a provisional agreement and organization. The original intention was to create a third institution to

handle the trade side of international economic cooperation, joining the two 'Bretton Woods' institutions, the World Bank and the International Monetary Fund. Over 50 countries participated in negotiations to create an International Trade Organization (ITO) as a specialized agency of the United Nations. The draft ITO Charter was ambitious. It extended beyond world trade disciplines, to include rules on employment, commodity agreements, restrictive business practices, international investment, and services. The aim was to create the ITO at a UN Conference on Trade and Employment in Havana, Cuba in 1947. Meanwhile, 15 countries had begun talks in December 1945 to reduce and bind customs tariffs. With the Second World War only recently ended, they wanted to give an early boost to trade liberalization, and to begin to correct the legacy of protectionist measures which remained in place from the early 1930s. This first round of negotiations resulted in a package of trade rules and 45 000 tariff concessions affecting USD10 billion of trade, about one fifth of the world's total. The group had expanded to 23 by the time the deal was signed on 30 October 1947. The tariff concessions came into effect by 30 June 1948 through a 'Protocol of Provisional Application'. And so the new General Agreement on Tariffs and Trade was born, with 23 founding members (officially 'contracting parties'). The 23 were also part of the larger group negotiating the ITO Charter. One of the provisions of GATT says that they should accept some of the trade rules of the draft. This, they believed, should be done swiftly and 'provisionally' in order to protect the value of the tariff concessions they had negotiated. They spelt out how they envisaged the relationship between GATT and the ITO Charter, but they also allowed for the possibility that the ITO might not be created. They were right. The Havana conference began on 21 November 1947, less than a month after GATT was signed. The ITO Charter was finally agreed in Havana in March 1948, but ratification in some national legislatures proved impossible. The most serious opposition was in the US Congress, even though the US government had been one of the driving forces. In 1950, the United States government announced that it would not seek Congressional ratification of the Havana Charter, and the ITO was effectively dead. So, the GATT became the only multilateral instrument governing international trade from 1948 until the WTO was established in 1995. For almost half a century, the GATT's basic legal principles remained much as they were in 1948. There were additions in the form of a section on development added in the 1960s and 'plurilateral' agreements (i.e. with voluntary membership) in the 1970s, and efforts to reduce tariffs further continued. Much of this was achieved through a series of multilateral negotiations known as 'Trade Rounds' – the biggest leaps forward in international trade liberalization have come through these rounds which were held under GATT's auspices. In the early years, the GATT trade rounds concentrated on further reducing tariffs. Then, the Kennedy Round in the mid-sixties brought about a GATT Anti-Dumping Agreement and a section on development. The Tokyo Round during the seventies was the first major attempt to tackle trade barriers that do not take the form of tariffs, and to improve the system. The eighth, the Uruguay Round of 1986–94, was the last and most extensive of all. It led to the WTO and a new set of agreements. Before 1995:- GATT (short for the General Agreement on Tariffs and Trade) signatories before the WTO came into being the countries that had signed the General Agreement on Tariffs and Trade by the end of 1994 when the WTO replaced GATT as the organization overseeing the multilateral trading system. The 128 countries that had signed GATT by 1994 on 1995-January-01, the WTO replaced GATT, which had been in existence since 1947, as the organization overseeing the multilateral trading system. The governments that had signed GATT were officially known as GATT Contracting Parties. Upon signing the new WTO agreements (which include the updated GATT, known as GATT 1994), they officially became known as WTO Members. See also General Agreement on Tariffs and Trade. The World Trade Organization (WTO) deals with the global rules of trade between nations. Its main function is to ensure that trade flows as smoothly, predictably and freely as possible. Members and Observers:- 153 members and 31 observers (with the exception of the Holy See, observers must start accession negotiations within five years of becoming observers) on 10 February 2011 (with dates of membership). The World Trade Organization (WTO) deals with the rules of trade between nations at a global or near-global level. But there is more to it than that. There are a number of ways of looking at the WTO. It's an organization for liberalizing trade. It's a forum for governments to negotiate trade agreements. It's a place for them to settle trade disputes. It operates a system of trade rules. But it's not Superman, just in case anyone thought it could solve – or cause – all the world's problems! Above all, it's a negotiating forum …:- Essentially, the WTO is a place where member governments go, to try to sort out the trade problems they face with each other. The first step is to talk. The WTO was born out of negotiations, and everything the WTO does is the result of negotiations. The bulk of the WTO's current work comes from the 1986–94 negotiations called the Uruguay Round and earlier negotiations under the General Agreement on Tariffs and Trade (GATT). The WTO is currently the host to new negotiations, under the 'Doha Development Agenda' launched in 2001. Where countries have faced trade barriers and wanted them lowered, the negotiations have helped to liberalize trade. But the WTO is not just about liberalizing trade, and in some circumstances its rules support maintaining trade barriers – for example to protect consumers or prevent the spread of disease. It's a set of rules …:- At its heart are the WTO agreements, negotiated and signed by the bulk of the world's trading nations. These documents provide the legal ground-rules for international commerce. They are essentially contracts, binding governments to keep their trade policies within agreed limits. Although negotiated and signed by governments, the goal is to help producers of goods and services, exporters, and importers conduct their business, while allowing governments to meet social and environmental objectives. The system's overriding purpose is to help trade flow as freely as possible – so long as there are no undesirable side-effects – because this is important for economic development and well-being. That partly means removing obstacles. It also means ensuring that individuals, companies and governments know what the trade rules are around the world, and giving them the confidence that there will be no sudden changes of policy. In other words, the rules have to be 'transparent' and predictable. And it helps to settle disputes …:- This is a third important side to the WTO's work. Trade relations often involve conflicting interests. Agreements, including those painstakingly negotiated in the WTO system, often need interpreting. The most harmonious way to settle these differences is through some neutral procedure based on an agreed legal foundation. That is the purpose behind the dispute settlement process written into the WTO agreements. The WTO began life on 1995-January-01, but its trading system is half a century older. Since 1948, the General Agreement on Tariffs and Trade (GATT) had provided the rules for the system. The second WTO ministerial meeting, held in Geneva in May 1998, included a celebration of the 50th anniversary of the system. It did not take long for the General Agreement to give birth to an unofficial, de facto international organization, also known informally as GATT. Over the years GATT evolved through several rounds of negotiations. The last and largest GATT round, was the Uruguay Round which lasted from 1986 to 1994 and led to the WTO's creation. Whereas GATT had mainly dealt with trade in goods, the WTO and its agreements now cover trade in services, and in traded inventions, creations and designs (intellectual property). The World Trade Organization (WTO) is the independent multilateral agency negotiating and administering world trade agreements, handling trade disputes, and monitoring national trade policies. WTO, headquartered in Geneva, Switzerland, resulted from the Uruguay round of General Agreement on Trade and Tariffs (GATT) concluded in 1995. WTO's tasks include fostering trade relations among its members, resolving disputes, and serving as a forum for future multilateral trade negotiations. World Trade Organization is an organization for trade opening. It is a forum for governments to negotiate trade agreements. It is a place for them to settle trade disputes. It operates a system of trade rules. Essentially, the WTO is a place where member governments try to sort out the trade problems they face with each other. The WTO was born out of negotiations, and everything the WTO does is the result of negotiations. The WTO is currently the host to new negotiations, under the 'Doha Development Agenda' launched in 2001. Where countries have faced trade barriers and wanted them lowered, the negotiations have helped to open markets for trade. But the WTO is not just about opening markets, and in some circumstances its rules support maintaining trade barriers – for example, to protect consumers or

Although negotiated and signed by governments, the goal is to help producers of goods and services, exporters, and importers conduct their business, while allowing governments to meet social and environmental objectives. The system's overriding purpose is to help trade flow as freely as possible – so long as there are no undesirable side effects – because this is important for economic development and well-being. That partly means removing obstacles. It also means ensuring that individuals, companies and governments know what the trade rules are around the world, and giving them the confidence that there will be no sudden changes of policy. In other words, the rules have to be 'transparent' and predictable. Trade relations often involve conflicting interests. Agreements, including those painstakingly negotiated in the WTO system, often need interpreting. The most harmonious way to settle these differences is through some neutral procedure based on an agreed legal foundation. That is the purpose behind the dispute settlement process written into the WTO agreements. What we do? The WTO is run by its member governments. All major decisions are made by the membership as a whole, either by ministers (who usually meet at least once every two years) or by their ambassadors or delegates (who meet regularly in Geneva). While the WTO is driven by its member states, it could not function without its Secretariat to coordinate the activities. The Secretariat employs over 600 staff, and its experts – lawyers, economists, statisticians and communications experts – assist WTO members on a daily basis to ensure, among other things, that negotiations progress smoothly, and that the rules of international trade are correctly applied and enforced. (i) Trade Negotiations:- the WTO agreements cover goods, services and intellectual property. They spell out the principles of liberalization, and the permitted exceptions. They include individual countries' commitments to lower customs tariffs and other trade barriers, and to open and keep open services markets. They set procedures for settling disputes. These agreements are not static; they are renegotiated from time to time and new agreements can be added to the package. Many are now being negotiated under the Doha Development Agenda, launched by WTO trade ministers in Doha, Qatar, in November 2001. (ii) Implementation and Monitoring:- the WTO agreements require governments to make their trade policies transparent by notifying the WTO about laws in force and measures adopted. Various WTO councils and committees seek to ensure that these requirements are being followed and that WTO agreements are being properly implemented. All WTO members must undergo periodic scrutiny of their trade policies and practices, each review containing reports by the country concerned and the WTO Secretariat. (iii) Dispute Settlement:- the WTO's procedure for resolving trade quarrels under the Dispute Settlement Understanding is vital for enforcing the rules and therefore for ensuring that trade flows smoothly. Countries bring disputes to the WTO if they think their rights under the agreements are being infringed. Judgements by specially appointed independent experts are based on interpretations of the agreements and individual countries' commitments. (iv) Building Trade Capacity:- the WTO agreements contain special provision for developing countries, including longer time periods to implement agreements and commitments, measures to increase their trading opportunities, and support to help them build their trade capacity, to handle disputes and to implement technical standards. The WTO organizes hundreds of technical cooperation missions to developing countries annually. It also holds numerous courses each year in Geneva for government officials. Aid for Trade aims to help developing countries develop the skills and infrastructure needed to expand their trade. (v) Outreach:- the WTO maintains regular dialogue with non-governmental organizations, parliamentarians, other international organizations, the media and the general public on various aspects of the WTO and the ongoing Doha negotiations, with the aim of enhancing cooperation and increasing awareness of WTO activities. What we stand for? The WTO agreements are lengthy and complex because they are legal texts covering a wide range of activities. But a number of simple, fundamental principles run throughout all of these documents. These principles are the foundation of the multilateral trading system. Non-discrimination:- a country should not discriminate between its trading partners and it should not discriminate between its own and foreign products, services or nationals. More open:- lowering trade barriers is one of the most obvious ways of encouraging trade; these barriers include customs duties (or tariffs) and measures such as import bans or quotas that restrict quantities selectively. Predictable and transparent:- foreign companies, investors and governments should be confident that trade barriers should not be raised arbitrarily. With stability and predictability, investment is encouraged, jobs are created and consumers can fully enjoy the benefits of competition – choice and lower prices. More competitive:- discouraging 'unfair' practices, such as export subsidies and dumping products at below cost to gain market share; the issues are complex, and the rules try to establish what is fair or unfair, and how governments can respond, in particular by charging additional import duties calculated to compensate for damage caused by unfair trade. More beneficial for less developed countries:- giving them more time to adjust, greater flexibility and special privileges; over three-quarters of WTO members are developing countries and countries in transition to market economies. The WTO agreements give them transition periods to adjust to the more unfamiliar and, perhaps, difficult WTO provisions. Protect the environment:- the WTO's agreements permit members to take measures to protect not only the environment but also public health, animal health and plant health. However, these measures must be applied in the same way to both national and foreign businesses. In other words, members must not use environmental protection measures as a means of disguising protectionist policies. On 04 December 2013, Yemen cleared the final hurdle to become a WTO member. WTO Ministers adopted Yemen's WTO terms and conditions of entry at the 9th Ministerial Conference in Bali, Indonesia. Yemen will have until 02 June 2014 to ratify the deal and would become a fully-fledged WTO member 30 days after it notifies the acceptance of its Protocol of Accession to the WTO Director-General. World Trade Organization (WTO) is the international organization composed of the more than 100 nations that signed the General Agreement on Tariffs and Trade (GATT), which contained 38 Articles that lay out the rules and procedures which signatory countries must observe in their conduct of international trade and trade policy. GATT was WTO's predecessor body. The WTO permits signatory countries to ban specific imports from other countries in order to protect the health of humans, animals, or plants. Such import bans are allowed based on the (GATT/WTO) Agreement on Sanitary and Phytosanitary Measures, or the Agreement on Technical Barriers to Trade; which were approved in 1994 by GATT. WTO was established on January 01, 1995. Yemen applied for WTO membership on 12 April 2000. The Working Party was established on 17 July 2000. The General Council established a Working Party to examine Yemen's request for accession in July 2000. Yemen's Memorandum on the Foreign Trade Regime was circulated in November 2002, and the First meeting of the Working Party took place in November 2004. The Working Party held its 11th and final meeting on 26 September 2013, thus putting an end to multilateral and bilateral negotiations between WTO members and Yemen. The accession package will be presented to the 9th Ministerial Conference in Bali, 03–06 December, for a formal decision by ministers. World Trade Organization (WTO) is the international trade body formed by the agreement of member nations. The WTO is an evolution of the GATT process designed to resolve trade disputes and work for the lowering of tariff and non-tariff trade barriers. Brazil's World Trade Organization (WTO) Dispute Regarding US Upland Cotton:- In 2002, Brazil initiated a WTO consultation process claiming its cotton exports had been reduced due to subsidies by the United States. At that time, US cotton production received support through several mechanisms, including the marketing loan program, direct payments, countercyclical payments, crop insurance, and user marketing certificates. User marketing certificates are generally referred to as 'Step-2 Payments', and were unique to cotton; the remaining programs apply to a range of grains and oilseeds (see the ERS Cotton Briefing Room for more information on US commodity programs and the special provisions that apply to cotton:- http://www.ers.usda.gov/Briefing/Cotton/Policy.htm). In June 2004, a WTO dispute settlement panel ruled that the US cotton program significantly suppressed Brazilian cotton prices. The United States appealed this ruling, but a 2005 appellate body report supported the panel findings. Subsequently, the United States ceased operating the GSM-103

and Supplier Credit Guarantee (SCGP) programs, two of three export credit guarantee programs that Brazil challenged as being prohibited export subsidies. The sole remaining export guarantee program (GSM-102) was modified. The panel found that the Step 2 program was both a prohibited import substitution subsidy and a prohibited export subsidy. The United States terminated the Step 2 program at the beginning of the next marketing year. Brazil regarded these changes as insufficient, and requested a WTO compliance panel (Schnepf, 2010). The panel's report in 2007, and the subsequent appellate body's report in 2008, found that the United States had not fully complied with the WTO's 2005 ruling. These findings cleared the way for Brazil to pursue retaliatory measures, which were submitted to the WTO's Dispute Settlement Body, and resulted in an unappealable ruling from an arbitration panel in August 2009. The ruling's awards specified the level of countermeasures that Brazil could impose against US trade, annually in two parts:- (1) a fixed amount of USD147.3 million for the cotton payments, and (2) an amount for the GSM-102 program that varied based upon program usage. According the Office of the US Trade Representative, the total of authorized countermeasures was more than USD800 million (USTR, 2010). The arbitrators also ruled that Brazil could impose countermeasures in sectors outside of trade in goods, specifically intellectual property and services). (Retaliation for violation of WTO obligations concerning trade in goods under the General Agreement on Tariffs and Trade has traditionally been confined to countermeasures with respect to trade in other goods. Cross-sectoral countermeasures are instead directed at trade in non-goods sectors, such as services and intellectual property, in response to a violation in the goods sector (USDA, ERS, 2010(a)).) These cross-sectoral countermeasures were permitted in accord with annual thresholds related to total countermeasures. Of the approximately USD820 million in countermeasures Brazil could impose in June 2010, about USD260 million of that could be cross-sectoral. In 2010, the United States and Brazil reached an agreement under which the United States agreed to further changes in the GSM-102 program, agreed to set up a technical assistance fund for Brazilian cotton growers of USD147.3 million annually, and agreed to a process for continued discussions of reducing support for cotton in the next farm bill. Under the agreement, Brazil suspended its retaliatory measures, until a mutual agreement is reached or the agreement is terminated. Kazakhstan became the 162nd member of the WTO on 30 November 2015. World Trade Organization (WTO) is a multilateral agency that administers world trade agreements, fosters trade relations among nations, and solves trade disputes among member countries. The World Trade Organisation (WTO) is the successor body to the General Agreement on Tariffs and Trade (GATT), established formally on 01 January 1995 as part of the final agreement of the Uruguay Round of multilateral trade negotiations. Its main objectives include:- (i) to administer trade agreements; (ii) to act as a forum for trade negotiations; (iii) to settle trade disputes; (iv) to review national trade policies; and (v) to assist developing countries in trade policy issues. International organization dealing with the global rules of trade between nations. Its main function is to ensure that trade flows as smoothly, predictably and freely as possible. The system – known as the Multilateral Trading System – is centred around WTO agreements, negotiated and signed by a large majority of the world's trading nations, and ratified in their parliaments. These agreements are the legal ground-rules for international commerce. Essentially, they are contracts, guaranteeing member countries important trade rights. They also bind governments to keep their trade policies within agreed limits. The agreements were negotiated and signed by governments. But their purpose is to help producers of goods and services, exporters, and importers conduct their business. Members of the Working Party on the Accession of Yemen agreed on 26 September 2013 the terms of WTO membership for Yemen. At the 9th Ministerial Conference in Bali (2013-December-03–07), the accession package will be presented to ministers, who are expected to formally approve Yemen's membership. Yemen will have until 02 June 2014 to ratify its accession package. World Trade Organization (WTO) was established on January 01, 1995, as a result of the Uruguay Round negotiations (1986–94). The seat of the WTO is located in Geneva, Switzerland. It performs various functions including administering WTO trade agreement, organizing forums for trade negotiations, handling trade disputes, monitoring national trade policies, providing technical assistance and training for developing countries, and cooperate with other international organizations. / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Всемирная Организация Торговли (ВОТ) или, как это звучит на Французском языке по месту её регистрации, Организасьён Мондьяль дю Комэрс (О.Эм.Сэ.) (Organisation Mondiale du Commerce (OMC)), была учреждена Марракешским Соглашением, подписанным 15 Апреля 1994 министрами 128 стран в Марракеше, Марокко на основе решений Уругвайского Раунда – многостороннего переговорного процесса по вопросам торговли, запущенного в Сентябре 1986 в Пунта дэль Эстэ, Уругвай и заключённого в Декабре 1993 в Женеве, Швейцария, посредством преобразования действовавшего с 1947 Генерального Соглашения о Тарифах и Торговле (ГСТТ или ГЯТ (GATT)). Организация обрела свои полномочия с 01 Января 1995. Штабквартира ВОТ располагается в Женеве, Швейцария. Всемирная Организация Торговли (ВОТ), основанная в 1995, глобальная международная организация, которая занимается правилами международной торговли. Основу ВОТ составляют соглашения, согласованные, подписанные и ратифицированные большинством стран-участниц международной торговли. Цель ВОТ – помощь производителям товаров и услуг, экспортёрам и импортёрам в ведении их бизнеса. ВОТ является преемником ГСТТ.

WORLD TRADE ORGANIZATION AGREEMENT = СОГЛАШЕНИЕ О ВСЕМИРНОЙ ОРГАНИЗАЦИЯ ТОРГОВЛИ – World Trade Organization (WTO) Agreement:- the Uruguay Round agreements:- the 'Final Act' signed in Marrakesh, Morocco on 15 April 1994 is like a cover note. Everything else is attached to this. Foremost is the Agreement Establishing the WTO (or the WTO Agreement), which serves as an umbrella agreement. Annexed are the agreements on goods, services and intellectual property, dispute settlement, trade policy review mechanism and the plurilateral agreements. The schedules of commitments also form part of the Uruguay Round agreements. See also World Trade Organization (WTO).

WORLD TRADE ORGANIZATION APPELLATE BODY = АПЕЛЛЯЦИОННЫЙ ОРГАН ВСЕМИРНОЙ ОРГАНИЗАЦИИ ТОРГОВЛИ – The Appellate Body was established in 1995 under Article 17 of the Understanding on Rules and Procedures Governing the Settlement of Disputes (DSU). It is a standing body of seven persons that hears appeals from reports issued by panels in disputes brought by WTO Members. The Appellate Body can uphold, modify or reverse the legal findings and conclusions of a panel, and Appellate Body Reports, once adopted by the Dispute Settlement Body (DSB), must be accepted by the parties to the dispute. The Appellate Body has its seat in Geneva, Switzerland. The Appellate Body is composed of seven Members who are appointed by the DSB to serve for four-year terms, with the possibility of being reappointed once. The Appellate Body membership shall be broadly representative of membership in the WTO. The Appellate Body receives administrative and legal support from the Appellate Body Secretariat. World Trade Organization Appellate Body (WTO Appellate Body) is a standing body of seven persons that hears appeals from reports issued by panels in disputes brought by WTO Members. The Appellate Body can uphold, modify or reverse the legal findings and conclusions of a panel. Appellate Body Reports, once adopted by the Dispute Settlement Body (DSB), must be accepted by the parties to the dispute (WTO). The Appellate Body is composed of seven Members who are appointed by the Dispute Settlement

Body (DSB) to serve for four-year terms. Each person may be reappointed for another four-year term. Terms are staggered, ensuring that not all Members begin and complete their terms at the same time. Each Member of the Appellate Body is required to be a person of recognized authority, with demonstrated expertise in law, international trade and the subject-matter of the covered agreements generally. They are also required to be unaffiliated with any government and are to be broadly representative of the Membership of the WTO. A Chairman is elected among the Members to serve a one-year term, which can be extended for an additional period of one year. The Chairman is responsible for the overall direction of Appellate Body business. The current Chairperson is Thomas R. Graham. A Division of three Members is selected to hear each appeal; each Division elects a Presiding Member. The process for the selection of Divisions is designed to ensure randomness, unpredictability and opportunity for all Members to serve regardless of their national origin. To ensure consistency and coherence in decision-making, Divisions exchange views with the other Members of the Appellate Body before finalizing Appellate Body Reports. The conduct of Members of the Appellate Body and of the Appellate Body Secretariat is regulated by the Rules of Conduct for the Understanding on Rules and Procedures Governing the Settlement of Disputes (DSU). These Rules emphasize that Appellate Body Members shall be independent, impartial, and avoid conflicts of interest. A copy of the Rules of Conduct can be found as Annex II to the Working Procedures for Appellate Review. Appellate Body Members have also been called upon to determine, through binding arbitration under Article 21.3(c) of the DSU, the 'reasonable period of time' for the implementation by a WTO Member of Appellate Body or panel rulings as recommended by the DSB. In carrying out arbitrations under Article 21.3(c), Appellate Body Members act in an individual capacity. / Томэс Ар. Грэйэм (Thomas R. Graham). Апелляционный Орган Всемирной Организации Торговли (Апелляционный Орган ВОТ) – орган ВОТ в составе семи экспертов, рассматривающий апелляции докладов третейских групп, поданные странами-членами ВОТ. Апелляционный Орган может согласиться с правовыми выводами и заключениями третейской группы, а также изменить их или отозвать. Доклады Апелляционного Органа после их принятия Органом по Урегулированию Споров (ОРС) должны быть приняты всеми сторонами спора (ВОТ).

WORLD TRADE POINT FEDERATION = ВСЕМИРНАЯ ФЕДЕРАЦИЯ ПУНКТОВ ТОРГОВЛИ – World Trade Point Federation (WTPF):- an international non-governmental organization established in 2000, grew out of an innovative programme of the United Nations Conference on Trade and Development (UNCTAD). Through a network of more than 100 trade information and facilitation centres, known as Trade Points, the WTPF assists small and medium enterprises (SMEs) in over 70 countries worldwide to trade internationally through the use of electronic commerce technologies. Capitalising on over a decade of Trade Point market presence, the Federation constantly seeks strategic partners for the development of new value-added services to enable it to better serve its clients. WTPF Activities:- The WTPF is involved in the following activities:- (i) Helping SMEs find reliable business partners through its Trade Point Network in over 70 countries worldwide and encourages them to become more digitally active in trade transactions; (ii) Providing access to international market and investment information worldwide; (iii) Providing a unique Electronic Trade Opportunities (ETO) system allowing SMEs to post and receive trade leads free of charge; (iv) Offering companies a non-stop presence on the web through the Global Trade Directory System (GTDS); (v) Entering into public and private partnerships to promote its goals; (vi) Receiving official government and trade missions in its headquarters in Geneva; (vii) Engaging in outward missions to promote the Trade Point network; (viii) Organising annual general assembly meetings and regional meetings; and (ix) Representing Trade Points in international trade-related forums. What is a Trade Point? The WTPF describes a Trade Point as 'a trade facilitation center where participants in foreign trade transactions are grouped together under a single physical (i.e. an actual office) or virtual roof to provide all the necessary services for trade transactions. Examples of such trade facilitation centers might include chambers of commerce, customs, foreign trade institutes, banks, freight forwarders, transport agencies and insurance companies, etc. The Trade Point is also see as a 'source of trade-related information, providing actual and potential traders with data about business and market opportunities, potential clients and suppliers, trade regulations, standard and certification requirements, etc'. Ultimately, the Trade Point network is a gateway to a global networking, accelerating the access of SMEs to electronic commerce. The Global Trade Directory System:- The Global Trade Directory System has been developed to be an extensive database of companies worldwide. This service is still in the early stages of development, however. It is a membership-based service (currently costing USD200) and it gives you the opportunity of giving your company global visibility. The benefits of the GTDS for registered companies are:- Global Visibility:- (i) Your company data is freely available to anyone with internet access; (ii) You will have a presence on each local Trade Point website; (iii) It gives you a chance to find new trading partners and to penetrate new markets; (iv) It generates new business right where trade is being promoted; (v) It helps you save costs on marketing and business travel; and (vi) It give you access to the Company Alert service. Companies registered with the GTDS who are Certified Trade Point Members also have access to the password protected areas of the WTPF integrated website and preferential ranking in the GTDS search engine. Becoming a Certified Trade Point Member essentially means that your company is evaluated and certified as a bona fide trading company giving credence to your standing in the international community. http://www.tradepoint.org. The World Trade Point Federation (WTPF), is a non-governmental organization registered in Geneva, Switzerland. Its purpose is to bring together, within one working philosophy all the Trade Points established in accordance with the guidelines of the Trade Point Programme and to serve as an institutional framework for them. Does this by:- (i) Fostering greater participation in international trade of small and medium-sized enterprises MEs, giving special attention to the Least Developed Countries and other countries less advanced in the area of trade efficiency through the use of e-commerce technologies; (ii) Reducing transaction costs in international trade by contributing to the simplification and harmonization of trade procedures worldwide; and (iii) Opening international trade to new participants, especially SMEs, by contributing to the simplification and harmonization of trade procedures worldwide and giving traders access to advanced technologies and information networks. The World Trade Point Federation (WTPF) is an international non governmental non-profit organization established in 2000. It originates from the innovative trade efficiency programme initiated by UNCTAD (United Nations Conference on Trade and Development) and has as its main goal the increased participation of SME's in Global Trade. The objectives are to:- (i) Encourage and increase participation of Small and Medium Enterprises in global e-tradel trade; (ii) Provide Small and Medium Enterprises with global trade information; and (iii) Collection and dissemination of trade opportunities to members. What Is The Global Trade Directory? The Global Trade Directory System (GTDS) is a comprehensive database providing registered companies with instant global visibility in 70 countries through a network of 100 Trade Point offices, allowing you the chance to penetrate new markets. Through the GTDS you can freely search for reliable companies to meet your purchasing needs or service requirements. Having registered your company onto the GTDS through a Trade Point, vouches for a sound and trustworthy trading environment. Benefits of The GTDS:- (i) Providing your company with International Visibility and presence on the Trade Point's website; (ii) Cost saving on marketing and business travel; (iii) Placing your company profile onto the Trade Point Website thus providing global visibility; (iv) Providing your company the opportunity to place its catalogues of products and services onto the Trade Point network; (v) Regularly receiving direct updates of new and existing products for sale; and (vi) Registered companies have access to additional password protected areas through your own Trade Point listing, providing additional detailed information on:- (a) Trade Related information – important to exporting; (b) Market Intelligence – advantage in penetrating new markets; and (c) Links to other value added WTPF services – added value for global trade. / Всемирная Федерация Пунктов Торговли:- .

WORLDWIDE FARMER–TO–FARMER INITIATIVE = ВСЕМИРНО РАСПРОСТРАНЁННАЯ ИНИЦИАТИВА ОТ ФЕРМЕРА–К–ФЕРМЕРУ – Worldwide Farmer-To-Farmer Initiative (WW FTF):- the US Agency for International Development (USAID) Farmer-To-Farmer (FTF) Program was first authorized by Congress in 1985. Its goal is to provide for the transfer of knowledge and expertise from US agricultural producers and businesses to farmers, farm groups, and agribusinesses in developing and transitional countries. FTF utilizes the experience and expertise of volunteers from all sectors of the US farm community, including Extension faculty and agents. The transfer of agricultural expertise and knowledge is accomplished by supporting various short-term development projects aimed at reducing poverty and stimulating sustainable and broad-based economic growth. Program areas typically address income diversification, horticulture and high value crops, natural resource management, dairy and livestock, financial and agribusiness management, and commodity processing and marketing. USAID has cooperative agreements with eight implementing organizations, and between 2004–08 FTF plans to support over 3 000 volunteer assignments in almost 40 host countries. Have you ever passed by an international opportunity because of time constraints? FTF projects are often less than 3 weeks in length. In addition, agencies usually are flexible on assignment timing, enabling Extension personnel to select travel times compatible with existing research or teaching commitments. Are you under the impression that gaining international experience requires significant financial resources? All FTF project costs are covered by the implementing agency and the host organization requesting the assistance. Your only cost as a volunteer is your time. Have you ever hesitated to volunteer for an international assignment because you do not speak a second language? The FTF program provides qualified translators for the duration of the assignment and also handles all logistical arrangements. WORLD WIDE FUND FOR NATURE = ВСЕМИРНЫЙ ФОНД ПРИРОДЫ – The World Wide Fund for Nature (formerly World Wildlife Fund (WWF®)) aims to conserve nature and ecological processes by preserving biodiversity, ensuring sustainable use of natural resources and promoting the reduction of pollution and wasteful use of resources and energy. Headquartered in Washington, DC, the United States. For 50 years, WWF has been protecting the future of nature. The world's leading conservation organization, WWF works in 100 countries and is supported by 1.2 million members in the United States and close to 5 million globally. WWF's unique way of working combines global reach with a foundation in science, involves action at every level from local to global, and ensures the delivery of innovative solutions that meet the needs of both people and nature. The World Wide Fund for Nature (WWF®) is an international non-governmental organization founded on April 29, 1961, working in the field of the biodiversity conservation, and the reduction of humanity's footprint on the environment. It was formerly named the World Wildlife Fund, which remains its official name in Canada and the United States. It is the world's largest conservation organization with over 5 million supporters worldwide, working in more than 100 countries, supporting around 1 300 conservation and environmental projects. WWF is a foundation, with 55% of funding from individuals and bequests, 19% from government sources (such as the World Bank, Department for International Development (DFID), United States Agency for International Development (USAID)) and 8% from corporations in 2014. The group's mission is 'to stop the degradation of the planet's natural environment and to build a future in which humans live in harmony with nature'. Currently, much of its work focuses on the conservation of three biomes that contain most of the world's biodiversity:- oceans and coasts, forests, and freshwater ecosystems. Among other issues, it is also concerned with endangered species, sustainable production of commodities and climate change. / Всемирный Фонд Дикой Природы (WWF) – одна из крупнейших независимых международных природоохранных организаций, объединяющая около 5 миллионов постоянных сторонников и работающая более чем в 100 странах. Миссия WWF – в предотвращении нарастающей деградации естественной среды планеты и достижении гармонии человека и природы. Главная цель – сохранение биологического разнообразия Земли. Более половины нашего мирового бюджета составляют пожертвования частных лиц, которых мы называем сторонниками WWF. В России сторонников WWF с каждым годом становится все больше и больше, и мы приглашаем каждого присоединиться к этому доброму и по-настоящему важному делу – помогать сохранять природу. Первые проекты WWF в России начались в 1988, а в 1994 открылось Российское представительство WWF. В 2004 WWF России стал Российской национальной организацией. За 20 лет Фонд успешно осуществил более 300 полевых проектов в 47 регионах России и вложил свыше 70 миллионов Евро в работу по сохранению и приумножению природных богатств страны.

WORLDWIDE INCOME = ВСЕМИРНЫЙ ДОХОД (или ДОХОД СО ВСЕГО МИРА) – Worldwide Income is the total aggregate of revenue generated by a tax-paying entity from all sources that includes foreign, domestic, passive and active income from operations and investments that must be reported to the Internal Revenue Service (IRS) for tax purposes. An exclusion may apply to a portion of earnings generated by US citizens who work abroad.

WORLDWIDE INSURANCE ELECTRONIC COMMERCE = ВСЕМИРНАЯ ОБШИРНАЯ СТРАХОВАЯ ЭЛЕКТРОННАЯ КОММЕРЦИЯ – Worldwide Insurance Electronic Commerce (WISe™):- the three original European networks, Limnet, Rinet and WIN, and Joint Venture merged in 1999 and operated until November 2001 under the name WISe (Worldwide Insurance Electronic Commerce). Before the merger, Limnet estimated that, among its members, 15 per cent of all risks were being handled electronically as opposed to 90 per cent of claims. Rinet estimated that 60 per cent of world and 80 per cent of European reinsurance income was transacted through its network, as well as 50 per cent of United States gross reinsurance premium income. In addition to its basic mission to develop e-commerce solutions for insurers, WISe was involved in developing e-insurance data standards through its Joint Venture activities. In October 2001, WISe merged its standard-setting activities with the Association for Cooperative Operations Research and Developments (ACORD®; headquartered in New York, NY, the United States). As a result ACORD® has become the de facto global e-commerce standards body for insurance. WISe's commercial activities have since been acquired by Ins-sure, which provides the London insurance market and European insurers with electronic business processing, policy administration, premium and claim settlement services. Worldwide Insurance Electronic Commerce headqurtered in Brussels, Belgium. Organizations within the global insurance market have banded together to try and save e-commerce costs. WISE, worldwide insurance e-commerce, has undertaken the roles of LIMNET (the London Insurance Market Network), RINET (the Brussels Reinsurance and Insurance Network) and WIN (World Insurance Network). WISE plans to combine insurance claim processing systems to save money. The common platform which WISE will use to simplify data transfer between brokers and insurers has yet to be selected, although an announcement is expected by the end of the month (July 1999). / Всемирная Обширная Страховая Электронная Коммерция (ВОСЭК) – компьютерная сеть, объединившая крупнейшие страховые компании мира. Эта специализированная система обмена данными в электронной форме является важнейшим инфраструктурным образованием системы страховых услуг.

WORLD WIDE WEB = ВСЕМИРНАЯ ОБШИРНАЯ СЕТЬ (или ВСЕМИРНАЯ ПАУТИНА) – The World Wide Web (WWW) is a part of the Internet designed to allow easier navigation of the network through the use of graphical user interfaces and hypertext links between different addresses. Originally developed by the European Laboratory for Particle Physics Consortium (CERN) in Switzerland as a system to distribute electronic documents that are composed of, or point to many different files of various formats that are located around the world. Documents are created in a standardized hypertext markup language (HTML) that can be interpreted by Web browsers on a user's computer. The location of HTML documents are defined by links or addresses called universal resource locators (URLs). The WWW has been rapidly growing and is becoming an important channel for distributing documents and data. World Wide

Web is the computer-based text retrieval system (hypertext) that enables the user to access or gain information (text, image, voice, video) via the Internet. Abbreviation:- WWW or W3. / Базирующаяся на компьютерах система доставляемого текста (гипертекста), которая позволяет пользователю получить доступ к или раздобыть информацию (текст, картинку, голос, видео) через Интернет. Обозначение:- Дабл.Ю.Дабл.Ю.Дабл.Ю. (WWW).

WORLD WIDE WEB CONSORTIUM = КОНСОРЦИУМ ВСЕМИРНОЙ ОБШИРНОЙ СЕТИ – The World Wide Web Consortium (W3C) is an international industry consortium founded in October 1994 to develop common protocols that promote the evolution of the World Wide Web and ensure its interoperability. Services provided by the Consortium include:- a repository of information about the World Wide Web for developers and users; reference code implementations to embody and promote standards; and various prototype and sample applications to demonstrate use of new technology. / Консорциум Всемирной Обширной Сети (W3C) – это международный промышленный консорциум, основанный в Октябре 1994 для разработки общих протоколов, которые будут способствовать развитию Всемирной Обширной Сети и обеспечивать взаимодействие с ней. Услуги, предоставляемые консорциумом, включают следующее:- хранилище информации о Всемирной Обширной Сети для разработчиков и пользователей; внедрение нормативов для реализации и продвижения стандартов; разработка различных прототипов и примеров приложений, показывающих использование новой технологии.

WORM = W/M = WEIGHT OR MEASUREMENT

WORM = ЧЕРВЬ – (1) Worm:- any of various unrelated invertebrate animals that typically have soft, slender, elongated bodies and usually lack appendages. Worms are members of several invertebrate phyla, including Platyhelminthes (flatworms), Annelida (segmented worms), Nemertea (ribbon worms), Aschelminthes (roundworms, pinworms, eelworms, threadworms, hairworms, etc), Sipuncula (peanutworms), Echiura (spoonworms), Acanthocephala (spiny-headed worms), Pogonophora (beardworms), and Chaetognatha (arrowworms). The term is also loosely applied to centipedes and millipedes; to larval (immature) forms of other invertebrates, particularly those of certain insects; and to some vertebrates – e.g., the Blindworm (Anguis fragilis), a limbless, snakelike lizard. At one time all phyla of wormlike animals were classed as Vermes, a term no longer in common use. The major groups of worms include various species of flatworm, annelid, ribbon worm, spiny-headed worm, and aschelminth. Worms typically have an elongated, tubelike body, usually rather cylindrical, flattened, or leaflike in shape and often without appendages. They vary in size from less than 1 mm (0.04 inch) in certain aschelminths to more than 30 m (100 feet) in certain ribbon worms. Worms are universal in distribution, occurring in marine, freshwater, and terrestrial habitats. Some types of worms are parasitic, others are free-living. From a human perspective, worms are important as soil conditioners (e.g., annelids, aschelminths) and as parasites of people and domestic animals (e.g., platyhelminths, aschelminths) and of crops (e.g., aschelminths). Ecologically, worms form an important link in the food chains in virtually all ecosystems of the world.

(2) Worms are network viruses, primarily replicating on networks. Usually, a worm will execute itself automatically on a remote machine without any extra help from a user. However, there are worms, such as mass-mailer worms, that will not always automatically execute themselves without the help of a user. A Worm is a self-replicating type of malware that can spread to other computers. Worms can spread through computer networks, e-mails, instant-messaging services, social networks, removable media and other channels. Unlike viruses, worms do not attach themselves to existing programs, however, some viruses do make use of worm-like propagation methods to spread themselves. See also Malware, and Virus. / Вирусная программа – Червь (Worm-virus) – паразитическая программа, обладающая механизмом саморазмножения. Программа способна размножать свои копии, но не поражать другие компьютерные программы. Проникает на компьютер из сети (чаще всего как вложение в сообщениях электронной почты или через сеть Интернет) и рассылает свои функциональные копии на другие компьютерные сети.

WORM GEAR = ЧЕРВЯЧНАЯ ПЕРЕДАЧА – Worm Gears are usually used when large speed reductions are needed. The reduction ratio is determined by the number of starts of the worm and number of teeth on the worm gear. But worm gears have sliding contact which is quiet but tends to produce heat and have relatively low transmission efficiency. As for the materials for production, in general, worm is made of hard metal while the worm gear is made from relatively soft metal such as aluminum bronze. This is because the number of teeth on the worm gear is relatively high compared to worm with its number of starts being usually 1 to 4, by reducing the worm gear hardness, the friction on the worm teeth is reduced. Another characteristic of worm manufacturing is the need of specialized machine for gear cutting and tooth grinding of worms. The worm gear, on the other hand, may be made with the hobbing machine used for spur gears. But because of the different tooth shape, it is not possible to cut several gears at once by stacking the gear blanks as can be done with spur gears. The applications for worm gears include gear boxes, fishing pole reels, guitar string tuning pegs, and where a delicate speed adjustment by utilizing a large speed reduction is needed. While you can rotate the worm gear by worm, it is usually not possible to rotate worm by using the worm gear. This is called the Self Locking Feature. The self locking feature cannot always be assured and a separate method is recommended for true positive reverse prevention. Also there exists duplex worm gear type. When using these, it is possible to adjust backlash, as when the teeth wear necessitates backlash adjustment, without requiring a change in the center distance. There are not too many manufacturers who can produce this type of worm. The worm gear is more commonly called Worm Wheel in Japan. Worm Gear is a gear that is in the form of a screw. The screw thread engages the teeth on a worm wheel. When rotated, the worm pulls or pushes the wheel, causing rotation. See also Gear. Worm Gear is a mechanism consisting of a worm engaging with and driving a worm wheel, the two axes usually being at right angles, used where a relatively low speed and a relatively large amplification of power are desired. / Червячное Колесо (Worm Wheel) в Японии. Червячная Передача – механическое устройство для передачи вращения между скрещивающимися (обычно под прямым углом) валами посредством червяка (винта) и сопряжённого с ним червячного колеса. Червяк представляет собой винт с трапецеидальной или близкой к ней резьбой, а Червячное Колесо является Зубчатым Колесом, зубья которого имеют особую дугообразную форму. Червячное колесо охватывает червяк на некоторой дуге (обычно до 100°). Ведущим в червячной передаче является обычно червяк, ведомым – червячное колесо; в редких случаях (для повышающих передач) ведущим может быть червячное колесо. В наиболее распространённых червячных передачах используются цилиндрические червяки; червяки с витками на тороидной поверхности применяются в Глобоидных Передачах. В зависимости от числа заходов резьбы (ниток нарезки) различают одно-, двух- и четырёхзаходные червяки; по форме профиля витка – архимедовы, с вогнутым профилем и другие червяки. Витки архимедовых червяков в осевом сечении очерчены трапецией и легко изготовляются точением. Перспективны червяки с вогнутым профилем витков резьбы, обеспечивающим меньшие контактные напряжения и лучшие условия для образования масляного клина. Для Силовых Передач предпочтительны эвольвентные червяки, профиль витка которых в поперечном сечении очерчен по эвольвенте (смотрите Эволюта и Эвольвента). Передаточное Число червячной передачи $i = z_2 / z_1$, где z_1 – число заходов резьбы червяка, z_2 – число зубьев червячного колеса. Обычно передаточное число червячной передачи равно 8–100 (в ряде случаев, например, в приводах станочных столов большого диаметра, до 1 000). Благодаря возможности получения больших передаточных чисел при сравнительно небольшом габарите передачи червячные передачи применяются в приводах машин, устройствах управления и другом. Достоинства червячной передачи – плавность и бесшумность работы. Червячные передачи могут быть самотормозящими, то есть передающими вращение только от червяка к колесу, что иногда

даёт возможность выполнить механизм без тормозного устройства. Недостаток червячной передачи – значительное относительное скольжение сопряжённых элементов – витков червяка и зубьев колеса. Это вызывает усиленное тепловыделение, повышенный износ и склонность к заеданию, определяет сравнительно низкий коэффициент полезного действия (кпд) (в среднем 0.7–0.75 в однозаходной передаче, 0.8–0.85 в двухзаходной, 0.86–0.92 в четырёхзаходной). Для уменьшения износа и повышения сопротивляемости заеданию червячные колёса изготовляют из материалов с высокими антифрикционными свойствами, главным образом из бронзы:- оловянистой (при скоростях скольжения 5–35 метров в секунду (м/сек)) и алюминиево-железистой (при скоростях скольжения до 10 м/сек). Для экономии цветных металлов их делают составными:- бронзовый венец (обод) устанавливается на стальную или чугунную ступицу. При скоростях скольжения до 2 м/сек и больших диаметрах колёса можно отливать целиком из чугуна. В приборах и небольших силовых передачах могут использоваться колёса из текстолита, полиамидов и тому подобного. Червяки обычно изготовляют из качественных углеродистых или легированных сталей, термически обработанных до высокой твёрдости. Для повышения качества поверхности червяки шлифуют и полируют. Пониженный кпд и значительное тепловыделение ограничивают применение червячной передачи областью небольших и средних мощностей (обычно до 50, реже до 200 кВт). Они используются в подъёмно-транспортных машинах, металлорежущих станках, автомобилях, троллейбусах, металлургических машинах, гидротехнических сооружениях и так далее. Основное применение имеют закрытые хорошо смазываемые червячные передачи в виде червячных редукторов.

WORN CURRENCY = ВЕТХАЯ ВАЛЮТА (или ИЗНОШЕННАЯ ВАЛЮТА) – Worn Currency:- currency notes that are torn, damaged or badly soiled. Banks separate such currency notes daily from the amounts that they collect from the public and exchange them for crisp new bills at the Federal Reserve Bank. Worn currency notes are assessed by the Federal Reserve Bank, which reviews the notes and determines whether they can be recirculated or should be retired from the money system. The Federal Reserve destroys worn currency notes at some of its banks located throughout the country. Worn Currency:- cash and coin that has been used so much it is no longer recognizable. Worn currency ceases to be legal tender and is no longer useable. In the United States, the Federal Reserve burns worn currency. / .

WORN SLIP = ИЗНОШЕННАЯ КОМБИНАЦИЯ (или ПОТЁРТАЯ КОМБИНАЦИЯ) – Worn Slip:- Garment:- woman's white satin slip; Fabric Construction:- (i) Count:- 218 x 90; (ii) Warp:- 55/20 bright acetate rayon; (iii) Filling:- 75/24 dull acetate rayon. Complaint:- slip was badly worn in front after only a few wearings and one laundering. Analysis:- tensile-strength tests made on the warp and filling of the upper portion of the slip, where there was no sign of unusual wear, showed the fabric to be about 40% weaker than file head ends of the identical construction. In addition, breaking strength tests were made on the shoulder straps taken from the garment, and an appreciable loss of strength was observed. (This was determined by calculating the theoretical normal strength of the original strap fabric from the construction.) Since the shoulder straps were of a different construction, not made by the weaver of the underwear fabric, it appeared that the garment had been abused in laundering, perhaps by the use of chlorine bleach. A similar deterioration was obtained in the laboratory by such treatment. The fuzzy and badly worn appearance in the lower part of the garment was to be expected, since this is the area most subjected to rubbing and wear in use. / Уточина:- 75/24 .

WORRIED WELL = ХОРОШО ВОЛНУЕМЫЙ – Worried Well:- the people who do not need medical treatment, but who visit the doctor to be reassured, or with emotional problems. / Хорошо Волнуемый:- пациенты, избыточно исследующие свои болезни и приносящие этим больше вреда, чем пользы.

WORST = XX – Worst is the use of the least advantageous/most prudent price quote in mark-to-market. See also Ask; Best; Bid/Ask; Last; Mark-To-Market; and Mid.

WORST CASE DISCHARGE = ХУДШИЙ СЛУЧАЙ РАЗЛИВА (или XX) – Worst Case Discharge (WCD) is a calculation used by the Bureau of Ocean Energy Management, Regulation and Enforcement to determine the maximum flow rate for an offshore oil well in the event of an oil spill. WCD first came to prominence in the aftermath of the Deepwater Horizon Oil Spill to determine potential liability if another oil spill were to occur. The now defunct Minerals Management Service planned to implement Worst Case Discharge studies before the Deepwater Horizon Oil Spill though the first actual was performed in August 2010 to model the Deepwater Horizon spill. In January 2011, several major oil and gas companies were allowed to resume deepwater drilling while Worst Case Discharge studies were being completed. In March 2011, the Worst Case Discharge study on the Deepwater Horizon Oil Spill was released to the public in the Flow Rate Technical Group final report. Analytical equations are the simplest method for calculating WCD. However analytical equations cannot account for the rapid change in pressure and saturation near the well bore and have been replaced by simulation modeling. Reservoir simulation is the method used by the Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) to calculate WCD as simulation can accurately model the rapid changes near well bore that occur in an uncontrolled blow out event. The BOEMRE currently uses the Merlin finite difference simulator and nodal analysis package to perform all WCD studies since using the software to determine the official flow rate for the Deepwater Horizon Oil Spill. Engineers typically use radial modeling to calculate WCD as a radial model can employ sufficiently small grid cell sizes around the well bore that increase in volume as cells extend into the aquifer. Full field modeling is generally only needed if a geologic barrier like a fault or pinch out is close enough to the well being studied there is pressure interference. Engineers also need to calculate the highest rate in each combination of geologic layers as the well is drilled. The WCD rate can be higher in certain cases if specific layers blowout rather than the entire reservoir as different combinations of aquifers, gas layers, and oil layers can limit or enhance flow. Worst Case Discharge is the largest foreseeable discharge of oil, including a discharge from fire or explosion, in adverse weather conditions. This volume will be determined by each pipeline operator for each response zone and is calculated according to 49 CFR 194.105. Worst Case Discharge (WCD) for exploratory and development drilling operations is the daily rate of an uncontrolled flow of natural gas and oil from all producible reservoirs into the open wellbore. The package of reservoirs exposed to an open borehole with the greatest discharge potential is considered the worst case discharge scenario. Operators must submit WCD calculated volumes, and associated data according to NTL 2010-N06 (Information Requirements for Exploration Plans, Development and Production Plans, and Development Operations Coordination Documents on the Outer Continental Shelf (OCS)) and the associated frequently asked questions as part of every Exploration Plan and every Development Operations Coordination Document/Development and Production Plan. Each Region is responsible for WCD verifications and decision documentation associated with plans under their jurisdictions. Resource Evaluation geoscientists and engineers independently verify the validity of the volume calculations, assumptions, and analogs used by the operator for the WCD. The Bureau of Ocean Energy Management (BOEM) Worst Case Discharge model outputs are also used by the Bureau of Safety and Environmental Enforcement (BSEE) in oil spill response plans and cap and stack or cap and containment decisions made as part of the Application for Permit to Drill process (a BSEE responsibility).

WORSTED = КАМВОЛЬНАЯ – Worsted:- a fabric made from worsted yarn, namely a smooth compact yarn from long wool fibers used especially for firm napless fabrics. Worsted Merino, commercial term in the United States for a combination supposed to contain half wool and half cotton and spun according to the French system (1924). Worsted yarn is smooth-surfaced, spun from long staple,

evenly combed wool. Worsted fabric is made from worsted yarns, is tightly woven, with a smooth 'hard' surface. Original gabardine and serge are examples. One story is that worsted is so named because when William the Conqueror came to Britain in 1066 he found many of the peasants combing wool in the area which, since he had worsted the people, he called Worsted! However, worsted was made in Worstead, once Worthstead (meaning Homestead), in Norfolk. Worsted yarns are made from long fibers of 3 to 6 inches, which are combed to lie parallel to each other, producing a smooth, clean look. They are usually fine, tightly twisted ply yarns. Worsted refers to two different processes which are combined to produce a smooth, clean yarn. Originally it referred to a woolen yarn manufactured in Worstead, Norfolk, England. It now refers to yarn (and fabric) made of long fibers, combed, and tightly twisted in spinning. Fabrics made from worsted yarns are smooth and cool to wear. Fiber Preparation:- yarns spun from wool where the wool fibers are markedly 'parallelized' as distinct from woolen yarns in which anything but a parallel position is noticeable. In commercial yarns, almost without exception, worsted yarns are combed yarns. One of my reference texts states:- '... but it is quite conceivable that wool fibers might be so parallelized by careful drawing and spinning that practically a yarn of worsted characteristics might be produced without combing'. ('Analysis of Woven Fabrics' by Aldred Farrer Barker & Eber Midgley) For me, the important word is 'practically'. Traditionally, worsted yarns were from fibers 3+ inches in length, but this is no longer true as now many shorter wools are also worsted spun. Spinning:- the spinning process where the twist is not allowed into the drafting triangle. They are usually plied yarns, and are finer and more tightly twisted than woolen yarns. Worsted is a general term applied to fabrics and yarns from combed wool and wool blends. Worsted yarn is smooth-surfaced, and spun from evenly combed long staple. Worsted fabric is made from worsted yarns and is tightly woven with a smooth, hard surface, Gabardine and serge are examples of worsted fabrics. The term Worsted means a lot of different things depending on where you are in the knitting and spinning world. For knitters, most commonly worsted refers to a weight of yarn, also known as Medium Weight Yarn. Worsted weight yarn is generally knit on a US 7 to 9 knitting needle (4.5 to 5.5 mm) and works up 16 to 20 stitches per four inches. Sometimes worsted weight refers to a slightly lighter weight yarn as well; this is why many people are pushing for the wider use of the standard yarn weight system, which will make it easier to understand what you're getting when you shop for yarn. If you're a spinner, worsted refers to both a means of preparing fiber to be spun and a method for doing the spinning on a wheel. Worsted fiber preparation involves fibers that are basically all the same staple length and that have been combed so that they all face the same direction and are nice and straight. Spinning in a worsted method means that you don't allow the twist into the drafting zone; the fibers are smoothed and stretched before the twist is allowed in. This makes for a slow spinning process, but it's worth it if you want a very even, smooth, lovely yarn. Using these definitions of worsted, a worsted yarn provides firm stitch definition in a lustrous, strong and cool-wearing yarn. All that's true regardless of the actual weight of the yarn. In spinning, worsted is the opposite of woolen yarn preparation and spinning methods. / Алдэд Фарё Баркё Энд Эбё Мидьжли (Aldred Farrer Barker & Eber Midgley). Ткань, созданная из камвольной (или грубой) пряжи, а именно гладкой компактной пряжи из длинных шерстяных волокон, используемой главным образом для плотных безжгутиковых тканей. В Соединённых Штатах Америки торговый термин 'Грубый Меринос' (Worsted Merino) использовался для предполагаемой комбинации в содержании полушерстяных и полухлопковых и спряденных в соответствии с Французской системой (1924 год). Камвольная (или грубая) пряжа имеет гладкую поверхность, прядётся из длинноштапельной, равномерно гребнечёсаной шерсти. Камвольная (или грубая) ткань создаётся из камвольной (или грубой) пряжи и является плотно сотканной, с гладкой 'твёрдой' поверхностью. Прежде всего габардин (gabardine) и саржа (serge) являются примерами камвольной (или грубой) ткани. Одной из притчей возникновения такого названия является история, в которой Вильгельм Завоеватель (William the Conqueror), придя в Британию в 1066, увидел в данной местности множество крестьян, расчёсывающих шерсть, и с тех пор благодаря ему появилось понятие грубые люди (или камвольщики, или шерстянщики) (worsted the people), поскольку он называл их Грубиянами (или Камвольщиками, или Шерстянщиками) (Worsted). Тем не менее, слово (worsted) появилось в Норфолке (Norfolk) от слова (Worstead), некогда понятие Worstead применялось для обозначения Усадьбы (Homestead). Камвольная (или грубая) пряжа создаётся из длинных волокон, имеющих штапельную длину от 3 до 6 дюймов (от 76.2 до 152.4 миллиметров), которые расчёсываются с целью выкладывания их параллельно друг другу и с тем, чтобы быть гладкими и чистыми. Такая пряжа, обычно, тонкая, плотно скрученная в несколько сложений. Камвольная, от Немецкого слова Камволе (Kammwolle), означающее Чёсаная Шерсть. Шерстяные Ткани подразделяются на:- (i) Камвольные:- вырабатываются из тонкой гладкой, так называемой гребенной пряжи, для пошива платьев, костюмов, пальто и тому подобного; (ii) Тонкосуконные:- из более толстой, так называемой аппаратной пряжи, для пальто и костюмов; и (iii) Грубосуконные:- из самой грубой, толстой аппаратной пряжи, для пальто, одеял и другого. Под Камвольным Прядением, от Немецкого слова Kammwolle, означающейй Чёсаная Шерсть), понимается устаревшее, вышедшее из употребления название Гребенного Прядения шерсти.

WORSTED CARD = КАМВОЛЬНАЯ КАРДОЧЁСАЛЬНАЯ МАШИНА – Worsted Card is a type of roller card user for worsted-system processing. It usually comprises two cards in tandem; the unit has a roller that carries the stock from the first card to the feed-in of the second card.

WORSTED COUNT = НУМЕРАЦИЯ ПРЯЖИ ИЗ ГРЕБЕННОЙ ШЕРСТИ – The Worsted Count also expresses the number of hanks required to make a pound of yarn. A hank of worsted wool is equal to 560 yards. So 1 wc = 560 yards of cotton, the coarsest worsted yarn. Worsted sizes are expressed the reverse of cotton sizes. A two-ply number 6 worsted yarn would be expressed as 2/6 wc and would yield 1 680 yards per pound. You can covert worsted count to cotton count by multiplying the cc by 1.5, or wc = cc x 1.5. See also Bradford Count. Worsted Count is a woolen yarn measure. A 1's worsted yarn has 560 yards in one pound of yarn. / Брэдфод (Bradford).

WORSTED FABRIC = КАМВОЛЬНАЯ ТКАНЬ – Worsted Fabrics:- usually made with wool, the fibers of worsted fabric are maintained parallel before spinning, which makes tightly twisted yarns. Worsted fabric has a hard, smooth surface; an example of worsted fabric is gabardine. Worsted:- a fabric made from worsted yarn, namely a smooth compact yarn from long wool fibers used especially for firm napless fabrics. Worsted Fabric is a tightly woven fabric made by using only long staple, combed wool or wool-blend yarns. The fabric has a hard, smooth surface. Gabardine is an example of a worsted fabric. A common end use is men's tailored suits. / Полотно – сотканная ткань, выработанная с использованием только лишь длинноштапельной гребенной шерстяной или полушерстяной пряжи. Данная ткань имеет твёрдую, гладкую поверхность. Габардин (gabardine) является примером камвольной (или грубой) ткани. Наиболее распространённым конечным применением данной ткани является пошив мужских костюмов.

WORSTED KNITTING YARN = КАМВОЛЬНАЯ ТРИКОТАЖНАЯ ПРЯЖА (или ГРЕБНЕЧЁСАНАЯ ТРИКОТАЖНАЯ ПРЯЖА) – Worsted Knitting Yarn:- wool yarn made of long-staple fibers that have been combed to remove undesirable short fibers and make them lie parallel. In the spinning operation, which imparts the necessary twist to hold the fibers together, worsted yarns are more tightly twisted than are the bulkier woolen yarns. Two yarns may be twisted together to form two-ply yarn, or three or four yarns may be twisted together to form three- or four-ply yarn. The soft, heavy yarn is strong and durable and is often used for sweaters.

WORSTED SPINNING SYSTEM = СИСТЕМА КАМВОЛЬНОГО ПРЯДЕНИЯ (или СИСТЕМА ПРЯДЕНИЯ ЧЁСАНОЙ ШЕРСТИ) – Worsted Spinning System is a system of yarn production designed for medium or longer wools, and other fibers. The suitable fiber

lengths vary from 2.5 to 7 inches. The process includes, opening, blending, cleaning, carding, followed by combing, drawing and spinning. These yarns are compact, smooth and more even and stronger than similar yarns spun using the Woolen Spinning System. In the mid 1960s we succeeded in convincing leading worsted spinners to blend linen tops, after which totally new applications of linen blends were successfully developed. In order to spin fine counts on the Worsted Spinning Systems, the linen fibers have to be of the highest grade of cleanliness. The search for higher grades of raw materials remains one of our major challenges. Linen tops can be spun in fully normal circumstances up to Nm 50 and even finer. This implies a rigorous selection of the raw materials and the correct processing of the fibers (carding, intersecting, converting, gilling and combing). We have developed a wide range of grades to unable any requested application (knitted and woven garments, voile, upholstery etc). Our qualities can also be recombed, if necessary. One can choose to recomb the pure linen or the 50/50 blend. Combing equipment appropriate for wool with a medium micronaire should be used for this. After recombing the 50/50 blends, the final requested linen content will be adjusted on the intersecting gill frame. Worsted-yarn counts for both weaving and knitting purposes can vary from 18's metric to 50's metric, although some linen tops can be spun at 100's metric. The linen content ranges from 10 to 55%, depending on the yarn count or the requested outlook of the final fabric. The price of combed linen tops depends on its fineness and cleanliness, characteristics which also determine the spinning efficiency and spinning limits of the yarn. / Под Камвольным Прядением, от Немецкого слова Kammwolle, означающейй Чёсаная Шерсть), понимается устаревшее, вышедшее из употребления название Гребенного Прядения шерсти.

WORSTED SYSTEM = КАМВОЛЬНАЯ СИСТЕМА – Worsted System is a system of textile processing for manufacturing spun yarns from staple fibers usually over 3 inches in length. The main operations are carding, combing, drafting, and spinning. There are three basic systems of worsted yarn spinning:- the Bradford (or English system), the French (Alsatian or Continental system), and the American system. Worsted System:- the textile process of manufacturing spun yarns from staple fibers usually over 3 inches in length. The main operations are carding, combing, drafting, and spinning. Worsted System:- in the worst system, the wool is combed after drying. This is method is only used on longer wools, and as a result the fibers are laid parallel to one another. Worsted materials normally have a smooth finish, and are extremely durable. Some examples of worsted products include suits, dresses, and gabardines. / Брэдфод (Bradford) (или Английская система), Французская (Элсэйшэн (Alsatian) или Континентальная система (Continental system)), и Американская система.

WORSTED–WEIGHT YARNS = КАМВОЛЬНАЯ ВЕСОВАЯ ПРЯЖА – Worsted-Weight Yarns:- these yarns knit to a gauge of 4-1/2 to 5 stitches per inch on size 7, 8, or 9 US needles. These yarns have approximately 850–1 100 yards per pound. This category of yarns is the main weight of yarns used to make sweaters, and contains some of the yarns which are very fluffy like mohairs and angoras.

WORSTED YARN = КАМВОЛЬНАЯ ПРЯЖА – Worsted Yarns are spun from longer (three inches plus) fibers that have been carded, combed, and drawn. Combing machines further straighten the alpaca sliver, making the individual fibers lie parallel. The combing process also eliminates noils. The drawing process takes the worsted sliver, doubles it over onto itself and draws it out again to a thinner, more uniform diameter to ensure that all the Alpaca fibers are parallel. Worsted yarns are twisted tighter and thinner in the spinning process and are manufactured into lightweight fabrics, such as gabardine and crêpe. Worsted Yarn is a worsted yarn is compressed and slick and maybe a bit shiny. Think worsted for gansey or Aran sweaters. Worsted yarn makes for good stitch definition. In the manufacturing of worsted yarns, the Different steps involved are:- Carding; Gilling and Combing; Drawing; Roving; and Spinning. (i) Carding:- the carding process for worsted yarn production is intended to disentangle and lay them as parallel as possible. The fibers are passed between rollers covered with fine wire teeth. Since worsted yarns, however, should be smooth, the fibers are made to lie as parallel as this process will permit. Following this operation, the wool goes to the gilling and combing processes. (ii) Gilling and Combing:- gilling is carried out before (preparative gilling) and after (finisher gilling) combing. The preparative gilling is mainly to align the fibers in a parallel direction, further blend the wool through doubling and to add moisture and lubricants. Whereas finisher gilling is mainly aimed to remove the mild entanglement introduced to the combed sliver. The carded wool, which is to be made into worsted yarn, is put through gilling and combing operations. The gilling process removes the shorter staple and straightens the longer fibers. This process is continued in the combing operation, which removes the shorter fibers of 1 to 4 inch (25–100 mm) lengths (called Combing Noils), places the longer fibers (called Tops) as parallel as possible, and further cleans the fibers by removing any remaining loose impurities. (iii) Drawing:- drawing is an advanced operation which doubles and redoubles slivers of wool fibers. The process draws, drafts, twists, and winds the stock, making the slivers more compact and thinning them into slubbers. Drawing is done only for worsted process. (iv) Roving:- this is the final stage before spinning. Roving is actually a light twisting operation to hold the thin slubbers intact. (v) Spinning:- the type of spinning explained here is applicable both for woolen and worsted yarns. In the spinning operation, the wool roving is drawn out and twisted into yarn. There are two main methods used to produce woolen-spun yarns. These are:- (a) Ring Spinning; and (b) Mule Spinning. Mule-spun yarns generally are superior to ring-spun yarns but they tend to be much more expensive due to the slow production rates and high labor input. Worsted yarns are spun on any kind of spinning machine – mule, ring, cap, or flyer. The two principle systems of spinning worsted yarns are the English system and the French system. In the English system (Bradford), the fiber is oiled before combing, and a tight twist is inserted. This produces smoother and finer yarns. The more tightly twisted yarn makes stronger, more durable fabrics. In the French system, no oil is used. The yarn is given no twist; it is fuzzier, and therefore suitable for soft worsted yarns. / Брэдфод (Bradford).

WORT = СУСЛО (или СОЛОДОВАЯ ВЫТЯЖКА) – Wort is the sweet infusion of ground malt or other grain before fermentation, used to produce beer and distilled malt liquors:- yeast is added to the wort. Wort is the liquid portion of malted grain. It is a solution of malt sugar and other water-soluble extracts from malted mash. Wort is the liquid extracted from the mashing process during the brewing of beer or whisky. Wort contains the sugars that will be fermented by the brewing yeast to produce alcohol. The first step in wort production is to make malt from dried, sprouted barley. The malt is then run through a roller mill and cracked. This cracked grain is then mashed, that is, mixed with hot water and steeped, a slow heating process that enables enzymes to convert the starch in the malt into sugars. At set intervals, most notably when the mixture has reached temperatures of 45, 62 and 73 °C (113, 144 and 163 °F), the heating is briefly halted. The temperature of the mixture is usually increased to 78 °C (172 °F) for mashout. Lautering is the next step, which means the sugar-extracted grist or solids remaining in the mash are separated from the liquid wort. In homebrewing, the malt-making and mashing steps can be skipped by adding malt extract to water. The mixture is then boiled to sanitize the wort and, in the case of most beer production, to extract the bittering, flavour and aroma from hops. In beer making, the wort is known as 'Sweet Wort' until the hops have been added, after which it is called 'Hopped or Bitter Wort'. The addition of hops is generally done in three parts at set times. The bittering hops, added first, are boiled in the wort for approximately one hour to one and a half hours. This long boil extracts resins, which provides the bittering. Then, the flavouring hops are added, typically 15 minutes from the end of the boil. The finishing hops are added last, toward the end of or after the boil. This extracts the oils, which provide flavour and aroma but evaporate quickly. In general, hops provide the most flavouring when boiled for approximately 15 minutes, and the most aroma when not boiled at all. At the end of boiling, the hot wort is quickly cooled (in homebrewing, often using an immersion chiller) to a temperature favourable to the yeast. Once sufficiently cooled, the yeast is added, or 'pitched', to begin the fermentation process. The adjunct grains that can be

added to the mash include wheat, corn, rye, and rice. Adjunct grains may first need gelatinization and cooling. They are used to create varietal beers such as wheat beer and oatmeal stout, to create grain whisky, or to lighten the body (and cut costs) as in commercial, mass-produced pale lagers. / солодового зерна. солодового сахара и других растворимых в воде экстрактов из замешанного солода. Под Суслом понимается:- (i) водяной раствор экстрактивных веществ растительного сырья или солода, предназначенное к сбраживанию; или (ii) отпрессованный сок винограда.

WORT = ЯСМЕННИК – Wort is a plant or herb used as food or medicinally. Wort is any of various plants or herbs. The word is usually used in combination to refer to specific plants, e.g., St. John's wort; however, it may be used on its own as a generic term. Wort is archaic term for any plant or herb. Wort:- Used in names of plants and herbs, especially those used formerly as food or medicinally, e.g., butterwort, lungwort, woundwort. / Под Ясменником понимается род одно- и многолетних растений семейства Мареновых. Около 90 (по другим данным, до 200) видов, в Евразии, Северной Африке и Австралии; в бывшем СССР насчитывалось около 60 видов (по другим данным, до 90). Некоторые Ясменники декоративные растения, многие – медоносы.

WORTH = ЦЕННОСТЬ – Worth is a measure of value received, material or resources expended, satisfaction derived, or perceived importance of something tangible or intangible. It may be expressed either in monetary or in non-price terms. Worth is an indefinite quantity of something having a specified value. See also Value.

WOVEN–AS–DRAWN–IN = СОТКАНО–КАК–ПРОРИСОВАНО – Woven-As-Drawn-In:- used often with weaving overshot patterns. This is the order of treadling that will give the finished fabric a squared pattern with a diagonal line running through it.

WOVEN FABRIC = ТКАНАЯ ТКАНЬ (или СОТКАННАЯ ТКАНЬ) – Woven Fabrics are made of yarns interlaced in a regular order called a Binding System, or Weave. Weaving is the process of combining warp and weft components to make a woven structure. The components need neither be parallel to each other nor cross each other at right angles, but most woven structures are composed of two sets of components, both flexible and crossing at right angles. Weaving is differentiated from warp and weft knitting, braiding, and net making in that these latter processes make use of only one set of elements. In addition, there are geometrical differences, one of the most significant being the small angles through which the components of a woven structure are, in general, bent, in contrast with the components of other structures. Woven Fabric is a fabric made by interlacing two sets of yarn at right angles. The warp yarns run lengthwise in the fabric; the filling (weft) yarns are passed over and under the warp yarns. Woven Fabric:- generally used to refer to fabric composed of two sets of yarns, warp and filling, that is formed weaving, which is the interlacing of these sets of yarns. However, there are woven fabrics in which three sets of yarn are used to give a triaxial weave. In two-dimensional wovens, there may be two or more warps and fillings in a fabric, depending on the complexity of the construction. The manner in which the two sets of yarns are interlaced determines the weave. By using various combinations of the three basic weaves, plain, twill, and satin, it is possible to produce an almost unlimited variety of constructions. Other effects may be obtained by varying the type of yarns, filament or spun, and the fiber types, twist levels, etc. Woven Fabric is a term that generally used to refer to a fabric composed of two sets of yarns, warp and filling, that is formed by weaving, which is the interlacing of these sets of yarns. Woven Fabrics are fabrics composed of two sets of yarns. One set of yarns, the warp, runs along the length of the fabric. The other set of yarns, the fill or weft, is perpendicular to the warp. Woven fabrics are held together by weaving the warp and the fill yarns over and under each other. Woven fabric has basically three weaves:- twill weave, plain weave and satin weave. All weaves, either simple, elaborate or complex, are derived from these three weaves. Woven Fabric is a material (usually a planar structure) constructed by interlacing yarns, fibers, or filaments, to form such fabric patterns as plain, harness satin, or leno weaves. / уточина (уток) . Ткани, набранные переплетением двух наборов пряжи под прямыми углами. Нити пряжи основы выкладываются вдоль длины всей ткани, а нити пряжи уточины (утка) проходят над и под нитями пряжи основы. Ткани, составленные из двух наборов пряжи. Один набор пряжи, основа, проходит вдлину вдоль всей ткани. Другой набор пряжи, уточина или уток, выкладывается перпендикулярно основе. Сотканные ткани схватываются в одно целое посредством процесса ткачества пряжи основы и уточины, когда эти наборы пряжи укладываются сначала над, затем под каждой из друг друга.

WOVEN LABEL = ТКАНАЯ ЭТИКЕТКА – Woven Label:- the primary use of a woven label is to identify the brand name of a garment. It is generally placed on the inside neckline of a shirt or the inner waistband of a pant. The label is occasionally referred to as a Main Label or Garment Label. Fore example, the Apparel Search web site categorizes these items as main labels. Woven labels are sometimes confused with direct embroidery. This misconception could not be further from the truth. Woven labels of any kind are constructed from yarn in the same manner as any woven fabric. The background fabric is produced by combining either white or black warp yarns running in the length of the label with white, black or colored weft yarns running back and forth across the label's width. The label's design is simultaneously woven into the ground fabric by selectively inserting a colored design yarn across the warp in place of the weft yarn used to construct the ground.

WOVEN LINT = ЗАТКАНОЕ ВОЛОКНО – Woven Lint:- (i) poor house keeping; (ii) m/c cleaning, by air and same time other m/c works or runs; and (iii) Jacquard cleaning, dobby cleaning, all part cleaning, should be done at outside of loom shed. Weaving defect. / Жакяр (Jacquard). Порок или дефект ткачества.

WOVEN ROVING = ЗАТКАНАЯ РОВНИЦА – Woven Roving is a heavy glass fiber fabric made by weaving roving or yarn bundles.

WOVEN SEERSUCKER = ТКАНАЯ ЖАТКА (или ТКАНАЯ ГОФРИРОВАННАЯ ТКАНЬ, или ТКАНАЯ ЛЁГКАЯ ПОЛОСАТАЯ ТКАНЬ) – Woven Seersucker is a crinkly and stripy cotton fabric made by weaving some of the yarns in tighter tension than others. Seersucker is a thin, puckered, all-cotton fabric, commonly striped or chequered, used to make clothing for spring and summer wear. The word came into English from Hindustani (Urdu and Hindi), which originates from the words 'Kheer Aur Shakkar', meaning 'milk and sugar', probably from the resemblance of its smooth and rough stripes to the smooth texture of milk and the bumpy texture of sugar. Seersucker is woven in such a way that some threads bunch together, giving the fabric a wrinkled appearance in places. This feature causes the fabric to be mostly held away from the skin when worn, facilitating heat dissipation and air circulation. It also means that pressing is not necessary. Common items of clothing made from seersucker include suits, shorts, shirts, and robes. The most common colors for it are white and blue; however, it is produced in a wide variety of colors, usually alternating colored stripes and puckered white stripes slightly wider than pin stripes. History:- during the British colonial period, seersucker was a popular material in Britain's warm weather colonies like British India. When Seersucker was first introduced in the United States, it was used for a broad array of clothing items. For suits, the material was considered a mainstay of the summer wardrobe of gentlemen, especially in the South, who favored the light fabric in the high heat and humidity of the summer, especially prior to the arrival of air conditioning. The fabric was originally worn by the poor in the United States until preppy undergraduate students began wearing it in the 1920s in an air of reverse snobbery. Damon Runyon wrote that his new habit for wearing seersucker was 'causing much confusion among my friends. They cannot decide whether I am broke or just setting a new vogue'. Seersucker is comfortable and easily washed and was the choice for the summer service uniforms of the first female United States Marines. The decision was made by Captain Anne A. Lentz, one of the first female officers selected to run the Marine Corps Women's Reserve during the Second World War. Beginning in 1996, the US Senate held a Seersucker Thursday in June, where the participants dress in traditionally Southern clothing, but the tradition was

discontinued in June 2012. Weaving Process:- seersucker is made by slack-tension weave. The threads are wound onto the two warp beams in groups of 10 to 16 for a narrow stripe. The crinkle stripe may have slightly larger yarns to enhance the crinkle. The stripes are always in the warp direction and ongrain. Today, seersucker is produced by a limited number of manufacturers. It is a low-profit, high-cost item because of its slow weaving speed. Seersuckers are made in plain colors, stripes, plaids, checks (also known as Gingham) and prints. Seersucker is used in curtains and summer suiting, dresses, and sportswear. / В Индии, лёгкая полосатая ткань, плательная или декоративная. Кхир Аур Шакар (Kheer Aur Shakkar). WOVEN SEERSUCKER STRIPE = ТКАНАЯ СИЭСАКЁ ПОЛОСКА (или ТКАНАЯ ЛЁГКАЯ ПОЛОСАТАЯ ТКАНЬ) – Woven Seersucker Stripe:- One line of fabrics which has not been in very large demand for a number of years past, but which recently (in 1914) has been selling in large quantities, is that line ordinarily known as Seersuckers. It must not be supposed that these cloths do not have a more or less regular distribution, but as is the case with other materials, there are certain times when the demand is much larger than usual. Most of such fabrics are desirable for many uses such as dresses, waists, rompers, children's garments and various other purposes. Generally they are firm fabrics and will return quite a large amount of value, inasmuch as they are woven with comparatively coarse yarns and are of heavy weight. One of the great advantages of these fabrics is that they do not have to be ironed similar to most other materials after they have been washed. The nature of the cloth permits this process to be dispensed with, and therefore makes the material suitable for many uses where washing can be accomplished but where there is little opportunity for any ironing process. There are two distinct classes of woven seersucker materials. First, that class which is made from carded yarns, and, in the majority of instances, contains more or less colored yarn; and second, that class of fabrics which is woven from grey yarns and may by produced from either carded or combed stock and sold in the white state or may be piece dyed. Of course, it is possible to produce the first class of fabrics mentioned from combed stock, but due to competition in price and various other features, it is seldom done. Without question, the second class of fabrics returns much more value than the first class, but it has often happened that the style of this class of materials has been somewhat lacking, due to the absence of color. To-day this is not so necessary, inasmuch as colors fast to bleaching can be used, although up to the present few of such fabrics have been made. The noticeable feature of these seersucker fabrics is the crinkled appearance of a portion of the cloth. This crinkled portion is, in all the fabrics we have mentioned, a woven one, will not pull out and might be said to be permanent. The degree of crinkle will vary in different fabrics, depending upon the cloth construction and certain features in making. The effect is produced in the following manner:- In ordinary fabric weaving the beam upon which the warp yarn is placed is held quite tightly, either through weights or in some other manner. This beam is let off either mechanically or through friction, so that as the reed forces the picks into the cloth, enough yarn is pulled off to allow for the weaving of the fabric. This above condition is noted upon one of the beams used in making a seersucker fabric, and is the portion of the warp in which there is no crinkle. For the crinkle portion, an extra beam is necessary, and there is very little weight used upon such beam, so that as the reed forces the picks into the cloth it also pulls down a certain amount of yarn, which extra yarn creates the crinkle in the fabric. There are other reasons why the crinkle is formed, one of them being the fact that extra yarn is used in the stripe where the crinkle is made. This extra yarn causes greater friction and makes the effect more prominent. Crinkle effects can be produced without the use of extra yarn, but they are not likely to be so satisfactory as where extra yarn is used. Not only does the extra yarn cause more friction with a greater yarn let-off, but it also makes that portion of the fabric where the crinkle is produced more prominent, due to its heavier character. In our analysis we have given two different layouts for the warp patterns, the first one being that which relates to the different colors and their arrangement in the cloth. The second is the method of placing the yarn on the beam. The ground beam contains both white and colored yarn, for the take-ups on these ground yarns are identical. The second beam contains the crinkle yarn, upon which there is a much greater take-up. With these two layouts there should be no great difficulty in determining just the method which is used in making the cloth pattern. In addition to the layouts as given, we are presenting the fabric weave as it appears in the cloth. It will be noted that certain threads weave differently than others. In some instances a basket weave is used, in others a plain weave, while in still other instances the threads weave as plain, with the exception that instead of a single thread there are two alongside which work identical. Underneath the design we have given the reeding plan, which indicates the number of threads to be drawn in each dent in the reed. It will be noted that where the threads weave otherwise than the ordinary plain weave they are drawn four threads in a dent. The obtaining of desirable results in many varieties of cloth is partly due to the correct placing of the threads in the reed. It often happens that through a correct method satin stripes can be woven from the same beam as ground threads of a plain character and at other times incorrect reeding will cause a great deal of trouble in cloth making. Sometimes, the percentage of production will be unreasonably low, just because enough attention has not been given to this feature of cloth planning. In drawing in a fabric of the character analyzed, it is possible to use two methods, the first where a single thread is drawn in every heddle, even though some of them work the same as those alongside. The second method is where two threads are drawn in the same heddle whenever they operate in the same manner. This latter method is the one generally employed, although in a certain few instances it has oeen found more desirable to use the first method. One reason why the second method is better is because it decreases the number of heddles necessary and allows more space for the threads or harnesses to operate as the cloth is being woven. When this method is taken it is, however, possible for single threads to weave in the heddles where there should be two threads being used. Without doubt the sale of woven crinkle effects would have been much larger than it has been; in fact, it is believed that the sale would have been very much larger than it ever has in the past, were it not for the fact that many somewhat similar effects have been produced during the last two years by other methods than weaving. Inasmuch as many consider this second class of fabrics on the same basis as the ones previously mentioned, it may be well to give a short description regarding them and their methods of making. These latter materials are not produced by the weaving process, that is, the crinkle effects is not produced in such manner. Most manuiacturers and practically all converters and finishers are familiar with the fact that the mercerization process will cause quite a large cloth shrinkage if it is used and the fabric not held out tightly. It is upon this contraction that the printed crinkle effects are obtained. Upon certain portions of the fabric, by methods somewhat similar to the ordinary ones used in making printed patterns, is placed a solution of caustic soda. This solution causes the fabric to shrink radically where it is applied, and when this shrinkage occurs it causes the remainder of the fabric to crinkle up and makes the effects which are not used so extensively. On this style of fabric various printed patterns can be placed in different colors, and the large sale has been possible because the fabrics are desirable, not only because of style but also because of a comparatively low price. Finishers who handle fabrics of this character demand a 25 per cent working loss, which is about the extreme amount of shrinkage that mercerization is likely to cause, but it has been found that on most lines of these cloths the loss to a converter because of shrinkage will be about 18 per cent, though in some few instances it has run as high as 20 per cent. This loss in shrinkage is a serious matter to the converter and must be accurately known if a correct cloth price be obtained. When a fabric loses in length anywhere from a fifth to a sixth it naturally makes the value of the material just that amount greater than it previously was, for it increases the number of picks per inch the relative amount named. The fabric analyzed, and which, as stated previously, is a woven effect is produced In large quantities regularly. The retail price is 15 cents per yard, thus allowing the regular distribution prices to be noted. It is seldom that retailers can purchase such a fabric at less than 10-1/2 cents per yard, and it is almost impossible for jobbers to force retailers to pay over 11 cents per yard for this sort of fabric. The commission house price on the cloth is about 9-1/4 cents per yard. Retail prices show a much smaller advance over the cost of production on fabrics of this character than they do on most other

lines of fancy fabrics. This is because the materials are produced in large quantities, making it possible for satisfactory returns to be obtained because of large quantities sold rather than high profit through the sale of small amounts. One of the great advantages in a mill producing a fabric of the character described is that a great variety of results can be obtained, even though the cloth construction does not vary widely. In all these cloths the construction is identical, so far as the count in the ground cloth is concerned, although there is a small variation in warp count, due to the different arrangement of crinkle stripes. The effects are obtained through the color arrangements and the different spacings and arrangements of crinkle stripes and not through the variation in yarn size which is necessary in other styles of fancy fabrics made from grey yarns. One of the features which has been of decided advantage in the production of printed crinkle effects is that there has been a great variety of results possible, due to printed patterns and different arrangements of stripes. While different effects are possible in greater or less amount on many styles of plain fabrics it is not often that the variety possible is as great as is noted on the printed crinkle materials. Sellers all desire to purchase large amounts of a ground fabric, for in this manner they can obtain very low prices, but unless the ground cloth can be finished in many attractive ways which are in demand at the time, it is not always a good policy to make large purchases. In the majority of instances the yarns used in the making of woven crinkle effects, where colors are used, are in the vicinity of 30-1 warp and 40-1 to 45-1 filling. Of course, there are some finer lines than that mentioned produced, but their sale is comparatively small when the total distribution is considered. One of the great objections to all fabrics which are made from bleached and dyed yarns is that their appearance is not so regular as cloths which have been produced from grey yarns and then are afterward finished or dyed. The picks in fabrics woven from bleached and dyed yarns are not worked into thair positions so smoothly as those which are finished after being woven, and often the reed marks show in such a prominent way that much of the desirable fabric effect is lost. It is true that some styles of grey yarn fabrics show reed marks after they have been finished, but the number is so small in comparison to fabrics made of bleached yarn, that it is not worth while considering them. It is believed that manufacturers could have done much more with crinkle effects produced from grey yarns and with a certain amount of fast color used in their construction than they have done. Profits are often quite large through the adoption of methods not in general use and makers should allow no opportunities to slip past without making the most of them. Possibly one of the greatest advantages in making these cloths from grey yarns is that which is noted in most other styles of fabrics, and is that fine grey yarns can be handled much more satisfactorily and at a much smaller relative cost than bleached yarns of the same character. In the majority of instances it is not possible for colored yarn mills to handle yarns much finer than 50-1, while this is a comparatively low count for many grey cloth makers. The difficulties in weaving are not especially prominent, but it is not possible for a weaver to operate as many looms on constructions such as that analyzed, as it is on similar classes of ginghams, or shirting stripes. The uneven tension on the top beam, and the fact that the threads are reeded quite closely in the dent where the crinkle is produced is likely to cause a certain amount of trouble, though not of an especially serious nature. Whenever a fabric is produced which has a more or less staple sale, and where it is expected to operate looms continuously in the production, it is a paying proposition to advertise the fabrics and create a demand for them. It is certain that to-day there are very few lines which can be successfully distributed unless this method is taken. It is possible to sell a certain amount of cloth of a staple nature without advertising, but this amount will be neither regular nor will it be large enough to supply the looms with orders. Sometimes the amounts expended for advertising purposes appear large, but when they are distributed over the whole cloth production they are often of a negligible quantity. In certain instances it has been positively proven that lower quality goods can be sold successfully when they are sufficiently advertised. It is not an especially good policy to advertise goods and sell them because they are cheaper, and contain less value than others, but the instance shows how much influence advertising has in the distribution of fabrics such as that considered. There is no great difficulty in obtaining the weights of the various yarns used together with the weight of the cloth. The methods employed are exactly the same as for any ordinary fabric, the main item of importance being to obtain accurately the take-ups on the warp yarns. In the fabric analyzed the take-up on the crinkle portion was 29 per cent, or 23 per cent more than the ground cloth. The results are obtained as follows:- (i) 980 ends ÷ (30/1 x 840) = 0.038 9, weight of brown warp without take-up; (ii) 6% take-up in weaving; (iii) 0.038 9 ÷ 0.94 = 0.041 4, total weight of brown warp per woven yard; (iv) 504 ends ÷ (30/1 x 840) = 0.020 0, weight of white ground warp without take-up; (v) 6% take-up in weaving; (vi) 0.020 0 ÷ 0.94 = 0.021 3, total weight of white ground warp per woven yard; (vii) 960 ends ÷ (30/1 x 840) = 0.038 1, weight of crinkle warp without take-up; (viii) 29% take-up in weaving; (ix) 0.038 1 ÷ 0.71 = 0.053 7, total weight of crinkle white warp; (x) (60 picks x 30 5–6” width in reed x 36”) / 36” = 1 850 yards of filling per yard of cloth; (xi) 1 850 ÷ (40/1 x 840) = 0.055 1, total weight of filling per yard of cloth; (xii) 0.041 4 + 0.021 3 + 0.053 7 + 0.055 1 = 0.171 5, total weight per yard; (xiii) 1.000 0 ÷ 0.171 5 = 5.83 yards per pound. / уточина.

WRAP ACCOUNT = ОБЁРТОЧНЫЙ СЧЁТ (или ПОКРЫТЫЙ СЧЁТ) – Wrap Account:- investment consulting relationship in which a client's funds are placed with one or more money managers, and all administrative and management fees, along with commissions, are wrapped into one comprehensive fee, which is paid quarterly. The wrap fee varies, but usually ranges from 1% to 3% of the value of the assets in the account. Wrap accounts usually require a minimum initial investment of anywhere from USD25 000 to USD10 million for individual accounts. The term 'Wrap' has been expanded to involve mutual fund asset allocation programs. Technically, these are not wrap programs because they are not 'all inclusive'. Transaction commissions in these programs on mutual funds are still a variable and they are pooled accounts as distinguished from individual accounts. From the customer's point of view, a wrap account provides access to top investment managers. The broker overseeing the account is paid an ongoing fee to monitor the performance of the money managers. Although brokers may switch assets to other managers within the program if one manager consistently starts to underperform, most sponsors of wrap programs suggest a three- to five-year time horizon to reach investment goals. Wrap Account:- an investment consulting relationship for management of a client's funds by one or more money managers, that bills all fees and commissions in one comprehensive fee charged quarterly. Wrap Account at its most basic is an alternative form of commission arrangement between a securities firm and its client. Wrap accounts generally charge the client an annual fee based on assets in the account in lieu of a per transaction commission structure. In other words, the firm 'wraps' together all the costs and charges them off as a 'management fee'. Firms often add further features to wrap accounts such as investment management, custodial services, and enhanced reporting. / Упакованный Счёт (Wrap Account):- специальный брокерский счёт для богатых инвесторов, которые хотят переложить бремя решений назначения цен на акции на внешнего управляющего деньгами. В обмен на твёрдую ежегодную комиссию брокерская фирма помогает инвестору выбрать управляющего деньгами, платит комиссию за управление денежными средствами, выполняет любые сделки по распоряжениям управляющего и наблюдает за деятельностью. Упаковочный Счёт (Wrap Account):- взаимоотношения в области консультирования инвестиций, в ходе которых средства клиента размещаются у одного или более управляющих денежного рынка и вся плата за управление этими средствами, включая комиссии за выполнение отдельных операций, упаковывается в единое общее вознаграждение, которое выплачивается ежеквартально. Упакованные комиссии бывают разными, обычно составляют 1–3% от стоимости активов на счёте. Для открытия индивидуального упаковочного счёта обычно требуется примерно от 25 000 до 10 миллионов Долларов в качестве минимального первоначального вложения. Термин был расширен и теперь включает программы распределения активов взаимных инвестиционных фондов. Технически это всё-таки не в полном смысле упакованные программы, потому что они не 'включают в себя всё'. Комиссионные за операции в рамках этих программ по взаимным инвестиционным фондам всё ещё различаются, а сами счета по этим программам представляют собой объединённые счета – в отличие от индивидуальных счетов. С точки зрения клиента упаковочный счёт обеспечивает ему доступ к лучшим инвестиционным управляющим. Постоянная сумма комиссионных выплачивается брокеру и за наблюдение за операциями на счёте, это позволяет ему следить за результатами деятельности каждого управляющего денежного рынка. Брокер может передать активы другим управляющим в рамках той же программы, если увидит, что у какого-то управляющего устойчиво низкие результаты работы. Большинство инвесторов, вкладывающих средства в упакованные программы, полагают, что должно пройти 3–5 лет, прежде чем будут достигнуты цели инвестирования.

WRAPAROUND = ПЕРЕУПАКОВЫВАНИИ (или ПОКРЫТИЕ) – Wraparound is a financing device that permits an existing loan to be refinanced and new money to be advanced at an interest rate between the rate charged on the old loan and the current market interest rate. The creditor combines or 'wraps' the remainder of the old loan with the new loan at the intermediate rate.

WRAPAROUND = ХХ (или С ЗАПАХОМ) – Wraparound:- a garment, as a dress, made with a full-length opening and adjusted to the figure by wrapping around. Wraparound:- (of a garment) made to fold around or across the body so that one side of the garment overlaps the other forming the closure.

WRAPAROUND ANNUITY = ПЕРЕУПАКОВАННЫЙ АННУИТЕТ (или ПОКРЫТЫЙ ЕЖЕГОДНЫЙ ПЛАТЁЖ) – Wraparound Annuity is a contract allowing an annuitant discretion in the choice of underlying investments. Wraparound refers to the protection the annuity vehicle provides through its tax-deferred status, which becomes precarious when the annuity vehicle is being used as a

technical way to avoid tax payment. The tax courts have ruled against tax deferment where money can be allocated by an annuity owner to a portfolio managed by an annuitant and where the annuitant can switch among funds of the sponsoring insurance company that are also marketed independently of annuities. On the other hand, the US Internal Revenue Service (IRS) has upheld tax deferral where an individual could not buy such funds without also buying the annuity. In any event, the insurer must legally own the annuity money. Wraparound Annuity is an investment that allows the annuitant the choice of underlying investments tax-deferred. / Упаковочный Аннуитет:- программы отсрочки выплаты налогов, позволяющие физическому лицу обратить текущие процентные доходы по банковскому сберегательному сертификату или акциям во взаимном фонде в позволяющий отсрочивать выплату налогов аннуитет, управляемый страховой компанией. Обёртывающий Аннуитет – контракт, позволяющий выбирать лежащие в основе контракта инвестиции по усмотрению получателя средств. Термин обёртывающий (wraparound) характеризует уровень защиты, которую предоставляет такой способ инвестиций или аннуитет. Платежи налогов по нему отсрочены (tax-deferred), что становится опасным, если этот инвестиционный механизм используется как формальный способ избежать уплаты налогов вообще. Налоговые суды принимают решения против отсрочки налогообложения в том случае, если деньги могут быть направлены владельцем контракта на получение ренты в портфель вложений, управляемый владельцем обёртывающего контракта и когда он может переходить из одного фонда в фонд спонсирующей страховой компании. Эти фонды также рекламируются и предлагаются на рынке, независимо от аннуитетов. Сужба Внутренних Доходов (Internal Revenue Service) – налоговое управление США поддерживает возможность отсрочки налогообложения в тех случаях, когда частное лицо не может получить права на участие в этих фондах, кроме как путём приобретения аннуитета. В любом случае страхователь должен легально владеть деньгами аннуитета.

WRAPAROUND MORTGAGE = ПЕРЕУПАКОВАННАЯ ЗАКЛАДНАЯ (или ПОКРЫТАЯ ЗАКЛАДНАЯ) – Wraparound Mortgage is a type of loan that enables a borrower who is paying off an existing mortgage to obtain more financing from a second lender or seller. The new lender (typically a bank or the seller of the real property) assumes the payment of the existing mortgage and provides the borrower with a new, larger loan, usually at a higher interest rate. A wraparound mortgage is also known as a Wraparound Loan, Overriding Mortgage, or All-Inclusive Mortgage. This type of loan is used frequently as a method of refinancing property or financing the purchase of property when an existing mortgage cannot be paid off. The total amount of a wraparound mortgage includes the previous mortgage's unpaid amount plus the additional funds required by the borrower. The borrower makes payments to the new lender on the larger loan, and the new lender makes payments on the original loan. Wraparound Mortgage is a second mortgage that increases a borrower's indebtedness while leaving the original mortgage contract in force. The wraparound mortgage becomes the junior mortgage and is held by the lending institution as security for the total mortgage debt. The borrower makes payments on both loans to the wraparound lender, who in turn makes scheduled installment payments on the original senior mortgage. It is a convenient way for a property owner to obtain additional credit without having first to pay off an existing mortgage. The Wraparound Mortgage is an excellent and perfectly legal way for investors and homeowners to sell their properties faster and for more money than by selling for cash only. It's also a great way for realtors to get their listings sold before they expire and avoid losing their commissions. The traditional, 'garden-variety' house sale works like this:- Sam Seller owns a house. He'd like to sell it for USD210 000. He owes USD160 000 on his first mortgage (deed of trust in Texas) to Big Bank. Sam puts his house on the market, either with a realtor or FSBO (For Sale By Owner). Bill Buyer comes along and wants to buy Sam's house, and they agree on a purchase price of USD200 000. Bill puts down some earnest money, they sign a contract, and then Bill applies for a new mortgage from Bigger Bank. Bigger Bank checks Bill's credit, asks for his tax returns, pay stubs, and a pint of blood, and makes Bill pay for a new appraisal, a new survey, loan fees, underwriting fees, fee fees, etc. At closing, Bill pays Sam a down payment and Bigger Bank pays off Big Bank's mortgage, Sam's realtor, the title company, etc, before giving Sam whatever is left over. Big Bank's mortgage is paid off completely and goes away when Big Bank files a 'release of lien' in the county records. Bill now owns the house and Bigger Bank has a first position lien on the house with the new mortgage. The wraparound mortgage works a little differently. Remember, Sam Seller owes USD160 000 on his mortgage with Big Bank. Sam enters into a contract to sell his house to Bill Buyer for USD210 000. But this time, Bill does not apply for a new mortgage with Big Bank. Instead, Sam acts as Bill's bank and mortgage lender. At closing, Bill pays Sam a USD21 000 down payment (10%) and gives Sam a promissory note for the balance of the purchase price (USD189 000), plus a deed of trust or wraparound mortgage securing Sam's lien against the property. Sam gives Bill a deed, so Bill now owns the property, but Sam does not pay off Big Bank. Instead, Bill pays Sam every month, and then Sam pays Big Bank out of what he receives from Bill. Bill's new debt has 'wrapped around' Sam's old debt – hence the name. ('Hence the name' is a phrase that should be used more often, in my opinion.) This arrangement – Bill pays Sam, Sam pays Big Bank – can continue indefinitely, with Sam getting monthly cash flow from the spread between his payment to Big Bank and Bill's payment to him. If Bill and Sam agree, they can include a balloon payment in Bill's note, so that Bill will need to re-finance or re-sell the house within a certain time, usually 3–5 years. When that happens, Bill will pay off his note to Sam and Sam will pay off his note to Big Bank, and the new loan will take a new first position lien on the property. But until Bill sells the property or refinances, there will be two mortgages on the property – Sam's mortgage with Big Bank and Bill's mortgage with Sam. What are the advantages of the wraparound mortgage? Well, for Sam Seller, he gets a cash down payment at closing, monthly cash flow for as long as both mortgages are in place, and another cash payment when Bill Buyer re-finances in a few years. He also gets a better price, better terms and a quicker closing for his sale, because he doesn't have to wait for Big Bank to process the loan, do the appraisal, etc. And if he sells with 10% down, he can still pay his realtor commissions and keep everybody happy. Bill Buyer also gets the advantage of a quick closing, and he doesn't have to go through the lengthy loan application process, credit check, etc. If Bill has some credit issues or other reasons why he wouldn't be able to qualify for a new mortgage loan right now, he can still buy a house now and have a couple of years to get his credit issues straightened out. Now, it is true that selling a house on a wrap usually violates triggers the due-on-sale clause in the original deed of trust. That clause, which is included in almost every deed of trust, says that if the seller conveys the property without paying off the first note, then the lender can accelerate the note and call it due. It is not necessarily a violation of, or a default under, the deed of trust, and it is absolutely not 'illegal' to do this type of transaction. It is simply a clause that gives the lender the right, but not the obligation, to call the note due. It is true that this is a risk for both seller and buyer in this type of transaction. But how great a risk? Banks are not in the business of foreclosing on houses and owning real estate. Banks are in the business of making loans and getting paid back. As long as the payments remain current, what incentive does the bank have to accelerate the note? They have enough non-performing loans to worry about, why would they care about one that was being paid on time? As a practical matter, banks almost never 'call notes due' based on the due-on-sale clause as long as they are still getting paid. In fact, I have never even heard of it happening if there were no other violations of the mortgage or other issues with the note. It is a minuscule risk, but it is an actual risk and one that should be disclosed to everyone – the seller, the buyer, the title company, even the lender itself. And Texas law requires a notice to the lender and the buyer if a property is being sold on a wrap and no one is buying title insurance. For more on that particular issue, click here. With more and more buyers having trouble getting financed for a traditional bank loan, seller financing in general and wraparound mortgages in particular will become more and more common. Wraparound Mortgage is a second mortgage that leaves the original mortgage in force. The wraparound mortgage is held by the lending institution as security for the total mortgage debt. The borrower makes payments on both loans to the wraparound lender, which in turn makes payments on the original senior mortgage. Wraparound Mortgage:- seller as mortgagor retains an existing low rate mortgage, from

original lender, on property being sold. Buyer gets from lender (who may be seller) a mortgage at a rate higher than that on seller's existing mortgage but lower than market, which 'wraps around' the existing one, and with both, provides buyer with needed funds at an effective rate lower than market. Buyer lender, who transmits the portion due to original lender on seller's existing mortgage. / Вторая Закладная (Wraparound Mortgage):- ссуда по такой закладной предполагает участие двух кредиторов:- кредитора, представляющего первоначальную ипотечную ссуду, и второго ('упаковывающего') кредитора. Вместо предоставления совершенно новой закладной по текущим рыночным ставкам покупателю дома второй кредитор обязуется продолжать выплачивать ежемесячные очередные взносы по существующей закладной на покупаемый дом по первоначальной контрактной процентной ставке по закладной, а также совершать любые дополнительные платежи, необходимые для достижения цены покупки дома. В результате условия первоначальной закладной продолжают выполняться, продавец получает возмещение за продажу своих инвестиций, а покупатель дома имеет возможность купить дом и воспользоваться льготами ставки с ценой ниже рыночной, выплачиваемой вторым кредитором по части финансируемых денег. Обёртывающая Закладная – вторая закладная, которая увеличивает сумму задолженности заёмщика, оставляя одновременно в силе первоначальный контракт на закладную. Обёртывающая закладная превращается в Младшую Закладную (Junior Mortgage) и хранится у организации-кредитора в качестве обеспечения под весь кредит в целом. Заёмщик производит выплаты по обеим закладным займодавцу, предоставившему дополнительный ипотечный кредит, который, в свою очередь, делает запланированные платежи по взносам по первоначальной Старшей Закладной (Senior Mortgage). Это удобный способ получить дополнительное кредитование без необходимости сначала оплачивать существующую закладную.

WRAPPED BOND = ПОКРЫТАЯ ОБЛИГАЦИЯ – Wrapped Bond is a bond that is guaranteed by a monoline. A wrapped bond has the same credit rating as the insuring monoline which is generally higher than the credit rating of the bond issuer. As a result of the guarantee and higher credit rating, the issuer can obtain financing at a lower interest rate than it may have otherwise received. Wrapped bonds were originally used in municipal bond issuances but now are used to reduce the borrowing costs associated with a wide variety of financial products including project finance bonds and mortgage backed securities. Following the 2007 subprime mortgage crisis and the increased number of mortgage defaults, several monolines who insured these bonds were downgraded, resulting in reduced usage of wrapped bonds. Bond insurance (also known as Financial Guaranty Insurance) is a type of insurance whereby an insurance company guarantees scheduled payments of interest and principal on a bond or other security in the event of a payment default by the issuer of the bond or security. As compensation for its insurance, the insurer is paid a premium (as a lump sum or in installments) by the issuer or owner of the security to be insured. Bond insurance is a form of 'credit enhancement' that generally results in the rating of the insured security being the higher of (i) the claims-paying rating of the insurer and (ii) the rating the bond would have without insurance (also known as the Underlying or 'Shadow' Rating). Bond insurers are sometimes also referred to as 'Financial Guaranty Insurance Companies' or 'Financial Guarantors'. Companies whose sole line of business is providing a particular type of insurance, in this case bond insurance, are called Monoline Insurers. Note that the insurance term 'Monoline' means only that these companies do not have other insurance lines, such as life or property/casualty. It does not mean they operate only in one securities market, such as municipal bonds, as the term is sometimes misconstrued. Bonds insured by these companies are sometimes said to be 'wrapped' by the insurer. A Wrapped Bond is insured by a third party, most commonly by a monoline insurance company, such as Municipal Bond Insurance Association (MBIA), MBIA Insurance Corporation, Ambac Assurance Corporation, Financial Guaranty Insurance Company (FGIC), Financial Security Assurance Inc. (FSA), or XL Capital Assurance Inc. (XCLA). This is very prevalent in the municipal bond market and somewhat common in asset-backed securities (ABS), e.g., the bond is A under with a FGIC wrapper. Translation:- the bond is rated AAA/Aaa due to FGIC insurance, and would be rated A without insurance. / Экс.Эл. Кэпитэл Эшурэнс Инк. (Экс.Си.Эл.Эй.; XL Capital Assurance Inc. (XCLA)). Покрытая Облигация или Гарантированная Облигация – облигация, по которой специализированная страховая/гарантийная компания предоставляет безусловную финансовую гарантию. Гарантия позволяет повысить рэйтиньг облигации до рэйтиньга страховой/гарантийной компании.

WREATH = ВЕНОК (или ВЕНЕЦ) – Wreath is something intertwined into a circular shape, especially a garland or a chaplet.

WRECK = ОСТАТКИ КОРАБЛЕКРУШЕНИЯ – Wreck material includes any part of a vessel, aircraft or hovercraft including any of its cargo or equipment. According to the UK Merchant Shipping Act 1995, wreck can include:- (i) derelict is property which has been abandoned and deserted at sea by those who were in charge without any hope of recovering it (this includes vessels and cargo); (ii) flotsam are goods lost from a ship which has sunk or otherwise perished which are recoverable because they have floated; (iii) jetsam are goods cast overboard (jettisoned) in order to lighten a vessel which is in danger of sinking, even if they ultimately perish; and (iv) lagan (or ligan) are goods cast overboard from a ship, buoyed so that they can be recovered later. Boats that have come off their moorings are not normally classified as wreck as they have not been abandoned without hope of recovery. Also, buoys including marker buoys, mooring buoys etc, other than those that are fishing equipment, are not normally classed as wreck. Wreck:- a wrecked vessel, either submerged or visible, which is attached to or foul of the bottom or cast up on the shore. / ; и (iv) ляган (lagan) (или лигэн (ligan)) – товары, выброшенные за борт, отмеченные буем с тем, чтобы они могли бы быть найдены и подняты спустя какое-то время.

WRECKAGE = МЕСТО КОРАБЛЕКРУШЕНИЯ – Wreckage is an area identified as a danger to maritime navigation containing the ruined remains of one or more vessels.

WRECKAGE = РАЗВАЛИНЫ (или ОБЛОМКИ) – Wreckage is the broken parts of a vehicle, building, etc, that has been badly damaged or destroyed. Wreckage:- the debris or remains of something wrecked; the wreckage of a plane crash; flood wreckage. Wreckage is the remaining parts of something that has been badly damaged or destroyed. The scattered debris and plane parts after a devastating air crash is an example of wreckage.

WRECKER = АВАРИЙНЫЙ ТЯГАЧ (или ЭВАКУАТОР) – Wrecker is a truck designed for hoisting and towing disabled vehicles.

WRENCH = ГАЕЧНЫЙ КЛЮЧ – Wrench:- also called Spanner, tool, usually operated by hand, for tightening bolts and nuts. Basically, a wrench consists of a stout lever with a notch at one or both ends for gripping the bolt or nut in such a way that it can be twisted by a pull on the wrench at right angles to the axes of the lever and the bolt or nut. Some wrenches have ends with straight-sided slots that fit over the part being tightened; these tools are known as Open-End Wrenches and are made in various sizes to fit specific bolt and nut sizes. Box-end wrenches have ends that enclose the nut and have 6, 8, 12, or 16 points inside the head. A wrench with 12 points is used on either a hexagonal or a square nut; the 8- and 16-point wrenches are used on square members. Because the sides of the box are thin, these wrenches are suitable for turning nuts that are hard to reach with an open-end wrench. When a nut or a bolt head is in a recess below the surface of a bolted member, a socket wrench must be used; this is essentially a short pipe with a square or hexagonal hole and either an integral or a removable handle. Modern socket wrenches are made in sets, consisting of a number of short sockets with a square hole in one end that fits a removable handle and 8- or 12-point holes in the other end to fit various bolt and nut sizes. There are several types of handles and extensions, such as a T handle, screwdriver-grip handle, and a ratchet handle (see Ratchet). A useful accessory for a socket-wrench set is a handle equipped with a mechanism that measures the amount of torque, or turning effort, exerted by the wrench on the nut or bolt. One type of torque handle has two arms attached to the head, which carries the socket that fits the bolt or nut to be tightened; one arm carries the torque-indicating scale and remains fixed relative to the head, while the other arm carries the handgrip and is bent, relative to the head and the scale, when a bolt is tightened. A pointer on the bent arm indicates the torque on the scale. The purpose of a torque wrench is to make sure that screws and bolts in bolted assemblies are installed with sufficient tightness to prevent loosening during use, without being overtightened. Wrenches with one fixed and one adjustable parallel jaw can be used on various sizes of bolts and nuts within a limited range. On one type the jaws are at right angles to the handle; this wrench, invented by Charles Moncky, is known as a Monkey Wrench. On another type, originally called a Crescent Wrench, the jaws are almost parallel to the handle; on both types the movable jaw is adjusted by turning a worm that engages a rack of teeth cut into the jaw. The adjustable pipe, or stillson, wrench is used to hold or turn pipes or circular bars. This wrench has serrated jaws, one of which is pivoted on the handle to create a strong gripping action on the work. Recessed-head screws or set screws commonly have a hexagonally shaped recess and require a special wrench, usually referred to as an Allen Wrench; it consists of a hexagonal bar of tool steel shaped into the form of an L, either end of which fits into the recess. Power or impact wrenches are used for tightening or loosening nuts quickly. They are essentially small hand-held electric or pneumatic motors that can rotate socket wrenches at high speed. They are equipped with a torque-limiting device that will stop the rotation of the socket wrench when a preset torque is reached. Pneumatic wrenches are commonly used in automobile service stations, where compressed air is available and the sparking of electric motors is a fire hazard. / Серпообразный (или Серповидный) Гаечный Ключ (Crescent Wrench). Балтиморский механик Чалз Манки (Charles Moncky) изобрёл свой гаечный ключ, известный как Разводной Гаечный Ключ (Monkey Wrench), где-то около 1858.

WRIGHT DUST FEEDER = ПЫЛЕПИТАТЕЛЬ РАЙТА – The Wright Dust Feeder has been available to research scientists for almost 60 years, since its development by Martin Wright. A number of improvements and upgrades were introduced by BGI, Inc., in the current model WDF-II. BGI's contribution to the technology has been the standardization of stainless steel parts, the small and mini dust chamber, the development of the Venturi outlet for superior de-agglomeration, the variable speed motor and the development of the carbide cutter head. Because carbide is so long wearing and superior to the stainless steel blades they are now furnished as standard. Stainless steel heads and blades are only available as replacement parts. CH Technologies (USA), as the new owner of the Wright Dust Feeder product line, is committed to maintain and further the quality standards established by the original developer, BGI. We do this by maintaining the standard gages developed by BGI to ensure parts interchangeability among the thousands of Wright Dust Feeders, both Mark I and Mark II, currently in service. The Wright Dust Feeder, Mark-II (WDF-II) has been designed to provide uniform, airborne concentrations of dust for long periods of time. As with all aerosol generation equipment, not all materials are suitable for use with the mechanism. If there is a question which cannot be answered in the literature, consultation with the manufacturer is suggested. All component parts of the instrument in contact with the dust are fabricated from stainless steel. Considering unit density materials, the instrument has a feed rate ranging from 8 milligrams to 63 grams per hour. With the optional Mini chamber assembly (DF 300), the range may be extended down to 2.6 milligrams per hour. The WDF II is a test apparatus whose sole purpose is the generation of dry dust concentrations. It is designed and intended to be operated by skilled professionals whose background and training qualify them to do so. Every effort has been made to ensure electrical and mechanical safety. Use and operation in excess of technical specifications can lead to injury or death. The electrical module is intended for use in dry environments. Care must be taken to position it so that access to the on/off switch, which is located on the back of the electronic module, is not obstructed. The WDF-II is intended to generate concentrations of dusts which may be hazardous or toxic in nature. The chief facilities using this equipment are engaged in either filter testing or toxic exposure studies. All personnel must be under the direct supervision of a safety/occupational health professional. Unskilled operation can cause injury. The equipment may be installed in any orientation as there is no restriction in this regard. All safety guards must be in place during operation. No electrical grounding/earthing provisions may be disconnected. The electrical cord used must be of an earthing type. There is no organization which has direct jurisdiction over the instillation and use of Aerosol Generation equipment. However, there may be jurisdictions imposed by the safety regulations of the organization using the equipment or the organization for which tests are being performed. / Матин Райт (Martin Wright). WRINKLE = ЗАСЕЧКА (или МОРЩИНА) – In textile, Wrinkle is an objectionable crease, generally short and irregular in shape. Wrinkle is a surface imperfection in laminated plastics that has the appearance of a crease or fold in one or more outer sheets of the paper, fabric or other base which has been pressed in. / Засечка – порок ткани. Засечки:- представляют собой полосы, окрашенные менее интенсивно, чем вся ткань, образуются при крашении в расправленном состоянии вследствие образования складок, часто из-за плохого оформления шва между кусками.

WRINKLE = МОРЩИНА (или МУШКА, или ИЗЮМИНКА) – Wrinkle:- novel feature that may attract a buyer for a new product or a security. For example, zero coupon securities were a new wrinkle when they were introduced but soon thereafter became quite commonplace. Wrinkle:- a feature of a new product or security intended to entice a buyer. / Мушка или Морщина или Изюминка – любая вымышленная характеристика, которая может привлечь покупателя ценной бумаги. Морщина – новая черта, которая может привлечь покупателей нового продукта или ценных бумаг. Например, бескупонные ценные бумаги в начале 1980-х были новым продуктом, когда они впервые вышли на рынок, но вскоре стали распространёнными.

WRINKLED = СМОРЩЕННОЕ (или МОРЩИНИСТОЕ, или СМЯТОЕ) – Wrinkled:- creased or folded up irregularly in every direction. Wrinkled (apophyses):- with small folds or creases. / Сморщенное, например, о зерне.

WRINKLE FREE = НЕСМОРЩЕННОЕ (или БЕЗ СМЯТИН, или БЕЗ СМИНАНИЯ) – Wrinkle Free:- a resistant to wrinkling created through the use of a variety of finishes and treatments.

WRINKLE IN COLLAR = СМИНАНИЕ (или СМЯТИЕ, или ЗАСЕЧКА) В ВОРОТНИЧКЕ – Wrinkle In Collar:- Garment:- man's white broadcloth shirt with attached, fused collar; Fabric Construction:- (i) Count:- 136 x 60; (ii) Warp:- 40/1 combed cotton; (iii) Filling:- same as warp. Complaint:- a wrinkle was observed in the back portion of the fused collar which was not removed after laundering and pressing. Analysis:- in the particular garment submitted, the collar lining which is the base fabric for manufacture of the fused or starchless 'permanent-stiff' construction was woven with one end of acetate-rayon yarn in the warp, alternating with two ends of cotton yarn. The acetate ends are so woven in as to permit the subsequent fusing or bonding operation, usually consisting of a solvent and heat application to the two outer layers of shirting broadcloth, forming a 'spot-welded', laminated collar. Analysis of the collar in the returned shirt showed that, where the wrinkle was present, one end of acetate warp yarn was missing, and that this resulted in an open nonfused section. This was obviously a weaving fault which passed by gray- and finished-goods inspection unnoticed. / Уточина:- такая же как основа.

WRINKLE MARK = ОТМЕТИНА ОТ СМИНАНИЯ (или ОТМЕТИНА ОТ СМЯТИЯ, или ЗАСЕЧКА) – Wrinkle Mark or Crease:- caused by uneven tension and tautness on the cloth as it goes through the wet and dry finishing departments of the mill. They have to be combated in the finishing of cloth. See also Seam Mark. / Засечка – порок ткани.

WRINKLE RECOVERY = ВОССТАНОВЛЕНИЕ ПОСЛЕ СМИНАНИЯ (или РАСПРАВЛЕНИЕ ПОСЛЕ СМЯТИЯ) – That property of a fabric that enables it to recover from folding deformations. Wrinkle Recovery is the similar to resiliency. It is the ability of a fabric to bounce back after it has been twisted, wrinkled, or distorted in any way. Some fabrics are able to eliminate wrinkles because of their own resilience. Wool is among those, as are thermo- plastic manufactured fibers and chemically-treated cottons. Laboratory tests are made to determine the amount or degree a fabric will recover from wrinkling.

WRINKLE RESISTANCE = УСТОЙЧИВОСТЬ К СМИНАНИЮ (или НЕСМИНАЕМОСТЬ, или НЕМНУЩЕЕСЯ) – Wrinkle Resistance is that property of a fabric that enables it to resist the formation of wrinkles when subjected to a folding deformation. Wrinkle resistance in a fabric is a desirable attribute, but it is not easily measured quantitatively. Wrinkle resistance varies from quite low in many fabrics to very high in resilient fabrics. In order to form a wrinkle, a fabric's wrinkle resistance must be overcome. The fabric may, however, produce strains and store potential energy that can become evident as wrinkle recovery under suitable conditions.

WRISTBAND = НАПУЛЬСНИК (или ХХ, или БРАСЛЕТ) – Wristband is a band encircling the wrist. Generally use by athletes for wiping sweat from the forehead.

WRISTLET = НАПУЛЬСНИК (или ХХ, или БРАСЛЕТ) – Wristlet is a band encircling the wrist, especially one that is close-fitting, knitted, and attached to the top of a glove or end of a sleeve. / запястье.

WRIT = (СУДЕБНЫЙ) ПРИКАЗ – Writ is a legal document written by a judge or other body with administrative or judicial jurisdiction, such as a court, that orders the person to whom it is addressed to perform or cease performing a specified action. Writ of habeas corpus, for example, can be used to evaluate the constitutionality of criminal convictions delivered by state courts. Another writ in current use by the US federal courts is the writ of certiorari, which is issued by the Supreme Court of the United States to a lower court to review that court's judgment for legal error or when no appeal is available. Warrants and subpoenas are common types of writs. A Warrant is a writ issued by a judge or magistrate that allows a sheriff, constable or police officer to search a person or property (search warrant), arrest an individual or individuals (arrest warrant) or execute an individual who has been sentenced to death in a trial court (execution warrant). A Subpoena is a writ that compels a witness to testify or compels an individual or organization to produce evidence. Certain writs have been eliminated because relief that used to be available only through a writ is now accessible through a lawsuit or a motion in a civil action. Writ is an official court document, signed by a judge or bearing an official court seal, which commands the person to whom it is addressed, to do something specific. A Writ is commonly endorsed or delivered by a sheriff (who may be instructed to seize property, for example) or as a notice to a defendant (for whom the writ is the first notice of formal legal action. In these cases, the writ would command the person to answer the charges laid out in the suit, or else judgment may be made against them in their absence). Some jurisdictions may prefer the term Summons, Citation or even Notice. In Painter v. Berglund, Justice Ward of the California Court of Appeals wrote:- 'A Writ is an order in writing issued by a competent official in a judicial proceeding and, as applied to execution in civil cases, is part of the remedy to effectuate the action by the enforcement of the judgment'. The Writ has a long history in the English common law as the formal document by which the machinery of the courts of law were put in motion and directed to a person, the defendant, by the plaintiff. The endorsement of the writ was done personally by the seal of reigning monarch and later, by his agent on his (or her) behalf and, more recently, by the clerk of the issuing court. The Writ directs the named recipient to do something, usually to answer the allegations or suffer judgment in absentia. Circa 2012, here is the still archaic form of a writ in one jurisdiction:- 'Elizabeth The Second, by the Grace of God, of the United Kingdom, Canada and Her other Realms and Territories, Queen, Head of the Commonwealth, Defender of the Faith. 'To the defendant(s):- 'Take Notice that this action has been commenced against you by the plaintiff(s) for the claim(s) set out in this writ'. 'If You Intend To Defend this action, or if you have a set off or counterclaim that you wish to have taken into account at the trial, You Must ...'. As the law evolved, it became necessary for the plaintiff to specify the basic facts behind the writ, either directly within the writ, or in a companion document such as a Statement of Claim. Writ is a legal document summoning a person to attend at a certain place or to perform a certain act. There are penalties for failure to comply. Writ:- in common law, order issued by a court in the name of a sovereign authority requiring the performance of a specific act. The most common modern writs are those, such as the summons, used to initiate an action. Other writs may be used to enforce the judgment of a court (attachment, delivery) or to require a lower court to furnish certain records (error) or perform a certain act (mandamus). Writs can be traced back to the Anglo-Saxon kings, who used them primarily to convey grants of land, although they also made some effort to employ them for judicial purposes. Three main types of writ were in use by the early XIII century:- charters, normally for grants of land and liberties in perpetuity; letters patent, for grants of limited duration and for commissions to royal officials; and letters close, to convey information or orders to a single person or to a definite group of people (differing from the other two types of writ in that the king's seal authenticated and closed the document). Writs began to be used in judicial matters by the Norman kings, who developed set formulas for them. The most important were original writs, for beginning actions; in many instances they served much the same purpose as the modern summons. They were issued to the defendant, requiring that he make amends or else appear in court. Other important writs were those of assistance, for the transference of property, and entry, for the recovery of land from which one had been wrongfully dispossessed. The European civil-law system never developed a series of clearly defined writs, although it found other means to accomplish the same ends. / Судебный Приказ – приказ, издаваемый судом.

WRITE = ВЫПИСЫВАТЬ (или XX) – (1) In insurance, a term Write:- same as 'Underwrite', i.e. insure. / , то есть страховать. Выписывать или Подписывать – термин, обозначающий покрывать страховой риск, принимая на себя обязательства, вытекающие из страхового договора, как это делает андеррайтер (underwritter).

(2) In option trading, a term Write:- sell an option. Applies to derivative products. Write:- to sell an option that is not owned through an opening sale transaction. While this position remains open, the writer is subject to fulfilling the obligations of that option contract; i.e. to sell stock (in the case of a call) or buy stock (in the case of a put) if that option is assigned. An investor who so sells an option is called the Writer, regardless of whether the option is covered or uncovered. / Выписывать или Продавать опцион:- в торговле опционами – акт продажи опциона на покупку или опциона на продажу путём его поставки покупателю за премию.

WRITE DOWN = УЦЕНКА – Write-Down is a reducing the book value of an asset because it is overvalued compared to the market value. A write-down typically occurs on a company's financial statement, when the carrying value of the asset can no longer be justified as fair value and the likelihood of receiving the cost (book value) is questionable at best. Write-downs are typically reflected in a company's income statement as an above-the-line expense, thereby reducing net income. This, however, is not always a bad thing, since a write-down is simply a paper loss, which, since it lowers net income, will reduce a firm's tax burden. Companies will usually attempt to time large write-downs together, so they can 'take a bath' in one reporting period with the hope of quickly recovering in the next period. Write Down is a revaluation of an asset downwards. The opposite of Write Up. Write-Down or Writedown is an accounting treatment that recognizes the reduced value of an impaired asset. The value of an asset may change due to fundamental changes in technology or markets. One example is when one company purchases another and pays more than the net fair value of its assets and liabilities. The excess purchase price is recorded on the buying company's accounts as goodwill. If it becomes apparent that the purchased company no longer has the value recorded in the goodwill account (it can't be resold at the same price), the value in the goodwill asset account is 'written down'. Rupert Murdoch's News Corp. bought Wall Street Journal publisher Dow Jones at a 60 percent premium in 2007, which News Corp. later had to write down by USD2.8 billion because of declining ad revenues. A writedown is sometimes considered synonymous with a write-off. The distinction is that while a write-off is generally completely removed from the balance sheet, a writedown leaves the asset with a lower value. As an example, one of the consequences of the 2007 subprime crisis at financial institutions was a revaluation under mark to market rules:- 'Washington Mutual will write down by USD150 million the value of USD17 billion in loans ...'. See also Debt Write-Down. Write Down is a decrease in the recorded value of an asset, usually because of a decrease in the market value of the asset. Also known as Impairment. Write Down is a downward revision of the book value of an asset to reflect its current market value that has dropped below the book value. The amount by which the book value is reduced is charged against the earnings as an expense or loss. Differences between write-off and writedown? When you write off you eliminate the value of an asset. When you writedown you reduce the asset in value. The difference is all vs. some. Write-Down is a downward adjustment to the value of loans recorded in the balance sheets of the Monetary Financial Institutions (MFIs) when it is recognised that the loans have become partly unrecoverable. See also Monetary Financial Institution. Write-Down is the reduction in the book value of an asset if its is overstated compared to current market values. A Write-Down occurs when a business reduces the carrying amount of an asset, other than through normal depreciation and amortization. A write-down is normally done when the market value of an asset declines below its current carrying amount. The entire amount of the write-down charge appears on the income statement, while the reduced carrying amount of the asset appears on the balance sheet. A write-down is a non-cash expense, since there is no associated outflow of cash when a write-down is taken. A write-down should be taken as soon as management is aware that the market value of an asset has fallen; they are not supposed to delay this recognition, as often happens when a company wants to manage its earnings. Write-Down:- companies sometimes carry assets on their balance sheet which are over-valued. In this case, the assets may be written-down (i.e. reduced) in value to more conservatively reflect their value on a financial statement. / Компания Рупёта Мёдока Ньюз Корп. (Rupert Murdoch's News Corp.) купила Вол Стрит Дьонэл (Wall Street Journal) Дау Дьонз (Dow Jones).

WRITE–DOWN ON AN ITEM–BY–ITEM BASIS = УЦЕНКА НА ПООБЪЕКТНОЙ ОСНОВЕ – Write-Down On An Item-By-Item Basis:- all items subject to risk are written down on an item-by-item basis; where items are subject to a general credit risk, a general allowance is recognised. Individually identifiable risks were accounted for by writedowns on an item-by-item basis.

WRITE–OFF = СПИСАНИЕ – (1) Write-Off is a reduction in the value of an asset or earnings by the amount of an expense or loss. Companies are able to write off certain expenses that are required to run the business, or have been incurred in the operation of the business and detract from retained revenues. For example, if you spend money on dinner to take out a client, that meal is a possible write-off towards your income because you presumably discussed business opportunities during the dinner. Suppose, for another example, you made a sale on credit to a customer, but two weeks later the client's business declared bankruptcy and became completely unable to pay off the credit account with you. This uncollectible debt would then be written-off by your company and recorded as an expense by accountants. To delete an asset from the accounts because it has depreciated, or been written down, so far that it no longer has any book value. Also known as Charge-Off in the United States. Write-Off:- something is written-off when its recognized value is reduced. In accounting, this is a recognition of the reduced or zero value of an asset. In income tax statements, this is a reduction of taxable income as recognition of certain expenses required to produce the income. In income tax calculation, a write-off is the itemized deduction of an item's value from one's taxable income. Thus, if a person in the USA has a taxable income of USD50 000 per year, a USD100 telephone for business use would lower the taxable income to USD49 900. If that person is in a 25% tax bracket, the tax due would be lowered by USD25. Thus the net cost of the telephone is USD75 instead of USD100. In business accounting, the term Write-Off is used to refer to an investment (such as a purchase of sellable goods) for which a return on the investment is now impossible or unlikely. The item's potential return is thus canceled and removed from ('written off') the business's balance sheet. Common write-offs in retail include spoiled and damaged goods. Similarly, banks write off bad debt that is declared noncollectable (such as a loan on a defunct business or a credit card due that is now in default), removing it from their balance sheets. A negative write-off refers to the decision not to pay back an individual or organization that has overpaid on an account. Negative write-offs can sometimes be seen as fraudulent activity if those who overpay a claim or bill are not informed that they have overpaid and are not given any chance to reconcile their overpayment or be refunded. Some institutions such as banks, hospitals, universities, and other large organizations regularly perform negative write-offs, especially when the amount is considered low dollar, e.g., USD5.00 at some places or up to USD15.00 or more at others. Writeoff is a removal of the book value of a destroyed or obsolete asset, or an uncollectible sum, from the account books by reducing it to zero. The amount written off is charged against the earnings as an expense or loss. Write-Off is the removal of the value of loans from the balance sheets of the Monetary Financial Institutions (MFIs) when the loans are considered to be totally unrecoverable. See also Monetary Financial Institution (MFI). Write-Off:- similar to write-down, except that in this case the asset as no value and is being reduced to a zero value. This may be the case if inventory is not usable (e.g., spoiled food) or shareholdings in a bankrupt or defunct company. A Write Off is a reduction in the recorded amount of an asset. A write off occurs upon the realization that an asset no longer can be converted into cash, can provide no further use to a business, or has no market value. For example, a write off is mandated when an account receivable cannot be collected, when inventory is obsolete, when there is no longer any use for a fixed asset, or when an employee leaves the company and is not willing to pay the company back for a

pay advance. In general, a write off is accomplished by shifting some or all of the balance in an asset account to an expense account. The accounting can vary, depending on the asset involved. For example:- (i) when an account receivable cannot be collected, it is usually offset against the allowance for doubtful accounts (a contra account); (ii) when inventory is obsolete, it can either be charged directly to the cost of goods sold or offset against the reserve for obsolete inventory (a contra account); (iii) when there is no longer any use for a fixed asset, it is offset against all related accumulated depreciation or accumulated amortization, with the remainder being charged to a loss account; and (iv) when a pay advance cannot be collected, it is charged to compensation expense. When an allowance account (contra account) is used, then the credit is to an allowance account. Later, when a specific write off is found, it is offset against the allowance account. A write off usually occurs at once, rather than being spread over several periods, since it is usually triggered by a single event that should be recognized immediately. A variation on the write off concept is a Write Down, where part of the value of an asset is charged to expense, leaving a reduced asset still on the books. For example, a settlement with a customer might allow for a 50% reduction of the amount of an invoice that the customer will pay. This represents a write down on one-half of the amount of the original invoice. Management sometimes accelerates the use of write downs and write offs in order to recognize expenses and thereby reduce the amount of taxable income. When taken to an extreme, this can result in fraudulent financial statements. Write-Off is to decrease the value of an item, e.g., a tax write-off decreases tax liability, a vehicle involved in an accident can be declared a write-off if the cost to repair is in excess of the value of the vehicle. / Удаление актива со счетов вследствие того, что он обесценился или был уценён настолько, что перестал иметь какую-либо ценность для его учёта в бухгалтерских книгах. Известно также как Списание (Charge-Off) в Соединённых Штатах Америки. Под Списанием понимается:- (1) уменьшение балансовой стоимости актива до нуля. Арендованное оборудование после окончания срока аренды, устаревшие машины либо неудачные инвестиции должны списываться. (2) Уменьшение до нуля суммы задолженности, которая не может быть взыскана (безнадёжный долг (bad debt)). Этот убыток должен быть показан в Счёте Прибылей и Убытков (Profit and Loss Account) организации. Списание – списание стоимости актива в расходы или убытки. Следствием списания является сокращение или снятие стоимости активов и уменьшение прибыли. Списания обычно производятся в соответствии с разрешённой налоговой амортизацией (depreciation) долгосрочных активов (fixed asset) и с амортизацией (amortization) других, например, нематериальных активов (intangible asset) и профинансированных убытков, например, премий по инвестициям. Списания также производятся в том случае, когда активы по какой-либо причине считаются бесполезными. Наиболее известным примером является невзимаемая дебиторская задолженность (accounts receivable). Когда подобные списания можно предусмотреть и, следовательно, оценить, обычно производятся регулярные вычеты из дохода в размерах, необходимых для поддержания резерва, а реальные убытки затем вычитаются из резерва. Акт о Налоговой Реформе от 1986 (Tax Reform Act of 1986) потребовал, чтобы списания ‘плохих долгов’ (bad debt) вычитались непосредственно из дохода налогоплательщиков, за исключением небольших банков и финансовых организаций. (2) Write-Off is charging an asset amount to expense or loss. The effect of a write-off is to reduce or eliminate the value of the asset and reduce profits. Write-offs are systematically taken in accordance with allowable tax depreciation of a fixed asset, and with the amortization of certain other assets, such as an intangible asset and a capitalized cost (like premiums paid on investments). Write-offs are also taken when assets are, for whatever reason, deemed worthless, the most common example being uncollectible accounts receivable. Where such write-offs can be anticipated and therefore estimated, the usual practice has benn to charge income regularly in amounts needed to maintain a reserve, the actual losses then being charged to the reserve. The US Tax Reform Act of 1986 required that bad debt write-offs be charged directly to income by taxpayers other than small banks and thrift institutions. Write-Off:- charging an asset amount to expense or loss, such as through the use of depreciation and amortization of assets. Write-Off is the accounting process whereby a loan which is classified as a worthless asset has its status changed from an earning asset on the balance sheet and is charged to credit risk reserves. See also Amortization, Depreciation, and Extraordinary Item. Write-Off:- is a procedure for the deleting debts or receivables from the State’s (Florida) Account. Write-Off:- a financial claim that a creditor regards as unrecoverable and so no longer carries on its books. / В бухгалтерском учёте под Списанием понимается процесс, посредством которого ссуда, классифицировавшаяся как ничего не стоящий актив (worthless asset), изменила свой статус в балансовом отчёте на зарабатывающий актив и переместилась в разряд резервов по кредитным рискам. WRITE OUT = ВЫПИСКА (или ВЫСТАВЛЕНИЕ) – Write Out is a procedure followed when a specialist on an exchange makes a trade involving his own inventory, on one hand, and an order he is holding for a floor broker, on the other. Exchange rules require a two-part transaction:- the broker first completes a trade with the specialist, who then completes the transaction by a separate trade with the customer. The write out involves no charge other than the normal broker’s commission. Write Out:- the procedure used when a specialist makes a trade involving his own inventory, on one hand, and a floor broker’s order, on the other. The broker must first complete the trade with the specialist, who then transacts a separate trade with the customer. / Выписка:- когда специалист выбирает, действуя в рамках биржевых правил, сделку с распоряжением, записанным в его книге. Специалист должен вызвать брокера, который получил распоряжение и который затем испоняет это распоряжение, совершая сделку со специалистом в качестве другой стороны сделки, что позволяет брокеру получать комиссионные за совершённую сделку. Выписывание – процедура происходит в том случае, когда специалист биржи совершает сделку на бирже с применением собственных ценных бумаг и приказа, который он хранит для брокера на полу. Правила биржи требуют, чтобы сделка была двухсторонней:- брокер сначала совершает сделку с биржевым брокером, который затем совершает самостоятельную сделку с клиентом. Эта процедура не связана с какими-либо дополнительными сборами, помимо обычных брокерских комиссионных.

WRITER = ВЫПИСАВШИЙ – (1) Writer is the seller of an option who collects the premium payment from the buyer. For example, a writer holds a short position on a call option. If the call option is exercised, then the writer has to sell the underlying stock at the strike price of the option. Conversely, if you are the writer of a put option, you are said to be long, and must purchase the underlying stock at the particular price. Being a writer is relatively risky – especially on a naked position. This technique should not be used by those who are new to option markets. Alternative terms for the seller of an option (whether it is a put or call is irrelevant). Writer is the person who originates an option contract by promising to perform a certain obligation in return for the price or premium of the option. Writer is the seller or granter of an option. Writer is a person who sells put option and call option contracts, and therefore collects premium income. The writer of a put option is obligated to buy (and the writer of a call option is obligated to sell) the underlying security at a predetermined price by a particular date if the option is exercised. In option trading, an individual who sells or grants or writes any exchange option, establishing a short position. He is obligated to deliver the underlying asset if the option is exercised. Also known as Grantor, and Seller. Writer is one who sells an option. A writer obligates himself to deliver the underlying futures position to the option purchaser should he decide to exercise his right to the underlying futures contract position. Option writers are subject to margin calls, because they may have to produce thelong or short futures position. A call writer must supply a long futures position upon exercise, and thus receive a short futures position. A put writer must supply a short futures position upon exercise, and thus receive a long futures position. Writer is the issuer, grantor, or seller of an option contract. Writer is the seller of an option, usually an individual, bank,

or company that issues the option and consequently has the obligation to sell the asset (if a call) or to buy the asset (if a put) on which the option is written if the option buyer exercises the option. Writer is a person who assumes the obligation to sell (call) or buy (put) the underlying security at an option's exercise. Writer or Seller or Grantor is an individual who sells an option, establishing a short position. Writer or Grantor:- alternative terms for the seller of an option (whether it is a put or call is irrelevant). Writer is the option seller that receives the premium but is obligated to perform if the option is exercised. / В торговле опционами, частное лицо, продающее или предоставляющее, или выписывающее любой биржевой опцион, и создающее тем самым короткую позицию (позицию продажи). Эмитент опциона обязан поставить соответствующий актив в случае исполнения опциона. Известен также как Предоставивший (Grantor), и Продавец (Seller). Выписавший – лицо, которое продаёт опционы на продажу и покупку и благодаря этому получает доход в виде премии (premium income). Продавец опциона на продажу обязуется купить (а продавец опциона на покупку обязуется продать) лежащие в основе опциона ценные бумаги (underlying security) по предварительно определённой цене до наступления определённой даты, если опцион исполняется. Смотрите также Covered Call, Naked Option и Writing Maked. Выписавший – участник рынка, который продаёт опционный контракт, получая за это вознаграждение в виде премии. Выписавший – продавец опционного контракта на акции, обязывающего купить или продать лежащие в основе акции по заранее установленной цене в течение данного периода времени. Синоним термина Выписавший Опцион (Option Writer).

(2) In insurance, a Writer is underwriter. / Выписавший – продавец (underwriter) страхового полиса.

WRITE UP = ДООЦЕНКА – Write-Up is the increase in value of an asset, but it is seldom used and is not allowed in GAAP (Generally Accepted Accounting Principles). A Write-Up is an increase in the carrying amount of an asset. It is triggered by an increase in the market value of the asset. Write-ups are more generally allowed under international financial reporting standards than under the generally accepted accounting principles framework. Write Up is a revaluation of an asset upwards. The opposite of Write Down. Write-Up/Write-Up Work:- an accountant will process a company's financial statements without going through a formal audit review. / Переоценка при повышениях стоимости актива. В противоположность Уценке (Write Down).

WRITE–UP SERVICE = УСЛУГА ДООЦЕНКИ – Write-Up Service is the provisioning of all reporting requirements of bookkeeping and accounting services. The following is a non-exhaustive list of reporting services provided:- (i) 1099s report preparation for subcontractors; (ii) bank account reconciliation; (iii) check coding; (iv) fixed asset schedules; (v) maintenance of general ledger; (vi) payroll deposit calculations; (vii) payroll tax filings; (viii) personal property tax returns; and (ix) preparation of internal financial statements. Professional Write-Up Services can help you manage your finance and accounting needs in an efficient way and ease the workload on your in-house staff. Write-up service providers maintain your entire accounting and transactional information; create financial statements, account receivables, account payables, general ledger; manage account reconciliation; manage fixed assets; perform tax filings; handle payroll; and more. By utilizing these write-up services, you can reduce accounting and finances related stress and ensure accuracy of all your financial reports and records. Service providers leverage popular accounting software like Quickbooks, NetSuite, Quicken, Peachtree, Sage, and Intuit for better management of even complex accounting requirements. They take financial data inputs in any format (Excel, Access, PDF, image files, hard copies, etc) and then produce financial reports in the format of your choice. Teams of experienced accountants, who make the write-up process faster and more accurate, complement this. You may outsource write-up services for your entire financial year or get it done periodically, or at the end of the year, based on your business requirements. Most providers offer flexible options that can be customized for the needs of your organization. Efficient financial management directly translates into informed business decisions, regulatory compliance, better forecasting, and overall a well-managed organization. By outsourcing write-up services, you will not only reduce cost but also get completed and error-free financial statements on time. Of course, initially you would need to spend a bit of time with your outsourcing services provider to ensure sufficient knowledge transfer for clear understanding of your business processes. You must also attest the quality processes and security methodologies followed by the service provider that guarantees complete safety and accuracy of your critical financial data.

WRITE UP/WRITE DOWN = ДООЦЕНКА/УЦЕНКА – Write Up/Write Down is the upward or downward adjustment of the accounting value of an asset according to Generally Accepted Accounting Principles (GAAP). See also Write-Off. / Дооценка/Уценка – переоценка в сторону повышения или понижения отчётной (бухгалтерской) стоимости актива в соответствии с Общепринятыми Принципами Бухгалтерского Учёта (ОПБУ; Generally Accepted Accounting Principles (GAAP)). WRITING = ПИСЬМЕННАЯ ФОРМА (или ПИСЬМО) – Writing means, inter alia, telegram or telex.

WRITING AN OPTION = ВЫПИСЫВАНИЕ ОПЦИОНА – The expression Writing An Option refers to the act of selling an option. An option is the right, but not the obligation, to buy or sell a particular trading instrument at a specified price, on or before its expiration. When someone writes (or 'sells') an option, he or she must deliver to the buyer a specified number of shares if the option is excercised The writer has an obligation to perform a duty while the buyer has the option to take action. There are two general types of option writing:- covered and naked. In a covered call, the option writer already owns the underlying trading instrument and wishes to make extra money from the position. He or she can write (or sell) an option based on the expectation that the underlying's price will move in a particular way. The buyer pays the writer a premium in exchange for writing the option. If the option trades at a value that benefits the buyer, the seller is obligated to hand over the shares. If the option expires at a value that does not benefit the buyer, the seller retains the original shares. If the option writer does not own the underlying instrument, it is said to be a 'naked' option. This is more risky than writing a covered call since the writer is still obligated to produce the specified number of shares of the particular contract (without already owning them). / Выписывание Опциона – акт продажи опциона.

WRITING CASH–SECURED PUTS = ВЫПИСЫВАНИЕ ОПЦИОНОВ НА ПРОДАЖУ, ОБЕСПЕЧЕННЫХ НАЛИЧНЫМИ – Writing Cash-Secured Puts is the option strategy that a trader who wants to sell put options uses to avoid having to use a margin account. Rather than depositing margin with a broker, a put writer can deposit cash equal to the option exercise price. With this strategy, the put option writer is not subject to additional margin requirements in the event of changes in the underlying stock's price. The put writer can also be earning money by investing the premium he or she receives in money market instruments. Writing Cash-Secured Puts is an option strategy to avoid using a margin account. Instead of depositing margin with a broker, a put writer can deposit a cash balance equal to the option exercise price, and can avoid additional margin calls. / Выписывание Опционов На Продажу, Обеспеченных Наличными – опционная стратегия, которую продавец, желающий продать опционы на продажу, использует, стремясь избежать создания счёта по сделкам с маржёй. Вместо депонирования маржи у брокера продавец опциона на продажу вкладывает наличные на сумму, равную цене исполнения опциона. Используя эту стратегию, продавец опциона на продажу не подвергается требованиям дальнейшего увеличения маржи в случае изменения цены лежащих в основе опциона акций и может получать деньги путём вложения получаемой им премии в краткосрочные инструменты денежного рынка. Выписывание Обеспеченных Наличными Опционов На Продажу – стратегия в операциях с опционами, которую использует торговец, желающий продать опционы на продажу, чтобы не иметь дела с маржинальным счётом (margin account). Вместо помещения

маржи (margin) у брокера продавец опциона (writer) может поместить наличную сумму, равную цене исполнения опциона. При такой стратегии продавец опциона на продажу не должен вносить дополнительного обеспечения в случае, если цена лежащих в основе опциона акций изменяется. Продавец опциона на продажу может также получить прибыль, инвестируя премию (premium), которую он получает, в ценные бумаги денежного рынка.

WRITING DOWN ALLOWANCE = ОТЧИСЛЕНИЕ НА УЦЕНКУ (или УСТУПКА НА УЦЕНКУ) – Writing Down Allowance (WDA) is a type of capital allowance where the cost of assets acquired in the current year is added to the written down value of the assets acquired in the previous years. The allowance is computed as a specified percentage of the total value. Writing Down Allowances are the capital allowances given against tax for the cost of certain fixed assets on a year by year basis. May be replaced by first year allowances in the year the expenditure is incurred, and by a balancing allowance or balancing charge in the year the asset is sold. Writing-Down Allowance:- a reduction in the taxable income of a corporation due to assets acquired in a year. To calculate the writing-down allowance, one adds a percentage of the value of the assets purchased in the current year to the depreciation on assets purchased in previous years. The writing-down allowance reduces a company's corporate tax liability. Writing-Down Aloowance is the percentage of the value of assets that a company can include in its profit calculations for a particular period to reduce the amount of tax it pays:- The writing-down allowance for most plant and machinery purchases is 20%.

WRITING NAKED = ВЫПИСЫВАНИЕ НЕОБЕСПЕЧЕННОГО – Writing Naked:- an investment strategy that involves selling naked options. A naked option is an option contract without another, opposite option hedging the risk. Unlike more complex spreads and straddles, which involve the purchase or sale of multiple options in order to profit in different ways, naked options are straight forward calls or puts. An investor with a naked option makes a profit or loss depending on the movement of the underlying asset. See aslo Naked Option. / Выписывание Необеспеченного Опциона или Выписывание Голого Опциона или Выписывание Непокрытого Опциона:- опционная стратегия продавца опциона, согласно которой продавец не имеет лежащих в основе опциона акций. Это может привести к значительным доходам, если курс акций двинется в ожидаемом направлении, и к значительным убыткам, если курс акций двинется в другом направлении, поскольку тогда продавцу такого опциона придётся выйти на рынок для покупки акций с целью их поставки покупателю опциона.

WRITING NAKED OPTION = ВЫПИСЫВАНИЕ НЕОБЕСПЕЧЕННОГО ОПЦИОНА – Writing Naked Option:- as investors become more educated and savvy, they look for new and exciting ways to trade the markets. This often leads investors to seek out the concept of Selling or Writing Naked Options. What does it mean to trade options naked? It doesn't mean they are trading from a European beach somewhere getting a line-free tan, but rather, the trader is selling options without having a position in the underlying instrument. For example, if one is writing naked calls, they are selling calls without owning the underlying stock. If they did own the stock, the position is deemed to be clothed or 'covered'. The concept of selling naked options is a topic for advanced traders. As with any advanced topic, a short discussion such as this cannot cover every possible aspect of profit potential, risk control and money management. This article is designed to be an introduction to the topic and will attempt to shed some light on the riskiness of these trading setups. This type of trading should only be attempted by advanced traders. Naked Calls:- a naked call position is usually taken when the investor expects the stock price to be trading below the option strike price at expiration. It is important to note that the maximum possible gain is the amount of premium collected when the option is sold. Maximum gain is achieved when the option is held through expiration and the option expires worthless. A call allows the owner of the call to purchase the stock at a predetermined price (the strike price) on or before a predetermined date (the expiration). If you sell the call without owning the underlying stock and the call is exercised by the buyer, you will be left with a short position in the stock. When writing naked calls, the risk is truly unlimited, and this is where the average investor generally gets in trouble when selling naked options. Most options seem to expire worthless; therefore, the trader may have more winning trades than losers. But with the unbalanced risk versus reward, a single bad trade can wipe out an entire year's gain (or more). Sound money management and risk control are critical to success when trading this way. Controlling Risk:- the call writer does have some risk-control strategies available. The easiest is to simply cover the position by either buying the offsetting option or, alternatively, the underlying stock. Obviously, if the underlying stock is purchased, the position is no longer naked, and it does incur additional risk parameters. Some traders will incorporate additional risk controls, but these examples require a thorough knowledge of options trading and go beyond the scope of this article. Generally, writing naked options is best done in months that are closer to expiring rather than later. Time decay (theta) is one of your best friends in this type of trade, as the closer the option gets to expiration, the faster the theta will erode the premium of the option. While it won't change the fact that this trade has unlimited risk, choosing your strike prices wisely can alter your risk exposure. The farther away you are from where the current market is trading, the more the market has to move in order to make that call worth something at expiration. Example 1:- let's consider stock X for an example of a naked call write. The hypothetical trade mentioned below would be considered by a trader who expected the stock to move lower for the next few months or that the trend would trade sideways. For the sake of simplicity, let's assume X shares are trading at approximately USD20 per share at the time of the trade and that the May 22.50 calls were trading at USD1. A naked call write would be established by selling the May 22.50 naked (the trader has no position in X stock), bringing in USD100 in premium per option sold. If X stock is below 22.50 at the May expiration, this option will expire worthless and we will keep the USD100 premium for each option sold. If it is higher, the option will be exercised and will have to deliver X stock at USD22.50 per share. Applying the USD1 received for the option against this, the trader's cost basis is short X from USD21.50 per share, making the investor's risk the difference between wherever X is trading above USD21.50. You can see that makes the maximum risk an unknown. This is why understanding risk management and money management are critical to successfully trading naked calls. Note:- it is important to note that the right part of the chart above showing the risk of loss would extend indefinitely as the stock price continues to climb. Because naked call writing is an unlimited-risk proposition, many brokerage firms will require you to have a large amount of capital or high-net worth in addition to a great deal of experience before they will let you make these types of trades. This will be outlined in their options agreement. Once you are approved for trading naked calls, you will also need to familiarize yourself with your firm's margin requirements for your positions. This can vary widely from firm to firm, and if you are trading at a firm that does not specialize in options trading, you may find the margin requirements unreasonable. Naked Puts:- a naked put is a position in which the investor writes a put option and has no position in the underlying stock. Risk exposure is the primary difference between this position and a naked call. A naked put is used when the investor expects the stock to be trading above the strike price at expiration. As in the naked call position, the potential for profit is limited to the amount of premium received. The investor can make the most if the stock is trading above the strike price at expiration and expires worthless. If this occurs, the trader will keep the entire premium. While this type of trade is often referred to as Having Unlimited Risk, this is not actually the case. The risk in the naked put is slightly different than that of the naked call in that the trader could lose the most if the stock went to zero. That is still a significant risk when compared to the potential reward. And unlike the naked call, if the put is exercised against you, you will receive the stock (as opposed to receiving a short position in the stock, as is the case of the naked call). This would allow you to simply hold the stock as part of your possible exit strategies. Example 2:- as an example of writing naked puts, we'll consider the hypothetic stock Y. Let's assume that today is March 01 and that the Y is trading at USD45 per share. For the sake of simplicity, let's also assume that the May 44 puts are at USD1. If we sell a May 44 put, we will receive USD100 in premium for each put sold. If Y is trading above USD44 per share at expiration, the put will expire worthless and

we will achieve our maximum potential profit of USD100 per option sold. However, if Y is below this price at expiration, we can expect Y to be assigned to us, 100 shares for each option sold, at a price of USD44. Our cost basis is USD43 per share (USD44 less the premium received), so that is where our losses would begin. Contrary to the naked call example, we have a maximum loss on this trade of USD4 300 per option sold (100 shares of Y x USD43 cost basis). This would only be if the stock (or An exchange-traded fund (ETF) in this case) went to zero (unlikely in an index ETF, but very possible with an individual stock). Generally, brokerage requirements will be a little more accommodating with naked puts than with naked calls. The primary reason for this is that if the put is exercised you will be receiving the stock (as opposed to a short stock position, as in the naked call). This makes the maximum risk exposure the value of that stock position less the premium received for the option. The Bottom Line:- trading naked options can be attractive when considering the number of potential winning trades versus losing trades. However, do not be taken in by the lure of easy money, because there is no such thing. There is a tremendous amount of risk exposure when trading in this manner, and the risk often outweighs the reward. Certainly, there is potential for profit in naked options and there are many successful traders doing it. But make sure you have a sound money management strategy and a thorough knowledge of the risks before you consider writing naked options. If you are new to options trading or you are a smaller trader, you should probably stay away from naked options until you have gained experience and capitalization. See also Naked Option. Writing an Option means selling a certificate that guarantees the holder can buy a traded item for a guaranteed price (strike price). The person who writes the option is betting that the price of the underlying stock will go down (shorting a stock, also known as (AKA) a Short Position). If the person writing the option is correct, then she makes money off the sale of the option, but does not have to worry about honoring the option, since it is out of the money and has no intrinsic value. If the person writing the option is wrong, and the price of the underlying stock goes up, then she must buy the item at the higher spot price specifically to sell it at the low strike price ('short cover'). In rare cases, a person who makes this sort of error will actually drive the spot price much higher than it would have gone ordinarily. Naked Option Writing is quite risky because you can make only a limited amount of money, yet the risks are high. / Выписывание Необеспеченного Опциона (Writing Naked Option) – стратегия в операциях с опционами, используемая продавцами, при которой торговец не владеет ценными бумагами, которые лежат в основе опциона (underlying security). Эта стратегия может помочь получить значительные прибыли, если котировки акций изменяются в желательном направлении, но могут привести и к значительным убыткам, если котировки акций изменяются в противоположном направлении, поскольку торговцу придётся приобрести на рынке акции и поставить их покупателю опциона. WRITING PUTS TO ACQUIRE STOCK = ВЫПИСЫВАНИЕ ОПЦИОНОВ НА ПРОДАЖУ ДЛЯ ПОГЛОЩЕНИЯ АКЦИЙ – Writing Puts To Acquire Stock:- selling a put option at an exercise price that would represent a good investment by an option writer who believes a stock's value will fall, so that the writer cannot lose. If the stock price unexpectedly goes up, the option will not be exercised and the writer is at least ahead the amount of the premium received. If the stock loses value, as expected, the option will be exercised, and the writer has the stock at what he had earlier decided was originally a good buy, and he has the premium income in addition. / Выписывание Опционов На Продажу Для Поглощения Акции:- опционная стратегия, используемая продавцом опциона. Продавая опцион на продажу по цене исполнения, что могло бы представлять хорошее вложение, продавец верит в то, что курс ценной бумаги будет падать и что сам он не понесёт убыток. Если же курс ценной бумаги вопреки его ожиданию пойдёт вверх, опцион не будет использован, а ему достанется по меньшей мере сумма полученной премии. Если же курс акций снизится, как и предполагалось, опцион будет использован, продавец получит в качестве надёжной покупки первоначально запланированную акцию, а в добавок получит также и премиальный доход.

WRITING PUTS TO PURCHASE STOCKS = ВЫПИСЫВАНИЕ ОПЦИОНОВ НА ПРОДАЖУ ДЛЯ ПРИОБРЕТЕНИЯ АКЦИЙ – Writing Puts To Purchase Stocks:- if you are very bullish on a particular stock for the long term and is looking to purchase the stock but feels that it is slightly overvalued at the moment, then you may want to consider writing put options on the stock as a means to acquire it at a discount. So, instead of entering a limit order to purchase the stock, you can write an equivalent amount of near-month slightly out-of-the-money naked puts with a strike price that is equal to the target price at which you wish to purchase the underlying stock. Thereafter, on expiration date, if the stock price and your sentiments towards the underlying stock remains unchanged, the puts that you sold will expire worthless. This lets you pocket the premiums received and write some more put options. Should the stock price take a dive and goes below the put strike price, you can either follow through with your obligation and pickup the stock or you can buy back the put options at a loss. The decision you make will depend on whether your outlook towards the underlying stock has changed since taking up the position. You should probably buy back the put options at a loss if a significant piece of bad news had surfaced which negatively impacted the fundamentals of the underlying stock, causing you to be no longer bullish on the stock. The premiums that you received should help to cushion some of the losses. Otherwise, if the drop in stock price is minor and your target price is hit, you will be able to buy the stock at a reasonable discount along with the extra premiums received from the sale of the put options. / Выписывать Опционы На Продажу С Целью Приобретения Акций (writing puts to acquire stock) – стратегия продавцов опционов, полагающих, что котировки акций должны упасть и покупка их по данной цене будет представлять собой выгодное вложение. Выписывая опцион на продажу, исполняемый по этой цене, продавец опциона не может потерять. Если акции, в противоположность его ожиданиям вырастут и опцион не будет исполнен, он по крайней мере получит премию. Если, как ожидалось, акции упадут в цене и опцион будет исполнен, то он приобрёл акции по цене, по которой он ранее счёл их выгодным вложением, и в дополнение он получает премиальный доход.

WRIT OF DELIVERY = ПРИКАЗ СУДА ОБ ИСПОЛНЕНИИ СУДЕБНОГО РЕШЕНИЯ О ПЕРЕДАЧЕ – A Writ Of Delivery is another form of High Court writ that is used to recover specific goods. For example, if a finance company needs to repossess the vehicle they financed because their client has stopped payments, then they will do so under a writ of delivery. Another example might be where someone has provided items, such as jewellery, paintings or a car, to a dealer or auctioneer to sell, and the item is neither sold nor returned, then a writ of delivery would be used to recover them. An order for money can also be added to a writ of delivery, so that the enforcement officer can recover any debt at the same time and under the same writ. Counterfeits:- When goods are counterfeited, the couterfeits are deemed to also belong to the brand owner. A writ of delivery may, therefore, also be used to remove counterfeit goods from warehouses, retailers, wholesalers etc. Applying for a writ of delivery:- You can apply for a writ of delivery using Form 293A. Once you have instructed The Sheriffs Office, we will manage the process of obtaining the writ on your behalf. We make no charge for this service. All you pay is the £66 court fee. Writ Of Delivery:- a writ of execution employed to enforce a judgment for the delivery of chattels. It commands the sheriff to cause the chattels mentioned in the writ to be returned to the person who has obtained the judgment; and, if the chattels cannot be found, to distrain the person against whom the judgment was given until here turns them. / Приказ Суда Об Исполнении Судебного Решения О Передаче – это исполнительный лист, адресованный шерифу и предписывающий ему арестовать товары и передать их истцу либо взыскать с ответчика их стоимость в деньгах согласно произведённой оценке. Если ответчик не в состоянии заплатить установленную сумму денег, приказ называется Приказом Суда Об Особом Исполнении Судебного Решения О Передаче (Writ Of Specific Delivery).

WRIT OF EXECUTION = ИСПОЛНИТЕЛЬНЫЙ ЛИСТ – Writ Of Execution is a legal term that describes a court order that is granted in order to satisfy a judgment awarded to a plaintiff in a court of law. If a court issues a writ of execution, usually a local sheriff is charged with taking possession of property owned by the debtor. The property can then be sold in a sheriff's sale, with the money (or portion) from the sale given to the plaintiff to satisfy the terms of the judgment. A writ of execution is necessary when a defendant is required by law to make a payment to a plaintiff, but will not do so voluntarily. The writ of execution allows the sheriff to collect property that can be sold to produce funds for repayment. In certain cases, the debtor's bank account can be accessed. Certain funds of a debtor may be off limits to debt collectors even with a writ of execution, including Social Security income, IRA (short for the individual retirement account) money and unemployment income. Writ Of Execution is a writ to put in force the judgment or decree of a court. A Writ of Execution is a court order authorizing the seizure of an asset, such as of a noncustodial parent who owes past due child support. The order may be used to repay past due child support owed under the judgment. It is also refered to as a Levy. A Writ of Execution is a legal document which states who the money is owed to, the 'judgment creditor', and the amount of the debt. When a writ of execution is attempted, notice will be served upon the judgment debtor, indicating details of the goods seized. Writ Of Execution is a court order to a sheriff to enforce a judgment by levying on real or personal property of a judgment debtor to obtainfunds to satisfy (pay the winning plaintiff) the judgment amount. Writ Of Execution is a court order that directs law enforcement personnel to take action in an attempt to satisfy a judgment won by the plaintiff. Specifically, a writ of execution usually addresses a sheriff. The sheriff, in turn, attempts to levy property owned by the defendant. / Исполнительным Листом постановление суда вводится в силу. Исполнительный Лист адресуется судебному чиновнику и предписывает ему предпринять определённые действия, например, взыскать деньги или наложить арест на имущество.

WRIT OF SUMMONS = ПРИКАЗ О ВЫЗОВЕ В СУД – Writ Of Summons is an official order for someone to appear in a court of law when they have been accused of committing an offence against someone:- The civil action was heard in the High Court two years after the writ of summons was issued. Writ Of Summons is a writ requiring one to appear in court to answer a complaint. Writ Of Summons is the writ by which, under the English judicature acts, allactions are commenced. / Под Приказом О Вызове В Суд понимается приказ, которым открывается судебный процесс в Высоком Суде. Этот приказ требует от ответчика предстать перед судом и ответить по обвинению, выдвинутому истцом и указанному в приказе. Судебный приказ издаётся при рассмотрении дел о гражданских правонарушениях (tort), по обвинениям в мошенничестве (fraud) и дел, связанных с требованием выплаты компенсации (возмещения ущерба) (damages) за нанесение травм, за действия, повлекшие смерть или нарушение патентных прав (patent).

WRITTEN–DOWN VALUE = УЦЕНЁННАЯ СТОИМОСТЬ – Written-Down Value (WDV) is the value of an asset after accounting for depreciation or amortization. Written-down value is also called Book Value or Net Book Value. It is calculated by subtracting accumulated depreciation or amortization from the asset's original value. Written-down value reflects the asset's present worth from an accounting perspective. An asset's written-down value will appear on the company's balance sheet. Written-down value can be calculated by a method of depreciation that is sometimes called the Diminishing Balance Method. This accounting technique reduces the value of an asset by a set percentage each year. Different depreciation techniques are used to capitalize the expenses of different types of assets. The taxable gain on a sale is often determined by comparing the sales from the item to its written-down value. When an asset is intangible, such as a patent, it is amortized rather than depreciated. Written-Down Value is the net value of an asset, i.e. its original cost (its book value) minus depreciation and amortization. Sometimes referred to as the Net Book Value, the Written-Down Value has to do with the current worth of fixed assets that appear on the financial records of a company. The actual amount of written-down value is adjusted from the original cost of the item to more accurately reflect the fair market value of the asset or assets in the current economic climate. As a result, it is not unusual for companies to adjust the written-down value of some assets on at least an annual basis. Two of the key factors that go into calculating a current written-down value are depreciation and amortization. The process will always begin with the original or initial value of the asset in question. That historical figure will then be adjusted based on the amount of depreciation that is currently allowed under the existing tax structure. In many cases, this means there is a percentage of depreciation that can take place within a given calendar year, based on normal usage of the asset. Amortization of the asset further helps to bring the posted net value of the asset into line with current economic conditions, resulting in a realistic picture of the current worth of the asset. Companies may allow the concept of written-down value to any number of fixed assets. Production machinery is an excellent example of assets that are eligible for this process. Over time, the machinery will become somewhat less valuable, due to the release of upgraded versions combined with the continuous use of the equipment in the production process. Maintaining a properly calculated written-down value for the machinery helps to make the task of ascertaining the current assets of the company much more accurate. This can be especially helpful when quarterly and annual tax documents are prepared, since the tax breaks can be very helpful to the business. Knowing the current net book value will also come in handy when applying for business loans. Lenders will want to know the current market value of tangible assets, not what the business paid for the asset three or four years ago. From this perspective, the written-down value can help to ensure the lender that the applicant has sufficient resources to call upon if needed to settle the outstanding balance of the loan. Written-Down Value (WDV) is the net book value of an asset computed by deducting the accumulated depreciation or amortization from the value shown in the account books (the book value). Written Down Value is the cost of an asset, such as a car, after deducting amounts written off. For tax purposes it is the cost less capital allowances given to date. The expenditure on items of plant and machinery may be pooled to facilitate the calculation of capital allowances. In this case the written down value will be the total of expenditure incurred, less any proceeds of sale, less any capital allowances given, and plus any balancing charges made. Written-Down Value is the book value of an asset after allowing for depreciation and amortization. Written Down Value is an accounting term for the cost or valuation of an asset, less the written-off depreciation. It is no indication of the present selling price or true valuation of that asset. / Уценённая Стоимость – стоимость актива, показанная в отчётности, после вычета из неё суммы износа или – при калькуляции налога – суммы налоговой скидки на инвестиции в основной капитал. Уценённая Стоимость – балансовая стоимость (book value) активов за вычетом износа (depreciation) или других списаний (amortization), также называется Чистой Балансовой Стоимостью (net book value). Например, если первоначальная стоимость оборудования составляла 1 000 Долларов, а суммы списаний 400 Долларов, то уценённая стоимость будет составлять 600 Долларов.

WRITTEN–DOWN (NET) VALUE OF A FIXED ASSET = УЦЕНЁННАЯ (ЧИСТАЯ) СТОИМОСТЬ ФИКСИРОВАННОГО АКТИВА – The Written-Down (Net) Value Of A Fixed Asset is the actual or estimated current purchaser's price of a new asset of the same type less the cumulative value of the consumption of fixed capital accrued up to that point in time.

WRITTEN LINE = ПОДПИСАННЫЙ ПРЕДЕЛ УДЕРЖАНИЯ (или ПОДПИСАННАЯ ДОЛЯ УДЕРЖАНИЯ) – Written Line is the amount of a risk that an underwriter is willing to accept on behalf of the members of the syndicate or company for which he underwrites. This is commonly expressed as a percentage of the sum insured which is written on the broker's placing slip. If, on completion of the broking exercise, the written lines exceed 100% then, absent some contrary instruction, they will be signed down by the broker, which is to say they will be reduced proportionately so that they total 100%.

WRITTEN PREMIUM = ПОДПИСАННАЯ ПРЕМИЯ (или ВЫПИСАННАЯ ПРЕМИЯ) – In reinsurance, Written Premium is premium registered on the books of an insurer or reinsurer at the time a policy is issued and paid for. Premium for a future exposure period is said to be unearned premium for an individual policy, written premium minus unearned premium equals earned premium. Earned premium is income for the accounting period, while unearned premium will be income in a future accounting period. Written Premium:- the cumulative amount of premium income due to be received by an insurer. Written Premium is an accounting term in the insurance business used to describe the total premiums on policies issued by an insurance company during a specific period of time regardless of what portions have been earned. Written premiums are the amount of premium charged for a policy that has already become effective. Written premiums refer to the amount of premiums customers are required to pay for insurance policies written during the accounting period. This is different from premium earned, which is the amount of premiums that a company has earned by providing insurance against various risks during the year. Written premiums may be measured as a gross (before deduction of reinsurance costs) or net (after reinsurance costs) number. Written Premium is the amount of the premiums that have been collected, before deducting any premiums sent to reinsurers. Written Premiums are the premiums registered on the books of an insurer or reinsurer at the time a policy is issued and paid for. Written premiums may include direct and assumed premiums written. Direct premiums written are the premiums written by the insurer's subsidiaries for all policies. Assumed premiums written are the premiums received from an authorized state mandated pool. When an insurance company enters into a contract to provide insurance against a loss, the expected premiums are gross premiums. Usually, insurance companies purchase reinsurance to protect themselves against the risk of a loss above a certain threshold. When the cost of reinsurance is deducted from the expected premiums (gross premiums), the result is the net written premiums. Written Premiums are the premiums paid on all of the policies an insurer has written during a given time frame.

WRITTEN REPORT = ПИСЬМЕННЫЙ ОТЧЁТ – Written Report (for valuation):- for many analyst, the style of a written report is the culmination of many valuation engagements. In certain circumstances, particularly related to litigation, counsel in the case may request an oral report through testimony at deposition and/or trial. In certain consultation engagements, the client may request only an oral report or brief written summary. The type and format of the report to be provided may be dictated by the nature of the valuation engagement and/or the needs of the client. The written report must answer six questions:- (i) What was the analyst asked to do? (ii) What standard of value was used? (iii) What information did the analyst reference or utilize? (iv) What procedures did the analyst perform? (v) What assumptions and limiting conditions were applicable? And (vi) What conclusion of value was reached? A full written report should provide the detail necessary to permit another qualified analyst to use similar information and to understand the work done and the valuation conclusion reached. / Письменный Отчёт (Written Report):- результаты оценки, сообщаемые клиенту в письменной форме, которая включает электронную связь. Письменные отчёты могут представлять собой описательные документы, содержащие все изученные соответствующие материалы и проведённый анализ с целью получения заключения о стоимости или сокращённые описательные документы, включая периодические пересмотры стоимости, формы, используемые государственными и иными агентствами или письма клиентам. Смотрите также Устный Отчёт.

WRITTEN SALES = УЧТЁННЫЕ ПРОДАЖИ (или ЗАЧТЁННЫЕ ПРОДАЖИ) – Written Sales are sales which have been written and accepted by the customer but may or may not become Delivered Sales. Used to track work-in-process, and to evaluate advertising and sales effectiveness. See also Delivered Sales.

WRMA = WEATHER RISK MANAGEMENT ASSOCIATION

WRO = WAR RISK ONLY

WRONG COLOR PICK = ПОПЕРЕЧНАЯ НИТЬ НЕНАДЛЕЖАЩЕГО ЦВЕТА (или ПОПЕРЕЧНАЯ НИТЬ НЕПРАВИЛЬНОГО ЦВЕТА) – Wrong Color Pick:- xxxxxx. See also Filling, and Mixed End. Wrong Color:- color-contaminated warp yarns. A wrong color appearing in several warp yarns and over short yarn lengths. Note:- this defect may be caused by the contamination of warp yarns of, for example, one beam during warp preparation or warp dying. / Смотрите также Уточина (Filling), и .

WRONG DENTING = НЕПРАВИЛЬНАЯ ПРОБОРКА ОСНОВНЫХ НИТЕЙ В БЕРДО – Wrong Denting:- denting order is given on draft or on piece ticket. If we miss that order while drawing or denting the ends through reed, i.e. called Wrong Denting. Weaving defect. Wrong Drawing In/Denting:- (i) ends drawn with out looking to the draft; (ii) wrong work practices of workers; (iii) incorrect drawing hooks/denters; (iv) lighting conditions if poor also causes difficult; and (v) to drawing action and generates faults. Wrong Denting/Drawing:- the wrong order of drawing ends through healds and reeds respectively also creates fabric defects. / Порок или дефект ткачества.

WRONG DRAFT = НЕНАДЛЕЖАЩАЯ ПРОБОРКА ОСНОВНЫХ НИТЕЙ В РЕМИЗ (или НЕПРАВИЛЬНАЯ ПРОБОРКА ОСНОВНЫХ НИТЕЙ В РЕМИЗ) – Wrong Draft or Misdraw or Wrong Draw:- warp yarns that do not conform to the required draft plan. Note:- this defect is caused by yarns being drawn into the heald wires in the wrong sequence. See also Wrong Draw. Fabrics defect.

WRONG DRAWING = НЕПРАВИЛЬНЫЙ РИСУНОК – Wrong Drawing of warp end, which is not as per healding sheet or draft. Weaving defect. Wrong Drawing In/Denting:- (i) ends drawn with out looking to the draft; (ii) wrong work practices of workers; (iii) incorrect drawing hooks/denters; (iv) lighting conditions if poor also causes difficult; and (v) to drawing action and generates faults. / Порок или дефект ткачества.

WRONG DRAWS = СБИТЫЕ РИСУНКИ – Wrong Draws:- warp threads that have been drawn through incorrect heddle eye of the harness or through the wrong reed split in the reed. Wrong draws often result, as well, from careless work on the part of the weaver. These blemishes are very detrimental to woven goods, since they show aggravating, fine lines in the warp direction that are not in accord with the layout of the pattern as set down by the designer or styler. Weavers should do their utmost to always follow the drawing-in and reeding for the warp in the loom. Wrong Draw:- in woven fabric, one or more incorrectly drawn warp ends in the harness or reed. Synonym:- Misdraw, and Wrong Draft. / Неправильно пробранные в ремиз основные нити (ошибки, парочки, помехи).

WRONG END = НЕНАДЛЕЖАЩАЯ (или НЕПРАВИЛЬНАЯ) ПРОДОЛЬНАЯ НИТЬ (или РАЗНАЯ ПРОДОЛЬНАЯ НИТЬ) – Wrong End:- lack of control of warp tension. Woven fabric defect. Wrong End:- 'S' 'Z' - in warp and weft pattern 'S' twisted and 'Z' twisted ends are there. If we warp 'Z' twisted yarn in place of 'S' twisted yarn it is called Wrong End 'S' 'Z'. Weaving defect. Wrong End:- in a warp-knitted fabric, a yarn that differs from normal yarns in respect of composition, thickness, lilament or color. Note:- this defect is caused by a lack of control of incoming material. / Порок или дефект ткачества. Неправильно Заведённая или Неправильно Пробранная Нить (wrong end):- порок основы в виде участка, который значительно отличается рисунком переплетения от смежной нити основы ткани. Примечание:- этот порок вызван неправильной заводкой нити основы в галево или бёрдо.

WRONG END COLOR = НЕНАДЛЕЖАЩИЙ (или НЕПРАВИЛЬНЫЙ) ЦВЕТ ПРОДОЛЬНОЙ НИТИ – Wrong End Color:- in warp and weft different shades are used and its sequence is given on piece ticket, if we miss that sequence then fault like wrong end color will occur. Weaving defect. Wrong Ends Color and of S and Z:- these are created at warping when supervisor concern does not check

properly, marking not visible, more shades works one another or closer shades are kept near looms if works also can cause wrong ends in fabric. Also, wrong drawing in warping, due to twist, marking or color wise. / Порок или дефект ткачества.

WRONGFUL DISMISSAL = НЕПРАВОМЕРНОЕ УВОЛЬНЕНИЕ (или НЕПРАВОМЕРНОЕ ОТСТРАНЕНИЕ ОТ РАБОТЫ) – Wrongful Dismissal is the unlawful termination of an employment contract. Wrongful Dismissal is one of several terms used by a variety of jurisdictions to refer, essentially, to the same cause of action:- a claim in breach of contract or in tort for the ending of an employment contract by an employer, for some unlawful reason:- (i) Canada prefers the term Wrongful Dismissal; (ii) United Kingdom and Australia prefer Unfair Dismissal and, less frequently, Wrongful Dismissal; and (iii) The United States defers to the term Wrongful Discharge and, less frequently, Wrongful Termination. The word Wrongful in employment law has been used to define Unjustified Dismissal or in other words Dismissal Without Cause. Wrongful Dismissal:- termination of a contract of employment without due process or in a manner that violates the terms of the contract. In such cases, the courts usually take the employee's contractual rights into consideration in awarding damages. Also called Wrongful Discharge or Wrongful Termination. See also Unfair Dismissal. What is wrongful dismissal? This is essentially a breach of contract claim by the employee. If the employer acts in breach of the employee's contractual obligations or in breach of his minimum statutory obligations to give the employee notice, the employer then becomes liable to pay the employee damages for wrongful dismissal. An employee can in the alternative seek redress by making an unlawful deduction of wages claim in the employment tribunal, which can be quicker and more cost effective. In either case, the damages recoverable by the employee will be the wages and other benefits that would have been earned or accrued during the contractual notice period, such as pension entitlement, private health cover, car allowance and bonus(especially where the bonus is tangible). Those that are on a high salary may find it more preferable to bring a claim for wrongful dismissal, as opposed to unfair dismissal, especially where they have lengthy notice periods. This is because they stand to gain more from damages for breach of contract (possibly representing the whole of the notice period they should have been given) as opposed to the amount they could receive on an unfair dismissal claim (which is largely governed by their loss of earnings). If an employee is dismissed as a result of gross misconduct, ie theft, and the employer was justified in dismissing the employee in this way, there can be no claim for wrongful dismissal, as the employee will have been treated as repudiating the implied term of trust and confidence between the parties, which the employer then accepts by the summary dismissal. Dismissals with pay in lieu of notice:- it is common for an employer not to require an employee to work out his notice period and to pay him in lieu of notice. Such payment in lieu of notice is usually regarded as damages for wrongful dismissal (unless otherwise specified in the contract). In these circumstances, the employer would not be in breach of contract by making a payment in lieu and it is therefore unlikely that there could be any claim for wrongful dismissal. If there is no contractual right to terminate by making a payment in lieu of notice, then the making of such a payment may not extinguish the employee's claim for damages unless, in all respects, the employee is put in the same position as he would have been in if notice had been given. Amount of damages:- the amount of damages for wrongful dismissal is based on pay and other benefits, such as the use of a company car, which the employee would have received if the employer had complied with his contractual obligations. An employee may put in a claim for other contractual benefits such as discretionary bonus payments which they will have missed out on, although it can be difficult to prove such a claim. If the employee finds a new job within the period of notice, which he would have been entitled to from his old employer, then he is not entitled to a double recovery. The new salary received must be taken into account in calculating the loss to the employee. It should be remembered that the employee is under a duty to take all steps to mitigate his loss, ie seek such alternative employment. Any damages which an employee receives under wrongful dismissal will reduce the amount of the compensatory award under unfair dismissal by the same amount. When should an employee make a claim? An employee should make a claim for wrongful dismissal in the Employment Tribunal within 3 months from the effective date of termination of his employment. / Неправомерное Увольнение или Неправомерное Отстранение От Работы – прекращение действия трудового соглашения по причинам или в порядке, не предусмотренных соглашением. Таким образом, если работник увольняется без предварительного уведомления (при обстоятельствах, которые не могут быть оправданы массовым увольнением) или если работодатель увольняет работника до истечения срока договора, заключённого на определённый срок, работник имеет право обратиться в суд с требованием возмещения ущерба (damages), нанесённого незаконным увольнением. Под юрисдикцию суда подпадают только случаи, связанные с нарушением вытекающих из трудового соглашения прав сторон; суд не рассматривает случаи нарушения законных прав сторон, определённых в законодательстве, регулирующем производственные отношения (сравните с Незаконным Увольнением (Unfair Dismissal)). Закон О Защите Прав Трудящихся (Консолидации) 1978 уполномочивает Государственного Секретаря по Делам Занятости наделять суды по рассмотрению производственных конфликтов правом рассматривать дела, связанные с неправомерным увольнением.

WRONGFUL TRADING = НЕПРАВОМЕРНАЯ ТОРГОВЛЯ – Wrongful Trading applies when:- (a) the company has gone into insolvent liquidation, (b) at some time before the commencement of the winding up of the company, that person knew or ought to have concluded that there was no reasonable prospect that the company would avoid going into insolvent liquidation, and (c) that person was a director of the company at that time. In deciding whether or not a director of a company ought to have known or ascertained the company was insolvent, the conclusions which he ought to reach and the steps which he ought to have taken are those which would be known or ascertained, or reached or taken, by a reasonably diligent person having both – (a) the general knowledge, skill and experience that may reasonably be expected of a person carrying out the same functions as are carried out by that director in relation to the company, and (b) the general knowledge, skill and experience that that director has. Of course, these points are not a definitive 'you're guilty', and the Insolvency Practitioner will investigate into the affairs of the company in detail to conclude whether or not you have committed an offence. Defence For Directors In Relation To Wrongful Trading Proceedings:- The Insolvency Practitioner will need to apply to court to proceed with action against a director for Wrongful Trading. The Court will then have regard to any director falling under (b) above and will not make the order if it is satisfied that that person took every step with a view to minimizing the potential loss to the company's creditors as they ought to have taken. (assuming him to have known that there was no reasonable prospect that the company would avoid going into insolvent liquidation). Therefore it is very important to ensure all actions taken are well documented in the company records and you do not breach your 'fiduciary duty' as a director. Wrongful Trading:- allowing a firm to continue trading in a situation where a reasonably diligent person would realize that the firm's insolvency is inevitable. Directors of a firm who know (or ought to have known) that its insolvency could not be avoided may be held personally liable to its creditors if it becomes bankrupt or is liquidated. See also Fraudulent Trading. Wrongful Trading v Insolvent Trading – which is the unlawful act that you need to watch out for? The short answer is Wrongful Trading is the unlawful act as set out in Section 214 of the Insolvency Act 1986 (UK). Insolvent Trading or trading whilst insolvent would be part of the evidence of an act of Wrongful Trading, however it is not necessarily an unlawful act. It depends upon the facts of the case. So what is the difference between the two? There is no statutory recognition afforded to Insolvent Trading. Whilst undesirable in many instances it is not necessarily unlawful. Wrongful Trading is an action that can only be undertaken by a person occupying the position of Director of a limited company. That position of 'Director' can be determined in a number of ways, being official (recognized at Companies House and in a company's statutory register), de facto or shadow as set out in the Companies Act. Wrongful trading is the act by Directors of a period of trading in which debts and liabilities are incurred and typically increase, whilst having no reasonable prospect of a company avoiding insolvent liquidation. It is the action by Directors of

accepting credit when it is highly unlikely that the same would be discharged due to the financial position of a company. Wrongful Trading only applies to company Directors, whereas Insolvent Trading can be undertaken by individuals such as sole traders. There are two tests for solvency defined in Section 123 of the Insolvency Act 1986, being (1) are your assets exceeded by your liabilities and (2) are you failing to discharge your debts as and when they fall due. If you satisfy either criteria then you are technically insolvent in accordance with the definition of the same in the legislation. What is the risk? Well if you are accused by a liquidator of a company of Wrongful Trading then as Director you could be personally liable for the damage the company suffered during a period of Wrongful Trading – so do not do it! If in any doubt take professional advice at the earliest possible opportunity. Often such advice can be obtained without charge for an initial consultation with a Licensed Insolvency Practitioner. / Неправомерная Торговля – торговля компании в тот период, когда у неё уже нет возможности избежать ликвидации по причине неплатёжеспособности. Ликвидатор компании может просить суд вынести распоряжение, требующее от директора компании, вступившей в стадию ликвидации по причине неплатёжеспособности, пополнить активы компании. Если директор знал или обязан был знать о положении компании, суд имеет право приказать директору пополнить активы компании в любой форме, которую суд сочтёт подходящей. Ответственность возлагается на директора и в том случае, если какое-либо лицо в компании, выполняющее функции, аналогичные директорским, осознавало положение компании; доказательств преднамеренного обмана приводить не требуется. WRONG MENDED = НЕПРАВИЛЬНО ОТШТОПАННОЕ (или НЕПРАВИЛЬНО ПОЧИНЕННОЕ) – Wrong Mended:- during mending repair if end or pick is not properly filled as per weave or not relaxed. Mending defect. / Порок или дефект штопки (mending defect).

WRONG MENDING = НЕНАДЛЕЖАЩАЯ (или НЕПРАВИЛЬНАЯ) ШТОПКА (или ПОЧИНКА) – Wrong Mending:- this defect is the failure of mending work, i.e. mending is done to save the fabric to go as fresh but some times the defect is of serious nature and after making attempts it can not be made as original and looks different or shining and hence fabric can not pass as good, Some fabric are very delicate nature such as polyester, viscose where if attempts for repair done it shows and fabric does not pass as good. For improving mending work, we identify that the needle which were being used by the mender is creating shining because it ruptures and abrades the yarn surface. A suitable needle is found which is having a ball point at the tip and which is not abrading the yarn when used, hence avoiding shining in the yarn after finishing of the fabric. Also, we avoid the use of pincher rubber for relaxing the filled yarn which is attended by the mender. This technique helps a lot for improving the quality of mending. Also, we identified certain weak menders those who poorly perform in terms of their C&D%. We educate them and training is further provided so that they improve their performance. / Порок или дефект. Ремонтный мастер (mender).

WRONG NAME SELVEDGE = НЕПРАВИЛЬНОЕ НАЗВАНИЕ КРОМКИ – Wrong Name Selvedge:- there are different name wording for name selvedges required as per quality numbers. If woven fabric contains any other name rather than printed name on piece ticket called Wrong Name Selvedge. Weaving defect. / Порок или дефект ткачества.

WRONG PICK = НЕНАДЛЕЖАЩАЯ (или НЕПРАВИЛЬНАЯ) ПОПЕРЕЧНАЯ НИТЬ (или РАЗНАЯ ПОПЕРЕЧНАЯ НИТЬ) – Wrong Pick:- weft which is distinctly different from the normal weft in a fabric. Note:- this defect is caused by a lack of control of incoming material. See also Mispick. / Разный Уток – порок ткани в виде наработанных в одном куске мест различными номерами утка. Порок или дефект ткачества.

WRONG PINNING = НЕПРАВИЛЬНОЕ НАКАЛЫВАНИЕ – Wrong Pinning:- improper pinning on selvedge of fabric. Finishing defect. / Дефект заключительной отделки.

WRONG SEAM OR STITCH TYPE = НЕПРАВИЛЬНЫЙ ТИП ШВА ИЛИ СТЕЖКА – Wrong Seam or Stitch Type:- management error in selection – or operating personnel failing to follow specifications. Sewing Room Defects. / Порок или дефект швейного производства.

WRONG SHADE OF THREAD = НЕНАДЛЕЖАЩИЙ (или ЕПРАВИЛЬНЫЙ) ОТТЕНОК НИТИ – Wrong Shade Of Thread:- either caused by basic purchasing error, manufacturing defect by thread supplier or operator selecting wrong color from thread bin. Sewing Room Defects. / Порок или дефект швейного производства.

WRONG STARTING POINT = НЕПРАВИЛЬНЫЙ ПУНКТ ПУСКА – Wrong Starting Point:- in dobby design, lifting order is given while making dobby card. Instead of 1st pick we start to punch from 2nd pick then fabric produced will be called wrong starting point. Weaving defect. Wrong Starting Point:- design break, faulty pick finding, faulty punch card, mal functioning of dobby, improper joining of cards and faulty working of any m/c parts. / Порок или дефект ткачества.

WRONG STITCHES PER INCH = НЕНАДЛЕЖАЩЕЕ (или НЕПРАВИЛЬНОЕ) КОЛИЧЕСТВО СТЕЖКОВ НА ДЮЙМ – Wrong Stitches Per Inch:- normally caused by operators who lengthen stitch to increase machine speed. Sewing Room Defects. / Порок или дефект швейного производства.

WRONG WEFT = НЕНАДЛЕЖАЩИЙ УТОК (или НЕПРАВИЛЬНЫЙ УТОК, или РАЗНЫЙ УТОК) – Wrong Weft is the weft which is distinctly different from the normal weft in a fabric. Note:- this defect is caused by a lack of control of incoming material. See also Wrong Pick. / Неправильный Уток (wrong weft):- порок утка; уток, который значительно отличается от обычного утка ткани по толщине, по цвету, по составу сырья, по крутке. Примечание:- этот порок вызван недостаточным контролем за используемым материалом.

WRONG YARN = НЕНАДЛЕЖАЩАЯ ПРЯЖА (или НЕПРАВИЛЬНАЯ ПРЯЖА) – Wrong Yarn is the yarn in a weft-knitted fabric that differs from normal yarn in respect of composition, thickness, filament or color. Note:- this defect is caused by a lack of control of incoming material.

THE WTO AGREEMENT ON SANITARY AND PHYTO–SANITARY MEASURES = СОГЛАШЕНИЕ ВОТ ПО САНИТАРНЫМ И ФИТОСАНИТАРНЫМ МЕРАМ – For the purposes of the Agreement on the Application of Sanitary and Phytosanitary Measures (the SPS Agreement), sanitary and phytosanitary measures are defined as any measures applied:- (i) to protect human or animal life from risks arising from additives, contaminants, toxins or disease-causing organisms in their food; (ii) to protect human life from plant- or animal-carried diseases; (iii) to protect animal or plant life from pests, diseases, or disease-causing organisms; and (iv) to prevent or limit other damage to a country from the entry, establishment or spread of pests. These include sanitary and phytosanitary measures taken to protect the health of fish and wild fauna, as well as of forests and wild flora. Measures for environmental protection (other than as defined above), to protect consumer interests, or for the welfare of animals are not covered by the SPS Agreement. These concerns, however, are addressed by other WTO agreements (i.e. the TBT Agreement or Article XX of GATT 1994). The WTO Agreement on Sanitary and Phyto-sanitary measures (SPS Agreement), including standards used to protect human, animal or plant life and health. The Agreement on the Application of Sanitary and Phytosanitary Measures (the SPS Agreement) entered into force with the establishment of the World Trade Organization on 01 January 1995. It concerns the application of food safety and animal and plant health regulations. This introduction discusses the text of the SPS Agreement as it appears in the Final Act of the Uruguay Round of Multilateral Trade Negotiations, signed in Marrakesh on 15 April 1994. This agreement and others contained in the Final Act, along with the General Agreement on Tariffs and Trade as amended (GATT 1994), are part of the treaty which established the World Trade Organization (WTO). The WTO superseded the GATT as the umbrella organization for international trade. The WTO Secretariat has

prepared this text to assist public understanding of the SPS Agreement. It is not intended to provide legal interpretation of the agreement. The Agreement on the Application of Sanitary and Phytosanitary Measures sets out the basic rules for food safety and animal and plant health standards. It allows countries to set their own standards. But it also says regulations must be based on science. They should be applied only to the extent necessary to protect human, animal or plant life or health. And they should not arbitrarily or unjustifiably discriminate between countries where identical or similar conditions prevail. Member countries are encouraged to use international standards, guidelines and recommendations where they exist. However, members may use measures which result in higher standards if there is scientific justification. They can also set higher standards based on appropriate assessment of risks so long as the approach is consistent, not arbitrary. The agreement still allows countries to use different standards and different methods of inspecting products. All countries maintain measures to ensure that food is safe for consumers, and to prevent the spread of pests or diseases among animals and plants. These sanitary and phytosanitary measures can take many forms, such as requiring products to come from a disease-free area, inspection of products, specific treatment or processing of products, setting of allowable maximum levels of pesticide residues or permitted use of only certain additives in food. Sanitary (human and animal health) and phytosanitary (plant health) measures apply to domestically produced food or local animal and plant diseases, as well as to products coming from other countries. Sanitary and phytosanitary measures, by their very nature, may result in restrictions on trade. All governments accept the fact that some trade restrictions may be necessary to ensure food safety and animal and plant health protection. However, governments are sometimes pressured to go beyond what is needed for health protection and to use sanitary and phytosanitary restrictions to shield domestic producers from economic competition. Such pressure is likely to increase as other trade barriers are reduced as a result of the Uruguay Round agreements. A sanitary or phytosanitary restriction which is not actually required for health reasons can be a very effective protectionist device, and because of its technical complexity, a particularly deceptive and difficult barrier to challenge. The Agreement on Sanitary and Phytosanitary Measures (SPS) builds on previous GATT rules to restrict the use of unjustified sanitary and phytosanitary measures for the purpose of trade protection. The basic aim of the SPS Agreement is to maintain the sovereign right of any government to provide the level of health protection it deems appropriate, but to ensure that these sovereign rights are not misused for protectionist purposes and do not result in unnecessary barriers to international trade. The SPS Agreement, while permitting governments to maintain appropriate sanitary and phytosanitary protection, reduces possible arbitrariness of decisions and encourages consistent decision-making. It requires that sanitary and phytosanitary measures be applied for no other purpose than that of ensuring food safety and animal and plant health. In particular, the agreement clarifies which factors should be taken into account in the assessment of the risk involved. Measures to ensure food safety and to protect the health of animals and plants should be based as far as possible on the analysis and assessment of objective and accurate scientific data. The SPS Agreement encourages governments to establish national SPS measures consistent with international standards, guidelines and recommendations. This process is often referred to as ‘Harmonization’. The WTO itself does not and will not develop such standards. However, most of the WTO’s member governments (132 at the date of drafting) participate in the development of these standards in other international bodies. The standards are developed by leading scientists in the field and governmental experts on health protection and are subject to international scrutiny and review. International standards are often higher than the national requirements of many countries, including developed countries, but the SPS Agreement explicitly permits governments to choose not to use the international standards. However, if the national requirement results in a greater restriction of trade, a country may be asked to provide scientific justification, demonstrating that the relevant international standard would not result in the level of health protection the country considered appropriate. Due to differences in climate, existing pests or diseases, or food safety conditions, it is not always appropriate to impose the same sanitary and phytosanitary requirements on food, animal or plant products coming from different countries. Therefore, sanitary and phytosanitary measures sometimes vary, depending on the country of origin of the food, animal or plant product concerned. This is taken into account in the SPS Agreement. Governments should also recognize disease-free areas which may not correspond to political boundaries, and appropriately adapt their requirements to products from these areas. The agreement, however, checks unjustified discrimination in the use of sanitary and phytosanitary measures, whether in favour of domestic producers or among foreign suppliers. Alternative Measures:- an acceptable level of risk can often be achieved in alternative ways. Among the alternatives – and on the assumption that they are technically and economically feasible and provide the same level of food safety or animal and plant health – governments should select those which are not more trade restrictive than required to meet their health objective. Furthermore, if another country can show that the measures it applies provide the same level of health protection, these should be accepted as equivalent. This helps ensure that protection is maintained while providing the greatest quantity and variety of safe foodstuffs for consumers, the best availability of safe inputs for producers, and healthy economic competition. Risk Assessment:- the SPS Agreement increases the transparency of sanitary and phytosanitary measures. Countries must establish SPS measures on the basis of an appropriate assessment of the actual risks involved, and, if requested, make known what factors they took into consideration, the assessment procedures they used and the level of risk they determined to be acceptable. Although many governments already use risk assessment in their management of food safety and animal and plant health, the SPS Agreement encourages the wider use of systematic risk assessment among all WTO member governments and for all relevant products. Transparency:- Governments are required to notify other countries of any new or changed sanitary and phytosanitary requirements which affect trade, and to set up offices (called Enquiry Points) to respond to requests for more information on new or existing measures. They also must open to scrutiny how they apply their food safety and animal and plant health regulations. The systematic communication of information and exchange of experiences among the WTO’s member governments provides a better basis for national standards. Such increased transparency also protects the interests of consumers, as well as of trading partners, from hidden protectionism through unnecessary technical requirements. A special Committee has been established within the WTO as a forum for the exchange of information among member governments on all aspects related to the implementation of the SPS Agreement. The SPS Committee reviews compliance with the agreement, discusses matters with potential trade impacts, and maintains close co-operation with the appropriate technical organizations. In a trade dispute regarding a sanitary or phytosanitary measure, the normal WTO dispute settlement procedures are used, and advice from appropriate scientific experts can be sought.

WULFENITE = ВУЛЬФЕНИТ – Wulfenite:- lead molybdate, $PbMoO_4$, a minor source of molybdenum and the second most common molybdenum mineral. It occurs in the oxidized zone of lead and molybdenum deposits. Fine crystals have been found at Příbram, Czech Republic; Yuma County, Arizona, the United States; and Mapimi, Durango, Mexico. Other localities include Germany, Austria, Sardinia, and Australia. Wulfenite ordinarily crystallizes as thin, beveled, square plates that have a resinous to adamantine luster, and they are yellow to orange in color. The Mohs hardness is 3 (named after the German mineralogist, Friedrich Mohs (1773-January-29–1839-September-29), who invented a scale of hardness based on the ability of one mineral to scratch another); specific gravity, 6.5–7; and crystal system, tetragonal. / твёрдость по Мосу (Mohs hardness; названа в честь Немецкого минералога Фридриха Моса (Friedrich Mohs; 1773-Январь-29–1839-Сентябрь-29)). WURTZITE = ВЮРЦИТ – Wurtzite:- a zinc sulfide mineral that occurs typically in Potosí, Bolivia; Butte, State of Montana, the United States; and Goldfield, State of Nevada, the United States. It is a rare and unstable (at temperatures below 1 020 °C (1 870 °F)) hexagonally symmetrical modification of sphalerite, to which it inverts crystallographically; it may be made artificially from sphalerite by rapid cooling from 1 020 °C. For detailed physical properties, see Sulfide Mineral (table). / Вюрцит – минерал класса сульфидов, полиморфная гексагональная модификация ZnS. Примеси Fe, Cd. Радиально-лучистые агрегаты, колломорфные выделения. Твёрдость 3.5–4; плотность 4 г/см^3. В основном гидротермальный минерал. Руда цинка, иногда кадмия.

WUZZING = ВЗВИНЧИВАНИЕ – Wuzzing is a way of removing excess moisture by centrifugal force. Hold onto the end of the skein firmly and spin it around like a heliocopter blade. Wuzzing is when you put your wool into a mesh bag and swing it around, using centrifugal force to evacuate the water from wool. It is a good way to spin your wool without putting it in the washing machine. My front loader will not spin without putting some water in and sometimes I am too lazy to turn off the water. / способ удаления избыточной влаги с помощью центробежной силы.

WYCKOFF UP THRUST = ВЫКОФСКИЙ ВЫНОС ВВЕРХ – Wyckoff Up Thrust (in technical analysis):- (i) there must be a line of visible resistance on the chart (this is a supply line); (ii) a Wyckoff Up Thrust occurs when price moves above a resistance line but the move attracts sellers not buyers, an Up Thrust is a failed breakout; and (iii) the initial decline from the Up Thrust finds a short-term bottom and prices lift in an attempt to retest the High of the Up Thrust, but the attempted retest, generally on lower volume, turns out to be a swing failure and price resumes downside. These 3 points are the bare bones of a Wyckoff Up Thrust. The opposite of a Wyckoff Up Thrust is a Wyckoff Spring which is a failed breakdown below established support, (lower prices are rejected and reverse to the upside). Richard D. Wyckoff pioneered using price action as a means of identifying supply and demand in the markets. He began his Wall Street career as a runner in 1888 and eventually became a very successful trader using observations developed over years of experience on 'The Street'. / Ричод Ди. Выкоф (Richard D. WYTHE = ИЗОЛЯЦИОННЫЙ СЛОЙ (или НОКОВЫЙ БУГЕЛЬ) – Wythe:- the masonry wall that must separate multiple flue liners in a masonry chimney. Also referred to as Partition. A Wythe is a continuous vertical section of masonry one unit in thickness. A wythe may be independent of, or interlocked with, the adjoining wythe(s). A single wythe of brick that is not structural in nature is referred to

as a Veneer. A multiple-wythe masonry wall may be composed of a single type of masonry unit layered to increase its thickness and structural strength, or different masonry units chosen by function, such as an economical concrete block serving a structural purpose and a more expensive brick chosen for its appearance. Wythe is a single thickness of bricks in masonry construction. Origin:- early XVIII century (as with):- probably an alteration of width. Wythe, or Withe, is a term for a vertical section of masonry that is one unit thick, meaning that it is constructed from a single line of masonry units. The units are usually bricks, made of clay or terracotta, or blocks, like those made of concrete. This term is often used when describing different kinds of wall construction. A masonry wall can be a single or a multiple wythe wall, and each type has its strengths and drawbacks. Brick veneer is a special kind of construction, and it is usually used to provide attractive, durable siding without performing a structural function. In the past, structural walls were commonly made up of multiple wythes, using several layers of different masonry units like stone, clay, and concrete. These walls were often very solid and very thick but are also difficult to insulate because of the solid nature of the masonry. Examples of this type of construction include most clay brick and terracotta brick walls built in the early XX century. One common type of wall construction is made up of two wythes, usually with an outer layer of brick and an inner layer consisting of cinder or concrete blocks. The two sections are usually held together by metal ties or rows of header bricks, which are installed sideways at regular intervals. There are also rain-screen veneer walls that have an exterior made out of masonry, usually brick, that is separated from an inner, structural wall by a cavity. The cavity wall makes it easier to insulate, and also provides weatherproofing, by allowing water that gets inside the exterior wall to escape. In recent times, structural walls have been commonly constructed as single wythe walls. This kind of wall is often built using over-sized bricks or concrete blocks. A wall like this is relatively cheap to build and low maintenance, is fire and sound proof, and can be very durable if built right. It has no cavity wall inside, however, so it needs to be constructed carefully to be weatherproof. Flashing and weep-holes have to be installed, and the surface has to be treated with a water repellent or paint. When constructing a single wythe wall, it is important to use the appropriate materials, both for the units, whether they are bricks or blocks, and for the mortar.

X.25 = ИКС.25 (или ЭКС.25) – X.25 is an International Telecommunication Union-Telecommunication Standardization Sector (ITU-T) protocol standard for WAN communications that defines how connections between user devices and network devices are established and maintained. X.25 is designed to operate effectively regardless of the type of systems connected to the network. It is typically used in the packet-switched networks (PSNs) of common carriers, such as the telephone companies. Subscribers are charged based on their use of the network. The development of the X.25 standard was initiated by the common carriers in the 1970s. At that time, there was a need for WAN protocols capable of providing connectivity across public data networks (PDNs). X.25 is now administered as an international standard by the ITU-T. X.25 is the standardized communication protocol for the networked computers. X.25 is the international standard of the CCITT (short for the International Telegraph and Telephone Consultative Committee which is now named ITU-T (short for the ITU Telecommunication Standardization Sector)) for packet switching. / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Стандартизированный протокол связи для компьютеров, работающих в одной сети. В 1976 был принят стандарт X.25, который стал основой всемирной системы PSPDN (Packet-Switched Public Data Networks), базирующейся на 7-уровневой модели ISO OSI. Стандарт X.25 был усовершенствован в 1984. X.25 – протокол (ISO 8208:1989; RFC-887, -1381, -1382, -1461, -1598, -1613), который определяет синхронный интерфейс между Терминальным Оборудованием для Данных (Data Terminal Equipment (DTE)) и Оборудованием Передачи Данных (Data Communication Equipment (DCE)) для терминалов, работающих в пакетном режиме. По существу это протокол связи оборудования с сетью. Главный недостаток протокола X.25 – большие задержки отклика (типовое значение 0.6 сек). Терминалом может служить ЭВМ или любая другая система, удовлетворяющая требованиям X.25. Соединение DTE – DTE осуществляется через DCE. В протоколе X.25 DCE и DTE используют статистическое мультиплексирование с делением по времени. Одновременно могут реализовываться несколько обменных процессов. Протокол X.25 был разработан в 1970-х. Этот протокол является представителем протоколов, использующих метод коммутации пакетов, и поддерживает работу как с коммутируемыми, так и постоянными виртуальными каналами. Административное управление развитием протокола X.25 осуществляет Международный Союз Дальней Связи (The International Telecommunication Union (ITU)) – агентство, работающее под эгидой Организации Объединенных Наций. Ввиду международного признания протокола X.25 он, возможно, является одним из самых распространённых протоколов глобальных сетей. Так же, как и все технологии с коммутацией пакетов, протокол X.25 рассматривает сеть передачи данных, по сути, как обыкновенную телефонную сеть и передаёт данные, используя виртуальные каналы. Обмен данными между двумя устройствами начинается с того, что одно устройство дозванивается до другого для создания коммутируемого или постоянного виртуального канала. Затем происходит сам процесс передачи данных, после чего выполняется процедура завершения звонка. Протокол X.25 предусматривает двухточечный обмен данными между оконечным пользовательским устройством (DTE) и оконечным устройством канала передачи данных (DCE). Устройства DTE (например, маршрутизаторы) подключаются к устройствам DCE (например, модемам), которые, в свою очередь, подключаются к одному или нескольким коммутаторам сети X.25 и, в конечном итоге, к другим устройствам DTE. Оконечное устройство канала передачи данных (DCE) – это устройство, которое является концевым устройством интерфейса пользователь-сеть со стороны сети. Устройства DCE обеспечивают физическое соединение с сетью, пропускают через себя трафик и вырабатывают сигналы синхронизации, используемые для синхронизации передачи данных

между устройствами DCE и DTE. Оконечное пользовательское устройство (DTE) – это устройство, находящееся с другой, пользовательской стороны интерфейса пользователь-сеть. Эти устройства могут выступать в роли отправителя данных, получателя или совмещать эти функции. Устройство DTE соединяется с сетью передачи данных с помощью устройств DCE (например, модемов) и обычно использует сигналы синхронизации, вырабатываемые устройствами DCE. Так называемый 'звонок' в сети X.25 начинается с того, что устройство DTE, выступающее отправителем данных, совместно с тем устройством DCE, с которым соединено, инициирует сеанс связи. Коммутаторы в сети X.25 определяют маршрут передачи звонка от отправителя к получателю. Затем все данные коммутируются от устройства DTE-отправителя на устройство DTE-получателя. В протоколе X.25 используется схема адресации, называемая X.121. Форматы адресов отправителя и получателя канального уровня для протокола X.25 определены рекомендательным документом ITU-T Recommendation X.121. Коммутаторы сети X.25 маршрутизируют звонок вдоль пути виртуального канала, основываясь на X.121-адресах устройства-отправителя и устройства-получателя. Адреса, определяемые документом X.121, не имеют четко фиксированной длины и могут содержать до 14 десятеричных цифр. Первые четыре цифры адреса называются Идентификационным Кодом Сети Передачи Данных (Data Network Identification Code (DNIC)). Оставшиеся цифры адреса могут быть использованы администратором сети по своему усмотрению.

XANTHA = КСАНТА (или ЗОЛОТИСТО–ЖЁЛТЫЙ) – The term Xantha is derived from the Greek word Xanthós, for Yellow. Xantha is a condition wherein seedlings have pale yellow leaves and perish shortly after germination. / Под Ксантой от Греческого слова Xanthós, означающий Жёлтый или Золотисто-Жёлтый или Рыжий или Светло-Золотистый, понимается состояние, при котором . А недостаток азота вызывает пожелтение всходов. При массовом поражении всходов всё поле принимает жёлтую окраску, почему болезнь и получила название 'пожелтение всходов' (научное название – Антракноз). Позже болезнь обнаруживается на листьях в виде бурых пятен. Поражённая ткань буреет и засыхает, особенно по краям и на верхушках листьев. Стебли взрослых растений также покрываются бурыми пятнами и трещинками. Увядание ботвы – пожелтение (побурение) большей части листьев у большинства растений, прекращение вегетации. На всходах отмечается пожелтение семядолей, а на молодых листьях – появление жёлтых пятен и посветление вдоль главных жилок. Затем листья сморщиваются, рост растения задерживается, и нередко оно погибает. На взрослых растениях на листьях жёлтые пятна или общее пожелтение (хлороз) в различной степени.

XANTHATE = КСАНТАТ – Xanthate:- any of a class of organic salts formed by treatment of an alcohol with carbon disulfide in the presence of an alkali. The term is derived from the Greek word Xanthos, for 'Yellow', in reference to the compound potassium ethyl xanthate ($C_2H_5OCS_2K$), which gives a yellow precipitate when combined with copper sulfate. The most important group of xanthates are the sodium salts produced from cellulose; these materials are processed to form the synthetic fiber rayon or the transparent film cellophane, then reconverted to cellulose. The xanthates of some low-molecular-weight alcohols are used as flotation agents for the concentration of ores.

XANTHATING = КСАНТОГЕНИРОВАНИЕ (или ПРЕВРАЩЕНИЕ В КСАНТОГЕНАТ) – Xanthating is a process in rayon manufacture in which carbon disulfide is reacted with alkali cellulose to produce bright orange cellulose xanthate. Xanthate is any of a class of organic salts formed by treatment of an alcohol with carbon disulfide in the presence of an alkali. The term is derived from the Greek word Xanthós, for Yellow. / Щёлочь (Alkali). Ксантат. Под Ксантогенированием (Xanthation) понимают обработку алкалицеллюлозы сероуглеродом и образование тиокарбоновых эфиров целлюлозы. Для снижения межмолекулярного взаимодействия и облегчения перевода в растворимое состояние щелочную целлюлозу подвергают ксантогенированию. Под Ксантогенированием, от Греческого слова Xanthós, означающее Жёлтый, понимают комплекс химических и физико-химических процессов, протекающих при взаимодействии щелочной целлюлозы с сероуглеродом. Процесс ксантогенирования протекает в гетерогенных условиях многофазной системы. В общем случае в начале процесса можно выделить следующие фазы:- (i) газовая многокомпонентная фаза переменного состава, состоящая из паров сероуглерода, воды и азота; (ii) две жидких фазы – сероуглерод и многокомпонентная щелочная фаза, состоящая из аморфной набухшей целлюлозы, едкого натра, воды и небольшого количества сероуглерода; и (iii) твёрдая фаза, состоящая из кристаллических или близких по своей степени упорядоченности к кристаллическим участкам щелочной целлюлозы. В зависимости от содержания целлюлозы в реакционной массе и, соответственно, её гетерогенности различают следующие разновидности процесса ксантогенирования:- (i) сухое ксантогенирование (содержание целлюлозы 28–35%); (ii) мокрое ксантогенирование (содержание целлюлозы 18–24%); и (iii) эмульсионное ксантогенирование (содержание целлюлозы 1–5%). Наибольшее распространение получило сухое ксантогенирование, которое иногда называют ксантогенированием в волокнистом состоянии. Процесс ведут при достаточно высокой температуре 26–35 °C, так что значительная часть сероуглерода находится в газообразном состоянии. Мокрое ксантогенирование, рекомендуемое для ускорения процесса и повышения качества вискозы, проводят обычно при более низких температурах (18–24 °C) с добавкой дополнительной щёлочи. Сероуглерод находится в большей мере в жидкой фазе. Эмульсионное ксантогенирование чаще применяют в исследовательских целях, например, для определения реакционной способности целлюлозы. Практически весь сероуглерод находится в эмульсированном состоянии в виде жидкой фазы. В промышленности основным является способ сухого ксантогенирования в ксантогенераторах периодического действия. Для интенсификации процесса ксантогенирования целесообразен переход к непрерывному ксантогенированию. Это возможно при переходе к мокрому ксантогенированию или проведении сухого ксантогенирования при повышенной температуре и упругости паров с использованием эффекта дополнительного ксантогенирования во время растворения ксантогената. Продолжительность мокрого ксантогенирования может быть сведена до 30 минут. Однако, для осуществления непрерывного ксантогенирования по мокрому способу необходимы интенсивные смесители непрерывного действия, например, шнеки, которые в следствие высоких напряжений сдвига нельзя выпускать в расчёте на производительность выше, чем 10–15 тонн в сутки (т/сут) по целлюлозе. Второе направление – сухое ксантогенирование при повышенной температуре и упругости паров сероуглерода – оказалось более перспективным. В ксантогенатор производительностью 50–60 т/сут по целлюлозе щелочная целлюлоза подаётся в циклон и через герметичный бункер поступает на ленту транспортёра, расположенную в герметичной

ёмкости. На ленту сероуглерод подаётся через дозатор. Частично проксантогенированная щелочная целлюлоза пересыпается на нижнюю транспортёрную ленту, на которой продолжается ксантогенирование. Общая продолжительность ксантогенирования 30 минут. Ксантогенат пересыпается в углубление, в котором он с помощью мешалки смешивается с растворительной щёлочью, подаваемой через дозатор и поступает на измельчитель. Образовавшаяся суспензия подаётся на растворение и фильтрацию. Ксантогенат целлюлозы растворяют в разбавленном растворе едкого натра, и при достаточной концентрации образуется вязкий раствор, называемый вискозой, который используется для формирования волокна. Процесс растворения ксантогената целлюлозы – одна из важнейших стадий вискозного производства, где формируется структура вискозы. От того, насколько полно осуществлено растворение ксантогената целлюлозы, в большей степени зависят параметры проведения последующих стадий:- фильтрации вискозы и формования волокна. Современный промышленный способ растворения ксантогената целлюлозы практически не отличается от способа 40–50 летней давности и характеризуется большой продолжительностью (3–6 часов). В настоящее время на предприятиях для вискозного волокна применяются растворители ксантогената целлюлозы разной конструкции 12,13,14:- вертикальные, горизонтальные, объёмом от 7 до 40 $м^3$, с одной, двумя или тремя мешалками. С увеличением частоты вращения мешалки резко сокращается время получения гомогенной вискозы. Основным путём интенсификации процесса растворения ксантогената целлюлозы было создание растирателей – лопастных, дисковых, центрифуг. С начала 1970-х широко используются конструктивно более современные аппараты роторного типа:- роторно-импульсивные (РИА), гидродинамические (ГАРТ), роторно-пульсационные (РПС или ПРГ).

XANTHINE OXIDASE = КСАНТИНОКСИДАЗА – Xanthine Oxidase is an enzyme responsible for production of free radicals in the body. / Ксантиноксидаза – фермент, катализирующий окисления гипоксантина в ксантин.

XANTHINURIA = КСАНТИНУРИЯ – Xanthinuria:- rare inherited disorder of purine metabolism that results from a deficiency in the enzyme xanthine oxidase. Normally this enzyme breaks down the purine base xanthine to uric acid, which is then excreted. In the absence of the enzyme, xanthine is not metabolized by the body and its concentration builds up in the blood and urine. Xanthinuria is not a serious condition, and many individuals are symptomless. Some patients, however, develop xanthine stones in their kidneys. Treatment in these instances includes an increase in fluid intake and a reduction in consumption of foods rich in purines, such as organ meats, asparagus, and mushrooms.

XANTHOPHYLL = КСАНТОФИЛЛ – Carotenoids occur as two major types:- (i) the hydrocarbon class, or carotenes; and (ii) the oxygenated (alcoholic) class, or xanthophylls. Some animals exhibit a high degree of selectivity for the assimilation of members of one or the other class. The horse (Equus Caballus), for instance, absorbs through its intestine only the carotenes, even though its green food contains mostly xanthophylls; the domestic hen (Gallus Domesticus), on the other hand, stores only members of the xanthophyll class, as do many fishes and invertebrates. Other animals, including certain frogs, Octopus species, and humans, assimilate and store both classes in the liver and in fat deposits. Carotenoids are synthesized by bacteria, fungi, algae, and other plants to highly evolved flowering forms, in which they are most conspicuous in petals, pollen, fruit, and some roots, e.g., Carrots, sweet Potatoes, Tomatoes, and citrus fruits. All animals and protozoans contain carotenoids, although the blood plasma of a number of mammals (e.g., swine, sheep, goats, some carnivores) is almost entirely free of these pigments. The livers of animals often yield carotenoids; all animals depend upon a nutritional supply of vitamin A or one of its precursors, such as carotene, for maintenance of normal metabolism and growth. Carotenoids are relatively more concentrated in such structures as ovaries, eggs, testes (some animals), the liver (or the liver-like analogue of invertebrates), adrenal glands, skin, and eyes. In birds, carotenoid pigmentation may be conspicuous in the yellow tarsal (lower leg) skin, external ear, body fat, and egg yolk (especially in poultry) and in red-colored feathers. Carotenoids are also found in the wings or wing covers of many insects and in the milk fat of cattle. Xanthophyll is a class of orange oxygenated carotenoid pigments in which one or more double bonds of a carotene have been substituted with hydroxy, methoxy, carboxy, epoxy and oxo (ketone) groups. Like carotene, xanthophylls assist photosynthesis. Carotenoid is any of a group of nonnitrogenous yellow, orange, or red pigments (biochromes) that are almost universally distributed in living things. There are two major types: the hydrocarbon class, or carotenes, and the oxygenated (alcoholic) class, or xanthophylls. Synthesized by Bacteria, fFungi, lower Algae, and green plants, carotenoids are most conspicuous in the petals, pollen, and fruit (e.g., Carrots, sweet Potatoes, Tomatoes, and citrus fruits) of the flowering plants. They can also be seen in the autumn foliage of deciduous trees and shrubs. In the leaves of green plants, carotenoids serve as accessory pigments in photosynthesis, trapping solar energy and passing it to chlorophyll, the primary photosynthetic pigment. All animals and protozoans also contain carotenoids, which they obtain by ingestion. Vitamin A, for example, is one of the substances that animals obtain from the ingestion of carotene. Carotenoids also play a major role in the biological coloration of animals. Xanthophylls:- a Family of Carotenoids, i.e. plant-produced pigments that act as protective antioxidants in photosynthetic plants, and in the bodies of animals that consume those carotenoids. Among other plants, xanthophylls are produced by Yellow Carrots. / виды (species). Под Ксантофиллами, от Греческих слов Xanthós, означающее Жёлтый, и Phýllon, означающее Лист, понимаются природные пигменты из группы каротиноидов; кислородсодержащие производные каротинов. Содержатся в листьях, цветках, плодах и почках высших растений, а также во многих водорослях и микроорганизмах. Участвуют в фотосинтезе в качестве дополнительных пигментов. По-видимому, играют роль светофильтров, защищающих чувствительные к свету ферменты от разрушения. Ксантофил, $C_{40}H_{56}O_2$, жёлтый пигмент листьев. Под Каротиноидами понимается группа природных пигментов жёлтого и оранжевого цвета. по химической природе – изопреноиды; насыщенные углеводороды (каротины) или их окисленные производные (ксантофиллы). Синтезируются некоторыми микроорганизмами и всеми растениями, в клетках которых участвуют в фотосинтезе и процессе, связанных с поглощением света (фототаксисы, фототропизмы и другие). Обусловливают окраску плодов, осенней листвы, колоний ряда микробов. В организме животных и человека из каротинов, поступающих с пищей, образуется витамин А (ретинол). X AXIS = ОСЬ ИКС. – The X Axis is the horizontal scale used in a graph. It serves as a reference line from which measurements are made on the coordinate plane. The distance from the X axis and the Y axis describes the location of an item on that plane. X Axis:- on graphs, the bottom axis. Analysts generally use the X axis for the independent or fixed information (times, dates, numbers of securities). They generally use the Y axis for the dependent or variable information (total returns, prices, yields). / Ось Икс. (или Ось X):- на плоскости задаются две взаимно перпендикулярные прямые (координатные оси), пересекающиеся в точке 0, называемой началом координат. Одна из них – ось X, или ось абсцисс, обычно выбирается горизонтальной, другая – ось Y, или ось ординат, – вертикальной. Справа от 0 выбирается точка, у которой ставится отметка, например, 1. Если принять отрезок от 0 до 1 за единицу длины, то откладывая последовательно этот отрезок вдоль прямой, мы получаем числовую ось. Считается, что эта ось продолжается вправо до бесконечности. Точки на оси X слева от 0 помечаются отрицательными числами, как на шкале термометра. Например, точка –2 расположена от точки 0 слева на таком же расстоянии, как точка 2

справа. Аналогичным образом с той же единицей длины размечается и ось Y. Положительные числа располагаются выше точки 0, отрицательные – ниже.

XBRL = EXTENSIBLE BUSINESS REPORTING LANGUAGE

XBRL = ЭКС.БИ.АР.ЭЛ. (или РЯДО) – XBRL is a language for the electronic communication of business and financial data which is revolutionising business reporting around the world. It provides major benefits in the preparation, analysis and communication of business information. It offers cost savings, greater efficiency and improved accuracy and reliability to all those involved in supplying or using financial data. XBRL stands for eXtensible Business Reporting Language. It is one of a family of 'XML' languages which is becoming a standard means of communicating information between businesses and on the internet. XBRL is being developed by an international non-profit consortium of approximately 450 major companies, organisations and government agencies. It is an open standard, free of licence fees. It is already being put to practical use in a number of countries and implementations of XBRL are growing rapidly around the world. This site provides information about the nature, uses and benefits of XBRL. It explains how individuals and companies can join the effort to move forward and make use of the language. A Simple Explanation:- The idea behind XBRL, eXtensible Business Reporting Language, is simple. Instead of treating financial information as a block of text – as in a standard internet page or a printed document – it provides an identifying tag for each individual item of data. This is computer readable. For example, company net profit has its own unique tag. The introduction of XBRL tags enables automated processing of business information by computer software, cutting out laborious and costly processes of manual re-entry and comparison. Computers can treat XBRL data 'intelligently':- they can recognise the information in a XBRL document, select it, analyse it, store it, exchange it with other computers and present it automatically in a variety of ways for users. XBRL greatly increases the speed of handling of financial data, reduces the chance of error and permits automatic checking of information. Companies can use XBRL to save costs and streamline their processes for collecting and reporting financial information. Consumers of financial data, including investors, analysts, financial institutions and regulators, can receive, find, compare and analyse data much more rapidly and efficiently if it is in XBRL format. XBRL can handle data in different languages and accounting standards. It can flexibly be adapted to meet different requirements and uses. Data can be transformed into XBRL by suitable mapping tools or it can be generated in XBRL by appropriate software. The How XBRL Works page gives further explanation of XBRL, while Benefits and Uses sets out how different types of organisation can gain from the standard. eXtensible Business Reporting Language (XBRL) is an XML based framework that provides the financial community with a method to prepare, publish in a variety of formats, extract and exchange financial statements – it is expected to have major implications for all concerned with presentation and analysis of company accounts. Development is led by a Steering Committee of over 100 organizations and corporations including the US Census Bureau. XBRL taxonomies already existed for some specific reporting schemes, such as US GAAP, and are under development for many others, including IAS and several national GAAPs. XBRL stands for eXtensible Business Reporting Language. XBRL is a language for the electronic communication of business and financial data which is revolutionizing business reporting around the world. It is also one of a family of 'XML' languages which is becoming a standard means of communicating information between businesses and on the internet. XBRL is a language for the electronic communication of business and financial data which is revolutionizing business reporting around the world. It provides major benefits in the preparation, analysis and communication of business information. It offers cost savings, greater efficiency and improved accuracy and reliability to all those involved in supplying or using financial data. XBRL is being developed by an international non-profit consortium of approximately 450 major companies, organizations and government agencies. It is an open standard, free of licence fees. It is already being put to practical use in a number of countries and implementations of XBRL are growing rapidly around the world. The idea behind XBRL, eXtensible Business Reporting Language, is simple. Instead of treating financial information as a block of text – as in a standard internet page or a printed document – it provides an identifying tag for each individual item of data. This is computer readable. For example, company net profit has its own unique tag. The introduction of XBRL tags enables automated processing of business information by computer software, cutting out laborious and costly processes of manual re-entry and comparison. Computers can treat XBRL data 'intelligently':- they can recognize the information in a XBRL document, select it, analyse it, store it, exchange it with other computers and present it automatically in a variety of ways for users. XBRL greatly increases the speed of handling of financial data, reduces the chance of error and permits automatic checking of information. Companies can use XBRL to save costs and streamline their processes for collecting and reporting financial information. Consumers of financial data, including investors, analysts, financial institutions and regulators, can receive, find, compare and analyse data much more rapidly and efficiently if it is in XBRL format. XBRL can handle data in different languages and accounting standards. It can flexibly be adapted to meet different requirements and uses. Data can be transformed into XBRL by suitable mapping tools or it can be generated in XBRL by appropriate software. XBRL is a contraction of the term eXtensible Business Reporting Language. XBRL uses tags to specifically identify various types of information within a financial report, which are then used by software to convert the data into an electronic spreadsheet for further analysis. Thus, XBRL is a step in the process of converting plain-text financial information into a spreadsheet format for further analysis. XBRL, eXtensible Business Reporting Language, is a standard for exchanging business information. It can be used for financial reporting, and for transferring data between accounting systems. Other are likely to emerge in time. XBRL, like many other open formats, is based on XML. There are different 'taxonomies', additional standards built on XBRL, for different countries and accounting standards, as well as one designed to exchange data between accounting systems (very useful for a company with different systems in different units). Companies House has developed its own taxonomy, to allow companies to file accounts electronically. XBRL is an IT standard, not an accounting one. It allows different pieces of software to exchange information. It does not solve the more complex and fundamental problem of the exact meaning of numbers changing with different accounting standards, company choices, and other circumstances. The above is a common limitation of IT standards:- they allow better exchange of information, but not better understanding of it. As an aside, it is worth mentioning that information in databases of company accounts frequently suffers from this problem. A person entering complex data, that is also inconsistent between different companies and countries, into a limited set of database fields has to make simplifying choices. This is made worse by the fact that data entry staff rarely have a deep understanding of accounts. / Расширяемый Язык Деловой Отчётности (РЯДО или, как это звучит на Английском языке, Экс.Би.Ар.Эл. (XBRL)). коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). XBRL – аббревиатура от eXtensible Business Reporting Language, что в переводе на Русский язык означает Расширяемый Язык Деловой Отчётности. XBRL – это формат подготовки финансовой отчётности согласно US GAAP (ОПБУ США) и IFRS (МСФО), применяемый в большинстве стран мира с крупной развитой экономикой. XBRL – очень перспективный формат, основанный на языке разметки XML (eXtensible Markup Language), введённому в дейстие в Феврале 1998. Использование XBRL существенно упрощает обработку

разнообразной деловой отчётности, включая её сбор, проверку, систематизацию, распространение и проведение других операций. Благодаря XBRL становится возможным быстрое сравнение и анализ финансовых данных совершенно разных компаний или одной компании за разные отчётные периоды времени. XBRL – формат, в развитии которого заинтересован широких круг пользователей деловой информации, начиная от специалистов и управляющих компании, заканчивая её акционерами, финансовыми аналитиками и государственными контролирующими и регулятивными органами. XBRL International Inc. (штабквартира в Laytonsville, State of Maryland, US) это некоммерческий консорциум, состоящий из примерно 550 компаний и организаций со всего мира, вместе работающих для развития языка XBRL, его продвижения и поддержки. Члены консорциума ежедневно связываются по телефону и через электронную почту, регулярно работают в комитетах и периодически встречаются на международных конференциях. Совместная работа началась в 1998. Она привела к появлению ряда спецификаций и таксономий, обеспечивающих стандартный, основанный на XML язык для представления деловых отчётов в электронном виде. Эти отчёты соответствуют существующим в каждой стране бухгалтерским стандартам или другим требованиям, предъявляемым к отчётности, таким, как банковское регулирование или оценка эффективности. Заинтересованные компании и организации приглашаются к сотрудничеству с консорциумом XBRL International Inc и к совместному созданию будущего электронной деловой отчётности. История:- Июль 1999 – American Institute of Certified Public Accountants (AICPA) принимает решение о выделении бюджета на создание на основе XML языка финансовой отчетности – EFRML (Extensible Financial Reporting Markup Language). Август 1999 – Создан Управляющий Совет EFRML, состоящий из 13 членов (AICPA, Арсур Анэсэн (Arthur Andersen), Коэн Кампьютё Кансалтин (Cohen Computer Consulting), Дельват И Тушэ (Deloitte & Touche), и-контэнт кампэни (e-content company), Энст Энд Ян (Ernst & Young), ФриЭДГА.дат.кам (FreeEDGAR.com (сейчас ЭДГА Онлайн (EDGAR Online)), Эф.Ар.экс. Июль 2000 – Принимается новое название – Экс.Би.Ар.Эл. (XBRL). Отход от традиционного использования Экс.Эм.Эл. (XML). Выпуск первой XBRL спецификации 1.0 и таксономии US GAAP. Январь 2001 – Первая международная конференция по XBRL в Лондоне, Соединённое Королевство. Январь–Декабрь 2001 – Первое внедрение XBRL – Australian Prudential Regulatory Authority (APRA). Принятие решения правительством Японии об использовании XBRL в качестве стандарта для регулятивных органов (Агентство по Ценным Бумагам, Агентство по Налогам). Формирование юрисдикций XBRL Australia, XBRL Canada, XBRL Germany, XBRL IASB, XBRL Japan, XBRL Netherlands, XBRL UK и XBRL US. Декабрь 2001 – Выход XBRL спецификации 2.0. Декабрь 2003 – Выход XBRL спецификации 2.1. 2004 – Фондовые биржи в Китае, Японии, Сингапуре и Южной Кореи принимают XBRL в качестве стандарта. Еврокомиссия выделяет грант в размере 1 миллиона Евро на повышение осведомленности об XBRL. Крупные проекты по XBRL в Европе. Сентябрь 2006 – US SEC выделяет 56 миллионов Долларов на приведение своей системы EDGAR (the Electronic Data Gathering, Analysis, and Retrieval system) в соответствие с XBRL и 5 миллионов Долларов на создание таксономий US. XBRL US выделяется из AICPA в отдельную некоммерческую организацию. Апрель 2008 – Выход таксономии XBRL US (более 15 000 тегов и определений). Май 2008 – US SEC анонсирует предлагаемое правило, требующее от публичных компаний представлять отчётность в XBRL формате. Июнь 2009 – Крупнейшие публичные компании США начали представлять отчётность в формате XBRL.

XBRL TAXONOMY = ТАКСОНОМИЯ ЭКС.БИ.АР.ЭЛ. (или ТАКСОНОМИЯ РЯДО) – Taxonomies, as explained in How XBRL Works (a publication of XBRL International, Laytonsville, State of Maryland, the United States, which gives further explanation of XBRL, while benefits and uses sets out how different types of organization can gain from the standard), are the reporting-area specific hierarchical dictionaries used by the XBRL community. They define the specific tags that are used for individual items of data (such as 'net profit'), their attributes and their interrelationships. Different taxonomies will be required for different business reporting purposes. Some national jurisdictions may need their own reporting taxonomies to reflect local accounting and other reporting regulations. Many different organizations, including regulators, specific industries or even companies, may require taxonomies or taxonomy extensions to cover their own specific business reporting needs. Taxonomies which have been officially recognized by XBRL International are listed under the 'XII Recognized Taxonomies' tab. Details on how the taxonomy recognition process operates along with instructions on submitting taxonomies can be found under the 'Taxonomies Recognition Process' tab. A special taxonomy developed and recommended by XII itself has also been designed to support collation of detailed, drill-down data focusing on internal reporting within organizations. This is the Global Ledger (GL) taxonomy. / Таксономия – это документ, описывающий содержащиеся в отчёте концепции (статьи отчёта) и связи между ними.

XCHANGING PLC = КСЧЭНДЬЖИН ПИ.ЭЛ.СИ. – Xchanging PLC (London, UK) is an international company providing business processing outsourcing services to global blue chip customers. It is listed on the London Stock Exchange and is a constituent of the FTSE 250 Index. Our core business is re-inventing and operating our customers' non-core or back- office activities. We provide business processing services across a broad range of functions and industries. Our areas of expertise include:- (i) Finance & Accounting (F&A); (ii) Human resources (HR); (iii) Technology; (iv) Procurement; and (v) Customer Administration. An outsource provider of policy, premium and claims processing services to the Lloyd's market and others. These services are delivered via its operating subsidiaries, Ins-Sure Services and Xchanging Claims Services. Xchanging PLC (Xchanging) is a UK based industry specific processing services provider. The company is principally engaged in offering procurement services, integrated HR and payroll services, and immigration services to its clients present across various nations. In addition, it offers resourcing services, and managed recruitment services to its customers. Further, the company is engaged in offering procure to pay (P2P) accounting services and hosting services to a variety of customers across various verticals. Xchanging has its operations across 9 nations and customers in around 47 countries. Some of the company's key clients include Citibank, Deutsche Bank AG, Tech Mahindra, Wal-Mart, Cintas, American Express, Southwest.com, Lloyds, Illium Insurance, etc. The company has its headquarters located at London in the United Kingdom. / Инш-Шуэ Сёвисиз (Ins-Sure Services) и Ксчэньдьжинь Клэймз Совисиз (Xchanging Claims Services). для рынка Лойда и других. X CHROMOSOME = ИКС. ХРОМОСОМА (или Х ХРОМОСОМА) – X Chromosome is one of the two sex chromosomes in humans (the other is the Y chromosome). The sex chromosomes form one of the 23 pairs of human chromosomes in each cell. The X chromosome spans about 155 million DNA building blocks (base pairs) and represents approximately 5 percent of the total DNA in cells. Each person normally has one pair of sex chromosomes in each cell. Females have two X chromosomes, while males have one X and one Y chromosome. Early in embryonic development in females, one of the two X chromosomes is randomly and permanently

inactivated in cells other than egg cells. This phenomenon is called X-Inactivation or Lyonization. X-inactivation ensures that females, like males, have one functional copy of the X chromosome in each body cell. Because X-inactivation is random, in normal females the X chromosome inherited from the mother is active in some cells, and the X chromosome inherited from the father is active in other cells. Some genes on the X chromosome escape X-inactivation. Many of these genes are located at the ends of each arm of the X chromosome in areas known as the Pseudoautosomal Regions. Although many genes are unique to the X chromosome, genes in the pseudoautosomal regions are present on both sex chromosomes. As a result, men and women each have two functional copies of these genes. Many genes in the pseudoautosomal regions are essential for normal development. Identifying genes on each chromosome is an active area of genetic research. Because researchers use different approaches to predict the number of genes on each chromosome, the estimated number of genes varies. The X chromosome likely contains 800 to 900 genes that provide instructions for making proteins. These proteins perform a variety of different roles in the body. X Chromosome is a sex chromosome that usually occurs paired in each female cell, and single (i.e. unpaired) in each male cell in those species in which the male typically has two unlike sex chromosomes (e.g., humans). / Икс. Хромосома – половая хромосома; хромосома, обычно парная в женской клетке, и, как правило непарная в мужской. Каждая женщина – это не просто загадка, а мозаика, состоящая из клеток с разными наборами активных хромосом. У человека 23 пары хромосом, и хромосомы одной пары несут одни и те же наборы генов. Исключение составляет пара половых хромосом. У мужчин одна из них называется Икс. (X), а другая – Игрэк. (Y), и они существенно отличаются своими наборами генов. X-хромосома значительно крупнее, чем Y, и содержит больше генов. Обе половые хромосомы женщин – X, и они отличаются между собой также, как хромосомы внутри других 22 пар. У каждой женщины по две X-хромосомы, а у каждого мужчины – только по одной, и чтобы они были одинаково активны у женщин и мужчин, организм регулирует их работу. Для этого во всех клетках тела женщины одна из X-хромосом инактивируется. Какая именно из двух половых хромосом будет отключена, для каждой клетки решает случай, так что в части клеток тела женщины работает одна X-хромосома, а в оставшихся – другая. Как следствие такой мозаичности у женщин редко проявляются болезни, связанные с повреждениями X-хромосом. Даже если у женщины оказывается X-хромосома с дефектом какого-либо гена, другая хромосома пары, работающая в половине клеток, спасает положение и не даёт болезни проявиться. Чтобы болезнь, связанная с повреждением X-хромосомы ‘разыгралась’ на полную мощь, женщине должны достаться целых две копии этой хромосомы с дефектом одного и того же гена. Это маловероятное событие. В то же время, если мужчина получает дефектную X-хромосому (она приходит от матери), у неё не будет пары, чтобы скомпенсировать ущерб, и заболевание покажет себя. X-хромосома, к несчастью для мужчин, несёт множество жизненно важных генов, так что её поломка чревата печальными последствиями. Дальтонизм, гемофилия, миопатия Дюшена, синдром ломкой X-хромосомы, X-сцеплённый иммунодефицит – это только самые известные генетические заболевания, от которых страдают почти исключительно мужчины. Цветовая Слепота:- распространено заблуждение, что дальтониками могут быть только мужчины. Это неверно, однако, женщины-дальтоники встречаются намного реже. Сложности с различением некоторых цветов испытывают лишь 0.4 процента женщин и около 5 процентов мужчин. Дальтонизм – это потеря или нарушение работы одного из пигментов, связанных с распознаванием света определённого цвета. Всего таких пигментов три, и они чувствительны к волнам красного, зелёного и синего цвета. Любой сложный цвет можно представить как комбинацию этих трёх. В каждой клетке-колбочке, которые находятся в сетчатке и отвечают за распознавание цвета, находится лишь один тип пигмента. По неизвестным пока причинам, неполадки с работой пигментов, с помощью которых мы различаем красный и зелёный цвета, встречаются чаще, чем дефекты пигмента, необходимого, чтобы правильно узнавать синий цвет. За синтез пигментов отвечают гены, находящиеся на X-хромосоме. Если мужчине досталась хромосома с дефектным геном, определяющим за узнавание, к примеру, красного цвета, то во всех колбочках его сетчатки будет активна лишь эта дефектная X-хромосома – другой у него просто нет. Поэтому у такого мужчины не будет колбочек, способных правильно распознать красный цвет. Сетчатка женщины имеет мозаичное строение, и если даже одна из X-хромосом несёт повреждённый ген, эта хромосома будет активна лишь в части колбочек, отвечающих за распознавание соответствующего цвета. В других колбочках будет активна вторая хромосома, которая несёт нормальный ген. Восприятие цвета у такой женщины будет немного изменённым, но всё же она будет способна различать все цвета, которые обычно различают люди. Гемофилия:- другое известное заболевание, связанное с дефектами генов X-хромосомы – это гемофилия, нарушение свёртывания крови. После травмы в крови здорового человека запускается сложная система реакций, приводящая к образованию нитей белка фибрина. Благодаря накоплению этих нитей, в месте повреждения кровь становится более густой и закупоривает рану. Если любая из стадий процесса нарушается, кровь не свёртывается вовсе или делает это слишком медленно, так что больной может умереть от кровопотери даже после удаления зуба. Кроме того, больные с гемофилией страдают от спонтанных внутренних кровоизлияний из-за уязвимости стенок сосудов. Каскад реакций, приводящий в итоге к образованию нитей фибрина и загустению крови, очень сложен, а чем сложнее система, тем больше мест, где она может сломаться. Известно три типа гемофилии, связанных с дефектами трёх генов, кодирующих белки-участники каскада. Два из этих генов располагаются на X-хромосоме, поэтому гемофилией страдает один мужчина из 5 000, а случаев заболеваний женщин за всю историю было зафиксировано лишь 60. Миопатия Дюшена:- ещё один важный ген, располагающийся на X-хромосоме – ген белка дистрофина, необходимого для поддержания целостности мембран мышечных клеток. При миопатии Дюшена работа этого гена нарушается, и дистрофин не образуется. У мужчин, которым досталась X-хромосома с таким повреждённым геном, развивается прогрессирующая мышечная слабость, в результате чего мальчики с такой болезнью уже к 12 годам не могут самостоятельно ходить. Как правило, больные погибают в возрасте около 20 лет из-за связанных со слабостью мышц нарушений дыхания. У девочек, получивших X-хромосому с неисправным геном дистрофина, из-за мозаичности белок отсутствует лишь в половине клеток тела. Поэтому женщины-носительницы дефектного гена дистрофина страдают лишь лёгкой мышечной слабостью, и то не всегда. X-Сцеплённый Тяжёлый Иммунодефицит:- больные с тяжёлыми иммунодефицитами вынуждены жить в полностью стерильной среде, потому что они крайне уязвимы перед инфекционными заболеваниями. X-сцеплённый тяжёлый иммунодефицит возникает из-за мутации в гене, который кодирует общий компонент нескольких рецепторов, необходимых для взаимодействия клеток иммунной системы. Как очевидно из названия болезни, этот ген тоже располагается в X-хромосоме. Из-за неработающих рецепторов иммунная система с самого начала развивается неправильно, её клетки малочислены, плохо функционируют и не могут координировать свои действия. К счастью, это тяжёлое заболевание встречается редко:- им страдает один мальчик из 100 000. У девочек появление этой болезни можно считать практически невероятным. Синдром Ломкой X-Хромосомы:- ещё один важный ген, расположенный на X-хромосоме – ген Эф.Эм.Ар.1 (FMR1), необходимый для нормального развития нервной системы. Работа этого гена может быть нарушена из-за патологического процесса, при котором в гене увеличивается число повторяющихся фрагментов ДНК. Дело в том, что точное копирование повторяющегося числа единиц всегда представляет собой трудность. Представим себе, что нам нужно аккуратно переписать длинное число, в котором есть много одинаковых цифр подряд – легко ошибиться и написать на несколько цифр больше или меньше. Точно так и в ДНК. При делении клеток, когда ДНК удваивается, число повторов может случайно измениться. Именно из-за увеличения числа повторов в коротком фрагменте ДНК на X-хромосоме может появиться ‘ломкий’ участок, который легко рвётся при делении клеток. Ген FMR1 находится рядом с ‘ломким’ участком, и его работа нарушается. В результате такой патологии возникает умственная

отсталость, которая проявляется у мужчин с ‘ломкой’ Х-хромосомой более явственно, чем у женщин. Всегда Ли Лучше Иметь Две Х-Хромосомы, Чем Одну? Кажется, что иметь две Х-хромосомы выгоднее, чем одну:- меньше риск заболеваний из-за неудачных генов. Как насчёт самцов, имеющих такой состав половых хромосом:- XXY? Можно ли ожидать, что они будут иметь преимущество перед самцами с обычным составом половых хромосом XY? Оказывается, состав хромосом XXY – не благо, а совсем наоборот. Мужчины с таким набором хромосом страдают от Синдрома Клайнфельтера, при котором наблюдается множество патологий, но нет никаких преимуществ. Более того, известны заболевания, для которых характерны ещё большие количества Х-хромосом, вплоть до пяти на генотип. Такие патологии встречаются как у женщин, так и у мужчин. При наличии избыточных Х-хромосом все они, кроме одной, инактивируются. Однако, пусть лишние Х-хромосомы и не работают, чем их больше, тем тяжелее заболевание. Интересно, что особенно страдает от наличия избыточных Х-хромосом интеллект – каждая лишняя хромосома этого типа ведёт к понижению IQ в среднем примерно на 15 пунктов. Получается, что иметь запасной вариант Х-хромосомы хорошо, но не всегда (мужчинам от дополнительной Х-хромосомы лучше не становится). Иметь много запасных вариантов этой половой хромосомы – не выгодно ни для женщин, ни для мужчин. Чем же дополнительные неактивные Х-хромосомы вредны, и почему каждая лишняя хромосома усугубляет тяжесть заболевания? Во-первых, лишние Х-хромосомы выключаются далеко не сразу, а только спустя первые 16 суток развития эмбриона. А чем раньше во время развития возникает нарушение, тем более разнообразными и многочисленными будут его проявления. Поэтому лишние хромосомы могут успеть ‘навредить’ достаточно фундаментально, так, что патологии будут проявляться в совершенно разных сферах. Во-вторых, некоторые гены на инактивированных Х-хромосомах каким-то образом избегают отключения. Хотя Х и Y-хромосомы очень непохожи, всё же они образуют пару и имеют небольшое количество одинаковых генов. Если половых хромосом слишком много, и на всех них эти гены останутся активными, в клетках нарушается генный баланс. Поэтому чем больше лишних хромосом, тем тяжелее болезнь. Х-хромосома несёт на себе множество жизненно важных генов, и неудивительно, что её дефекты имеют крайне неприятные проявления. Женщинам от природы дана возможность ‘подстраховаться’ за счёт дополнительной копии хромосомы, которая может уменьшить тяжесть заболевания. Однако такая ‘запаска’ хороша только в единственном числе, а все дополнительные Х-хромосомы ведут к развитию тяжёлых патологий. Ну а мужчинам, у которых нет второй Х-хромосомы, с самого их зачатия достаётся больше риска.

XD = ЭКС.ДИ. – XD or X Div. (in stock listings of newspapers) is a symbol that indicating that stock is trading ex-dividend, with no dividend. Also known as X. See also Ex-Dividend. xd:- stands for Ex-Dividend (i.e. without dividend) and means that the investor who buys the stock xd will not receive the coupon/dividend which is due to be paid in a few days time on the next coupon date as this coupon will go to the seller. British Government Stocks normally go xd 7 days before the next coupon date (i.e. the xd date is 7 days before the coupon date). In respect of ordinary shares/equities it means the investor who buys the stock xd will not receive the dividend due to be paid in a few days time as it will go to the seller. Shares normally go xd some days before the date when the next dividend is to be paid. If the buyer is entitled to the dividend payable in a few days time then the stock has not yet gone xd and is still cum dividend (i.e. with dividend). / ‘Без Дивидендов’ (в приводимых в газетах перечнях акций). XDSL = ЭКС.ДИ.ЭС.ЭЛ. – A term xDSL refers collectively to all types of digital subscriber lines, the two main categories being ADSL and SDSL. Two other types of xDSL technologies are High-data-rate DSL (HDSL) and Very high DSL (VDSL). DSL technologies use sophisticated modulation schemes to pack data onto copper wires. They are sometimes referred to as Last-Mile Technologies because they are used only for connections from a telephone switching station to a home or office, not between switching stations. xDSL is similar to ISDN inasmuch as both operate over existing copper telephone lines (POTS) and both require the short runs to a central telephone office (usually less than 20 000 feet). However, xDSL offers much higher speeds – up to 32 Mbps for upstream traffic, and from 32 Kbps to over 1 Mbps for downstream traffic. See also Digital Subscriber Line (DSL). xDSL refers to the sum total of digital subscriber line (DSL) technologies. Line-length limitations on DSL signal transmissions from the telephone exchanges speeds have resulted in the many types of DSLs. Some examples of DSL technologies (xDSL) include:- (i) Digital Subscriber Line (DSL); (ii) Integrated Services Digital Network (ISDN); (iii) Asymmetric Digital Subscriber Line (ADSL); (iv) Gigabit Digital Subscriber Line (GDSL); (v) High-Data-Rate Digital Subscriber Line (HDSL/HDSL2); (vi) Symmetric Digital Subscriber Line (SDSL); (vii) Rate-Adaptive Digital Subscriber Line (RADSL); (viii) Very-High Speed Digital Subscriber Line (VDSL/VDSL2); and (ix) Universal High-Bit-Rate Digital Subscriber Line (UHDSL). ADSL and SDSL were the main two categories of DSL. DSL technologies are sometimes referred to as ‘Last-Mile Technologies’ because they are used only between a telephone switching station and a home or office; DSL is not used between switching stations. Actual DSL transmission methods vary greatly with the carrier, equipment used, geographical location and the customer. Many DSL technologies support simultaneous voice and Internet transmission; some include video as well. / Цифровая Линия Подписчика (ЦЛП). xDSL — семейство технологий, позволяющих значительно расширить пропускную способность абонентской линии местной телефонной сети путём использования эффективных линейных кодов и адаптивных методов коррекции искажений линии на основе современных достижений микроэлектроники и методов цифровой обработки сигнала. xDSL – обобщённая аббревиатура для технологий DSL. Технологии xDSL позволяют передавать данные со скоростями, значительно превышающими скорости, доступные самым лучшим аналоговым и цифровым модемам. xDSL поддерживают передачу голоса, высокоскоростную передачу данных и видеосигналов, создавая при этом значительные преимущества как для абонентов, так и для провайдеров. Более того, многие технологии xDSL позволяют совмещать высокоскоростную передачу данных и передачу голоса по одной и той же медной паре. Существующие типы технологий xDSL, различаются, в основном, по используемой форме модуляции и скорости передачи данных. DSL (Digital Subscriber Line) – это аббревиатура, обозначающая Цифровую Абонентскую Линию или Цифровую Линию Подписчика (Digital Subscriber Line). DSL-технологии позволяют соединять пользователей с телефонными станциями, расширяя при этом используемый частотный диапазон имеющихся линий телефонной кабельной сети.

XEDAR = ЗЕДА (или КСЕДАР) – Xedar is infrared imaging equipment used in the detection of hot spots during wildfire control.

X–EFFICIENCY = ИКС.–ЭФФЕКТИВНОСТЬ – In economics, X-Efficiency is the effectiveness with which a given set of inputs are used to produce outputs. If a firm is producing the maximum output it can given the resources it employs, such as men and machinery,

and the best technology available, it is said to be x-efficient. X-inefficiency occurs when x-efficiency is not achieved. In a market with perfect competition, there will in general be no x-inefficiency because if any firm is less efficient than the others it will not make sufficient profits to stay in business in the long term. However, with other market forms such as monopoly it may be possible for x-inefficiency to persist, because the lack of competition makes it possible to use inefficient production techniques and still stay in business. X-inefficiency is not the only type of inefficiency in economics. X-inefficiency only looks at the outputs that are produced with given inputs. It doesn't take account of whether the inputs are the best ones to be using, or whether the outputs are the best ones to be producing, which is referred to as Allocative Efficiency. For example, a firm that employs brain surgeons to dig ditches might still be x-efficient, even though reallocating the brain surgeons to curing the sick would be more efficient for society overall. X-Efficiency is the degree of efficiency maintained by individuals and firms under conditions of imperfect competition. According to the neoclassical theory of economics, under perfect competition individuals and firms must maximize efficiency in order to succeed and make a profit; those who do not will fail and be forced to exit the market. However, x-efficiency theory asserts that under conditions of less-than-perfect competition, inefficiency may persist. The concept of x-efficiency was proposed by economist Harvey Leibenstein in a 1966 paper. The theory of x-efficiency is controversial because it conflicts with the assumption of utility-maximizing behavior, a well-accepted axiom in economic theory. Instead, some economists argue that the concept of x-efficiency is merely the observance of workers' utility-maximizing tradeoff between effort and leisure. Empirical evidence for the theory of x-efficiency is mixed. X Inefficiency occurs when a firm has little incentive to control costs. This causes the average cost of production to be higher than necessary. When there is this lack of incentives, the firm will not be technically efficient. X Efficiency would be when competitive pressures cause firms to combine the optimum combination of factors of production. Causes of X Inefficiency:- (1) Monopoly Power:- a monopoly faces little or no competition. Therefore, it might be easy for the monopolist to make supernormal profits. Therefore, in the absence of competitive pressures, they may not try very hard to control costs. (2) State Control:- a nationalized firm owned by the government may face little or no incentive to try and make profit. Therefore, it has less incentive to try and cut costs. Examples of X Inefficiency:- (i) employing workers who aren't necessary for the productive process. For example, a state owned firm may be more concerned about the political implications of making people redundant than getting rid of surplus workers. (ii) Lack of Management Control:- if a firm doesn't have supervision of workers, then productivity may fall as workers 'take it easy'; and (iii) Not Finding Cheapest Suppliers:- out of inertia, a firm may continue to source raw materials from a high cost supplier rather than look for cheaper raw materials. Theory of X Inefficiency:- X Inefficiency was first mentioned in Leibenstein, Harvey (1966), 'Allocative Efficiency vs. X-Efficiency', American Economic Review 56 (3):- 392–415. / Хави (Leibenstein, Harvey). Икс.-Эффективность – эффективность, состоящая в получении оптимального результата при заданной комбинации факторов производства; термин введён Американским экономистом Харви Лэйбэнстайном (Harvey Leibenstein; родился в 1924, Янушполе, Волынская Губерния, Украина, умер в 1992 в Кембридже, Штат Массачусетс, США) для отделения данного вида эффективности от аллокативной эффективности, поскольку было замечено, что при одних и тех же количестве и структуре затрат могут иметь место различные результаты; основным источником такой эффективности принято считать систему стимулов.

XENOBIOTIC = КСЕНОБИОТИК – Xenobiotic is a term for non-naturally occurring man-made substances found in the environment, i.e. synthetic material solvents, plastics. Xenobiotic is a compound that is foreign to a biological system. The presence of substances in soil that are not naturally produced by biological species is of great public concern. Many of these so-called Xenobiotic (from Greek Xenos, 'Stranger', and Bios, 'Life') chemicals have been found to be carcinogens or may accumulate in the environment with toxic effects on ecosystems. Although human exposure to these substances is primarily through inhalation or drinking water, soils play an important role because they affect the mobility and biological impact of these toxins. The abundance of xenobiotic compounds in soil has been increased dramatically by the accelerated rate of extraction of minerals and fossil fuels and by highly technological industrial processes. Most of the metals were typically found at very low total concentrations in pristine waters – for this reason they often are referred to as Trace Metals. Rapid increases of trace metal concentrations in the environment are commonly coupled to the development of exploitative technologies. This kind of sudden change exposes the biosphere to a risk of destabilization, since organisms that developed under conditions with low concentrations of a metal present have not developed biochemical pathways capable of detoxifying that metal when it is present at high concentrations. The same line of reasoning applies to the organic toxic compounds. Xenobiotics:- synthetic chemicals believed to be resistant to environmental degradation. A branch of biotechnology called Bioremediation is seeking to develop biological methods to degrade such compounds. Xenobiotics are any chemical compounds that are found in a living organism, but which are foreign to that organism, in the sense that it does not normally produce the compound or consume it as part of its diet. For example, in humans, most drugs are part of this category, since people don't produce them naturally, or consume them under normal circumstances. Xenobiotics can also be defined as substances that are present in higher-than-normal concentrations, or ones that are entirely artificial and did not exist before they were produced synthetically by humans. A compound that is normal to one organism may be a xenobiotic to another. A commonly used example of this is the effect experienced by fish that live downstream from the outlet of a sewage treatment plant. Hormones produced by humans may be present, even in treated water, and these compounds are foreign as far as fish are concerned. When an animal produces a toxin as a defense mechanism against predators, these toxins can also be thought of as xenobiotics from the point of view of the predator. Predators can also evolve defenses against these toxins, however. One interesting case in which this has occurred is in the rough-skinned newt and its predator, the garter snake. Tetrodotoxin is a xenobiotic made in the body of the newt, which is usually very poisonous to other animals, but the garter snake has evolved with a resistance to it in order to be able to continue to prey on the newt. It is speculated that as the newt species produced higher and higher concentrations of the poison over generations, the garter snake developed a progressively stronger resistance to it. When human bodies encounter a such a substance, they remove it through a process called Xenobiotic Metabolism. Through these processes, the chemical structure of the compound is modified and broken down to either be put to use by the body, or to be detoxified, in the case of some poisons. Sometimes, it is these chemical pathways and their reactions that can be fatal, as is the case with poisoning deaths and harmful drug interactions. The metabolic pathways that the body uses to process foreign substances have long been a subject of great interest on the part of medical science. It is largely through studying these pathways that new drugs are proposed and developed, especially in the case of chemotherapy drugs used in cancer treatment. They are also important in studying the potential effects of pollutants on an environment, to see whether the chemical will be broken down or remain in the environment and cause harm. / виды (species). outlet = припуск сверх шва. Под Ксенобиотиками, от Греческих слов Xénos, означающее Гость или Чужой или Посторонний, и Bios, означающее Жизнь, понимаются чужеродные для организмов соединения. К ним относятся промышленные загрязнения, пестициды, препараты бытовой химии, лекарственные средства и тому подобное, то есть вещества не образующиеся в живом объекте, а синтезируемые искусственно человеком. Ксенобиотики – чуждые, чужеродные для организма химические вещества. Ксенобиотики не являются естественными метаболитами живых организмов, и не входят в естественный биотический круговорот, так как порождаются активной хозяйственной деятельностью человека. Действие Ксенобиотиков:- ксенобиотики – не обязательно яды или токсины. Однако в большинстве случаев ксенобиотики, попадая в живые организмы, могут вызывать различные прямые нежелательные эффекты, либо вследствие биотрансформации образовывать токсичные метаболиты:- (i) токсические или аллергические реакции; (ii) изменения наследственности; (iii) снижение иммунитета; (iv) специфические заболевания (болезнь минамата, итай-итай, рак); и (v)

искажение обмена веществ, нарушение естественного хода природных процессов в экосистемах, вплоть до уровня биосферы в целом. Примеры Ксенобиотиков:- (i) свободные металлы (Кадмий, Cu, Pb, Zn, Hg); (ii) фреоны; (iii) нефтепродукты; (iv) пластмассы; и (v) полициклические и галогенированные ароматические углеводороды. Некоторые вещества, относимые к ксенобиотикам, могут быть найдены в природе, но в черезвычайно низких концентрациях. Так, диоксины могут синтезироваться при лесных пожарах. Многие вещества, например ксилол, стирол, толуол, ацетон, бензол, пары бензина или хлороводород – могут быть отнесены к ксенобиотикам, если будут обнаружены в окружающей среде в неестественно высоких концентрациях, связанных с промышленным производством. Биотрансформация:- липофильные ксенобиотики в настоящее время вызывают особенное внимание экологов и токсикологов, так как, накапливаясь в жировых тканях, способны переходить по пищевой цепи в организмы животных и человека, превращаясь в более полярные и, следовательно, более легко усваиваемые или экскретируемые вещества. Под Ксенобиотиками, от Греческих слов Xenos, означающее Чужой, и Bios, означающее Жизнь, понимаются чужеродные для организмов соединения (промышленные загрязнения, пестициды, препараты бытовой химии, лекарственные средства и тому подобное). Попадая в окружающую среду в значительных количествах, ксенобиотики могут служить причиной многих заболеваний, воздействовать на генетический аппарат организмов, вызывать их гибель, нарушать равновесие природных процессов в биосфере. Превращения ксенобиотиков в организмах, пути их детоксикации и деградации учитываются при организации санитарно-гигиенических мероприятий, мер по охране природы. Чужеродное для живых организмов вещество, появляющееся в результате антропогенной деятельности (пестициды или диоксины, препараты бытовой химии и другие загрязнители), способное вызывать нарушение биотических процессов, в том числе заболевание или гибель живого организма. Ксенобиотики – условная категория для обозначения чужеродных для живых организмов химических веществ, естественно не входящих в биотический круговорот. Как правило, повышение концентрации ксенобиотиков в окружающей среде прямо или косвенно связано с хозяйственной деятельностью человека. К ним в ряде случаев относят:- пестициды, некоторые моющие средства (детергенты), радионуклиды, синтетические красители, полиароматические углеводороды и другие. Попадая в окружающую природную среду, они могут вызвать повышение частоты аллергических реакций, гибель организмов, изменить наследственные признаки, снизить иммунитет, нарушить обмен веществ, нарушить ход процессов в естественных экосистемах вплоть до уровня биосферы в целом. Изучение превращений ксенобиотиков путём детоксикации и деградации в живых организмах и во внешней среде важно для организации санитарно-гигиенических мероприятий по охране природы. Человек живёт в окружении разнообразных химических веществ, многие из которых относят к группе ксенобиотиков. Совокупность чужеродных веществ, содержащихся в окружающей среде (воде, почве, воздухе и живых организмах) в форме (агрегатном состоянии), позволяющей им вступать в химические и физико-химические взаимодействия с биологическими объектами экосистемы составляют ксенобиотический профиль биогеоценоза. Ксенобиотический профиль следует рассматривать как один из важнейших факторов внешней среды (наряду с температурой, освещённостью, влажностью, трофическими условиями и так далее), который может быть описан качественными и количественными характеристиками. Важным элементом ксенобиотического профиля являются чужеродные вещества, содержащиеся в органах и тканях живых существ, поскольку все они рано или поздно потребляются другими организмами (то есть обладают биодоступностью). Напротив, химические вещества, фиксированные в твёрдых, не диспергируемых в воздухе и нерастворимых в воде объектах (скальные породы, твёрдые промышленные изделия, стекло, пластмасса и другие), не обладают биодоступностью. Их можно рассматривать как источники формирования ксенобиотического профиля. Ксенобиотические профили среды, сформировавшиеся в ходе эволюционных процессов, миллионы лет протекавших на планете, можно назвать естественными ксенобиотическими профилями. Они различны в разных регионах Земли. Биоценозы, существующие в этих регионах (биотопах), в той или иной степени адаптированы к соответствующим естественным ксенобиотическим профилям. Различные природные коллизии, а в последние годы и хозяйственная деятельность человека, порой существенным образом изменяют естественный ксенобиотический профиль многих регионов (особенно урбанизированных). Химические вещества, накапливающиеся в среде в несвойственных ей количествах и являющиеся причиной изменения естественного ксенобиотического профиля, выступают в качестве экополлютантов (загрязнителей). Далеко не всегда это приводит к пагубным последствиям для живой природы и населения. Лишь экополлютант, накопившийся в среде в количестве, достаточном для инициации токсического процесса в биоценозе (на любом уровне организации живой материи), может быть обозначен как экотоксикант. Ксенобиотические профили среды, сформировавшиеся в ходе эволюционных процессов, миллионы лет протекавших на планете, можно назвать естественными.

XENOBIOTIC COMPOUND = КСЕНОБИОТИЧЕСКОЕ ВЕЩЕСТВО – Xenobiotic Compound:- those compounds (e.g., veterinary drugs, agrochemical herbicides, etc) that are designed to be used in an ecosystem comprised of more than one species. For example, herbicides intended to kill weeds but leave commercial crops undamaged or veterinary drugs that are intended to kill parasitic worms but leave the host livestock unharmed. / Ксенобиотическое Вещество – вещество, вызывающее нарушение биотических процессов.

XENOCURRENCY = КСЕНОВАЛЮТА (или ИНОВАЛЮТА) – A Xenocurrency is one that trades outside its domestic boundaries. Xenocurrency is a currency circulating or traded in money markets of countries outside its country of issue. Xenocurrency is a currency that trades in markets outside of its domestic borders. The term ‘Xenocurrency’ is derived from the prefix ‘Xeno’, which literally means Foreign or Strange. An example of a xenocurrency would be the Euro traded in the United States, or the Japanese Yen traded in Europe. The term ‘Xenocurrency’ is seldom used in markets, perhaps because of the somewhat negative connotation of the word ‘xeno’. Xenophobia, for example, means an irrational fear or hatred of foreigners. ‘Foreign Currency’, therefore, is the preferred term when referring to a non-domestic currency. / Ксеновалюта:- приставка Ксено означает Иностранца или Незнакомца. Ксеновалюта – валюта, обращающаяся на рынках за пределами страны происхождения. Ксеновалюта – валюта, обращающаяся или продаваемая на денежных рынках стран за пределами страны, выпустившей её. Ксеновалюта – валюта, которая торгуется на рынке за пределами границы её хождения. Примером ксеновалюты может быть Китайский Юань, когда он торгуется в США или в России.

XENOGAMY = КСЕНОГАМИЯ – Xenogamy is a pollination of the stigma of a flower by pollen from a flower on another plant. Compare Geitonogamy. Xenogamy (Greek:- Xénos = Stranger + Gámos = Marriage) is cross pollination. Xenogamy (Greek Xenos = Stranger, Gamos = Marriage) is the transfer of pollen grains from the anther to the stigma of a different plant. This is the only type of pollination which during pollination brings genetically different types of pollen grains to the stigma. The term Xenogamy (along with geitonogamy and autogamy) was first suggested by an Austrian botanist and professor Anton Kerner Ritter von Marilaun in 1876. Cross-pollination involves the transfer of pollen grains from the flower of one plant to the stigma of the flower of another plant. / Антон Керна Рита фон Марилон (Anton Kerner Ritter von Marilaun). Под Ксеногамией, от Греческих слов Xénos, означающее Гость или Чужой или Посторонний, и Gámos, означающее Брак, понимается перекрёстное опыление, при котором цветки одного растения опыляются пыльцой цветков других растений того же вида.

XENOGENEIC ORGAN = КСЕНОГЕНЕИЧЕСКИЙ ОРГАН (или ЭКЗОГЕННЫЙ ОРГАН) – Xenogeneic Organ:- from the Greek word Xenos, meaning Stranger. Xenogeneic literally means 'Strange Genes'. Refers to genetically engineered (e.g., 'humanized') organs that have been grown within an animal of another species. For example, several companies are working to engineer and grow – inside swine – a number of organs to be transplanted into humans that need those organs (e.g., due to loss of their own organs via disease or accident). If successful, this would free human organ transplant recipients from having to continually use immunosuppressive drugs in order to keep their body from 'rejecting' the new organ. / Экзогенный Орган – генетически измененные органы, выращенные внутри животных относящихся к другому биологическому виду.

XENOGENESIS = КСЕНОГЕНЕЗИС (или ГЕТЕРОГЕНЕЗ) – Xenogenesis is the (theoretical) production of offspring that are genetically different from, and genotypically unrelated to either of the parents of that offspring. / Гетерогенез – теоретическое получение потомков генетически отличающихся от своих родителей.

XENOGRAFT = КСЕНОГРАФТ (или КСЕНОПРИВОЙ, или КСЕНОТРАНСПЛАНТАТ) – Xenograft is a graft of tissue taken from a donor of one species and grafted into a recipient of another species – called also Heterograft. Compare Homograft. See also Xenotransplant. Xenograft is a graft from a different species. Xenograft is a surgical graft of tissue from one species to an unlike species (or genus or family). A graft from a baboon to a human is a xenograft. The prefix Xeno- means foreign. It comes from the Greek word 'Xenos' meaning Stranger, Guest, or Host. Xeno- and Xen- are variant forms of the same prefix. / Под Ксенографтом, от Греческого слова Xénos, означающее Гость или Чужой или Посторонний, понимается привой от различных видов. Под Подвоем понимается растение (или часть его), на которое прививают часть (черенок, почку и тому подобное) другого растения – Привоя. Через корневую систему подвоя осуществляется минеральное питание и водоснабжение привитого растения. Привой снабжает подвой продуктами ассимиляции. Полнота срастания привитых компонентов и нормальное развитие полученного растительного организма зависят от физиологической совместимости подвоя и привоя. Подвой влияет на силу роста, урожайность и долговечность привоя, его зимостойкость, устойчивость к болезням и вредителям. Привой, в свою очередь, может влиять на зимостойкость подвоя, на развитие его корневой системы. В плодоводстве в зависимости от производственных задач для одной и той же культуры применяют разные подвои. Например, Яблоню прививают на Юге и в центральных районах бывшего СССР на сеянцах культурных сортов и лесной Яблони, в более Северных районах – на сливолистной Яблоне (Китайке), а на Востоке и Севере – на Сибирской Яблоне. В питомниках бывшего СССР для выращивания привитых саженцев плодовых культур использовали около 40 видов подвоев, различающихся происхождением (дикорастущие и культурные), силой роста и способом размножения (семенные и вегетативные). Ксенотрансплантат – ткань или орган, взятые для трасплантации от организма другого вида.

XENON = КСЕНОН – The name Xenon is derived from the Greek word Xenos, Strange or Foreign. Xenon is a heavy gas used in specialized electric lamps. Xenon (Xe) is a chemical element, heavy and extremely rare gas of Group 0 (noble gases) of the periodic table. Atomic Number:- 54; Atomic Weight:- 131.30; Melting Point:- –111.9 °C (–169.6 °F); Boiling Point:- –107.1 °C (–160.6 °F); Density (1 atm, 0 °C):- 5.887 g/liter; Valence:- 0,2,4,6,8; and Electronic Configuration:- 2-8-18-18-8 or $(Kr)4d^{10}5s^{2}5p^{6}$. It was the first noble gas found to form true chemical compounds. More than 4 ½ times heavier than air, xenon is colorless, odorless, and tasteless. Solid xenon belongs to the face-centered cubic crystal system, which implies that its molecules, which consist of single atoms, behave as spheres packed together as closely as possible. Xenon occurs in slight traces in gases within the Earth and is present to an extent of about 0.000 008 6 percent, or about one part in 10 000 000, by volume of dry air. Xenon is manufactured on a small scale by the fractional distillation of liquid air. The British chemists Sir William Ramsay and Morris W. Travers isolated the element (1898) by repeated fractional distillation of the noble gas krypton, which they had discovered six weeks previously. The element xenon is used in lamps that produce intense, extremely short flashes of light, such as stroboscopes and lights for high-speed photography. When a charge of electricity is passed through the gas at low pressure, it emits a flash of bluish-white light; at higher pressures white light resembling daylight is emitted. Xenon flash lamps are used to activate ruby lasers. Natural xenon is a mixture of nine stable isotopes in the following percentages:- xenon-124 (0.096); xenon-126 (0.090); xenon-128 (1.92); xenon-129 (26.44); xenon-130 (4.08); xenon-131 (21.18); xenon-132 (26.89); xenon-134 (10.44); and xenon-136 (8.87). The xenon found in some stony meteorites shows a large proportion of xenon-129, believed to be a product of radioactive decay of iodine-129, whose half-life is 17 000 000 years. Study of the xenon-129 content of meteorites casts light on the history of the solar system. More than a dozen radioactive xenon isotopes produced by fission of uranium and other nuclear reactions are known. For example, xenon-135 (9.2-hour half-life) is produced by uranium fission in nuclear reactors, where it is troublesome because it absorbs fission-producing neutrons. Noble gases were thought to be chemically inert until Neil Bartlett produced (1962) the first noble-gas compound, a red crystalline solid, xenon hexafluoroplatinate(V), that can best be formulated as $Xe(PtF_6)_x$, in which x varies in value from one to two. Xenon was later observed to combine directly with fluorine to form a series of fluorides, XeF_2, XeF_4, and XeF_6, of which the tetrafluoride (XeF_4) is the easiest to prepare. The oxides XeO_3 and XeO_4, made indirectly in aqueous solution, are explosively unstable when dry. Stable, insoluble xenate(VIII) salts, such as that of sodium, $Na_4XeO_6 \cdot 8H_2O$, and several other stable compounds – for example, the yellow solid cesium octafluoroxenate(VI), Cs_2XeF_8 – have been prepared and studied. / Британские химики Сэр Вильэм Рэмзэй (Sir William Ramsay) и Морис Дабл.Ю. Тчрэвёз (Morris W. Travers). Нил Батлет (Neil Bartlett). Дробная Перегонка или Фракционная Перегонка (Fractional Distillation). Под Ксеноном, от Греческого слова Xénos, означающее Чужой, понимается химический элемент (впервые был найден как примесь к криптону) VIII группы периодической системы Менделеева, из группы благородных газов. Символ Xe, на Латинском Ксэнонум (Xenonum), атомный номер 54, атомная масса 131.29. Ксенон – газ без цвета и запаха; плотность 5.851 кг/м^3, $t_{пл}$ – 111.8 °C, $t_{кип}$ – 108.1 °C. Ксенон – первый инертный газ, для которого удалось (в 1961) получить химическое соединение, например, $XePtF_6$. В промышленности ксенон получают при разделении воздуха; вследствие очень низкого содержания ксенона в атмосфере объём производства его невелик. Применяют ксенон в мощных газоразрядных лампах, а также для исследовательских и медицинских целей. Ксеноновые лампы применяются в прожекторах, кинопроекторах. Практическое применение находят также фториды ксенона XeF_2, XeF_4, являющиеся мощными окислителями и фторирующими агентами. Ксенон – это инертный газ, открытый Английскими учёными Вильямзом Рэмзэйем и Морисом Тчрэвёзом в 1898, как примесь к криптону. В 1962 в Канаде Нил Батлет получил первое устойчивое при комнатной температуре химическое соединение ксенона. Ксенон – редчайший газ земной атмосферы, содержание в воздухе $8.6 \cdot 10^{-5}$% по объёму. Общие запасы ксенона в атмосфере $1.6 \cdot 10^{11}$м^3. Название Ксенон произошло от Греческого слова Чужой – ксенон открыт, как примесь к другому элементу. Ксенон выделяют как побочный продукт при переработке воздуха на азот и кислород. Несмотря на высокую стоимость, ксенон незаменим в ряде случаев. Одной из основных областей применения ксенона является наполнение ламп накаливания, мощных газоразрядных и импульсных источников света (высокая атомная масса газа в колбах ксенон-наполняемых ламп

препятствует уносу вольфрама с поверхности нити накаливания), а также использование ксенона в системах высокоинтенсивного разряда (ВИР; High Intensity Discharge (HID)) (ксеноновый автосвет в классическом понимании).

XENON–ARC LAMP = КСЕНОНОВАЯ ЛАМПА С ДУГОЙ НАКАЛИВАНИЯ – Xenon-Arc Lamp is a type of light source used in fading lamps. It is an electric discharge in an atmosphere on xenon gas at a little below atmospheric pressure, contained in a quartz tube. A Xenon Arc Lamp is a specialized type of gas discharge lamp, an electric light that produces light by passing electricity through ionized xenon gas at high pressure. It produces a bright white light that closely mimics natural sunlight. Xenon arc lamps are used in movie projectors in theaters, in searchlights, and for specialized uses in industry and research to simulate sunlight. Xenon headlamps in automobiles actually use metal-halide lamps where xenon arc is only used during start-up. Xenon arc lamps can be roughly divided into three categories:- (i) continuous-output xenon short-arc lamps; (ii) continuous-output xenon long-arc lamps; and (iii) xenon flash lamps (which are usually considered separately). Each consists of a glass or fused quartz arc tube with tungsten metal electrodes at each end. The glass tube is first evacuated and then re-filled with xenon gas. For xenon flashtubes, a third 'trigger' electrode usually surrounds the exterior of the arc tube. The lamp has a lifetime of around 2 000 hours. History and Modern Usage:- Xenon short-arc lamps were invented in the 1940s in Germany and introduced in 1951 by Osram. First launched in the 2 kW size (XBO2001), these lamps saw wide use in movie projection, where they replaced the older, more complicated carbon arc lamps. The white, continuous light generated by the xenon arc is spectrally similar to daylight, but the lamp has a rather low efficiency in terms of lumens of visible light output per watt of input power. Today, almost all movie projectors in theaters employ these lamps, with power ratings ranging from 900 watts up to 12 kW. Omnimax (Imax Dome) projection systems use single xenon lamps with ratings as high as 15 kW. Lamp Construction:- all modern xenon short-arc lamps use a fused quartz envelope with thoriated tungsten electrodes. Fused quartz is the only economically feasible material currently available that can withstand the high pressure (25 atmospheres for an IMAX (an abbreviation for Image Maximum) bulb) and high temperature present in an operating lamp, while still being optically clear. The thorium dopant in the electrodes greatly enhances their electron emission characteristics. Because tungsten and quartz have different coefficients of thermal expansion, the tungsten electrodes are welded to strips of pure molybdenum metal or Invar alloy, which are then melted into the quartz to form the envelope seal. Because of the very high power levels involved, large lamps are water-cooled. In those used in IMAX projectors, the electrode bodies are made from solid Invar and tipped with thoriated tungsten. An O-ring seals off the tube, so that the naked electrodes do not contact the water. In low power applications the electrodes are too cold for efficient electron emission and are not cooled; in high power applications an additional water cooling circuit for each electrode is necessary. To save costs, the water circuits are often not separated and the water needs to be deionized to make it electrically non-conductive, which, in turn, lets the quartz or some laser media dissolve into the water. In order to achieve maximum efficiency, the xenon gas inside short-arc lamps is maintained at an extremely high pressure – up to 30 atmospheres (440 psi / 3 040 kPa) – which poses safety concerns. If a lamp is dropped, or ruptures while in service, pieces of the lamp envelope can be thrown at high speed. To mitigate this, large xenon short-arc lamps are normally shipped in protective shields, which will contain the envelope fragments should breakage occur. Normally, the shield is removed once the lamp is installed in the lamp housing. When the lamp reaches the end of its useful life, the protective shield is put back on the lamp, and the spent lamp is then removed from the equipment and discarded. As lamps age, the risk of failure increases, so bulbs being replaced are at the greatest risk of explosion. Because of the safety concerns, lamp manufacturers recommend the use of eye protection when handling xenon short-arc lamps. Because of the danger, some lamps, especially those used in IMAX projectors, require the use of full-body protective clothing. Light Generation Mechanism:- xenon short-arc lamps come in two distinct varieties:- pure xenon, which contain only xenon gas; and xenon-mercury, which contain xenon gas and a small amount of mercury metal. In a pure xenon lamp, the majority of the light is generated within a tiny, pinpoint-sized cloud of plasma situated where the electron stream leaves the face of the cathode. The light generation volume is cone-shaped, and the luminous intensity falls off exponentially moving from cathode to anode. Electrons passing through the plasma cloud strike the anode, causing it to heat. As a result, the anode in a xenon short-arc lamp either has to be much larger than the cathode or be water-cooled, to dissipate the heat. The output of a pure xenon short-arc lamp offers fairly continuous spectral power distribution with a color temperature of about 6200K and CRI close to 100. Intensity of light ranges from 20 000 to 500 000 cd/cm^2. Though even in a high pressure lamp there are some very strong emission lines in the near infrared, roughly in the region from 850–900 nm. This spectral region can contain about 10% of the total emitted light. An example is 'XBO lamp', which is a OSRAM trade name for pure xenon short-arc lamp. Some applications include light guide systems such as endoscopy and dental technology. In xenon-mercury short-arc lamps, the majority of the light is generated in a pinpoint-sized cloud of plasma situated at the tip of each electrode. The light generation volume is shaped like two intersecting cones, and the luminous intensity falls off exponentially moving towards the centre of the lamp. Xenon-mercury short-arc lamps have a bluish-white spectrum and extremely high UV output. These lamps are used primarily for UV curing applications, sterilizing objects, and generating ozone. The very small size of the arc makes it possible to focus the light from the lamp with moderate precision. For this reason, xenon arc lamps of smaller sizes, down to 10 Watts, are used in optics and in precision illumination for microscopes and other instruments, although in modern times they are being displaced by single mode laser diodes and white light supercontinuum lasers which can produce a truly diffraction limited spot. Larger lamps are employed in searchlights where narrow beams of light are generated, or in film production lighting where daylight simulation is required. All xenon short-arc lamps generate substantial ultraviolet radiation. Xenon has strong spectral lines in the UV bands, and these readily pass through the fused quartz lamp envelope. Unlike the borosilicate glass used in standard lamps, fused quartz readily passes UV radiation unless it is specially doped. The UV radiation released by a short-arc lamp can cause a secondary problem of ozone generation. The UV radiation strikes oxygen molecules in the air surrounding the lamp, causing them to ionize. Some of the ionized molecules then recombine as O_3, ozone. Equipment that uses short-arc lamps as the light source must contain UV radiation and prevent ozone build-up. Many lamps have a shortwave UV blocking coating on the envelope and are sold as 'Ozone Free' lamps. Some lamps have envelopes made out of ultra-pure synthetic fused silica (such as 'Suprasil'), which roughly doubles the cost, but which allows them to emit useful light into the vacuum UV region. These lamps are normally operated in a pure nitrogen atmosphere. Ceramic Xenon Lamps:- xenon short-arc lamps also are manufactured with a ceramic body and an integral reflector. They are available in many output power ratings with either UV transmitting or blocking windows. The reflector options are parabolic (for collimated light) or elliptical (for focused light). They are used in a wide variety of applications, such as video projectors, fiber optic illuminators, endoscope and headlamp lighting, dental lighting, and search lights. Power Supply Requirements:- xenon short-arc lamps have a negative temperature coefficient like other gas discharge lamps. They're operated at low-voltage, high-current, DC and started with a high voltage pulse of 20 to 50 kV. As an example, a 450 W lamp operates normally at 18 V and 25 A once started. They are also inherently unstable, prone to phenomena such as plasma oscillation and thermal runaway. Because of these characteristics, xenon short-arc lamps require a proper power supply. Automotive Headlamps:- in 1991 'xenon headlamps' were introduced for vehicles. These are actually metal-halide lamps; the xenon gas is used only to provide some light immediately upon lamp startup, as required for safety in an automotive headlamp application. Full intensity is reached 20 to 30 seconds later once the salts of sodium and scandium are vapourised by the heat of the xenon arc. The lamp envelope is small and the arc spans only a few millimeters. An outer hard glass tube blocks the escape of ultraviolet radiation that would tend to damage plastic headlamp components. The first xenon headlamps contained mercury; newer types do not. Xenon Long-Arc-Lamps:- these are structurally similar to short-arc lamps except that the arc-containing portion of the glass tube is greatly elongated. When mounted within

an elliptical reflector, these lamps are frequently used to simulate sunlight. Typical uses include solar cell testing, solar simulation for age testing of materials, rapid thermal processing, and material inspection. / Зупразиль ('Suprasil'). Ксеноновые Лампы или HID-лампы (High Intensity Discharge – Высокоинтенсивный Разряд):- это принципиально новая технология света, основанная на свечении электрической дуги, образующейся при пропускании электрического тока через газовую среду. Ксеноновая лампа – это газоразрядный источник света высокого давления. В отличие от обычной вакуумной или галогеновой лампы у ксеноновой лампы нет нити накаливания, источником света является электрическая дуга, которая возникает между двумя электродами, расположенными внутри герметичной стеклянной колбы, наполненной парами ртути и смесью инертных газов, одним из которых в частности является ксенон. Для образования электрической дуги необходим кратковременный разряд с достаточно высоким напряжением – около 25 000 Вольт (В). Чтобы преобразовать автомобильные 12 В в 25 000 В необходимо специальное устройство – ксеноновый блок (блок розжига (ignitor)). Для дальнейшего поддержания и стабилизации дуги также используется ксеноновый блок. У ксенона в 3 раза мощнее световой поток в сравнении с галогенными лампами при этом используется только 2/3 мощности. Ксеноновый свет по своему спектру максимально приближен к дневному свету. Это обеспечивает лучшую видимость в неблагоприятных условиях (тёмное время суток, ненастная погода), значительно повышая безопасность участников дорожного движения. Ксеноновые лампы – газоразрядные:- они наполнены смесью инертных газов и парами ртути, в них нет нитей накаливания, поэтому срок их службы гораздо дольше, чем у галогенных ламп. HID (High-Intensity Discharge) – эта аббревиатура в переводе с Английского означает, что в лампе для получения светового излучения используется электрический Разряд Высокой Интенсивности. Технически ксеноновая лампа состоит из колбы, в которую помещена капсула с двумя электродами, заполненная ксеноном с добавлением солей ртути. Для работы ксеноновой лампы необходим блок управления питанием (ballast) с трансформатором розжига (ignitor). Полный цикл розжига ксеноновой лампы и выход на рабочий режим занимает около 6 секунд (с). На первом этапе на электроды подаётся разряд 23 000 Вольт для возникновения дуги внутри капсулы, после возникновения дугового разряда на ксеноновую лампу подаётся напряжение 80 Вольт (В), 400 Герц (Гц). На всех этапах розжига ксеноновой лампы производится микропроцессорный контроль над параметрами на электродах ксеноновой лампы (потребляемый ток, напряжение). Ксеноновая лампа – газ ксенон и соли ртути позволяют создать внутри капсулы плазменный разряд (при помощи двух молибденовых электродов), который в свою очередь вызывает свечение газа внутри капсулы. Поджигающий трансформатор – электронный усилитель, который принимает управляющие импульсы от балласта и умножает напряжение для розжига дуги в капсуле ксеноновой лампы. Балласт – прибор электронного контроля и управления. Применяется для инициализации возникновения дуги в ксеноновой лампе с последующей подачей стабилизированного напряжения на лампу и поджигающий трансформатор во время нормальной работы ксеноновой лампы. Зачастую технически балласт и поджигающий трансформатор выполняются в одном корпусе. Ксеноновые лампы могут быть использованы в фарах ближнего, дальнего и противотуманного света. В настоящее время ксеноновые лампы выпускаются практически со всеми наиболее распространёнными цоколями:- H1, H3, H4, H7, H11, 9005(HB3), 9006(HB4), 9007(HB5), H27. Ксеноновая лампа не имеет нити накала, которая часто подвергается разрушению от неизбежной вибрации лампы, а стало быть виброустойчивость и повышенный срок службы до 2 000 часов взамен 400 у галогенных ламп. Ксенон имеет на 40% меньшее потребление от бортовой сети (экономия топлива), меньший нагрев деталей оптики, а также троекратное увеличение яркости свечения в сравнении с галогенной лампой. Правильное применение ксенона повышает активную и пассивную безопасность движения. Свет, излучаемый ксеноновой лампой подобен солнечному и не вызывает нарушений зрения у водителей. Видимость ночью и в дождливую погоду существенно улучшается, а качество отражения света дорожными знаками и разметкой увеличивается. Половина всех ночных автокатастроф происходит по причине плохого освещения дороги, к тому же водители пожилого возраста нуждаются в более ярком освещении по сравнению с молодыми водителями. На данный момент практически все крупные мировые производители автомобилей используют лампы ксенон HID, как стандартную комплектацию своих автомобилей. Би-ксенон – это инженерная мысль, воплощённая в стекле, металле и пластике, своего рода произведение искусств. Газоразрядная лампа, приводимая в действие электромагнитом, которая выходит и прячется в патрон, изменяя угол преломления лучей, решает проблему ближнего и дальнего света, при наличии всего лишь одного посадочного места. Ксенон + галоген – это эконом-вариант, который дарят некоторые производители ксенона для тех, у кого лампы типа H4, совмещающие в себе дальний и ближний свет. Установив Ксенон + Галоген, получаем полноценный ксенон на ближний свет и галоген – на дальний.

XENOTIME = КСЕНОТИМ – Xenotime:- widely distributed phosphate mineral, yttrium phosphate (YPO_4, though large proportions of erbium commonly replace yttrium), that occurs as brown, glassy crystals, crystal aggregates, or rosettes in igneous rocks and associated pegmatites, in quartzose and micaceous gneiss, and commonly in detrital material. Occurrences include Norway, Sweden, Madagascar, Brazil, and North Carolina. The name is from the Greek word meaning 'Vain Honour', because the yttrium in xenotime was mistakenly thought to be a new element. For detailed physical properties, see also Phosphate Mineral (Table). / Ксенотим – минерал класса фосфатов, YPO_4. Твёрдость 4–5; плотность около 4.3 г/см^3. Содержит TR группы иттрия, иногда Th, U, Zr. По происхождению магматический, накапливается в россыпях.

XENOTRANSPLANT = КСЕНОТРАНСПЛАНТАТ – Xenotransplant:- from the Greek word Xenos, meaning Stranger. Xenotransplant is the implantation of an organ or limb from one species to another organism in a different species. When performed in animals, 'rejection' of the transplant by the recipient's immune system is a common response. See also Xenograft. / Ксенотрансплантат:- .

XENOTRANSPLANTATION = КСЕНОТРАНСПЛАНТАЦИЯ – Xenotransplantation is any procedure that involves the transplantation, implantation or infusion into a human recipient of either (a) live cells, tissues, or organs from a nonhuman animal source, or (b) human body fluids, cells, tissues or organs that have had ex vivo contact with live nonhuman animal cells, tissues or organs. The development of xenotransplantation is, in part, driven by the fact that the demand for human organs for clinical transplantation far exceeds the supply. Currently ten patients die each day in the United States while on the waiting list to receive lifesaving vital organ transplants. Moreover, recent evidence has suggested that transplantation of cells and tissues may be therapeutic for certain diseases such as neurodegenerative disorders and diabetes, where, again human materials are not usually available. Although the potential benefits are considerable, the use of xenotransplantation raises concerns regarding the potential infection of recipients with both recognized and unrecognized infectious agents and the possible subsequent transmission to their close contacts and into the general human population. Of public health concern is the potential for cross-species infection by retroviruses, which may be latent and lead to disease years after infection. Moreover, new infectious agents may not be readily identifiable with current techniques. Xenotransplantation is any procedure that involves the transplantation, implantation, or infusion into a human recipient of either (a) live cells, tissues, or organs from a nonhuman animal source, or (b) human body fluids, cells, tissues, or organs that have had ex vivo contact with live nonhuman animal cells, tissues, or organs outside the organism. Xenotransplantation (Xenos- from the Greek meaning Foreign), is the transplantation of living cells, tissues or organs from one species to another. Such cells, tissues or organs are called Xenografts or Xenotransplants. In contrast, the term allotransplantation refers to a same-species transplant. Human xenotransplantation offers a potential treatment for end-stage organ failure, a significant health problem in parts of the industrialized world. It also raises many novel medical, legal and ethical issues. A continuing concern is that many animals, such as pigs, have shorter lifespans than humans,

meaning that their tissues age at a quicker rate. Disease transmission (xenozoonosis) and permanent alteration to the genetic code of animals are also causes for concern. A few successful cases of xenotransplantation are published. History:- an American infant girl known as 'Baby Fae' with hypoplastic left heart syndrome was the first infant recipient of a xenotransplantation, when she received a baboon heart in 1984. The procedure was performed by Leonard L. Bailey at Loma Linda University Medical Center in Loma Linda, California. Fae died 21 days later due to infection. / 'Младенец Фэ' (или 'Бэйби Фэ' ('Baby Fae')). Лэнад Эл. Бэйли (Leonard L. Bailey). Ксенотрансплантация – трансплантация органов, тканей и клеток животных человеку. В случае успеха ксенотрансплантации можно было бы обеспечить трансплантатом людей, которые в настоящее время находятся в листе ожидания сердца, почки и так далее и не могут получить ожидаемый орган. Ксенотрансплантация – любая процедура трансплантации, имплантации или инфузии в организм человека:- живых клеток, тканей или органов от живого источника нечеловеческого происхождения (животного). На разных этапах проводилось большое количество экспериментов, но ни одно исследование не привело к результатам, которые могли бы служить достаточным основанием для перехода к клиническим испытаниям. Животные – потенциальный источник неограниченного числа органов, тканей и клеток ксенотрансплантации – могут решить проблему нехватки донорских органов во всём мире, однако только в том случае, если будут решены основные проблемы ксенотрансплантации. Несостоятельность трансплантата, невозможность обеспечения адекватной функции. Органы животного не могут иметь запаса прочности и долговечности, чтобы поддерживать функции человеческого органа, и физиология животных отлична от физиологии человека. Отторжение чужеродного материала:- даже если сверхострое отторжение преодолено путём генетической модификации или созданием барьера, развитие клеточного или хронического отторжения всё ещё приводит к неудачам. Однако в настоящее время наибольшую опасность представляет передача инфекции от животного человеку. Все трансплантаты несут риск передачи серьёзной инфекции от донора реципиенту. Более того, риск передачи инфекционного агента животного пациенту с несостоятельностью иммунитета, может вызывать новые инфекции, которые могут передаваться более широкому кругу людей. Из-за вышеуказанных рисков клинические испытания ксенотрансплантации должны эффективно регулироваться. Все процедуры ксенотрансплантации в отсутствие эффективного регулирования в стране должны быть запрещены. Ксенотрансплантация:- нахождение способа использовать органы животных для трансплантации людям когда-то считалось крупной медицинской задачей. Однако врачи столкнулись с проблемой отторжения чужеродных тканей, и внимание их переключилось на стволовые клетки. Несмотря на это, некоторые исследователи и сейчас говорят, что животные-доноры вскоре могут стать реальностью. Острая необходимость в органах существует постоянно. В одной только Великобритании в так называемом 'листе ожидания' более 8 тысяч человек, причём ежедневно трое из них умирают, не дождавшись очереди. В итоге лишь 10% из страждущих получат надлежащее лечение. Решить проблему специалисты стараются сразу несколькими способами. Если речь идёт об относительно 'простых' структурах человеческого тела, то на помощь уже сегодня приходят стволовые клетки (как, например, в случае с пересадкой трахеи). Если ситуация серьёзная и требуется более сложный орган, его могут заменить механическим. В Августе 2011 подобная операция была проведена в Лондоне, сообщает Би.Би.Си. Ньюз (BBC News):- пациенту успешно пересадили искусственное сердце. Ксенотрансплантация в медицине по сей день является неоднозначной процедурой. В связи с ней неизбежно встают как этические, так и научные проблемы. Основные трудности заключаются в том, что:- (i) невозможно обеспечить адекватное функционирование трансплантата. Органы животного не могут иметь необходимого запаса прочности и долговечности, чтобы поддерживать функции человеческого органа, и физиология животных отлична от физиологии человека. (ii) Происходит отторжение чужеродного материала. Даже если острое отторжение преодолено путём генетической модификации или созданием барьера, развитие клеточного или хронического отторжения всё ещё приводит к неудачам. (iii) Есть риск передачи инфекции от животного к человеку:- Лондонские учёные представили данные о наличии в тканях свиньи разновидностей ретровирусов, которые способны заразить клетки человека после трансплантации и в дальнейшем вызвать онкологические заболевания. Именно поэтому наилучшим выходом остаётся трансплантация органов от человека к человеку. По статистическим данным, в настоящее время лишь в экономически развитых странах не менее 150 000 человек нуждаются в пересадке донорских органов и тканей. Мировая же потребность во много раз больше. По сравнению с 1980-ми она удвоилась и продолжает ежегодно увеличиваться на 15%, а удовлетворяется всего на 5–6%. Цена донорского органа очень велика. В США трансплантация почки стоит около 90 000 Долларов, не считая последующих ежегодных расходов в 7 000 Долларов на лекарства, которые необходимо принимать постоянно на протяжении всей жизни, чтобы предотвратить отторжение тканей. В России сегодня пересадка почки обойдется коммерческому больному не менее чем в 250 000 Рублей, опять же, не считая расходов на крайне дорогие привозные (или импортные) лекарства. Поэтому большинство трансплантаций почек в нашей стране осуществляется при финансовой поддержке организаций здравоохранения, которые в бюджетных средствах весьма ограничены. Следовательно, мы снова попадаем в ситуацию, когда помочь всем желающим не удаётся. В отдалённом будущем врачи надеются найти способ отказаться от трансплантации чужих органов и выращивать для человека 'собственные' на основе клеток пациента. Структуры из персонализированных стволовых клеток помогут решить проблему отторжения, так как будут полностью соответствовать остальным тканям организма. А на сегодняшний день органы животных в случае разработки эффективных и безопасных механизмов их пересадки человеку всё ещё имеют большой потенциал в качестве доступной альтернативы традиционному лечению. Самое подходящее животное-донор для человека это, как ни странно, свинья. В последние годы учёные вывели генетически модифицированные разновидности этого млекопитающего. Ещё в 2001 в Америке было клонировано 9 карликовых поросят, в результате чего у них была удалена одна из двух копий гена, вызывающего отторжение тканей при пересадке свиных органов людям. Речь идёт о белке, которого нет у человека, но есть у обладателей пятачков. Он отвечает за производство энзима 1,3-галактосилтрансфераз, который ферментирует специфический сахар, распознаваемый человеческим организмом как чужеродный, в силу чего иммунная система и отторгает свиные органы. На сегодняшний день выведены свиньи, полностью свободные от галактосилтрансферазы. Отчасти это помогло побороть иммунологический конфликт, но проблема с отёками, кровоизлияниями, закупоркой мелких сосудов и воспалениями после трансплантации осталась. В 1963 Американский хирург Доктор Кис Риэмцма (Keith Reemtsma; 1925–2000) пересадил человеку почку шимпанзе, которая успешно функционировала в течение девяти месяцев, позднее другие врачи пробовали повторить операцию, используя сердце и печень приматов, но результаты таких экспериментов не слишком обнадёживали. Почему же предпочтение отдаётся свиньям, а не приматам? Свиней гораздо проще разводить, чем обезьян. Можно добиваться выведения широкого поголовья практически в любых климатических условиях. Приматы очень тяжело размножаются в неволе. Приматы генетически слишком тесно связаны с человеком, в результате чего пересадка органов способна спровоцировать 'прыжки между видами' и различные заболевания. Кроме того, сходство животного с человеком поднимает целый ряд этических вопросов касательно правомерности изъятия органов у обезьян. Свиные органы аналогичны по размеру и физиологии человеческим.

XENOTROPIC VIRUS = КСЕНОТРОПНЫЙ ВИРУС – Xenotropic Virus is a virus which can grow/reproduce within one or more species other than its normal host species. / Ксенотропный Вирус – вирус, способный развиваться в необычном для своего жизненного цикла хозяине.

XERANTHEMOIDES = КСЭРАНТЭМОИДЭС (или КСЕРАНТЕМОИДЕС) – Xeranthemoides:- with a dry appearance. / Éidos, означающее Вид, .

XERIC = КСЕРИЧЕСКИЙ (или СУХОУСТОЙЧИВЫЙ) – (1) Xeric:- characterized as requiring very little water. The opposite of Hydric and Mesic. Relating or adapted to an extremely dry habitat. Succulents such as cacti, aloes, and agaves are xeric plants. In ecology, characterized by a scanty supply of moisture, tolerating, or adapted to, arid conditions. Describing an organism that requires little moisture or a habitat containing little moisture. Dry environmental conditions as compared to Hydric. Xeric is a microclimatic term which refers to an area in which the soils are dry, containing very little, if any, moisture. Compare to mesic. Requiring a miniscule amount of moisture. / Ксерический или сухоустойчивый .

(2) Xeric:- xerophytic. / Ксерофитный.

XERISCAPE = ЗИРОСКЭЙП (или СУХОСТОЙ) – A landscape is a Xeriscape if it needs little extra water or other assistance to look its best. Xeriscape is an arid landscape or water-conserving garden in which xerophytic plants grow. A desert garden. Xeriscaping is the art of creating water-conserving landscapes by efficient watering techniques and selecting Plants that are appropriate to the natural environment. The term Xeriscape is derived from the Greek word, Xeros, which means Dry. Xeriscapes are not dry and dull! Well-designed xeriscapes are beautiful and functional. The best xeriscapes use a fraction of the water needed by traditional lawn-dominated landscapes. Some xeric Plants require little or no supplemental watering once they are established and xeriscapes require far less ongoing maintenance. In today's world of concerns about depreciating water resources, xeriscape is an ideal way to 'live green'. More than fifty percent of residential water used, in the western United States, is used to keep landscapes and lawns green. Xeriscape can reduce this by 60% or more. With water demands and usage increasing rapidly, we need to find ways to use water more efficiently. Efficient water use means finding ways to have attractive, landscapes without excessive water use. Xeriscaping will help beautify your home and increase its value – as much as 15%! Using plants and landscaping that is native to the area in which you live can conserve water, time, money and the landscape will retain its beauty during times of drought. Step up and do your part to 'live green' – xeriscape your yard and cut down on your water usage. It's the 'green thing' to do. Xeriscape is a trademark used for a landscaping method that employs drought-resistant plants in an effort to conserve resources, especially water. / аридный (засушливый или сухой или безводный) ландшафт или .

XEROMORPHIC = КСЕРОМОРФНОЕ – Xeromorphic:- structural features of plants, xerophytes, adapted to dry conditions with a thickened cuticle or hairs protecting against moisture loss or with the appearance of such plants. / Под Ксероморфным, от Греческих слов Xērós, означающее Сухой, и Morphē, означающее Форма, понимается .

XEROPHILOUS MICROORGANISMS = КСЕРОФИЛЬНЫЕ МИКРООРГАНИЗМЫ (или СУХОЛЮБИВЫЕ МИКРООРГАНИЗМЫ) – Xerophilous Microorganisms (Greek:- Xeros = Dry, Philos = Love) are microorganisms that survive at a low relative humidity of (approximately 75%). Xerophilous is thriving in or tolerant or characteristic of a xeric environment. Xerophilous or Xerotolerant:- (1) in botany, growing in or adapted to dry, especially dry and hot, regions; and (2) in zoology, living or flourishing in a dry environment. / Под Ксерофильными Организмами, от Греческих слов Xērós, означающее Сухой, и Philéō, означающее Люблю, понимаются микроорганизмы, обитающие в среде с пониженной влажностью воздуха (приблизительно 75%). Ксерофильные – предпочитающие сухие места обитания. Микроорганизмы (микробы) – название собирательной группы живых организмов, которые слишком малы для того, чтобы быть видимыми невооружённым глазом (их характерный размер – менее 0.1 мм). К ним относятся бактерии, плесневые грибы, дрожжи, вирусы, простейшие. Некоторые из них положительно влияют на процесс преобразования органических веществ, другие являются патогенными. Микроорганизм – простейшее, чаще всего одноклеточное живое существо, не являющееся ни животным, ни растением и видимое только с помощью увеличительного прибора – микроскопа.

XEROPHYTES = КСЕРОФИТЫ – Xerophyte is any plant adapted to life in a dry or physiologically dry habitat (salt marsh, saline soil, or acid bog) by means of mechanisms to prevent water loss or to store available water. Succulents (plants that store water) such as cacti and agaves have thick, fleshy stems or leaves. Other xerophytic adaptations include waxy leaf coatings, the ability to drop leaves during dry periods, the ability to reposition or fold leaves to reduce sunlight absorption, and the development of a dense, hairy leaf covering. Xerophytes are plants that grow in or on extremely dry soils or soil materials. Xerophyte is a plant adapted to growth in arid (dry) conditions. / репозиция (или вправление; reposition). Под Ксерофитами, от Греческих слов Xērós, означающее Сухой, и Phytón, означающее Растение, понимаются растения, приспособленные к жизни в засушливых местообитаниях. Несколько типов:- (i) гемиксерофиты – не переносят длительного обезвоживания, корневая система достигает грунтовых вод (верблюжья колючка, шалфей); (ii) пойкилоксерофиты – при обезвоживании впадают в анабиоз (некоторые мхи); (iii) суккуленты – жароустойчивы, но не переносят обезвоживания (агава, алоэ, кактусы); (iv) эвксерофиты – жароустойчивы, способны переносить обезвоживание (вероника седая, полынь и некоторые коровяки). Под Ксерофитами понимаются растения, обитающие в условиях постоянного или сезонного дефицита влаги и выработавшие различные приспособления для поддержания водного баланса. Ксерофиты – древесные, кустарниковые и травянистые растения, широко представленные в пустынях, сухих степях, саваннах, колючих редколесьях. Наиболее выраженными ксероморфными признаками обладают склерофиты. Для них характерно общее уменьшение листовой поверхности (небольшое число листьев или полное их отсутствие, уменьшение листовой пластинки за счёт скручивания в трубку или завёрнутых краёв и так далее), а также сбрасывание листьев в наиболее жаркие и сухие периоды года, развитие толстостенных покровных тканей с сильно развитой кутикулой, воскового налёта, густого опушения, погруженных устьиц, усиленное развитиемеханической ткани, мелкоклетность, плотное расположение клеток и так далее. Одни из них – растения с неглубокой корневой системой и интенсивными ксероморфными чертами, способствующими сокращению транспирации, другие – с глубокими корнями, часто достигающими грунтовых вод, интенсивно транспирирующие, жаростойкие, но не выносящие длительного обезвоживания. Другая группа – суккуленты – растения, переживающие засуху вследствие накопления больших запасов воды в мясистых листьях (листовые суккуленты – Агава, Алоэ и другие), стеблях (Кактусы, некоторые Молочаи и другие) или подземных органах (многолетние травы – леофиты). Они также имеют защитные приспособления для уменьшения транспирации (восковой налёт, опушение, сокращение числа устьиц). Из культурных растений Артишок, Кукуруза, Просо, Сафлор, Сорго и другие, из плодовых – Маслина, Миндаль, некоторые виды Груши, Сливы. Ксерофиты – растения сухих местообитаний, способные переносить продолжительную засуху (засухоустойчивые). Растения засушливых областей (пустынь) или безводных почв, обладающие рядом характерных черт строения, препятствующих излишнему испарению и потере воды (ксероморфные признаки). Ксерофит – организм, приспособленный для обитания в условиях сухого и жаркого климата. Ксерофиты – растения сухих местообитаний или таких мест, где вода трудно усваивается растениями вследствие её низкой температуры (торфяные болота) или из-за содержания большого количества солей (солончаки). Ксерофиты обладают рядом приспособительных признаков, позволяющих существовать в условиях постоянного или сезонного дефицита влаги:- замедленной транспирацией, жаровыносливостью, способностью к длительному состоянию завядания. Высокое осмотическое давление в клетках корня

(несколько десятков атмосфер) позволяет всасывать почвенный раствор при его высокой концентрации и малых количествах влаги. Снижение транспирации достигается желатированием плазмы и попеременным закрыванием и раскрыванием устьиц, защитой их от прямого воздействия солнца и ветра. Листья у ксерофитов часто узкие и сложены вдоль (ковыль), мелкие, с завёрнутыми краями, толстой наружной клеточной оболочкой, восковым налётом или густо опушённые. Настоящие ксерофиты – ковыли и многие другие злаки, полыни, солянки, коровяк и другие.

XETRA® = КСЭТРА® – On 1999-October-05, in co-operation with Deutsche Börse AG, the Xetra® system was introduced on the Vienna Stock Exchange's cash and bond markets, replacing the ÖKB's EQOS system (a new Client-Server Electronic Quote and Order driven System). Xetra® is a screen-based trading system for shares and other securities; this system enables cross-border securities trading. The following types of securities are traded via Xetra®:- Austrian shares, Austrian participation certificates, Austrian investment certificates, international shares, international investment fund certificates, profit-sharing certificates and profit-sharing rights, subscription rights and debt securities. The Xetra® system is a platform which provides all market participants with equal access to the market regardless of their location. In Vienna, services such as market control, trading surveillance, fee schedules and rules and regulations are provided by Wiener Börse AG. Additional benefits offered by the central, open order book include the concentration of liquidity and improved market transparency. Furthermore, additional liquidity is provided by special intermediaries (market-makers and specialists). Low transaction costs are guaranteed by the electronic matching of orders. A more customer-oriented set of order placement rules allows individualized order specifications in terms of validity and type of execution. The new trading system is linked to an integrated clearing and settlement system. When Xetra® was introduced, the trading hours on the Vienna Stock Exchange were extended from 08:30 am to 05:30 pm. In general, orders of any size may be traded through Xetra®, as the minimum trading lot is one unit. All orders are anonymous, meaning that trading participants cannot see who places an order or a quote in the order book. Xetra® offers a wide range of options for individualized order specification. The Xetra® market model for the Vienna Stock Exchange supports continuous trading with several auctions as well as trading with only one auction per trading session. Xetra® trading at the Vienna Stock Exchange is open only to institutions admitted to trading on the exchange, such as banks and their representatives (dealers). The dealer responsible enters all investors' orders in the electronic order book. The system automatically checks whether a matching order is available on the opposite side of the order book and whether the order can be executed. If none match, the order remains in the order book. Exchange data provided by Wiener Börse AG:- Wiener Börse AG supplies real-time and historic data on prices, trading volumes and indices generated on the Vienna Stock Exchange in the Xetra® and OM trading systems. All data include all indications and estimated prices on the official and semi-official markets, the unregulated market and the ÖTOB market of the Vienna Stock Exchange. See also ÖTOB AG. The Exchange Electronic Trading (XETRA®) is a fully electronic market trading system for the German cash market. It features automated order settlement, an open order book that is fully transparent and accessible to all market participants everywhere. The exchange trades shares and warrants. Prices are determined through a combination of the auction principle and market maker principle. Due to its high speed and low costs, Xetra® has marginalized floor trading on the German stock exchanges. Any member of a German stock exchange can become a Xetra® member (banks, brokers). Daily trading hours are from 09:00 am to 05:30 pm. In November 1997, Deutsche Börse embarked on a new era in exchange history with Xetra®. With Xetra®, Deutsche Börse has since provided regulated and controlled exchange trading with integrity, stability and safety for all trading participants. Speed, transparency and cost-effectiveness are the decisive benefits offered by Xetra®. Deutsche Börse's electronic trading system works at extremely low cost, regardless of the trader's location. On Xetra®, buy and sell orders of licensed traders are collected in a centralized, fully electronic order book. In continuous trading, Xetra® initiates an automatic plausibility check on every buy and sell order. If a matching order exists, the transaction is executed immediately. Xetra® is one of the most efficient and flexible trading infrastructures worldwide. On its first day of operation, 221 market participants in seven countries began trading in the system and closed a total of 4 934 trades. Today, some 250 market participants in 18 countries are connected to the system. At peak times, Xetra® processes up to 2.1 million orders per day. Almost all the shares listed on Frankfurter Wertpapierbörse (FWB®, the Frankfurt Stock Exchange) can be traded on Xetra®. Some 97 percent of DAX® shares are traded on Xetra®. Since June 1999, Deutsche Börse has been calculating all indices on the basis of Xetra® prices. Xetra® and the other trading systems were developed by Deutsche Börse IT. / Эф.Ве.Бе.® (FWB®; Франкфота Вертпапиабёрзэ (Frankfurter Wertpapierbörse) или Франкфуртская Фондовая Биржа (Frankfurt Stock Exchange)):- Ксэтра® (Xetra®). X–INEFFICIENCY = ИКС.–НЕЭФФЕКТИВНОСТЬ – In The Wealth of Nations published in 1776, Adam Smith observed that 'Monopoly ... is a great enemy to good management'. This insight explicitly recognized that the problem of monopoly is not only one of price but also one of costs. While monopoly may provide the basis for extracting higher prices from customers, the lack of competitive stimulus may raise the costs of producing the goods and services it sells. The lack of incentives or competitive pressures may lead monopolistic firms to neglect minimizing unit costs of production, i.e. to tolerate 'X-inefficiency' (phrase coined by Harvey Leibenstein (American economist and economic demographer)). Included in X-inefficiency are wasteful expenditures such as maintenance of excess capacity, luxurious executive benefits, political lobbying seeking protection and favorable regulations, and litigation. X-Inefficiency is the failure to minimize costs or maximize returns. Sometimes referred to as X-Efficiency, but carrying the same meaning. In economics, X-Inefficiency is the difference between efficient behavior of firms assumed or implied by economic theory and their observed behavior in practice. Economic theory assumes that the management of firms act to maximize owners' wealth by minimizing risk and maximizing economic profits – which is accomplished by simultaneously maximizing revenues and minimizing costs, usually through the adjustment of output. In perfect competition, the free entry and exit of firms tends toward firms producing at the point where price equals long run average costs and long run average costs are minimized. Thus firms earn zero economic profits and consumers pay a price equal to the marginal cost of producing the good. This result defines economic efficiency or, more precisely, allocative economic efficiency. Empirical research suggests, however, that a number of firms do not produce at the point where long run average costs are minimized. Some of this can be explained away by the mechanics of imperfect competition; what cannot be explained by

traditional economics is described as X-inefficiency. Example:- a monopoly is a price maker in that its choice of output level affects the price paid by consumers. Consequently, a monopoly tends to price at a point where price is greater than long-run average costs. X-inefficiency, however tends to increase average costs causing further divergence from the economically efficient outcome. The sources of the X-inefficiency have been ascribed things such as overinvestment and empire building by managers, lack of motivation stemming from a lack of competition, and pressure by labor unions to pay above-market wages. X-inefficiency can also occur when monopolies or even oligoplies produce higher than the minimum average cost. See also X-Efficiency. / Эдэм Смис (Adam Smith). Хави Лайбэнштайн (Harvey Leibenstein). Икс.-Неэффективность – величина, показывающая падение эффективности деятельности компании ниже максимально возможной эффективности. Например, в 1981 было проведено сравнение двух абсолютно идентичных заводов компании Форд, один из которых размещался в Германии, а другой – в Великобритании. Оказалось, что Германский завод производил автомобилей на 50% больше при числе рабочих на 22% меньше. Икс.-неэффективность Британского завода обуславливалась несколькими причинами, среди которых назывались инерция, недостаточная информация, изолированность от свободной конкуренции, плохие производственные отношения и некомпетентность управления. The XLA fibers, blended with cotton, wool or knits, provide process advantages to manufacturers and performance features for end-users. Lastol is an elastic textile fiber produced by Dow Chemical. First classified in January 2003, Dow is marketing it as DOW XLA elastic fiber. Dow has created a division called Dow Fiber Solutions, or (DFS), to market this new fiber. It is resistant to chemicals and heat and is more abrasion resistant than cotton. XLA or DOW XLA™:- luxury stretch fiber technology from DOW XLA™. DOW XLA™ brings premium stretch fiber to a whole new level by inventing the world's first olefin-based elastic fiber that creates a perfectly smooth fit, less compressed feel, and more flexible give for everyday luxury all day long. As an ingredient brand belonging to Dow Fiber Solutions, DOW XLA™ is positioned in the premium segment. It is the perfect material for manufacturers who design clothing that is suited to today's active lifestyles – whether it is for tailored, ready to wear, denim, intimate, active, or professional wear. In order to match the premium quality of the brand, our task was to create an emotionally appealing new brand identity that communicated the key product benefits as well as the new brand idea. We focused our new brand positioning on the around the clock feeling of extreme comfort made possible through the use of the DOW XLA™ fiber in clothing. Like the XLA fiber itself, which is combined with a host fiber to create an easy-care weave that is also very comfortable to wear, the new logo communicated the sensation of luxuriousness and continuous ease of motion that is found within clothing using DOW XLA™. Conceived as a prototypical example for the future introduction of additional Dow product brands, the development of the DOW XLA™ brand worldwide demonstrates that a strong, emotionally appealing brand idea is the fundamental basis for positioning the brand for long-term success in a variety of cultures and business segments. / Ластэл (или Ластол (Lastol)) – эластичное текстильное волокно, производимое компанией Дау Кэмикэл (Dow Chemical). X PATENT = ПАТЕНТ (СЕРИИ) ЭКС. – In the 46 years prior to the Great Fire of 1836, the United States government had issued about 10 000 patents. Most of these could never be revived again, but Congress acted to restore those records that could be reconstructed from private files and reproduce models which were deemed critical. Patents whose records were not restored were cancelled. There were a total of 2 845 patents restored, most of which were eventually given a number beginning with 'X'. All patents after the date of the establishment of the Patent Office in July 1836 were numbered as a new series (without the X), beginning with a new Patent No. 1 to John Ruggles. A small number of the new series patents had been destroyed in the Great Fire but they were quickly recovered from their owners' records. X files bear numbers that range from X000001 to X011280. X0000001 is the first patent, issued to Samuel Hopkins in 1790. X – before 1836, patents were not numbered – they were simply described in terms of their inventor and date ('Brown's 1814 patent'). 9 957 patents issued between 1790 and 1836 were retroactively assigned 'X' series numbers in the order in which they were issued. A fire at the Patent Office in 1836 destroyed most records of the 'X' patents. Only 2 845 'X' series patents were reconstructed in the 1840's and are available today. Reissued 'X' patents have an 'RX' prefix. / Дьжон Раглз (John Ruggles). Сэмьюэл Хопкинз (Samuel Hopkins). (X) в порядке, в котором они были выданы. Пожар в Патентное Офисе в 1836 уничтожил большую часть записей по патентам серии 'Экс.'. В 1840-х только 2 845 патентов серии 'Экс.' были восстановлены и числятся по сегодняшний день. Переизданные патенты серии 'Экс.' имеют префикс (приставку) 'Ар.Экс.' (RX).

X RAY = ИКС. ЛУЧ (или РЕНТГЕНОВСКИЙ ЛУЧ, или РЕНТГЕНОВСКОЕ ИЗЛУЧЕНИЕ) – (1) X-Ray or XRay is high frequency electromagnetic ray of short wave-length, capable of penetrating most solid substances. X Ray:- any electromagnetic radiation of an extremely short wavelength produced by the deceleration of charged particles or the transitions of electrons in atoms. As can be seen in the Figure, the wavelengths of X rays range from about 10^{-8} meters (m) to 12^{-12} m, with corresponding frequencies of 10^{16} to 10^{21} Hertz (Hz). Like other forms of electromagnetic radiation (gamma rays, ultraviolet, visible light, infrared, and radio waves), X rays have the same speed in vacuo (c, equal to $3 \cdot 10^{10}$ centimeters per second (about 186 000 miles per second)) and show phenomena associated with its wavelike nature, such as interference, diffraction, and polarization. X rays were discovered in Würzburg, Germany, on November 08, 1895, by Wilhelm Conrad Röntgen. Röntgen made his discovery while investigating the effects of cathode rays that were produced by electrical discharges through gases at low pressures (cathode rays are electrons that are emitted from the negative electrode, or cathode, of the discharge tube). Although many scientists had studied the properties of cathode rays, Röntgen discovered an effect that had escaped these earlier investigators – namely, that a surface coated with barium platinocyanide placed outside a discharge tube would emit light (fluoresce) even when it was shielded from the direct visible and ultraviolet light of the gaseous discharge. He deduced that an invisible radiation from the tube passed through the air and fluoresced the screen. He named these strange new rays X Rays to indicate their unknown nature. General X-Ray Phenomena:- when a beam of X rays passes through a material, the material becomes a source of secondary X rays and electrons; and, because of these secondary processes, a portion of the primary beam is absorbed. The intensity of the secondary radiations is weak compared with the intensity of the primary X-ray beam, and some of it, too, may not escape from the material. Two types of secondary X rays are produced when a beam of X rays strikes a material. These are called Scattered X Rays, which are characterized by an energy that is nearly the same as the primary beam, and Fluorescence X Rays, which are less energetic than the primary X rays. The scattered X rays are primary X rays that have had their direction (and possibly, to a small extent, their energy) altered by passing through the material. The fluorescence X rays are characteristic of the target material and do not change with change in wavelength of the primary beam as long as the primary-beam wavelength is short enough to excite the fluorescence. The origin of the scattered X rays can be understood if the primary X rays are thought of as particles. An X-ray particle, called a Photon, may be scattered (deflected) when it passes close to an electron. In a small number of these scattering processes the X ray will lose a portion of its energy to the electron. The fluorescence X rays originate when electrons are ejected from some of the atoms of the target, leaving them in an ionized state, i.e. deficient in electrons. As the atoms regain their normal energy state, energy may be liberated in the form of fluorescence X rays. The two main types of fluorescence X rays that can be excited in most of the elements are known as the K and L characteristic X rays. Characteristic X rays are emitted from all elements. The energy of these X rays increases in a regular manner in going from one element to the next in atomic number (nuclear charge). The K X rays are the most energetic characteristic X rays emitted from an atom and are due to ejection of the most tightly bound electrons from the atom. In addition to the emission of secondary X rays from a material when it is irradiated with X rays, secondary electrons are also ejected. These are classified as recoil electrons and photoelectrons. The recoil electrons obtain energy from the primary X rays in a way that is given by the particle theory of X-ray scattering, whereas the photoelectrons are emitted by the same process that occurs in the photoelectric effect with light. When X rays are absorbed in gases, they eject photoelectrons from the gas. These electrons in turn ionize the molecules of the gas, thereby amplifying the effect of the primary X rays. When these processes occur in living tissue, the photoelectrons emitted from the complex organic molecules destroy the cells of the tissue. Dual Nature Of X Rays:- early experiments with X rays presented evidence that is difficult to explain unless one thinks of X rays as consisting of waves. Other experiments, however, indicated that X rays consist of particles. This dual nature is not restricted to X rays; indeed, it is a general property of all forms of energy and matter. X rays (and the other forms of electromagnetic radiation) should be considered as both

particles and waves; that is, as consisting of small packets of electromagnetic waves called Quanta, or Photons. X Rays As Waves:- according to classical electromagnetic theory, the deceleration of electrons will produce electromagnetic radiation, in the same way that accelerated electrons in a radio antenna produce radio waves. The failure of magnetic fields to deflect an X-ray beam seems to confirm this classical idea of the origin of X rays. Crucial evidence for the existence of waves is obtained if diffraction and interference phenomena are observed, which depend on the superposition of waves. In addition, if polarization effects are observed, the transverse (vibration at right angles to direction of propagation) nature of the waves is established. In the case of light, these effects were well known in 1895, when X rays were discovered. Röntgen's early experiments failed to observe these effects in the case of X rays. In 1906 a British physicist, Charles Glover Barkla, demonstrated that when X rays are scattered in certain directions by a block of carbon they are polarized. From these experiments it appeared likely that X rays were transverse electromagnetic waves, perhaps of the same nature as light except for wavelength. Many scientists attempted to show the wave nature of X rays by passing them through narrow slits and looking for diffraction fringes, and there was some evidence that X-ray wavelengths were about one angstrom. In 1912 a German physicist, Max von Laue, conceived of a way of measuring the wavelength of X rays. Laue used the idea that, in crystals, atoms are regularly arranged throughout the crystal structure with spacings of about one angstrom (10^{-10} meter) and concluded that the atoms of a single crystal would serve as a grating for the diffraction of X rays. Laue's coworkers directed a narrow beam of X rays at a crystal of zinc sulfide and placed a photographic plate behind it. The resulting photograph consisted of a dark central spot and a complex but symmetrical pattern of dots; the central spot was the result of X rays passing directly through the crystal, whereas the dots were produced by diffraction from the atoms of the zinc sulfide crystal. These experiments established that X rays are waves with wavelengths on the order of one angstrom and confirmed that crystals have their atoms arranged in regular structures, called a Lattice. Shortly after Laue's experiment, an English physicist, Lawrence Bragg, devised another technique for diffracting X rays. By considering how X rays are scattered from atoms in a crystal lattice, he concluded that, when an X ray of wavelength λ strikes a crystal of interplanar spacing d at an angle θ with respect to the crystal plane, constructive interference would occur when the product of an integer number n (called Order Of Diffraction) times the wavelength is equal to twice the lattice spacing times the diffraction angle:- $n\lambda = 2d \sin \theta$. This equation is known as Bragg's Law and is the foundation on which X-ray crystal-diffraction spectrometers are based. Using this theory, Bragg obtained a distribution of the intensity of ionization in a detector as a function of angle. This distribution indicated that X rays consist of two types, a line spectrum characteristic of the target material in the tube and a continuous spectrum. From the crystal spacing d, which Bragg obtained from the geometry of the crystal lattice, the density of the crystal, and mass of a single atom, he was able to calculate the wavelengths of the characteristic X-ray lines and to show that these wavelengths varied approximately as the inverse square of the atomic weight of the absorber. These experiments confirmed the earlier results of Barkla, who, by using the fact that short-wavelength X rays are absorbed to a lesser extent than long-wavelength X rays, found two regions of strong maxima. In 1911 Barkla named the long-wavelength maxima the L series and the short-wavelength maxima the K series. In 1923 the reflection of X rays from a polished surface of glass was demonstrated by an American physicist, Arthur Holly Compton. He found that, for angles of less than 10 minutes of arc, a strong reflected beam could be observed in the direction predicted by the specular-reflection law. The final proof of the wave nature of X rays, their diffraction by a ruled grating, was observed in 1925. Because the line spacing of a ruled grating is accurately known, this method has been used to determine the absolute value of X-ray wavelengths. X rays As Particles:- the particle nature of X rays is graphically demonstrated in the photoelectric effect and the Compton effect. In an attempt to explain blackbody radiation (radiation from a theoretically perfectly nonreflecting, or completely absorbing (i.e. 'black'), body), Max Planck postulated that energy is radiated in small packets, or quanta, with an energy given by hv, in which v is the frequency of the radiation and h is a constant (now called Planck's Constant). One of the most important successes of Planck's postulate, in addition to explaining blackbody radiation, was its use by Einstein in explaining the photoelectric effect. In the photoelectric effect, absorbed electromagnetic radiation ejects an electron from the absorber. Einstein's photoelectric equation gives the kinetic energy, E_{kin}, of the emitted electron as the energy of the incident photon, hv, minus the work required to pull the electron out of the sample, W_0:- $E_{kin} = hv - W_0$. Although this equation was first derived for light photons absorbed on metal surfaces, it also holds for X-ray photons if W_0 is the work required to eject the electron from a bound state of the atom. A second series of experiments that demonstrated the particle nature of X rays was carried out in 1922–23 by Compton. Using an X-ray spectrometer, he measured the wavelength of X rays scattered from light elements. In addition to scattered X rays that had the same wavelength as the primary beam, he found a second, or 'modified', peak at a longer wavelength. The intensity and wavelength of this second peak were functions of the scattering angle from the sample. The explanation of this effect (now known as the Compton Effect) was given by Compton and independently by a Dutch scientist, Peter Debye. They proposed that a primary X-ray photon could be considered as a small ball that could collide with one of the electrons in the scattering material in a manner similar to the collision of two smooth elastic balls of different mass. The photon would then lose some of its energy to the recoiling electron and would be of longer wavelength. By assuming that conservation of energy and momentum (mass times velocity) would hold in the collision between a photon and an electron, they were able to derive the shift of the wavelength of the scattered X ray to give the modified peak at higher wavelength. Detection And Measurement Of X Rays:- a beam of X rays is characterized by its intensity and its spectral (energy) distribution, and a number of methods for measuring these properties have been developed. There are two methods in general use for detecting X rays. The first method relies on the X rays producing a photochemical change in a photographic emulsion. The blackening of the film is related to the exposure, which is defined as the product of the X-ray intensity and the length of the exposure. The position and degree of blackening on film are determined by optical techniques. The second method for detecting X rays relies on the ability of X rays either to ionize gases or solids or to produce fluorescence in a crystal. Detectors utilizing these phenomena are called Electronic Detectors. Electronic detectors come in a wide variety of forms, including the ionization chamber, scintillation counter, and solid-state detector. These devices produce a voltage pulse for every absorbed photon. By counting the number of voltage pulses, the number of photons can be determined. In addition, the voltage pulses from all of the devices can be used in conjunction with a pulse-height analyzer, an electronic device that counts pulses and sorts them according to energy, in order to obtain a spectral distribution. The various counters described here have also been used as the detectors in X-ray diffraction spectrometers. An X-ray spectrometer basically consists of a source of X rays, a diffracting sample, and a detector system. If X rays of known wavelength are used, they can be used to study crystal structures. By using a diffracting crystal of known structure, X-ray spectrometers can be used for measuring X-ray spectra. Applications Of X Rays:- because of the many varied properties of X rays, they have been applied to a wide range of medical, industrial, and scientific problems. Some of these are differential absorption, quantitative measurement of absorption, diffraction by crystals, fluorescence of characteristic radiation, and biological effects produced by X rays. One of the earliest applications of X rays was to medicine, being used in both diagnosis and therapy. Diagnostics include the detection of bone fractures, foreign objects in the body, dental cavities, and diseased conditions such as cancer, whereas, in therapeutic treatment, X rays are used to stop the spread of malignant tumours. In industry, X-ray radiographs are used to detect flaws nondestructively in castings that are inaccessible to direct observation and to measure the thickness of materials. X rays have been applied to a wide range of quantitative materials characterization problems. By measuring quantitatively the amount of absorption in a sample of known composition, the thickness can be determined. If the thickness of a sample is known, the absorption can be used to measure accurately its composition even if it contains two elements. The fluorescence of X rays from a sample is used in many instruments for the qualitative and quantitative

analysis of materials. The primary beam may be X rays, gamma rays, electrons, or other charged particles. The energy of the fluoresced X rays is characteristic of the materials contained in the sample. By using suitable standards, quantitative determinations can be made. This principle is used in the electron microprobe, in which a narrow electron beam (about 0.000 1 centimeter (0.000 04 inch) in diameter) is used to determine the constituents of a given area of a sample. X rays are used in scanning electron microscopy to obtain a 'picture' of an elemental distribution in a sample. Also, Si(Li) detectors may be combined with a fluorescence source as energy analysis detectors for rapid material identification. X-Ray is a type of electromagnetic radiation having low energy levels. Because of the many varied properties of X Rays, they have been applied to a wide range of medical, industrial, and scientific problems. Some of these are differential absorption, quantitative measurement of absorption, diffraction by crystals, fluorescence of characteristic radiation, and biological effects produced by X rays. X-Rays are a form of electromagnetic radiation, just like visible light. In a health care setting, a machines sends are individual x-ray particles, called Photons. These particles pass through the body. A computer or special film is used to record the images that are created. Structures that are dense (such as bone) will block most of the x-ray particles, and will appear white. Metal and contrast media (special dye used to highlight areas of the body) will also appear white. Structures containing air will be black, and muscle, fat, and fluid will appear as shades of gray. For most conventional x-rays, the risk of cancer or defects due to damaged ovarian cells or sperm cells is very low. Most experts feel that this low risk is largely outweighed by the benefits of information gained from appropriate imaging. X-rays are monitored and regulated to provide the minimum amount of radiation exposure needed to produce the image. / 08 Ноября 1895 Вильхэльм Конрад Рентген (Wilhelm Conrad Röntgen). Рентгеновские Лучи были открыты в 1895 в Германии Вильхэльмом Рентгеном, в честь которого и названы. Это лучи, наподобие световых, обладают проникающей способностью. Они отличаются от световых лучей длиной волн и энергией. Самая короткая длина волны из рентгеновской трубки составляет от одной пятнадцатитысячной до одной миллионной от длины волны зелёного цвета. Из-за очень маленькой длины волн рентгеновские лучи проникают сквозь материалы, непреодолимые для света. Чем короче длина волны, тем выше проникающая способность этих волн. Рентгеновская трубка испускает рентгеновские лучи. Из трубки выкачивают воздух до одной сто миллионной первоначального объёма. В стеклянной трубке находятся два электрода. Один называется 'катод', он заряжен отрицательно. В нём расположена вольфрамовая катушка провода, которая при нагревании электрическим током испускает электроны. Другой электрод – это 'мишень', или 'анод'. Электроны с огромной скоростью движутся от катода к мишени. Они бомбардируют мишень со скоростью от 100 000 до 325 000 мм/сек. Мишень состоит из вольфрама и позволяет практически мгновенно остановить электроны. Почти вся энергия электронов превращается в тепло, но некоторые превращаются в рентгеновское излучение, которое выходит через окно в основании трубки в виде рентгеновских лучей. Как делают рентгеновский снимок костей человеческого тела? Рентгеновский снимок – это изображение тени. Рентгеновские лучи проходят сквозь исследуемый участок тела и переносят на пленку тени исследуемого предмета. На обе стороны плёнки наносится светочувствительная эмульсия. После съёмки её проявляют как обычную фотопленку. Кости и другие предметы, не пропускающие лучи, выглядят на плёнке темнее. В настоящее время рентгеновские лучи широко используются в медицине, науке и промышленности, оказывая большую помощь человеку. В этот день в 1895 Немецкий физик Вильхэльм Конрад Рентген, профессор и ректор Вюрцбургского Университета, проводил эксперименты в университетской лаборатории и неожиданно открыл всепроникающие лучи. Статья Рентгена под названием 'О Новом Типе Лучей' была опубликована 28 Декабря 1895 в журнале Вюрцбургского Физико-Медицинского Общества. Однако уже доказано, что рентгеновские лучи были отрыты ещё до этого. Катодолучевая трубка, которую Рентген использовал в своих экспериментах, была разработана другими учёными – Хитторфом и Круксом. Именно при работе этой трубки возникают рентгеновские лучи, однако ни один из физиков не осознал значения этого открытия и не опубликовал своих результатов. Использование инспекционно-досмотровых комплексов (ИДК) стало в последние годы качественным прорывом в организации таможенного контроля и одним из ключевых технических средств в борьбе с контрабандой. В целях защиты экономических интересов и безопасности страны на таможенных постах теперь действуют мобильные и стационарные рентгеновские комплексы для проверки крупногабаритных грузов и транспортных средств.

(2) X-Ray is a method of inspecting containers or other cargo. High frequency electromagnetic ray of short wave-length, capable of penetrating most solid substances.

X–RAY = ЭКС.–РЭЙ – X-Ray (pronunciation:- ECKS-ray) or X is international nautical signal flag meaning:- Stop carrying out your intentions and watch for my signals. Individual Recall (Sailing Regatta). Meaning:- stop carrying out your intentions and watch for my signals.

X–RAY CRYSTALLOGRAPHY = РЕНТГЕНОСТРУКТУРНАЯ КРИСТАЛЛОГРАФИЯ – X-Ray Crystallography:- the use of diffraction patterns produced by X-ray scattering from crystals (of a given material's molecules) to determine the three-dimensional structure of the molecules. / Рентгеноструктурная Кристаллография – методика определения пространственной структуры молекулы.

X–RAY DIFFRACTION = ДИФРАКЦИЯ ИКС.–ЛУЧЕЙ (или ДИФРАКЦИЯ РЕНТГЕНОВСКИХ ЛУЧЕЙ) – X-Ray Diffraction:- a phenomenon in which the atoms of a crystal, by virtue of their uniform spacing, cause an interference pattern of the waves present in an incident beam of X rays. The atomic planes of the crystal act on the X rays in exactly the same manner as does a uniformly ruled grating on a beam of light. See also Bragg Law; and Laue Diffraction Pattern. / Закон Брэга (Bragg Law); и Ляуэ (Laue Diffraction Pattern). Дифракция Рентгеновских Лучей – рассеяние рентгеновских лучей кристаллическими объектами, при котором в определённых направлениях появляются дифрагированные пучки – результат интерференции вторичного рентгеновского излучения, возникающего при взаимодействии первичного излучения с электронными оболочками атомов. Направление и интенсивность дифрагированных пучков связаны с атомной структурой объекта (смотрите Рентгеновский Структурный Анализ; и Условие Брэга-Вульфа).

X–RAY SOURCE = ИСТОЧНИК ИКС.–ЛУЧЕЙ (или ИСТОЧНИК РЕНТГЕНОВСКИХ ЛУЧЕЙ) – X-Ray Source:- in astronomy, any of a class of cosmic objects that emit radiation at X-Ray wavelength. Because the Earth's atmosphere absorbs X Rays very efficiently, X-Ray telescopes and detectors must be carried high above it by spacecraft to observe objects that produce such electromagnetic radiation. Advances in instrumentation and improved observational techniques have led to the discovery of an increasing number of X-Ray sources. By the late XX century, thousands of these objects had been detected throughout the universe. The Sun was the first celestial object determined to give off X Rays; rocket-borne radiation counters measured X-Ray emissions from its corona (outer atmosphere) in 1949. The Sun, however, is an intrinsically weak X-Ray source, and it is prominent only because it is so close to the Earth. The unambiguous detection of X Rays from other more distant ordinary stars was achieved 30 years later by the orbiting HEAO 2 satellite known as the Einstein Observatory. It detected more than 150 ordinary stars by the X-Radiation from their coronas. The stars

observed cover almost the entire range of star-types – main sequence, red giants, and white dwarfs. Most stars emit only an extremely small fraction of their energy in the form of X Rays. Young, massive stars are the most powerful X-Ray emitters. They usually occur in nebulas, and their hot coronal gases can expand to make a nebula itself a detectable X-Ray source. A more powerful type of X-Ray source is a supernova remnant, the gaseous shell ejected during the violent explosion of a dying star. The first to be observed was the Crab Nebula, the remnant of a supernova explosion whose radiation reached the Earth in AD 1054. It is, however, a very atypical remnant because its X Rays are synchrotron radiation produced by high-speed electrons from a central pulsar. The X-Radiation from most other supernova remnants emanates instead from hot gas. The gases ejected by a supernova explosion are relatively cool, but as they sweep outward at a speed of several thousand kilometers per second they accumulate interstellar gas. The strong shock wave heats this gas to a temperature high enough for X-Ray emission – namely, about 10 000 000 K. The most powerful X-Ray sources in the Milky Way Galaxy are certain binary stars. These so-called X-Ray Binaries have an X-Ray output 1 000 times as great as the Sun's output at all wavelengths. X-Ray binaries account for most of the sources discovered during the initial years of X-Ray astronomy, including Scorpius X-1. A typical X-Ray binary source consists of a close double star system in which one member is a very compact object. This object may be a neutron star that contains approximately the mass of two Suns condensed into a sphere only about 20 km (12 mi) across, or alternatively an even more compact black hole, a collapsed star whose gravity is so strong that not even light can escape from it. As gas from the companion star falls toward the compact star, the latter swirls round into an accretion disk. Viscous processes in the disk convert the orbital energy of the gas into heat, and when sufficiently high temperatures are attained large amounts of X Rays are emitted. There are several types of X-Ray binaries. In an X-Ray pulsar, the gas is channeled to the poles of a neutron star and the radiation is given off as pulses in very regular periods. In objects known as bursters, a neutron star's magnetic field suspends the gas until the accumulated weight crushes the field temporarily and the falling gas emits a sudden burst of X Rays. A transient occurs in stellar pairs in which the orbit is elongated and gas is only transferred occasionally (i.e. when the component stars are closest together). Astronomers generally classify the compact object in an X-Ray binary as a neutron star unless its calculated mass exceeds three solar masses. In such cases, they identify the object as a black hole. Two very strong black hole candidates are Cygnus X-1 (six solar masses) and LMC X-3 (10 solar masses). Nearby galaxies (e.g., the Andromeda Galaxy) are detected by the emission from constituent X-Ray binaries. They are relatively weak sources compared to active galaxies, which fall into various categories such as radio galaxies, Seyfert galaxies, and quasars. These galactic types are all characterized by violent activity at their cores, usually explained as arising from an accretion disk of hot gases that surrounds a central black hole having a mass of about 1 000 000 000 Suns. The X-Ray energy of these galaxies is highly variable. The quasar OX 169, for example, has been observed to vary substantially in X-Ray output in less than two hours, implying that the region producing this radiation is less than two 'light-hours' across (i.e. smaller than the solar system). Other powerful extragalactic X-Ray sources are galaxy clusters. The X Rays from a cluster do not come from its member galaxies but rather from a pool of hot gas between them, which is kept within the cluster by the galaxies' combined gravitational pull. The gas is typically at a temperature of 100 000 000 K, and it may have originated as hot gas ejected by numerous supernovas. Finally, there is a diffuse background of X-Radiation emanating from great distances and from all directions. Although it was discovered in 1962, its nature is still unclear. Such X-Radiation could come from very tenuous gas that pervades the entire universe. Currently, however, most astronomers favor the idea that the background consists mainly of X Rays from numerous quasars too remote to be observed individually. / галактики Зайфэта (или Сейферта; Seyfert galaxies).

X–RAY STYLE = СТИЛЬ ИКС.–ЛУЧЕЙ (или СТИЛЬ РЕНТГЕНОВСКИХ ЛУЧЕЙ) – X-Ray Style:- manner of depicting animals by drawing or painting the skeletal frame and internal organs, one of the characteristic styles of the art of prehistoric hunting cultures. The origin of the style can be traced to the Mesolithic art of northern Europe, where the earliest examples were found on fragments of bone in southern France dating from the late Magdalenian Period. Animals painted in the X-ray motif have also been discovered in the art of hunting cultures in northern Spain, Siberia, the Arctic Circle, North America, western New Guinea, New Ireland, India, and Malaysia. It is found today primarily in the Aboriginal rock, cave, and bark paintings of eastern Arnhem Land, in northern Australia. Figures painted in X-ray style vary in size up to 8 feet (2.5 meters) in length and are delicate, polychromed renderings of the interior cavity of the animal. Images are known in which only the outline and skeleton of the bird, fish, or mammal are indicated, and the entire internal system of organs is expressed by a 'life line', a single, horizontal line that runs from the animal's mouth to a dot representing the heart or stomach. Whether the depiction of an animal in the X-ray style had particular religious symbolism is not known.

X–RAY TELESCOPE = ИКС.–ЛУЧЕВОЙ ТЕЛЕСКОП (или РЕНТГЕНОВСКИЙ ТЕЛЕСКОП) – X-Ray Telescope:- instrument designed to detect and resolve X rays from sources outside the Earth's atmosphere. Because of atmospheric absorption, X-ray telescopes must be carried to high altitudes by rockets or balloons or placed in orbit outside the atmosphere. Balloon-borne telescopes are used to detect the more penetrating (harder) X rays, whereas those carried aloft by rockets or in satellites are used to detect softer radiation. Several types of X-ray detectors have been used, involving Geiger counters, proportional counters, and scintillation counters. These detectors require a large collecting area, because celestial X-ray sources are remote and therefore weak, and a high efficiency for detecting X rays over the cosmic-ray-induced background radiation is needed. Reflecting X-ray telescopes are constructed so that the highly penetrating rays strike the reflective surface at a grazing angle. / счётчики Гайге (или счётчики Гейгера; Geiger counters).

X–RAY TUBE = ИКС.–ЛУЧЕВАЯ ТРУБКА (или РЕНТГЕНОВСКАЯ ТРУБКА) – X-Ray Tube:- also called Roentgen Tube, vacuum tube that produces X rays by accelerating electrons to a high velocity with a high-voltage field and causing them to collide with a target, the anode. Because X rays can penetrate solid substances to varying degrees, they are applied in medicine and dentistry, in the exploration of the structure of crystalline materials, and in research. The tube consists of a source of electrons, the cathode, which is usually a heated filament, and an anode, usually of tungsten, which is enclosed in an evacuated glass envelope. The X-ray tube functions on the principle that X rays are produced wherever electrons moving at very high speeds strike matter of any kind. The X-ray tube design that became the prototype for subsequent devices was invented by the American engineer William D. Coolidge in 1913. / Американский инженер Вилъйэм Ди. Кулыдьж (William D. Coolidge) в 1913. Рентгеновская Трубка – электровакуумный прибор для получения рентгеновских лучей. Простейшая рентгеновская трубка состоит из стеклянного баллона с впаянными электродами – катодом и анодом (антикатодом). Электроны, испускаемые катодом, ускоряются сильным электрическим полем в пространстве между электродами и бомбардируют анод. При ударе электронов об анод их кинетическая энергия частично преобразуется в энергию рентгеновского излучения.

X RECEPTOR = ИКС. РЕЦЕПТОР (или Х РЕЦЕПТОР) – X Receptor:- xxxxx. See also Farnesoid X Receptor (FXR), Liver X Receptors (LXR), and Retinoid X Receptors (RXR). / Икс. Рецептор – ретинойдный ядерный гормон, играющий важную роль в репродукции и дифференциации клеток.

XRT = EX–RIGHTS

XS = EXCESS

XS = EXTRA SMALL

XS PT = EXCESS POINT

X STRAP = СЛАНЦЫ (или С РЕМЕШКАМИ В ФОРМЕ БУКВЫ X) – X Strap is a strap that crosses into an X at the back.

X STRONG = EXTRA STRONG

X TABLE = ТАБЛИЦА ИКС. – X Table is a designation sometimes used to refer to an experimental table or a draft of a table that has not developed to a point of satisfaction or for actual use in rating. / Определение, используемое иногда для обозначения экпериментальной таблицы или проекта таблицы, которая не разработана до конца с точки зрения удовлетворённости или для настоящего использования в тарификации.

XTF = EXCHANGE TRADED FUNDS

X–TRISOMY = ИКС.–ТРИСОМИЯ (или ЭКС.–ТРАЙСОМИЯ) – X-Trisomy:- sex chromosome disorder of human females, in which three X chromosomes are present, rather than the normal pair. More common than Turner's Syndrome, where only one X chromosome is present, X-trisomy usually remains undetected because affected individuals appear normal, experience puberty, and are usually fertile. Statistical studies suggest a slightly increased frequency of mental disturbance, retardation, or both. / Синдром Тчонёра (или Синдром Тёрнера) (Turner's Syndrome).

XW = EX–WARRANTS

XW = WITHOUT WARRANTS

XW = ЭКС.ДАБЛ.Ю. – XW or X-W is a symbol indicating that a stock is trading ex-warrants, with no warrants attached. See also Ex-Warrants. XW or X-W:- ex warrants in bond and stock listings of newspapers. / Экс.Дабл.Ю. – символ в Англоязычных средствах массовой информации, указывающий на то, что акция торгуется без варрантов (ex-warrants), то есть варранты к ней не преложены. 'Без Варрантов' (в приводимых в газетах перечнях акций и облигаций).

X–WARR = EX–WARRANTS

XX HEAVY = DOUBLE EXTRA HEAVY

XXL = EXTRA EXTRA LARGE

XXS = EXTRA EXTRA SMALL

XX STRONG = DOUBLE EXTRA STRONG

XXXL = 3XL = EXTRA EXTRA EXTRA LARGE

XYLAN = КСИЛАН – Xylan is a yellow water-soluble gummy polysaccharide component of the hemicellulose of woody tissues, made from (1–4) linked xylose monomers. Derivatives may have arabinose (arabinoxylan) or 4-O-methylglucuronic acid (glucuronoxylan) side chains. / Ксилан – жёлтый растворимый в воде гумми полисахаридный компонент гемицеллюлозы древесных тканей, сделанный из (1–4) связанных мономеров ксилозы. Производные могут иметь арабинозу (арабиноксилан) или 4-О-метилглюкуроновую кислоту (глюкуроноксилан) боковые цепи или побочные цепи или ответвления (side chains).

XYLEM = КСИЛЕМА (или ДРЕВЕСИНА) – Xylem is the non-living tissue in plants that functions primarily to conduct water and mineral nutrients from roots to the shoot. Tissue that conducts water and nutrients from the roots up through the plant. In botany, Xylem is a part of the vascular system that conveys water and dissolved minerals from the roots to the rest of the plant and may also furnish mechanical support. Xylem consists of specialized water-conducting tissues made up mostly of narrow, elongated, hollow cells. These cells may be of several types, including tracheids (the basic cell type), vessel members, fibers, and parenchyma. Xylem constitutes the major part of a mature woody stem or root; the wood of a tree is composed of xylem. Xylem formation begins when the actively dividing cells of growing root and shoot tips (apical meristems) give rise to primary xylem. As the growing part of the plant builds past the xylem thus formed, the vascular cambium produces secondary xylem tissues that cover the primary xylem. When this happens the primary xylem cells become dead and empty, losing their conducting function and forming a hard skeleton that serves only to support the plant. Thus, in the trunk and older branches of a large tree only the outer part of the wood (secondary xylem) serves in water conduction, while the inner part (heartwood) is composed of dead but structurally strong primary xylem. Xylem is the supporting and water-conducting tissue of vascular plants; plant tissue consisting primarily of tracheids and vessels; woody tissue. Xylem is the main upward water-conducting tissue in vascular plants characterized by tracheary elements. Xylem may also be a supporting tissue, especially secondary xylem (wood). / Ткань, которая проводит воду и питательные вещества от корней по всему растению. Под Ксилемой, от Греческого слова Xýlon, означающее Срубленное Дерево, понимается комплекс тканей в высших растениях, служащий для передвижения воды и растворов минеральных солей и других веществ от корней к листьям и другим органам ('восходящий ток') и выполняющий также механические и запасающие функции. Образуется из прокамбия (первичная ксилема) или камбия (вторичная ксилема, называемая также иногда Древесиной). Ксилема состоит из проводящих элементов (сосудов, трахеид), механических тканей (либриформ или древесинных волокон) и основных тканей (паренхима). Из перерезанных сосудов (ксилемы) стеблей или корней растений под действием корневого давления вытекает жидкость (пасока), в которой содержатся аминокислоты, органические кислоты, соли и другие вещества. Стенки клеток проводящих и механических элементов ксилемы лигнифицируются (одревесневают). Ксилема располагается сплошным кольцом (на поперечном срезе стебля) или в проводящих пучках (вместе с флоэмой). У древесных растений часто всю ксилему называют Древесиной, она у них составляет основную массу ствола, корней и ветвей. Характерна для всех Папоротникообразных и семенных растений, объединяемых в группу сосудистых растений. Ксилема или Древесина – комплекс тканей растения, выполняющих проводящие, механические и запасающие функции. Древесина составляет основную массу ствола, корней, ветвей дерева. В стволе древесина расположена между сердцевиной и корой. Различают древесину Хвойных (Сосны, Ели и других) и Лиственных (Дуба, Берёзы и других) пород. Срубленная древесина представляет совокупность оболочек растительных клеток. Элементный химический состав древесины всех пород практически однаков; она содержит 49–50% углерода; 43–44% кислорода; 6% водорода; 0.1–0.3% азота. Древесина состоит из 39–58% целлюлозы, 17–34% лигнина и 15–38% гемицеллюлоз. Древесина – анизотропный, гигроскопичный материал; содержит связанную и свободную (в полостях клеток) воду; усыхает, разбухает, коробится. Декоративность (цвет, блеск, текстура), прочность (при малой плотности), ударная вязкость, твёрдость, деформативность, акустические, тепловые и другие физико-механические свойства определяют широкое применение древесины в качестве конструкционного и поделочного материала. Древесина используется как сырьё для получения целлюлозы и других химических продуктов, а также как топливо.

XYLENE = КСИЛЕН (или ЗАЙЛИН) – Xylene is any of three isomeric dimethylbenzenes (which have the same chemical formula, $C_6H_4(CH_3)_2$, but different molecular structure), used as solvents, as components of aviation fuel, and as raw materials for the manufacture of dyes, fibers, and films. The three isomers, designated ortho (o), meta (m), and para (p), differ structurally only in the location of the methyl groups. All three are obtained from coal-tar distillate and petroleum as a mixture containing 50–60 percent by

volume of m-xylene and 20–25 percent of each of the other isomers. Fractional distillation of the mixture removes the meta and para isomers, which have very similar boiling points, from the less volatile ortho isomer. Upon cooling the mixture of meta and para isomers, much of the p-xylene crystallizes in nearly pure form. The meta isomer, the principal component of the remaining liquid, then can be purified by taking advantage of its solubility in a mixture of hydrofluoric acid and boron trifluoride. Meta- and para-xylene undergo nitration and reduction to give xylidines, used in making dyes. The meta isomer also is converted to trinitro-t-butyl-m-xylene, or xylene musk, a component of perfumes. Oxidation of the xylenes gives monocarboxylic acids (toluic acids), and then dicarboxylic acids (phthalic acids). The commercial xylene mixture is a colorless, nonviscous, flammable, toxic liquid that is insoluble in water but miscible with many organic liquids. Xylene is commonly used as a solvent for lacquers and rubber cements. Xylene is a major aromatic feedstock usually obtained from petroleum or natural gas distillates. Used in the manufacture of plastics and synthetic fibers as a solvent, and in the blending of gasoline. Xylene ($C_6H_4(CH_3)_2$) is a colorless liquid of the aromatic group of hydrocarbons made by the catalytic reforming of certain naphthenic petroleum fractions. Used as high-octane motor and aviation gasoline blending agents, solvents, chemical intermediates. Isomers are metaxylene, orthoxylene, paraxylene. / Дробная Перегонка или Фракционная Перегонка (Fractional Distillation). Ксилен ($C_6H_4(CH_3)_2$):- бесцветная жидкость из ароматической группы углеводородов, произведённая каталитическим риформингом определённых нафтеновых фракций нефти. Используется в качестве смешивающихся агентов для высокооктанового автомобильного и авиационного бензина, растворителей и химических промежуточных продуктов. Изомерами являются метаксилен (metaxylene), ортоксилен (orthoxylene) и параксилен (paraxylene). Ксилен или Диметилбензен (dimethylbenzene) – жидкость, которая применяется для увеличения прозрачности тканей в процессе их подготовки к микроскопическому исследованию после дегидратации.

XYLOID COAL = КСИЛОИДНЫЙ УГОЛЬ (или ДРЕВЕСНЫЙ УГОЛЬ) – Xyloid Coal is a brown coal or lignite mostly derived from wood. Xyloid Coal, also known as Lignite, often referred to as Brown Coal, is a soft brown fuel with characteristics that put it somewhere between coal and peat. / от Греческого слова Xýlon, означающее Срубленное Дерево, понимается . Древесный Уголь – твёрдый пористый высокоуглеродистый продукт, образующийся при нагревании древесины без доступа (или при незначительном доступе) воздуха в печах и ретортах. Теплота сгорания древесного угля 30 000–35 000 кДж/кг (7 000–8 100 ккал/кг). Плотность берёзового угля 380 кг/м^3, менее плотные угли дают сосна (300 кг/м^3) и ель (260 кг/м^3). Большая пористость древесного угля обусловливает его высокие адсорбционные свойства. При выгрузке из печей и реторт влажность древесного угля составляет 2–4%; при хранении она повышается до 7–15%. Зольность древесного угля должна быть не более 3%, содержание летучих – не более 20%. Особенность древесного угля – низкое содержание таких примесей, как фосфор и сера, что делает его необходимым для некоторых металлургических процессов. Древесный уголь широко применяют в производстве кристаллического кремния, сероуглерода, активного угля, электроугольных изделий и другого, а также как топливо в быту. В настоящее время активно развивается рынок древесного угля, используемого для приготовления пищи на мангалах в предприятиях общественного питания и на отдыхе. Это обусловлено рядом его неоспоримых преимуществ перед традиционными видами топлива:- отсутствие трудозатрат по подготовке, высокая теплоотдача, продолжительное время горения, экономичность, бездымность, компактность при хранении, повышенная пожаробезопасность и другие. Древесный Уголь, твёрдый пористый высокоуглеродистый продукт, образующийся при пиролизе древесины. Применяется в производстве кристаллического кремния, сероуглерода, активного угля и так далее, а также как топливо в быту (теплота сгорания 30–35 МДж/кг). Древесный Уголь представляет собой уникальный материал, состоящий почти полностью из химического вещества углерода, который, как известно, лежит в основе всей земной жизни. Бизнес по производству и продаже древесного угля давно известен и популярен. Сырьём для производства древесного угля обычно служат различные древесные отходы, неделовая древесина, например береза, также уголь можно делать из заранее брикетированной биомассы, например опилочных, торфяных и других брикетов, изготовленных на оборудовании обеспечивающих достаточную плотность при прессовании (не менее 1.2 кг/дм^3). Современная, экологически безопасная, технология производства древесного угля основана на применении углевыжигательных печей ретортного типа. Основной принцип работы таких печей состоит в том, что дрова помещаются в печь в выемных ретортах, имеющих специальные устройства для отвода парогазов в топку. Таким образом, выделяющиеся из древесины при нагреве пиролизные газы уходят в топку и там сжигаются, давая необходимый нагрев для работы установки. Применения древесного угля многообразны и розничные продажи на шашлыки лишь самое известное из его применений. Древесный уголь используется также:- в металлургической промышленности – древесный уголь исторически применяется в металлургической промышленности как восстановитель (позволяет отделить металл от руды). Его состав уникален – от любых других восстановителей древесный уголь отличается полным отсутствием серы и фосфора, присутствие которых меняет свойства восстановленных материалов. Хотя сегодня такие потребители как доменное производство, производство ферросплавов пользуются более дешёвыми восстановителями, получить, например, ковкий чугун, возможно только с применением древесного угля. Рост на мировых биржах цен на кокс выводит вновь на рынок металлургии древесный уголь, который кстати использовался для этих целей с древнейших времен и вплоть до последнего времени, например в Демидовских печах. Использование в качестве сырья при производстве угля предварительно забрикетированной биомассы даёт возможность получить продукцию стабильного высшего качества, независимо от изначальных пород древесины и фракционного состава исходного сырья. Это делает возможным поставлять металлургам промышленными партиями восстановитель превосходящий по качеству каменноугольный кокс. Древесный уголь используют также и как покровный флюс при выплавке ряда видов бронзы и латуни, никелевых сплавов (мельхиор, нейзильбер) Исключительно древесный уголь применяется при производстве кристаллического кремния для радиоэлектронной промышленности. В этом случае восстановитель должен быть особенно чистым, чтобы обеспечивать диэлектрические свойства кремния. Высокие требования по чистоте предъявляются и к кремнию, используемому при выплавке кремнистых бронз, силумина и других кремнистых сплавов. И в этом случае для производства кремния используется в основном древесный уголь. Сероуглерод CS_2 используется в производстве искусственного волокна, вискозного шинного корда, целлофана, в ряде химических синтезов, в частности, при выработке ядохимикатов. Один из наиболее распространённых в промышленности методов получения сероуглерода состоит в пропускании паров серы через слой раскалённого древесного угля. Расход угля составляет 0.2 … 0.3 т/т сероуглерода. Производство активированных углей:- активные угли применяют для улавливания паров многих растворителей из воздуха вентиляционных систем и промышленных помещений, для задержания находящихся в воздухе вредных и ядовитых примесей (в промышленных и боевых противогазах). В медицине и сельском хозяйстве:- сорбционные свойства угля используются при лечении некоторых отравлений и желудочно-кишечных заболеваний. В медицинских целях из него изготавливают таблетки или порошки для приёма внутрь. В сельском хозяйстве измельчённый древесный уголь вводят в рацион птиц, свиней, молодняка крупного рогатого скота. Угольную пыль вводят в почву при посадке корнеплодов и луковичных. Для бытовых целей:- в последние годы применение древесного угля для бытовых целей сильно возросло и имеет тенденцию и дальнейшему росту. Его применяют в барбекю, шашлычницах, грилях, каминах, камельках. Требования к углю для быта в разных странах отличаются и следует отметить, что в некоторых культурах (Восточных) потребление угля на душу населения на порядки превышает Российское, также древесный уголь имеет значительный вывозной (или экспортный) потенциал.

XYLOSE = КСИЛОЗА – Xylose (Greek:- Xýlon = Wood) is a white crystalline pentose (five-carbon) sugar isomeric with ribose, produced by hydrolysis or fermentation of xylans in straw or wood and an important dietary constituent of herbivores. Used in foods for diabetics as it can not be metabolized by humans. Non-fermentable by normal yeast. Also known as Wood Sugar. / Под Ксилозой, от Греческого слова Xýlon, означающее Срубленное Дерево, понимается белый кристальная пентоза (пятиуглеродный сахар), изомерная с рибозой, производимой гидролизом или ферментацией ксилана в соломе или древесине и важная диетическая составляющая травоядных. Известна также как Древесный Сахар (Wood Sugar). Ксилоза, моносахарид, одна из четырёх изомерных альдопентоз, $C_5H_{10}O_5$. Подробнее смотрите Сахара.

YACHT = ЯХТА – A Yacht is a recreational boat or ship. The term originates from the Dutch word Jacht 'Hunt', and was originally defined as a light fast sailing vessel used by the Dutch navy to pursue pirates and other transgressors around and into the shallow waters of the Low Countries. After its selection by Charles II of England as the vessel to carry him to England from the Netherlands for his restoration in 1660 it came to be used to mean a vessel used to convey important persons. In modern use of the term, yachts differ from working ships mainly by their leisure purpose. There are two different classes of yachts:- sailing and power boats. With the rise of the steamboat and other types of powerboat, sailing vessels in general came to be perceived as luxury, or recreational vessels. Later the term came to encompass large motor boats for primarily private pleasure purposes as well. Yacht lengths normally range from 10 meters (m) (33 feet (ft)) up to dozens of meters (hundreds of feet). A luxury craft smaller than 12 m (39 ft) is more commonly called a Cabin Cruiser or simply a Cruiser. A superyacht generally refers to any yacht (sail or power) above 24 m (79 ft) and a Megayacht generally refers to any yacht over 50 m (164 ft). This size is small in relation to typical cruise liners and oil tankers. Yacht is a medium or large luxury sailboat or ship that is used to cruise around or race. A medium-sized boat that is used to sail from port to port in the Mediterranean is an example of a yacht. Yacht is any of various relatively small vessels designed primarily for pleasure cruising. Origin of yacht:- Dutch Jacht, earlier Jaghte, short for Jaghtschip, Pursuit Ship (i.e. against pirates); from Jaght, a Hunt; from Jagen, to chase + schip, a ship; to sail or cruise in a yacht. Yacht is a Any of various relatively small, streamlined sailing or motor-driven vessels used for pleasure cruises or racing. Origin of yacht:- probably obsolete Norwegian Jagt, from Middle Low German Jacht, short for Jachtschip:- Jagen, To Chase (from Old High German Jag & omacron; n) + Schip, Ship. A Yacht is an upscale boat – often a sailboat – that is used for cruising or racing. If you're on a cargo ship, you're probably at work; if you're on a yacht, it's probably your day off. While today a yacht is usually a pleasure vessel, and associated with wealth and recreation, its origins are anything but:- the word Yacht comes from the early modern Dutch Jaghtschip, which referred to 'A Fast Pirate Ship', and Jacht meant 'Hunting'. You won't find many yachts doing any hunting today – but you might find one cruising around the bay or parked at the yacht club. Yacht can also be a verb meaning to travel in a yacht. Yacht is an expensive vessel propelled by sail or power and used for cruising or racing. Yacht is any of various recreational watercraft:- such as:- (a) a sailboat used for racing; or (b) a large usually motor-driven craft used for pleasure cruising. Yacht is a vessel used for private cruising, racing, or other noncommercial purposes. Yacht:- a sail- or power-driven vessel, usually light and comparatively small, used for racing or for recreation. In recreation the term applies to very large craft, originally powered by sail and later by steam or internal-combustion engines. It is in this sense that the generality of nonyachting (nonsailing) people usually think of the term. Technically, the word yacht excludes boats propelled by paddles, oars, or outboard motors. Also, recreational powered craft below the largest size are usually called Cabin Cruisers (see Motorboat). The English word Yacht and the equivalent word in many European languages comes from the Dutch use in the XVI and XVII centuries of the word Jaght, later Jacht, which, with the word Schip added, meant 'Ship For Chasing'. Yachting And Yacht Clubs:- as the Dutch rose to preeminence in sea power during the XVII century, the early yacht became a pleasure craft used first by royalty and later by the burghers on the canals and the protected and unprotected waters of the Low Countries. Racing was incidental, arising as private matches. English yachting began with King Charles II of England during his exile in the Low Countries. On his restoration to the English throne in 1660, the city of Amsterdam presented him with a 20-meter (66-feet) pleasure boat with a beam (maximum width) of 5.6 m (18 feet), which he named Mary. Charles and his brother James, the duke of York (James II, reigned 1685–88), built other yachts and in 1662 raced two of them for a £100 wager on the Thames from Greenwich to Gravesend and back. Yachting became fashionable among the wealthy and nobility, but at that time the fashion did not last. The first yacht club in the British Isles, the Water Club, was formed about 1720 at Cork, Ireland, as a cruising and unofficial coast guard organization, with much naval panoply and formality. The closest thing to a race was the 'chase', when the 'fleet' pursued an imaginary enemy. The club persisted, largely as a social club, until 1765 and in 1828 became, after merging with other groups, the Cork Yacht Club (later the Royal Cork Yacht Club). Yacht racing began in some organized fashion on the Thames about the mid-XVIII century. The duke of Cumberland founded the Cumberland Fleet for Thames racing in 1775. When George IV came to the throne in 1820, it came to be called the Fleet to His Majesty's Coronation Sailing Society. The Thames Yacht Club seceded after a racing dispute to become the Royal Thames Yacht Club in 1830. The first English yacht club had been formed at Cowes on the Isle of Wight in 1815, and royal patronage made the Solent, the strait between the mainland and the Isle of Wight, the continuing site of British yachting. The club at Cowes became the Royal Yachting Club, again at the accession of George IV. All

members were required to own boats of at least 20 tons (20 321 kg). Sailing matches for large stakes were held, and the social life was splendid. Ultimately Royal Yachting Club boats increased in size to more than 350 tons. In North America yachting began with the Dutch in New York in the XVII century and continued when the English gained control. Sailing was mostly for pleasure and reached its apogee in George Crowninshield's Cleopatra's Barge (1815), which cruised on the Mediterranean Sea and set a standard of luxury and elegance for the later yachts in those waters from the late XIX century. The first continuing American yacht club, the Detroit Boat Club, was formed in 1839. In 1844 John C. Stevens founded the New York Yacht Club aboard his schooner Gimcrack. Kinds Of Sailboats:- early sailing yachts followed the lines of such naval craft as brigantines, schooners, and cutters from the XVII century until the second half of the XIX century. The design of large yachts was first greatly affected by the success of America, which was designed by George Steers for a syndicate headed by John C. Stevens and was the boat for which the America's Cup was named after its victory at Cowes in 1851. Early yachts were not designed and built in the modern sense, only a model being used. Not until the second half of the XIX century did what was called Naval Architecture come into being. Not until the 1920s did the application of the science of aerodynamics do for the design of sails and rigging what science had earlier done for hulls. Because nearly all sailboats were individually custom-built, there arose a need for handicapping boats before the one-design class boats were built. Thus, a rating rule came into being, which resulted in the International Rule, adopted in 1906 and revised in 1919. Today, one of the fastest growing areas in the field of sailing is that of one-design class boats. All boats in a one-design class are built to the same specifications in length, beam, sail area, and other elements (for an example of a two-person sailboat). Racing between such boats can be held on an even basis with no handicapping necessary. A prime example is the uniform International America's Cup Class adopted for participants in the 1992 America's Cup race. So long as yachting belonged primarily to the royal and the rich, cost was no object, and the size of boats increased, in both length and weight. The promotion and popularity of smaller craft came in the second half of the XIX century from the sailing of the Englishmen Richard Turrill McMullen, a stockbroker, and Edward Frederick Knight, a barrister and journalist. A voyage around the world (1895–98) sailed single-handedly by the naturalized American captain Joshua Slocum in the 11.3-meter Spray demonstrated the seaworthiness of small craft. Thereafter in the XX century, notably after World War II, smaller racing and recreational craft became more common, down to the dinghy, a favourite training boat, of 3.7 m. In the late XX century boats of less than 3 m were sailed single-handedly across the Atlantic Ocean. Kinds Of Power Yachts:- after the decade 1840–50, when steam began to replace sail power in commercial vessels, the steam engine and, later, the internal-combustion engine were increasingly employed in pleasure vessels. Large power yachts were developed to a high degree, and long-distance cruising became a favourite pastime of the rich. The earliest power yachts were paddle-wheel boats; these then gave way to those powered by the completely submerged screw or propeller type of propulsion. As in the case of naval and merchant vessels, auxiliaries carrying both sail and power were the yacht fashion for a number of years. By the second half of the XX century many yachts were still auxiliaries, but the majority were exclusively power yachts containing gasoline or diesel engines. During the last decade of the XIX century there was a boom in the construction of large steam yachts. Conspicuous among these was the Mayflower (1897) of 2 690 tons, containing triple-expansion engines, twin screws, and a compartmented iron hull and manned by a crew of more than 150. The Mayflower, purchased by the United States Navy in 1898, was the official yacht of the president of the United States until 1929 and saw active service during World War II. As larger and more reliable internal-combustion engines were produced, many large yachts began using them for power. The development of the diesel engine, using heavy oil for fuel, advanced during World War I; and, in the decade that followed, large power-yacht building flourished, reaching a climax in the Orion (1930), 3 097 tons. During that period the largest auxiliary yacht built was the four-masted, steel, barque-rigged Sea Cloud (1931), 2 323 tons. The building of large power yachts declined after 1932, and the trend thereafter was toward smaller, less expensive craft. After World War II, many small naval vessels were sold to private owners for conversion to yachts. By the late XX century yachting had become a widespread popular sport enjoyed by thousands of yachtsmen personally manning and maintaining their own small pleasure craft. The number of yachts and yachtsmen increased steadily, not only in the traditional areas along the seacoasts but also on inland waterways and lakes. Racing Clubs:- in England by 1881 most of the important yacht clubs had become members of the Yacht Racing Association (founded 1875; from 1952 called the Royal Yachting Association). The organization made rules governing regatta sailing and later took on duties as a representative body for all British yachting, including dealing with port, harbour, and other governmental authorities. In the United States, where there is much freshwater sailing, yacht clubs were founded between 1849 and 1880 at New Orleans, State of Louisiana; Detroit, State of Michigan; Boston, State of Massachusetts; San Francisco, State of California; Marblehead, State of Massachusetts; Oyster Bay, State of New York; Chicago, State of Illinois; and Larchmont, State of New York. By the late XX century there were approximately 1 500 active yacht clubs in the United States. The Royal Canadian Yacht Club was founded in 1852, and the Australian Yacht Squadron (later the Royal Sydney Yacht Squadron) in 1862. Yacht clubs were founded in a number of countries throughout the world. The North American Racing Union was formed in 1925. A need for a body to set international racing rules and classes resulted in the founding of the International Yacht Racing Union (IYRU) in 1907. Yachting organizations with specialized interests also arose, including the Cruising Club of America (founded 1922) and the Royal Ocean Racing Club (founded 1925), both of which are active in offshore and ocean racing. Many other specialized organizations were formed for preparing charts and offering challenge cups for small sailing craft. During the second half of the XX century, many organizations were formed for boats of one class and design. Olympic Games:- the yacht races held in every Olympic meet since 1900, except for 1904, illustrate the general tendency in the period toward smaller boats and, after mid-century, the increasing popularity of one-class racing. Earlier Olympics included races for boats of various sizes and weights. The difficulty and expense of freighting boats and the increasing difficulty of recruiting large amateur crews often led to host countries winning the most races, sometimes by default. After World War II, the number of classes stabilized and the size of boats shrank. There were usually five classes, with 5.5-meter boats predominating, which included a monotype (one-person crew), a two-person centerboard boat, a two-person keeled boat, a three-person one-design boat, and a development boat. Certain models might not appear in Olympic competition one year but again be used in later games. Classes are named by the International Olympic Committee based on recommendations made by the IYRU. Windsurfing was added to the Olympic program in 1984. Courses:- sailboat races are held over two kinds of courses:- point-to-point and closed. Most ocean racing is point-to-point, as in transoceanic races, global circumnavigation, the Bermuda Race (first raced in 1906 from Newport to Bermuda), and the Transpacific Race (first raced in 1906 from California to Hawaii). Such offshore races as the America's Cup and the Fastnet Cup are closed course and point-to-point, respectively. The One Ton Cup, first raced in 1907, came to include both closed course and point-to-point races. Small boat races, on both inland water and inshore oceanic waters, are usually sailed on closed courses, most commonly triangular. Transatlantic racing And Global Circumnavigation:- ocean racing began in 1866 with a match race held under NYYC rules from Sandy Hook, State of Connecticut, the United States, to Cowes, Isle of Wight, England, the United Kingdom, by three schooners of 32- to 32.6-meter length:- Fleetwing, Vesta, and Henrietta. Henrietta, owned by the American newspaper publisher James Gordon Bennett, won in 13 days of sailing. The first single-sailor transatlantic voyage was made in a 6-meter boat by Alfred Johnson in 1876 to commemorate the centenary of US independence. The first single-handed race in 1891 was won by the American sailor Si Lawlor. A series of single-handed races, sponsored by the London Observer, began in 1960 and was held quadrennially thereafter. It was in these races that Francis Chichester (later Sir Francis Chichester) attracted attention. Interest in sailing around the world was greatly stimulated by his lone voyage around the world in 1966–67. Circumnavigation races included the Golden Globe Race, sponsored by the Sunday Times of London in 1968, and races later

organized by the Royal Naval Racing Association and held quadrennially from 1973. The introduction of self-steering gear did much to facilitate such racing. YACHT POLICY = ПОЛИС НА ЯХТУ – The Yacht Policy covers pleasure craft, such as yachts, motorboats and sailboats. It is written to cover both the property (boat, and contents) and its liability for collisions or injuries. There are two Yacht Hull Policies. The Limited Hull Policy will only cover the specified perils of fire, lightning and theft. The Full Marine Policy additionally covers explosions, perils of the sea, theft, collision and conversion. The Yacht Policy can also be written as all-risk coverage, in some cases. Like homeowners' all-risk policies, all hazards are covered unless specifically excluded. The perils generally excluded are wear and tear, gradual deterioration, or inherent vice, marine borers, vermin, loss caused by ice or freezing while afloat, loss to sails while racing, and petty theft or mysterious disappearance losses. / Под Страхованием Яхт обычно понимается страхование таких прогулочных судов, как моторные и парусные яхты, моторные катера и большие лодки. Страховой полис составляется таким образом, чтобы обеспечить страховое покрытие как имущества (плавсредство и его содержимое), так и ответственности за столкновение с другими объектами и травм пассажирам и экипажу. Страхование яхт, как специальный вид страхования, обычно применяется для стахования любого плавсредства длиной примерно 26 футов. Согласно общепринятым канонам, под 'Лодкой или Катером' подразумевают плавсредство длиной до 26 футов, а под 'Яхтой' – от 27 футов и более. Страхование рисков применительно к яхтам обычно шире и более специализировано, так как яхты предназначены для плавания в международных водах и на более удалённых от берега расстояниях, чем лодки или катера. Если вы владеете яхтой, то вам совершенно необходимо позаботиться о приобретении страховки на яхту с так называемым 'факультативным' страхованием или страхованием от всех рисков, включающем страхование корпуса, механизмов, мебели, навигационного оборудования и всех такелажных устройств, необходимых для управления и обслуживания яхты. Страховой Полис На Яхту состоит из двух основных частей – страхование корпуса и механизмов и страхование рисков судовладельца от ущерба ненесённого третьим лицам. Страхование корпуса и механизмов представляет собой страхование прямого ущерба от всех рисков, обеспечивающее весьма широкое страховое покрытие. Оно включает в себя согласованную сумму выплаты за корпус, то есть в этом случае все стороны в момент подписания полиса согласовали стоимость судна, и именно эта стоимость будет выплачена в случае полной утраты судна. В страховой полис на яхту включаются страховое покрытие расходов по замене частично повреждённых элементов оборудования, за исключением парусов, парусины, аккумуляторных батарей, подвесных двигателей и такелажного оборудования. Страхование рисков судовладельца от ущерба нанесённого третьим лицам включает в себя:- ущерб, нанесённый судам третьих лиц, ущерб, нанесённый плавучим и неподвижным объектам в результате столкновений, ущерб жизни и здоровью третьих лиц и ущерб, причинённый окружающей среде. В число исключений страхового полиса на яхту обычно входит:- обычный износ, постепенное ухудшение технических параметров, порчу, вмятины, царапины, повреждения наносимые животными, осмос, вздувание краски, электролиз, дефекты производства, дефекты проектирования, дефекты полученные в результате эксплуатации в ледовых условиях и обмерзания.

YAHOO! = ЯХУ! – Yahoo! is an Internet portal that incorporates a search engine and a directory of World Wide Web sites organized in a hierarchy of topic categories. As a directory, it provides both new and seasoned Web users the reassurance of a structured view of hundreds of thousands of Web sites and millions of Web pages. It also provides one of the best ways to search the Web for a given topic. Since Yahoo is associated with the most popular Web search sites, if a search argument doesn't lead to a Yahoo topic page, it will still lead to results from the six or seven popular search engine sites Yahoo links to. Yahoo! began as the bookmark lists of two Stanford University graduate students, David Filo and Jerry Yang. After putting their combined bookmark lists organized by categories on a college site, the list began to grow into an Internet phenomenon. It became the first such directory with a large following. Filo and Yang postponed their graduate work and became part of a public offering for a multimillion dollar corporation. As of October, 2005, Yahoo was serving approximately 3.4 billion page views worldwide. According to the site's official FAQ (frequently asked questions) list, Yahoo stands for 'Yet Another Hierarchical Officious Oracle'. Yahoo!:- an unrefined and often loud or disruptive person. Yahoo is a member of a race of brutes in Swift's Gulliver's Travels who have the form and all the vices of humans. / Яху! (Yahoo!) – название крупнейшего поискового сервера в Интернет, выросшего в одну из наиболее посещаемых страниц. Типично Американская 'история успеха' двух недоучившихся студентов, начавших бизнес в гараже и ставших мультимиллионерами. Вообще говоря, как зарегистрированная товарная марка, термин переводу не подлежит, но за ним стоит очень характерный пример неформального подхода к названиям Веб-страниц. В Английском, это слово представляет собой восклицание типа Русского 'Оба-на!', но также может означать хамоватое, невоспитанное и вообще недостойное создание вроде 'еху', описанных Свифтом в 'Путешествиях Гулливера'. Сами же основатели компании объявили о том, что оно представляет собой аббревиатуру от Yet Another Hierarchical Officious Oracle, что можно перевести как 'И ещё один иерархический оракул, навязчиво предлагающий свои советы'.

YAK = ЯК – Yak is a long haired wild or domesticated ox of Tibet and adjacent elevated parts of Central Asia. Yaks provide three kinds of hair for use in fabric. The coarsest is belly hair, and is used to make tent fabric and cushions for yak-saddles. The medium-grade is from the sides and back of the Yak, and is used to make saddlebags, storage covers, and blankets. The softest grade is from the neck of the Yak. It is very soft and has been likened to cashmere. Yak wool weaves into fabrics that are extremely warm, lightweight, and very durable. Yak hair is mostly black, though there is always some amount of white and gray hair. Yaks produce thick leather and Yak horns are sometimes used for buttons. Yak (Bos grunniens):- long-haired, short-legged oxlike mammal that was probably domesticated

in Tibet but has been introduced wherever there are people at elevations of 4 000–6 000 meters (14 000–20 000 feet), mainly in China but also in Central Asia, Mongolia, and Nepal. Wild yaks are sometimes referred to as a Separate Species (Bos mutus) to differentiate them from domestic yaks, although they are freely interbred with various kinds of cattle. Wild yaks are larger, the bulls standing up to 2 meters tall at the shoulder and weighing over 800 kg (1 800 pounds); cows weigh less than half as much. In China, where they are known as 'Hairy Cattle', yaks are heavily fringed with long black hair over a shorter blackish or brown undercoat that can keep them warm to –40 °C (–40 °F). Color in domesticated yaks is more variable, and white splotches are common. Like Bison (Genus Bison), the head droops before high massive shoulders; horns are 80 cm (30 inches) long in the males, 50 cm in females. It is not known with certainty when yaks were domesticated, although it is likely that they were first bred as beasts of burden for the caravans of Himalayan trade routes. Yaks' lung capacity is about three times that of cattle, and they have more and smaller red blood cells, improving the blood's ability to transport oxygen. Domesticated yaks number at least 12 million and were bred for tractability and high milk production. Yaks are also used for plowing and threshing, as well as for meat, hides, and fur. The dried dung of the yak is the only obtainable fuel on the treeless Tibetan plateau. Ruminant grazers, wild yaks migrate seasonally to the lower plains to eat grasses and herbs. When it gets too warm, they retreat to higher plateaus to eat mosses and lichens, which they rasp off rocks with their rough tongues. Their dense fur and few sweat glands make life below 3 000 meters difficult, even in winter. Yaks obtain water by eating snow when necessary. In the wild, they live in mixed herds of about 25, though some males live in bachelor groups or alone. Yaks seasonally aggregate into larger groups. Breeding occurs in September–October. Calves are born about nine months later and nursed for a full year. The mother breeds again in the fall after the calf has been weaned. Wild yaks once extended from the Himalayas to Lake Baikal in Siberia, and in the 1800s they were still numerous in Tibet. After 1900 they were hunted almost to extinction by Tibetan and Mongolian herders and military personnel. Small numbers survive in northern Tibet and the Ladakh steppe of India, but they are not effectively protected. They are also endangered because of interbreeding with domestic cattle. In the Family Bovidae, the yak belongs to the same genus as cattle as well as the Banteng, Gaur, and Kouprey of Southeast Asia. More distantly related are the American and European bison. Bos and Bison diverged from Water Buffalo (Genus Bubalus) and other wild bovines about three million years ago. Despite its ability to breed with cattle, it has been argued that the yak should be returned to its former Genus, Poephagus. / Под Яком (Bos mutus) понимается род жвачных млекопитающихся животных семейства Полорогих (подсемейства Быков или рода Быков). Иногда выделяют в отдельный род Phoephagus. Высотой до 1.9 метра, масса до 1 тонны. В диком виде сохранился лишь на плоскогорьях Тибета. Домашний Як (Bos m. grunnieus) мельче дикого, самцы весят около 400, самки – 250 килограмм. Телосложение сухое, крепкое, ноги короткие, сильные. Голова тяжёлая, с широким выпуклым лбом. Холка высокая (у самцов 120–135, у самок – 105–120 сантиметров), выступающая в виде горба. Рога сильно развиты, встречаются комолые животные. Туловище покрыто длинным густым волосяным покровом, образующим на плечах, боках и хвосте бахрому. Мать чаще чёрная, с серой полосой по хребту. Животные позднеспелы:- половой зрелости достигают к 18–24 месяцам. Продолжительность беременности 258 суток. Самки ежегодно рождают по одному телёнку. Период лактации 170–180 суток. Теляты выращиваются на подсосе. Средняя годичная молочная продуктивность (средний удой) самок 300–350 кг; жирность молока 6–7%. Содержат Яков круглый год под открытым небом на подножном корме. Разводят как рабочий, отчасти молочный скот в высокогорных районах Азии (в Китае и Монголии); в бывшем Союзе Советских Социалистических Республик (СССР) – в республиках Средней Азии (Киргизской ССР), а в России – в Горно-Алтайской Автономной Области и на Юго-Западе Тувинской АССР, в Бурятской АССР и в Якутии. Як силён и очень вынослив. Ценное рабочее животное. Легко переносит по горным тропам до 140 кг вьючного груза. Используют Яков и как мясное животное. Мясо грубоволокнистое, хорошего вкуса. Настриг шерсти до 3 кг в год, волос идёт на изготовление грубых сукон и арканов. Гибриды, получаемые при скрещивании с крупно-рогатым скотом, называются Хайнаками и Сарлыками (быки плодовиты с 3–4-го поколения), превосходят по массе и молочной продуктивности Яка и местный крупно-рогатый скот.

YANKEE = ЯНЬКИ – (1) Yankee is a native or citizen of the United States or, more narrowly, of the New England states of the United States (Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut). The term Yankee is often associated with such characteristics as shrewdness, thrift, ingenuity, and conservatism. It was applied to Federal soldiers and other Northerners by Southerners during the American Civil War (1861–65) and afterward. The origin of the term is unknown. The slang term for an American – a Yankee. The term Yankee (or Yank) itself is sometimes as a playful, sometimes derogatory, reference to US citizens. The term Yankee is often associated with such characteristics as shrewdness, thrift, ingenuity, and conservatism. It was applied to Federal soldiers and other Northerners by Southerners during the American Civil War (1861–65) and afterward. The origin of the term is unknown. The Oxford English Dictionary says that 'perhaps the most plausible conjecture' is that it comes from the Dutch Janke, the diminutive of Jan (John). British soldiers are recorded using it as a term of derision in 1775. Mitford Mathews (A Dictionary of Americanism on Historical Principles (1951)) traced its rise, pointing out that no evidence of use of the word by New Englanders before the Battle of Lexington (1775) has been found. Many fanciful derivations have been advanced. A mythical tribe of Massachusetts Indians, the Yankos ('Invincibles'), were said to have been defeated by brave New Englanders who then somehow assumed their name. Virginians countered with the story that the word means coward or slave and is derived from the Cherokee word Eankke; no such word exists in the Cherokee language. These and many other theories about the origin of Yankee and of Yankee Doodle are reviewed and are all rejected in a comprehensive study conducted for the Librarian of Congress by Oscar G. Sonneck (1873–1928):- Report on 'The Star-Spangled Banner', 'Hail Columbia', 'America', 'Yankee Doodle' (1909). / Нидерландское имя Янкэ (Dutch Janke), (уменьшительное от Ян (Jan; Дьжон (John)). Митфод Масъюз (Mitford Mathews). Янкос (Yankos). (Eankke). Чироки (Cherokee). Яньки (Yankee) и Яньки Дудэл (of Yankee Doodle). Аско Дьжи. Сонэк (Oscar G. Sonneck). Яньки – термин, получивший распространение с XVIII века. Первоначально прозвище Американцев – уроженцев и жителей Новой Англии; во время Войны за независимость в Северной Америке 1775–83 кличка, употреблявшаяся Английскими солдатами по отношению к восставшим колонистам; со времени Гражданской Войны 1861–65 прозвище жителей Северных штатов; позднее распространилось на всех Американцев. Яньки – общемировое пренебрежительное название жителей Новой Англии; позднее, в более широком смысле, – жителей США, то есть всех Американцев в целом. Прозвище, данное Европейцами Американцам, уроженцам США.

(2) Yankee:- the US securities on the London Stock Exchange (LSE). / Яньки – Американские ценные бумаги на Лондонской Фондовой Бирже.

(3) Yankee (pronunciation:- YANG-kee) or Y is international nautical signal flag meaning:- (i) International:- I am dragging anchor. (ii) Navy:- Ship has visual communications duty. (iii) Sailing Regatta:- Wear Life Jackets. Meaning:- I am carrying mail. This ship has visual communications duty. International Meaning:- I am dragging anchor.

YANKEE BOND MARKET = РЫНОК ОБЛИГАЦИЙ ЯНЬКИ – Yankee Bond Market is a market for Dollar-denominated bonds issued in the US by foreign corporations, banks and governments. / Рынок Облигаций Яньки – рынок деноминированных в Долларах США облигаций, выпущенных в США иностранными корпорациями, банками и правительствами.

YANKEE BONDS = ОБЛИГАЦИИ ЯНЬКИ – Yankee Bonds are foreign bonds denominated in US Dollars and issued in the United States by foreign banks and corporations. These bonds are usually registered with the Securities and Exchange Commission (SEC). Such as, bonds issued by originators with roots in Japan are called Samurai Bonds. Yankee Bonds are the US Dollar-denominated bonds issued by foreign borrowers on the US capital market. US Dollar-denominated securities issued by a foreign entity in the US domestic markets and registered with the Securities and Exchange Commission for sale in the United States. Yankee Bond is a Dollar bond issued by a non-US borrower in the United States. A Yankee Bond is a US Dollar denominated bond issued in the US by a foreign issuer. The reasons for issuing a yankee bond are much the same as for other foreign currency bonds, but:- (i) the size of the US bond market makes it attractive to borrowers who wish to raise very large amounts. These include countries issuing sovereign debt. (ii) The size of the US economy and the common use of the Dollar in international trade means that many companies have Dollar income streams with which to pay Dollar debt. Issuing and trading bonds in the US makes the issuer subject to US regulation. Complying with this is very expensive. This is one reason for the issue of, and trading in, US Dollar bonds off-shore. Yankee Bond is a foreign bond issued in Dollars on the New York bond market by an overseas borrower. Yankee Bond is a bond issued in the US domestic market by a non-US-domiciled borrower denominated in US Dollars. Unlike Eurobond issues Yankees pay interest semi-annually, rather than annually (cf. Bulldog Bond; Matador Bond; Samurai Bonds). Such issues are registered with the Securities and Exchange Commission (cf. registration ... / Облигации Яньки являются иностранными облигациями, деноминированными в Долларах США и выпущенные в Соединённых Штатах Америки иностранными банками и корпорациями. Эти облигации обычно регистрируются в Комиссии по Ценным Бумагам и Биржам (КЦББ; the Securities and Exchange Commission (SEC)). К числу подобных можно было бы отнести облигации, эмитированные структурами, обосновавшимися в Японии, которые называются Облигациями Самурай (Samurai Bonds); в данном случае речь также идёт об облигациях в национальной валюте, но выпущенных нерезидентами данной страны. Деноминированные в Долларах США облигации, выпущенные иностранными заёмщиками на Американском рынке капиталов. Облигации Яньки – это облигации, эмитированные компаниями, расположенными за пределами США, но деноминированные в Долларах и продающиеся в США. Yankee Bonds:- котирующиеся в США облигации. Деноминированные в Долларах облигации, выпущенные в США иностранными банками и корпорациями. Облигации выпускаются в США, когда рыночные условия там кажутся более благоприятными, чем на рынке Еврооблигаций (Eurobond) или на внутренних рынках соответствующих стран. Аналогичным образом, котирующиеся в США депозитные сертификаты (certificates of deposit, CDs) представляют собой подлежащие продаже или передаче депозитные сертификаты, выпущенные в США филиалами и агентствами иностранных банков. Облигация Яньки – облигация долгосрочного займа в Долларах США, эмитированная в США иностранным заёмщиком. Обычно такие облигации регистрируются в Комиссии по Ценным Бумагам и Биржам.

YANKEE CERTIFICATE OF DEPOSIT = ДЕПОЗИТНЫЙ СЕРТИФИКАТ ЯНЬКИ (или СВИДЕТЕЛЬСТВО ЯНЬКИ О ВКЛАДЕ) – Yankee Certificate of Deposit (Yankee CD):- negotiable time deposit issued in the United States by a foreign borrower, usually in denominations of USD1 million to USD5 million. These certificates pay a fixed or variable rate of interest for a specified maturity, usually under 12 months, and are sold directly or through dealers. They are unsecured obligations of the issuing institution. See also Yankee Bond. Yankee Certificate of Deposit is a certificate of deposit (CD) issued in the US market, typically in New York, by a branch of a foreign bank. Yankee CDs are negotiable instruments, and most have a minimum face value of USD100 000.00. Yankee CD is a certificate of deposit (CD) that is issued in the United States by a branch or agency of a foreign bank. A Yankee CD is a foreign certificate of deposit denominated in US Dollars, issued in the United States to American investors. A foreign company can raise capital from US investors by issuing Yankee CDs. Yankee CDs are negotiable instruments, and most have a minimum face value of USD100 000, making them appropriate for large investors. Unlike traditional CDs that can be cashed before maturity for a small penalty, Yankee CDs usually cannot be cashed in prior to their date of maturity. If they are cashed in before maturity, the penalty can be substantial. Yankee CDs are usually issued in New York by foreign banks with branches in the US, and, in particular, New York. Yankee CD is a CD issued in the domestic market, typically New York, by a branch of a foreign bank. Yankee Certificate of Deposit (Yankee CD) is a foreign certificate of deposit denominated in US Dollars and issued in the United States. In order to raise capital from American investors, a non-American company may choose to issue a CD in the United States. Yankee CD is a CD issued in the domestic market, typically New York, by a branch of a foreign bank. Yankee Certificate Of Deposit is a certificate of deposit issued by a foreign bank in the United States. As they usually have a minimum face value of USD100 000, Yankee certificates of deposit are generally used by institutional and other large investors looking to invest funds in instruments with a relatively high degree of safety, although they are unsecured. Yankee certificates of deposit can most often be found in New York financial markets. They are generally negotiable, which enables them to trade in a secondary market. Typically, they have a maturity of less than a year. Yankee CD is a Dollar-denominated, foreign-issued time deposit that is registered for sale in the United States. / Депозитный Сертификат Яньки (ДС Яньки) – депозитный сертификат, выпускаемый на внутреннем рынке США, типично в Нью Йорке, филиалом иностранного банка. Депозитный Сертификат Яньки – депозитный сертификат, выпущенный на внутреннем рынке США представительством иностранного банка. Иностранные Долларовые Депозитные Сертификаты (CDs); обращающиеся депозитные сертификаты, выпущенные в США филиалами крупных иностранных банков. Основная часть зарубежных банковских учреждений в США сосредоточена в Нью Йорке и Калифорнии. В Акте о Международной Банковской Деятельности, принятом 17 Сентября 1978 (International Banking Act of 1978), зарубежные банки, действующие в США через свои филиалы, агентства и кредитные компании, были впервые поставлены в одинаковое положение с национальными банками по отношению к федеральному законодательству. Этот закон уполномочил Совет Управляющих ФРС после консультации с представителями государственного банковского надзора предъявлять законные требования к филиалам и агентствам крупных зарубежных банков об обязательных резервах и ограничении процентной ставки. В начале 1979 Совет продолжал вырабатывать соответствующие нормативные акты. Ответственность за деятельность иностранных банков на территории США в соответствии с законом возлагалась также на Контролёра Денежного Обращения и Федеральную Корпорацию Страхования Депозитов; в соответствии с этим указанные три агентства создали межведомственный орган для решения поставленных задач. Привлекательность депозитных сертификатов Яньки:- после того как Акте о Международной Банковской Деятельности от 1978 ввёл деятельность филиалов основных зарубежных банков в рамки федерального законодательства, стало меньше причин для игнорирования депозитных сертификатов Яньки крупных зарубежных банков с учётом их высокой платёжеспособности, доступа на рынок и высокой ликвидности. В отличие от Евродолларовых Депозитных Сертификатов депозитные сертификаты Яньки не подвержены риску неплатёжеспособности суверенных государств, а также валютному контролю со стороны другой страны, поскольку ресурсы и эмитенты-должники находятся в США. По данным некоторых источников, доходность Долларовых депозитных сертификатов Яньки в последние несколько лет превышает доходность внутренних депозитных сертификатов на 10–35 базисных пунктов.

YANKEE MARKET = РЫНОК ЯНЬКИ – Yankee Market is a slang term for the stock market in the United States. Yankee market is usually used buy non-US residents and refers to the slang term for an American – a Yankee. The term Yankee market was used in business slang but has become widely accepted, much like the ‘Bulldog Market’ refers to the UK market and ‘Samurai Market’ refers to

the market in Japan. The term Yankee (or Yank) itself is sometimes as a playful, sometimes derogatory, reference to US citizens. Yankee market is the foreign market in the United States. / Рынок Яньки – иностранный или внешний рынок в Соединённых Штатах Америки. .

YARD = ДВОР – (1) Yard is a classification, storage or switching area. Fenced off, outdoor storage and repair area. Yard is the open or fenced off outdoor storage and/or repair area. To convey logs or trees to a landing, particularly by cable, balloon, or helicopter logging systems. Yard is a place where logs are accumulated. / Площадка для классификации, хранения или передачи. Огороженная площадка для хранения под открытым небом или проведения ремонтных работ. Открытая или огороженная площадка для хранения под открытым небом и/или проведения ремонтных работ. Лесоперевалочная База предназначена для приёма, хранения, частичной обработки древесного сырья и лесоматериалов, поступающих водным путём, и их отгрузки на сухопутный транспорт общего назначения (железнодорожный и автомобильный). В некоторых сочетаниях название производственных участков, учреждений. Машинный Двор (на сельскохозяйственном предприятии). Литейный Двор. Грузовой Двор (на железнодорожной станции). Монетный Двор (предприятие, изготовляющее металлические деньги, медали, ордена). Грузовой Двор, часть территории железнодорожной станции, имеющая комплекс сооружений и устройств, предназначенных для приёма, погрузки, выгрузки, сортировки грузов и их краткосрочного хранения. В зависимости от объёма и структуры грузопотока грузовой двор может быть общего типа и специализированный по роду груза. В комплекс сооружений механизированного грузового двора входят закрытые склады ангарного типа с внутренним вводом железнодорожных путей, открытые механизированные цехи перегрузки контейнеров и других грузов, эстакады и повышенные пути для перегрузки перевозимых навалом грузов. Грузовой двор имеет устройства для определения веса груза, проверки габарита погрузки, средства связи, водопровод, осветительную сеть и противопожарные средства. На крупных станциях оптимальная расстановка вагонов по местам разгрузки и загрузки, а также автомобилей для централизованного завоза и вывоза грузов производится с помощью ЭВМ. На территории грузового двора размещаются товарная контора, информационное бюро, контора грузового двора, служебные помещения, ремонтные мастерские, гаражи, а также козловые, мостовые и стреловые краны, электро- и автопогрузчики и другие средства механизации погрузочно-разгрузочных работ и складских операций. Грузовой Двор – выделенная территория на железнодорожной станции, где находятся склады, пункты взвешивания и оказываются услуги по приёму, хранению, погрузке и выгрузке грузов.

(2) Yard is a system of auxiliary tracks used exclusively for the classification of passenger or freight cars according to commodity or destination; assembling of cars for train movement; storage of cars; or repair of equipment.

(3) Yard is a system of tracks within defined limits, whether or not part of a terminal, designed for switching services, over which movements not authorized by time table or by train order may be made, subject to prescribed signals, rules and requirements.

YARD = ЯРД – (1) By the time of Magna Carta (1215), abuses of weights and measures were so common that a clause was inserted in the charter to correct those on grain and wine. A few years later a royal ordinance entitled ‘Assize of Weights and Measures’ defined a broad list of units and standards so successfully that it remained in force for nearly 600 years. A standard yard, ‘the Iron Yard of our Lord the King’, was prescribed for the realm, divided into the traditional 3 feet, each of 12 inches, ‘neither more nor less’. Yard is a measure of length, equaling 36 inches or 3 feet, being the standard of American and English linear measurement. Abbreviation:- yd. / Мера длины, равная 36 дюймам или 3 футам, являющаяся стандартной величиной в Американской и Английской линейных системах измерений. Ярд, единица длины в Британской Имперальной Системе. Обозначение:- ярд (yd). 1 ярд = 3 футам = 36 дюймам = 0.914 399 метра.

(2) Yard is a slang for one billion currency units. Used particularly in currency trading, e.g., for Japanese Yen since one billion Yen equals approximately USD10 million. It is clearer to say, ‘I’m a buyer of a yard of Yen’, than to say, ‘I’m a buyer of a billion Yen’, which could be misheard as ‘I’m a buyer of a million Yen’. Slang for a billion or milliard, one thousand million. Yard is investment banking slang for a billion. A yard may refer to a volume or to a value of a billion (1 000 000 000). Its original advantage over the word ‘billion’ is that it is unambiguous (although as the use of billion to mean a million million is becoming rare, this is becoming less important. It probably originated in currency trading where many conversations take place in international contexts. It also cannot be misheard as a million or trillion. Currency traders also tend to use concise wording anyway:- when trading mere millions the million is usually dropped: so a currency traders saying one dollar means a million Dollars. / Жаргонный термин, относящийся к миллиарду, одной тысяче миллионов. Ярд – жаргонное название одного миллиарда. В России для жаргонного обозначения миллиарда используется термин Арбуз. Наиболее часто употребляется в торговле валютой, например, торговле Японской Йеной, поскольку 1 миллиард Йен равен приблизительно 10 миллионам Долларов США. Фраза ‘Я покупаю ярд Йен’ будет более уместной и понятной, нежели ‘Я покупаю миллиард Йен’, поскольку из-за Англоязычной созвучности миллиарда (billion) и миллиона (million) возможна путаница с ‘Я покупаю миллион Йен’.

YARDA = ЯРДА – Yarda or Yarfa is a peaty bog. / торфяное болото. или Яфэ (Yarfa или Yarpha).

YARDAGE = ЯРДАЖ (или В ЯРДАХ) – (1) Yardage is the amount or length of a fabric expressed in yards. Yardage:- any fabric made and sold by the yard. Yardage:- fabrics sold to the consumer by the yard. Yardage is also called Piece Goods, Yard Goods, and Fashion Fabrics. / За рубежом в большинстве стран мира для указания количества ткани использовалась мера ярд, то есть количество ткани измерялось в ярдах. Отсюда и название – ярдаж. В России количество ткани измеряется в погонных (в большей мере) метрах или квадратных метрах. И в этой связи данный показатель имеет название Метраж.

(2) Yardage is a daily, per-head, feedlot cost, in addition to feed costs, for maintaining cattle at the feedlot.

YARDBIRD = ДВОРОВАЯ ПТИЦА – Yardbird is a driver who connects and disconnects tractor and semitrailer combinations and moves vehicles around the terminal yard. See also Spotter. / Смотрите также Метчик или Наводчик или Отметчик или Корректировщик или Указчик (Spotter).

YARD CABOOSE = ДВОРОВЫЙ КАМБУЗ – Yard Caboose is a caboose that is used exclusively in a single yard area.

YARD CREW = ДВОРОВЫЙ ЭКИПАЖ (или ДВОРНИКИ) – (1) Yard Crew:- train service employees work outdoors as part of a train crew or yard crew. They perform duties associated with the direct movement of cars and locomotives. See also Train Crew.

(2) The Yard Crew usually cuts the grass at the church on Friday so it will look good Sunday when we come to church. Many of you have full time jobs and cannot partake in the fellowship weekly with the yard crew while we spruce up our property. Cutting grass is only one of the tasks that the yard crew does while on the church property. Because of this, we are soliciting assistance in projects that can be done by anyone at any time.

YARD DENIER = ЯРДОВЫЙ ДЕНЬЕ – Yard Denier is the denier (den or D) of a filament yarn. It is the product of the denier per filament and the number of filaments in the yarn.

YARDER = ЛЕБЁДКА – Yarder is a system of power operated winches and a tower used to haul logs from a stump to a landing. / брёвна . Кран для укладки древесины.

YARD GOODS = ЯРДОВ ТОВАРА (или ТОВАРЫ В ЯРДАХ) – Yard Goods:- a fabric sold on a retail basis by the running yard. See also Fashion Fabrics, Piece Goods, and Yardage.

YARDING = ТРЕЛЁВКА – Yarding is the initial movement of logs from the point of felling to a central loading area or landing.

YARD JOCKEY = ДВОРОВЫЙ ЖОКЕЙ – Yard Jockey is a person who operates a yard tractor.

YARD LOCOMOTIVE = ДВОРОВЫЙ ЛОКОМОТИВ – Yard Locomotive is a locomotive that is operated only to perform switching functions within a single yard area. / Локомотив – машина, сама себя передвигающая и, при этом, могущая тянуть за собой груз. Под Локомотивом, от Французского слова Locomotive, от Латинского словосочетания Loco Moveo, означающее Сдвигаю С Места, понимается транспортное средство, предназначенное для использования на железной дороге. Локомотив имеет собственную энергетическую установку (двигатель) и используется для перемещения несамоходных вагонов.

YARD MULE = ДВОРОВЫЙ МУЛ – Yard Mule is a small tractor used to move semitrailers around the terminal yard. Also known as Yard Tractor.

YARD SWITCHING TRAIN MILE = МИЛЯ ДВОРОВОГО ПОЕЗДА ПЕРЕГОНА – Yard Switching Train Mile:- computed at the rate of 6 mph for the time actually engaged in yard switching service if actual mileage is not known.

YARD SWITCHING TRAINS = ДВОРОВЫЕ ПОЕЗДА ПЕРЕГОНА – Yard Switching Trains are those trains operated primarily within yards for the purpose of switching other equipment. Examples include the making up or breaking up of trains, service industrial tracks within yard limits, storing or classifying cars, and other similar operations. Switching performed by a road crew that is incidental to the road operation is not included.

YARD TRACK = ДВОРОВЫЙ ПУТЬ (или ПОДЪЕЗДНОЙ ПУТЬ) – Yard Track is a system of tracks within defined limits used for the making up or breaking up of trains, for the storing of cars, and for other related purposes, over which movements not authorized by timetable, or by train order may be made subject to prescribed signals, rules or other special instructions. Sidings used exclusively as passing track and main line track within yard limits are not included in the term yard track.

YARD TRACTOR = ДВОРОВЫЙ ТРАКТОР (или ДВОРОВЫЙ ТЯГАЧ) – Yard Tractor is a truck tractor used exclusively to move trailers around a motor or trailer yard. It is not used for over the road travel. Yard Tractor is a special tractor used to move trailers around a terminal, warehouse, distribution center, etc. Also known as Yard Mule. / Поскольку такие машины предназначены исключительно для внутреннего пользования, для них практически во всех странах даже не нужен государственный номерной знак:- его заменяет реестровый портальный номер, нанесённый краской на панели кабины. То есть это транспортное средство не имеет права выезжать за территорию порта на автомобильные дороги общего пользования. Кстати, именно по этой причине в Северной Америке терминальные тягачи называют Yard Tractor (YT), что дословно означает ‘дворовый тягач’ или ‘тягач с ограниченной зоной перемещения’. Этот термин постепенно приживается и в Европе, постоянно встречаясь в обозначениях моделей.

YARMULKES = ЯРМУЛЬКИ (или ЕРМОЛКИ, или ЯМЭКЭС) – Yarmulkes is a skullcap worn especially by Orthodox and Conservative Jewish males in the synagogue and the home. / Ярмульке или Ермолка – .

YARN = ПРЯЖА – Yarn is a generic term for an assemblage of fibers or filaments, either natural or man-made, twisted together to form a continuous strand which can be used in weaving, knitting, braiding, or plaiting, or otherwise made into a textile material. Spun yarn is the product of the spinning frame characterized by a continuous, evenly distributed, coherent arrangement of any type of fibers of varying or similar staple length, the relative positions of which are maintained by the introduction of a definite lateral twist to produce strength or coherence imparted in the final operation. Notable exception to the above would be the woolen-type yarn. Here the fibers are distributed at near right angles with relation to the continuous length of the yarn. An exception to even spinning would be the addition of noiled fibers to the base stock. Noils do not lend themselves to being properly drawn, in consequence a rough textile yarn, desirable for tweeds and shantungs, is produced. To produce spun yarns, the raw stock must be put through preparatory machinery for even distribution and blending, after which there is the carding or combing to achieve parallel fiber distribution; then a group of attenuating or drawing machine operations follow, ending with the spinning. Yarn in production is called a Lap, Sliver, and Roving, in that order, depending on the type of machine used. Yarns are definitely sized or numbered based on the number of standard yardage hanks contained in one pound. Filament yarn is made from various continuous filaments, such as silk and man-made yarn – acetate, nylon, viscose, etc. Yarn is a textile product of substantial length and relatively small cross section, composed of fibers with or without twist. This general term covers all the specific types of yarns, e.g., single yarn, multiplewound yarn, filament yarn, spun yarn. Yarn is a continuous strand of spun fibers, used for weaving and knitting. Besides being spun by hand, as it is still done in many parts of the world, yarn is manufactured in a large variety of ways. Cotton is spun with the ring frame (less expensive) or the mule (produces a finer twisted and softer yarn than the former). Flax, hemp, jute and ramie are spun either in dry state (for a very strong line or a soft and full tow yarn), or in wet state (for much finer counts than the former). For methods of worsted spinning, made of tops, such yarns are spun on the rings (for the softer yarns from the finest merino wool), on the cap (for fine merino and crossbred), on the flyer (for low crossbred, luster wool and hair yarn), and on the mule (for very soft and full dress goods and knitting yarns of short wool). Woolen yarns are spun on self-actors, producing a yarn which is more fuzzy, rough and uneven than frame spun. Yarn is made either single (consisting of one strand twisted in one direction), or ply or folded (consisting of two or more strands, or plies, twisted in directions opposite to that given to the composing strands). Yarns are made iether of one kind of fiber only or contain a mixture of two or more kinds of fibers, as for instance union yarns. As to the effect, yarns are classed as plain (single color throughout the entire yarn with uniform thickness and twist), and fancy. Fancy yarns, which can be singles or ply yarns, are produced:- (i) with the aid of color effects, like the mixtures, containing variously dyed fibers, the Vigoureux, and the double-and-twist; (ii) by the aid of irregular twist, as for instance, solid colored nub and loop yarns; or (iii) by the combination of the two, as in the cloud, spiral, colored nub and colored loop yarns. Yarns are twisted either to the right-hand or the left-hand direction, the number of twists per inch expressing the degree of the process. It is customary to twist cotton warp to the right hand, while worsted warps and single woolen yarns are spun usually with a left-hand twist. Ply yarn is twisted in opposite direction to the twist given to the singles composing it. Yarns for warps are usually twisted with more turns than yarns for weft, while knitting yarns have still fewer twists per inch. Yarns receiving more or less twist than customary are called Hard Spun and Soft Spun. While there is no rule strictly adhered to in the degree of twist imparted to yarns, certain rules are usually observed in figuring the number of turns required per inch. For linen yarns this is figured by multiplying the square root of the lea of the yarn by 1½ for weft yarn, by 1¾ for light warp, by 2 for full warp and by 2¼ or 2½ for thread. Average jute

yarn of 3 lb grist is usually given 8 twists for warp and 6 for filling; 6 lb grist 6.5 twists for warp, 4.2 twists for weft; 10 lb grist 4.87 twists for warp, 2.89 twists for weft. The standard twist for cotton yarns is figured by multiplying the square root of the number (count), of the yarn by 2.5 for hosiery and soft spun yarn, by 3.2 for filling, by 4.75 for warp and by 5 for extra hard twist yarn. In woolen and worsted yarns the number of twists depends on the length of the fiber and the various requirements as to the smoothness, softness, etc, of the cloth. Below will be found a number of particulars often observed in the given cases. The unit of measurement for cotton yarn is the hank of 840 yards (in Continental Europe 1 000 meters to 1/2 kilogramme). For linen yarn in England one bundle is 16 2-3 hanks, 200 cuts or leas, 24 000 threads, 60 000 yards; in Scotland one spangle is equal to two hasps, four hanks, 24 heers, 48 cuts, 5 760 threads, 14 400 yards; in Austria one schock or stoss is equal to 12 bundles, 60 pieces, 240 hanks, 4 800 cuts, 288 000 yards; for French shoe threads 1 000 meters per kilo is the unit. The Dorsel and Somerset system is based on the weight of 21 600 yards, or a 'dozen' of yarn. The unit of measurement for jute yarn is the same as the Scotch system for linen yarn given above. In Holland the count is expressed by the weight of 150 meters of yarn in hektogrammes (0.22 lb). In worsted yarns the number of hanks (each of 560 yards) in one pound is the count of the yarn, in Continental Europe the number of 1 000-meter units in a kilogramme. In America for woolen yarns the unit is the number of 1 600-yard hanks contained in a pound ('run' system). In the Philadelphia district the cut system is in use, the count being the number of 300-yard 'cuts' in a pound. In England the Aberdeen system is:- One thread (unit) equal to 2½ yards; 120 threads one cut, two cuts one heer, three heers one slip, two slips one hank, two hanks one hasp, two hasps one spindle or 14 400 yards. In Scotland the Galashiel count is the number of 300-yard cuts in 24 ounces. The count, or titre, of the silk yarns is the number of deniers (5 313 grammes), a skein of 500 meters will weight, although the Milan Turin and the old Lyons systems call for 476-meter skeins. Folded yarns are numbered similarly as singles, with the number of composing strands also indicated. In practical manufacturing yarns are very often spun into a lower count than their limit (shoddy and mungo often excepted). The practical limits of counts of the various woolen, worsted and cotton yarns are (approximately), as follows:- (i) Sea Island cotton up to 120's or 160's; Egiptian cotton up to 120's; upland cotton from 20's to 80's; Indian cottons to about 20's; (ii) Merino worsted up to 130s; Botany worsted up to 130's; crossbred worsted up to single 30's or double 40's; Lincoln worsted up to 32's; alpaca usually 40's; mohair 32's; woolens up to 40's. In order to find the counts of the folded (two-ply, three-ply, etc) yarns, the individual counts of the component threads are multiplied and then divided by the added total of the same counts. The same rule applies when the singles of the folded yarn are alike or different in size. Measure off one lea (120 yards) and divide its weight, in grains, by 1 000; the result will be the count of the cotton yarn. To find the diameter of a certain cotton yarn (expressed in inches), the number 0.027 8 should be divided by the square root of the number (size) of the yarn. To express two or more yarns used together by an equivalent, first of all the different counts must be expressed by the same yarn count system in case cotton, silk, wool, worsted, etc, yarns are combined. The single equivalent of two yarns is found by dividing the multiplication of their count by the sum of the same counts. In case three yarns are used, the single equivalent of them can be found by finding first the equivalent of two yarns and combining the result with the last remaining yarn to find the final equivalent. The breaking strength of the cotton yarn depends on various factors, viz., humidity, the amount of twist, the stock used. (1924). See also Spinning. Yarn is a generic term for a continuous strand spun from a group of natural or synthetic staple fibers (short lengths of fibers), filaments (long lengths), or other materials twisted or laid together for use in weaving, knitting, or some other method of intertwining to form textile fabrics. Yarn is a generic term for a continuous strand of textile fibers, filaments, or material in a form suitable for knitting, weaving, or otherwise intertwining to form a textile fabric. Yarn occurs in the following forms:- (i) a number of fibers twisted together (spun yarn); (ii) a number of filaments laid together without twist (a zero-twist yarn); (iii) a number of filaments laid together with a degree of twist; (iv) a single filament with or without twist (a monofilament); or (v) a narrow strip of material, such as paper, plastic film, or metal foil, with or without twist, intended for use in a textile construction. Yarn is a continuous strand of textile fibers created when a cluster of individual fibers are twisted together. These long yarns are used to create fabrics, either by knitting or weaving. Yarn is a continuous strand of textile fibers that may be composed of endless filaments or shorter fibers twisted or otherwise held together. It may be made up oof vegetable (Cotton, Hemp, Jute, linen, Ramie, Sisal), animal (mohair, silk, wool), or artificial fibers (gold, silver and other metals rayons, nylon, Orlon). Yarns are utilized in making fabric. Yarn is characterized by its composition, its thickness (or grist or count), number of strands (or plies), direction and degree of twist, and the color. Yarn is a textile product of substantial length and relatively small cross section, composed of fiber(s) with or without twist. This general term covers all the specific types of yarns, e.g., single yarn, multiple wound yarn, filament yarn, spun yarn. Yarn is continuous strand of fibers grouped or twisted together and used to construct textile fabrics. Yarns are made from both natural and synthetic fiber, in filament or staple form. Filament is fiber of great length, including the natural fiber silk and the synthetic fibers. Most fibers that occur in nature are of fairly short length, or staple, and synthetic fibers may be cut into short, uniform lengths to form staple. Spinning is the process of drawing out and imparting twist to a mass of fibers. Filament yarns generally require less twist than staple. A fairly high degree of twist produces strong yarn; low twist produces softer, more lustrous yarn; and tight twist produces crêpe yarns. Two or more single strands of yarn may be twisted together, forming ply yarn. Novelty yarns, used to produce special effects, include bouclé, characterized by projecting loops; nub yarn, with enlarged places, or nubs, produced by twisting one end of a yarn around another many times at one point; and chenille, a soft, lofty yarn with pile protruding on all sides. Textured yarns are synthetic filament yarns that are made bulky or stretchy by heating or other techniques. In yarns used for weaving, the warp, or lengthwise, yarns are usually made stronger, more tightly twisted, smoother, and more even than the filling, or crosswise, yarns. Knitting yarns have less twist than weaving yarns. Yarns used for machine knitting may be single or ply types; ply yarns are generally used for hand knitting. Thread, used for sewing, is a tightly twisted ply yarn having a circular cross section. Yarn is a continuous strand of textile fibers that may be composed of endless filaments or shorterfibers twisted or otherwise held together. Yarns are utilized in making fabric. Yarn is an assembling of twisted filaments, fibers, or other strands, to form a continuous length that is suitable for use in weaving or interweaving into textile materials. Yarn is a generic term for a continuous strand spun from a group of natural or synthetic staple fibers, or filaments, used in weaving, knitting to form textile fabrics. Yarn is a continuous strand of twisted (spun) fibers of any kind and of varying staple length, usually used in the weaving or knitting of fabric. Yarn is the final product of combined fibres after leaving the spinning frame or mule. Yarn is a long continuous length of interlocked fibres, suitable for use in the production of textiles, sewing, crocheting, knitting, weaving, embroidery, or ropemaking. Thread is a type of yarn intended for sewing by hand or machine. See also Spinning. / уточина. Найлан^{T3} (Nylon^{TM}). некручёная пряжа (zero-twist yarn). филаментная (комплексная) пряжа (filament yarn). мононить (monofilament). низкая крутка . Под Пряжей понимается нить, состоящая из волокон ограниченной длины и соединённых скручиванием, перепутыванием, склеиванием и тому подобным. Служит для выработки текстильных изделий. Различают пряжу однониточную (или одиночную, или в одну нить) и кручёную (из нескольких отдельных нитей); однородную (из волокон одного вида) и смешанную (из различных видов волокон). Основные характеристики пряжи:- линейная плотность, текс, относительная прочность сантиНьютонов/текс (сН/текс), крутка и другие. Пряжа, основной вид текстильных нитей; состоит из волокон, соединённых скручиванием (иногда склеиванием). Пряжи различают по виду волокон, назначению, способам выработки и отделки, свойствам и особенностям структуры. Пряжи получают из всех видов текстильных волокон; при изготовлении из какого-либо одного вида волокон она называется Однородной Пряжей, из смеси двух и более видов – Смешанной Пряжей. Пряжа, выработанная с использованием значительного количества отходов (угаров), называется Угарной Пряжей или Очёсковой Пряжей. По назначению различают пряжу для ткацкого (основную и уточную), трикотажного, ниточного,

канатного и других производств. В зависимости от способов подготовки продукта к прядению различают Кардную Пряжу, Гребенную Пряжу, Аппаратную Пряжу; в зависимости от машин, осуществляющих прядение, – пряжу Кольцевого, Безверетённого и другого прядения. По отделке и окраске пряжа подразделяется на Суровую (без какой-либо отделки), Отбеленную, Мерсеризованную (смотрите Мерсеризация), Окрашенную и другую. Пряжа, вырабатываемая из смеси окрашенных и неокрашенных волокон, называется Меланжевой Пряжей. По особенностям структуры различают пряжу Обычную (Однониточную), Текстурированную (Высокообъёмную), Кручёную (Скрученную из нескольких нитей) и другую. Хлопчатобумажную пряжу вырабатывают:- гребенную (наиболее тонкую) толщиной 5–18.5 текс, в основном из тонковолокнистого хлопка; кардную (средних толщин) – 13.3–100 текс, из средневолокнистого хлопка, и аппаратную (больших толщин) – более 100 текс, из угаров и низких сортов хлопка. Шерстяную пряжу вырабатывают:- гребенную толщиной 15.5–42 текс, грубогребенную – 30–83 текс и аппаратную – 42–500 текс. Льняную пряжу прядут сухим способом из длинного и короткого льняного волокна и очёсов, а также мокрым способом (ровница смачивается перед прядением) из длинного волокна и очёсов. При мокром прядении получается пряжа толщиной 24–200 текс; при сухом прядении и при прядении из других видов лубяных волокон (Пеньки, Джута и тому подобных) обычно вырабатывается пряжа больших толщин (33–666 текс). Шёлковая пряжа изготовляется из отходов натурального шёлка (сдира коконного, бракованных коконов и тому подобного), которые очищаются от примесей, отвариваются и расщипываются на отдельные волокна; выпускается толщиной до 7 текс. Волокна невысокой прочности (например, асбест) прядутся обычно в смеси с хлопком или химическими волокнами. Пряжа из химических волокон вырабатывается по системам прядения и в диапазоне толщин того ассортимента, для замены которого они предназначены. Основные характеристики пряжи – толщина, крутка, разрывные нагрузки и удлинение, равномерность по толщине и прочности, а также чистота (отсутствие пороков). Пряжа – нить, состоящая из текстильных волокон, соединённых скручиванием. Получают в прядильном производстве. Для получения пряжи из ровницы или ленты используется прядильная машина. Первая механическая прядильная машина была создана в Великобритании в 1738. В кольцевых (веретённых) прядильных машинах ровница (лента) вытягивается в вытяжном приборе, скручивается и наматывается с помощью веретена на патрон или шпулю. В безверетённых пневмомеханических прядильных машинах (наиболее распространены) ровница (лента) разъединяется на отдельные волокна, которые потоком воздуха подаются в быстровращающуюся камеру, где из них формируется пряжа, наматываемая на бобину. Производительность безверетённых прядильных машин в 2–3 раза выше, чем кольцевых. Из пряжи изготовляют ткани, трикотаж, нитки и тому подобное. , Найлан^{T3} (Nylon^{TM}), вискоза и так далее. Джут, лён, пенька и рами являются прядомыми лубяными волокнами (bast fibers). Под Пряжей понимается нить неопределённо большой длины и малого поперечного сечения, состоящая из сравнительно коротких волокон, соединённых скручиванием или склеиванием, и обладающая определённой прочностью и равномерностью. Для изготовления пряжи используют натуральные текстильные волокна (асбест, лубяные волокна, хлопок, шерсть, отходы натурального шёлка и другие), штапельные химические волокна и жгуты элементарных химических нитей. Геометрические свойства пряжи, такие как гладкость, линейная плотность, средняя плотность и пушистость; её структура – расположение волокон, крутка; и физические свойства, такие как, гигроскопичность, разрывная нагрузка, растяжимость, теплопроводность, упругость, зависят не только от свойств волокон, но и системы прядения. Смотрите также Прядение (Spinning). В Австрии кипа, или стопа, или пачка, или штабель (schock или stoss) равна 12 (моткам или бухтам или пачкам или связкам – bundles), 60 кускам (pieces), 240 початкам или моткам (hanks), 4 800 пасма или кусок или отрез или моток (cuts), 288 000 ярдам (yards). Нитки:- вышивальные, вязальные, швейные и штопка. Неотделанные или суровые нитки. , альпак обычно 40’s. Качество пряжи в большей степени зависит от свойств и вида сырья, а также от условий её формирования. При неправильном выборе технологических параметров заправки машины, при плохом уходе и неправильной наладке, износе деталей и узлов машины возникают пороки пряжи и дефекты намотки. К основным порокам пряжи относятся:- (i) грязная и замасленная пряжа, которая получается при небрежной смазке шеек цилиндров, шпинделей нажимных валиков, присучивании грязными, маслеными руками ровницы и пряжи; (ii) краксы, наибольшие утолщения, которые получаются из-за того, что группа волокон обвивается вокруг одного более длинного центрального волокна, вследствие слишком малой разводке цилиндров; (iii) непропрядки или невытянутая ровница образуется при недостаточном зажиме ровницы в вытяжном приборе, износе покрытия нажимного валика или чрезмерной крутке ровницы, когда не происходит сдвига волокон в процессе вытягивания; (iv) пересечки или повторение тонких мест через одинаковые промежутки вследствие задержки вращения цилиндров вытяжного прибора при пуске машины, поломки зубьев шестерен в передаче вытяжного прибора, скопления пуха между зубьями шестерен, неровной поверхности эластичных покрытий и ремешков, плохой смазки нажимных валиков, биения цилиндров и валиков, а также из-за пересечек в ровнице; (v) переслежистая пряжа, характеризуемая случайным чередованием толстых и тонких мест, образующихся в результате установки с перекосами нажимных валиков, неправильной разводки цилиндров, малой нагрузки на нажимные валики, несвободного их вращения и плохого состояния их покрытий, а также из-за переслежистой ровницы, скрытой её вытяжки на пути от рамки до вытяжного прибора, ослабления шпонок шестерен, тугой присадки сцепляющихся шестерен; и (vi) толстые рыхлые, короткие участки (шишки), возникающие в пряже при заработке пуха в пряжу, плохом присучивании, попадании пуха с чистителей из-за несвоевременной их очистки. К дефектам намотки относятся:- (i) мягкие початки, которые вырабатываются при недостаточном натяжении пряжи, использовании слишком лёгких бегунков, недостаточной смазке веретён, проскальзывании тесьмы и слабой насадке патронов; (ii) отсталые початки, которые получаются из-за повышенной обрывности пряжи, когда прядильщики не успевают вовремя ликвидировать обрывы; и (iii) толстые или тонкие початки, с тупым или острым верхним конусом, бугристые получаются при разладке мотального механизма и поломке зубьев храповика или шестерен мотального механизма. Под Веретеном или Шпинделем, от Немецкого слова Spindel, означающее Веретено, понимается . В ткацком производстве Снование – перематывание большого числа нитей (до 1 000) с бобин на одну общую паковку – сновальный валик. Выполняется на сновальных машинах. Впоследствии требуемое по ширине ткани число нитей с валиком наматывается на ткацкий навой. Пряжа – это нить из равномерно и параллельно расположенных и затем скрученных волокон шерсти, хлопка, льна, вискозы, синтетики и других волокнистых материалов. Различают основную пряжу, идущую на основу тканей, и уточную, идущую на уток тканей. Первая пряжа должна быть туже скручена, крепче и глаже, чем вторая, обычно более рыхлая. Важнейшие свойства пряжи:- тонина, прочная крутка, крепость, растяжимость, гигроскопичность и равномерность. Тонина пряжи выражается её номером, который указывает число мотков, заключающихся в 1 кг пряжи. Кручёная пряжа, состоящая из нескольких (2–3) нитей, скрученных между собой, идёт для производства швейных ниток и вязаных изделий. Швейные нитки при этом подвергаются ещё особой отделке. Номера кручёной пряжи определяются номером нитей, из которых она скручена, разделённым на число этих нитей. Шерстяная пряжа бывает кардная (иначе суконная, аппаратная), изготовляемая из коротких волокон, и камвольная, изготовляемая из более длинной камвольной шерсти. Номер (толщина) шерстяной пряжи определяется числом мотков (по 1 000 м в каждом) идущих на 1 кг пряжи. Пряжу делят на синтетическую, натуральную, смешанную, искусственную и комбинированную. Пряжей называют нити, образованные из волокон ограниченной длины и соединённых в процессе прядения скручиванием. Натуральная Пряжа бывает животного и растительного происхождения. К пряже животного происхождения относят шерсть и шёлк. Пряжа (текстильные нити) – основной вид нитей текстильных; состоит из волокон, соединённых скручиванием (иногда склеиванием). Пряжу различают по

виду волокон, назначению, способам выработки и отделки, свойствам и особенностям структуры. Пряжу получают из всех видов волокон текстильных; при изготовлении из какого-либо одного вида волокон она называется однородной, из смеси двух и более видов – смешанной. Пряжа, выработанная с использованием значительного количества отходов (угаров), называется угарной, очёсковой. По назначению различают пряжу для ткацкого (основную и уточную), трикотажного, ниточного, канатного и других производств. Пряжа, вырабатываемая из смеси окрашенных и неокрашенных волокон, называется меланжевой. По особенностям структуры различают пряжу обычную (однониточную), текстурированную (высокообъёмную), кручёную (скрученную из нескольких нитей) и другую. Хлопчатобумажную пряжу вырабатывают:- гребенную (наиболее тонкую) толщиной 5–18.5 текс, в основном из тонковолокнистого хлопка; кардную (средних толщин) – 13.3–100 текс, из средневолокнистого хлопка, и аппаратную (больших толщин) – более 100 текс, из угаров и низких сортов хлопка. Шерстяную пряжу вырабатывают:- гребенную толщиной 15.5–42 текс, грубогребенную – 30–83 текс и аппаратную – 42–500 текс. Льняную пряжу прядут сухим способом из длинного и короткого льняного волокна и очёсов, а также мокрым способом (ровница смачивается перед прядением) из длинного волокна и очёсов. При мокром прядении получается пряжа толщиной 24–200 текс; при сухом прядении и при прядении из других видов лубяных волокон (пеньки, джута и тому подобных) обычно вырабатывается пряжа больших толщин (33–666 текс). Основные характеристики пряжи – толщина, крутка, разрывные нагрузки и удлинение, равномерность по толщине и прочности, а также чистота (отсутствие пороков).

YARN BEAM = ПРЯЖНЫЙ НАВОЙ – Yarn Beam is the same as a Warp Beam. / Пряжный Навой – то же самое, что Навой Основы (Warp Beam).

YARN CONDITIONER = КОНДИЦИОНЕР ПРЯЖИ – Yarn Conditioner:- a chamber in which twisted yarn may be placed to be subjected to controlled conditions of moisture (usually through the use of steam) and temperature, to effect a conditioning or setting of the yarn. Cotton-yarn-type conditioners usually have provisions for controlling moisture only. The conditioning serves to remove the liveliness of the twisted yarn.

YARN CONTAMINATION = ЗАСОРЕНИЕ ПРЯЖИ (или ЗАГРЯЗНЕНИЕ ПРЯЖИ) – Yarn Contamination:- foreign fibers or soil knitted into the fabric. Contamination which is a 1/8” (0.3 cm) or greater in a critical area of a garment, which can be easily seen should be considered defective. Contamination greater than 1/4” (0.6 cm) in non critical area should be considered defective.

YARN CONSTRUCTION = СТРОЕНИЕ ПРЯЖИ (или СТРУКТУРА ПРЯЖИ, или КОНСТРУКЦИЯ ПРЯЖИ) – A standard notation for Yarn Construction is set out in the international standard ISO 1139, edition 1973. The notation reflects in a condensed form details of the components of a yarn, including values of the linear densities, direction of twist, twist level, number of folds, etc of these components and/or characteristics such as linear density resulting from this construction. Two methods for the notation of yarns are available:- (i) the ‘single to fold’ notation starts from the linear density of the single yarn; and (ii) the ‘fold to single’ notation starts from the linear density of the resultant yarn. The symbols used in both systems are identical; the differences are in the order of presentation, the use of the multiplication sign (x) in the single to fold notation, and of the solidus (/) in the fold to single notation. Distinction between the two methods does not apply to single spun yarn, monofilament and multifilament yarns without twist, nor to multiple wound yarns. The following symbols are used:- R – symbol for resultant linear density, to be put before its numerical value; f – symbol for filaments, to be put before the number of filaments, t0 – symbol for zero twist; other twist values are represented by the number of turns per meter of the twisted yarn, preceded by S or Z to indicate twist direction. If the S/Z notation cannot be used, for example in numerical fields of data banks, ‘S’ should be designated as (–) and ‘Z’ as (+). The notation is best illustrated by examples:- (i) ‘single to fold’ notation for cabled yarns with:- (a) similar components – 20 tex Z700 x 2 S400 x 3 Z200; R132 tex, and (b) dissimilar components – (20 tex Z700 x 3 S400 + 34 tex S600) Z200; and (ii) ‘fold to single’ notation for cabled yarns with:- (a) similar components – R132 tex Z200 / 3 S400 / 2 Z700; 20 tex, and (b) dissimilar components – R96 tex Z200 / (S600 + S400 / 3 Z700); 34 tex. Notes:- (i) prefixes and mutiples shall be written without space; (ii) a space shall be used to separate the different characteristics of the yarn construction; (iii) x or / used to mark multiple yarn components shall be separated with spaces; and (iv) units shall be written with a space in accordance with ISO 1000. Addition of the resultant linear density in the ‘single to fold’ notation, and of the single yarn linear density in the ‘fold to single’ notation, is not obligatory; such information is separated from the preceding notation by a semi-colon. If not needed, the direction of twist and the twist level may be omitted; however, the description of twistless yarns may include the symbol for zero twist. Values of linear density and of twist level used in commercial transactions are usually nominal values and are subject to agreed tolerances. Data obtained on yarn as to cable, count, hawser, ply, twist, etc, usually done by close inspection to meet certain requirements. Yarn Construction is a term used to indicate the number of singles yarns and the number of strands combined for form each successive unit of a plied yarn or cord. / филаментная (комплексная) пряжа (filament yarn). мононить (monofilament). некручёное (zero twist). Данные, полученные о пряже в отношении количества и последовательности сложений (кабельтовой свивки (cable)), номера (count), трощения (тросовой свивки (hawser)), числа сложений (ply), числа кручений (twist) и прочего, обычно, определённые при непосредственной инспекции для удовлетворения определённых требований. Под структурой пряжи понимается расположение волокон, крутка. В зависимости от назначения пряжи к её внешнему виду и свойствам предъявляются разные требования. Для выработки одних материалов нужна пряжа очень тонкая, гладкая, равномерная по толщине, для других – наоборот, более толстая, пушистая, рыхлая. Таким разнообразным требованиям могут удовлетворять только разные по структуре виды пряжи. Структура пряжи определяется видом волокнистого сырья, формой и размерами волокон, их расположением в нитях, количеством в поперечном сечении, равномерностью распределения по длине нити и круткой. В зависимости от волокнистого состава пряжа подразделяется на:- (1) однородную, состоящую из одноимённых волокон – хлопка, шерсти, льна и так далее; (2) смешанную – из волокон разного происхождения, соединённых в процессах прядильного производства – шерстяных с хлопковыми, шерстяных с вискозными и лавсановыми и так далее; (3) неоднородную из строщённых или скрученных нитей разного волокнистого состава – шерстяных с хлопчатобумажными, шерстяных с вискозными и так далее. Хлопчатобумажная и льняная пряжа обычно бывает однородной. При выработке пряжи для сорочечных, платьевых и костюмных тканей к хлопковым волокнам добавляют вискозные, лавсановые и нитроновые штапельные волокна, а к льняным – лавсановые. Особенно много смешанной пряжи вырабатывает шерстяная промышленность. При этом целью добавления к шерсти хлопковых и искусственных штапельных волокон является получение определённых эффектов, смягчение грубошерстного материала, а главным образом удешевление изделий из шерстяной пряжи. Добавление синтетических волокон улучшает механические свойства шерстяной пряжи и повышает её

износоустойчивость. Волокнистый состав оказывает существенное влияние на структуру пряжи. Длинные, грубые, прямые волокна (лён, грубая гребенная шерсть) располагаются в пряже компактно, нить получается плотной, жёсткой, её поверхность в большинстве случаев гладкая, только иногда на гладкой поверхности нити выступают отделившиеся концы прямых волокон. Тонкие, сильно извитые волокна, трудно поддающиеся распрямлению в прядении, образуют нить мягкую, более рыхлую, с пушистой поверхностью. Существенно влияют на структуру нити и расположение волокон в ней процессы прядильного производства. Наиболее правильную структуру нити обеспечивает гребенное прядение. Волокна, равномерно распределённые по длине и поперечному сечению пряжи, распрямлённые и ориентированные, дают нить плотную и равномерную по толщине. Гребенная пряжа (для данного вида волокон наиболее тонкая) используется для производства высококачественных тканей и трикотажа, некоторых видов лент и кружев. Из гребенной пряжи изготовляются также швейные нитки. В кардной пряже волокна распрямлены и ориентированы, но не так тщательно, как в гребенной. Поэтому кардная хлопчатобумажная пряжа менее равномерная, чем гребенная; выступающие кончики неудалённых коротких волокон делают её поверхность пушистой. Штапельная же кардная пряжа, выработанная из очень равномерных по длине и толщине химических волокон, обладает гладкой поверхностью и незначительными колебаниями по толщине. Кардная пряжа вырабатывается средней толщины и широко используется при производстве тканей и трикотажных полотен массового ассортимента, а также прошивных нетканых материалов, некоторых видов лент, тесьмы, шнуров и кружев. Волокна в аппаратной пряже почти не распрямлены и недостаточно ориентированы. Рыхлая, слабо скрученная аппаратная пряжа сообщает изделиям из неё хорошие теплозащитные свойства. Аппаратная пряжа имеет значительную неравномерность по толщине. Но вырабатываемые из неё материалы в большинстве случаев подвергают валке или начёсу, поэтому неравномерность толщины нитей мало заметна. Существенное влияние на структуру пряжи оказывает крутка. При скручивании волокна располагаются по винтовым линиям переменного шага и радиуса. Каждое волокно по своей длине лежит не в одном слое пряжи, а в ряде слоёв, переходя от центра пряжи к периферии и обратно. При этом участки волокон, находящиеся в наружных слоях нити, напрягаются сильнее, чем участки в центре нити. Это создаёт неуравновешенность структуры, в результате которой сматывающаяся с початка или бобины пряжа скручивается и петляет. Наклон витков, лежащих в определённом слое нити, подвержен колебаниям и изменяется вместе с её диаметром. Таким образом, чем менее равномерны по толщине нити, тем неравномернее распределяются по их длине витки крутки. Получаемая в процессе прядения одинарная пряжа в зависимости от требований может иметь слабую или сильную крутку. При слабой крутке пряжа получается менее прочной, но более мягкой, при сильной крутке – плотной и жёсткой. Волокна под действием радиальных давлений, возникающих в процессе скручивания, сжимаются плотнее, трение между ними растёт, благодаря чему они прочнее закрепляются в нити. Поэтому при увеличении крутки прочность пряжи увеличивается. В тканях для основы, от которой требуется большая прочность, обычно используется пряжа более высокой крутки, чем для утка. Из пряжи высокой крутки получают более жёсткие, упругие ткани. Обычно такие ткани обладают большей пористостью, а следовательно, лучшей воздухопроницаемостью и применяются для изготовления летней одежды. Из одинарной пряжи средней и пониженной крутки вырабатывают бельевые ткани, которые должны быть мягкими и хорошо впитывать влагу; ткани, предназначенные для начёса и валки; многие платьевые ткани. В трикотажном производстве при повышенной крутке нити в процессе петлеобразования закручиваются, петли получаются неравномерными, а обрывность нитей на машинах увеличивается. Поэтому трикотаж вырабатывается из пряжи пониженной крутки. Пряжа невысокой крутки используется также для производства нетканых материалов. В зависимости от направления крутку обозначают Латинскими буквами Z и S. При крутке Z витки идут снизу слева вверх направо, при крутке S – снизу справа вверх налево. Направление крутки пряжи влияет на внешний вид вырабатываемых из неё материалов. Например, при крутке нитей основы и утка в одну сторону витки пряжи в ткани располагаются в разных направлениях, вследствие чего рисунок переплетения получается более рельефным. При крутке нитей основы и утка разного направления волокна в ткани располагаются в одном направлении, благодаря чему легче осуществляется начёс и валка. Кручёная пряжа образуется при скручивании двух или более нитей одинаковой длины (пряжа простой крутки) или разной длины (пряжа фасонной крутки). Пряжа простой крутки гладкая, фасонной крутки – с узелками, петлями, спиралями. Направление прядильной и окончательной крутки простой кручёной пряжи должно быть разное (Z/S или S/Z), в противном случае нить оказывается неуравновешенной и петляет. При окончательной крутке по направлению обратной прядильной крутке составляющие нити раскручиваются до тех пор, пока не оказываются закреплёнными витками повторной крутки. Благодаря этому они соединяются, образуя плотную нить, округлую по форме, равномерно заполненную волокнами. Располагаясь спиральными витками, составляющие нити огибают друг друга, что даёт волокнам дополнительное закрепление, пряже большую прочность, а изделиям из неё большую износоустойчивость. Поэтому лучшие костюмные, платьевые и сорочечные ткани вырабатывают из кручёной пряжи. Нити фасонной крутки (фасонные нити) состоят из сердцевинной или основной нити, которую обвивает нагонная или эффектная нить большей длины, чем основная нить. Для закрепления полученного эффекта некоторые фасонные нити подвергают крутке с закрепительной нитью. В узелковых фасонных нитях образуются узелки – одноцветные из одной нагонной нити или многоцветные из нескольких нагонных нитей. В зависимости от соотношения длины сердцевинной и нагонной нитей, а также толщины и интенсивности крутки последней узелки могут быть больше или меньше, круглые или продолговатые. В спиральных фасонных нитях нагонные нити ложатся вокруг сердцевинной по винтовым линиям. Этот эффект может быть получен при одной или двух крутках. В фасонных нитях эпонж витки нагонной нити местами сгущаются, образуя рыхлые узелки. При разноцветной окраске нагонных и сердцевинных нитей создается впечатление рябоватости. Нить эпонж образуется при двух крутках. В петлистых фасонных нитях нагонная нить ложится петлями в виде колечек. Эффект получается при двух крутках. Нити фасонной крутки широко используются при выработке платьевых, костюмных и пальтовых тканей из волокон всех видов. Они позволяют получать сравнительно недорогие и внешне эффектные материалы. Высокообъёмная пряжа обладает повышенной объёмностью, пушистостью и мягкостью. Она получается из смеси разноусадочных химических волокон, перерабатываемых на обычном прядильном оборудовании. Выпряденная пряжа подвергается термообработке, при которой высокоусадочные волокна укорачиваются и благодаря трению сообщают низкоусадочным волокнам волнообразную извитость, увеличивающую пористость, толщину и объём пряжи. Изделия из такой пряжи получаются с хорошими теплозащитными свойствами.

YARN DEFECTS = ПОРОКИ ПРЯЖИ (или ДЕФЕКТЫ ПРЯЖИ) – Yarn Defects:- the defects originating from the spinning stage or winding stage. Different types of yarn defects are:- Broken Filaments, Colored Flecks, Knots, and Slub.

YARN DENIER = ДЕНЬЕ ПРЯЖИ – Yarn Denier:- the denier of a filament yarn. It is the product of the denier per filament and the number of filaments in the yarn.

YARN–DYED = КРАШЕНАЯ ПРЯЖА – Yarn-Dyed is a term applied to yarns dyed after spinning. Yarn dyed fabrics are dyed before the finishing of the fabric. Yarn dyed fabrics are considered more colorfast than piece dyed or printed fabrics. Yarn Dyed:- (1) the dyeing of yarn before weaving or knitting. (2) Fabrics woven or knitted with yarns which have been dyed. / Крашеная Пряжа – термин, применяемый к пряже, выкрашенной после прядения. Окрашивание пряжи производят в специальных машинах под высокими давлением и температурой. В чан красильной машины постепенно подаётся вода, краситель (натуральный или

синтетический) и специальные закрепляющие вещества. Контроль уровня и равномерности окраски, а также полоскание – все это происходит автоматически. Высококачественная пряжа обычно проходит несколько циклов окрашивания, для придания большей стойкости цвету. Крашеная пряжа применяется для производства некоторых тканей (обычно пёстрых, многоцветных). Это так называемые пёстротканные ткани, а также ткани с жаккардовым переплетением нитей.

YARN DYEING = КРАШЕНИЕ ПРЯЖИ (или ОКРАШИВАНИЕ ПРЯЖИ) – There are many forms of Yarn Dyeing. Common forms are the at package form and the at hanks form. Cotton yarns are mostly dyed at package form, and acrylic or wool yarn are dyed at hank form. In the continuous filament industry, polyester or polyamide yarns are always dyed at package form, while viscose rayon yarns are partly dyed at hank form because of technology. The common dyeing process of cotton yarn with reactive dyes at package form is as follows:- (i) the raw yarn is wound on a spring tube to achieve a package suitable for dye penetration; (ii) these softened packages are loaded on a dyeing carrier's spindle one on another; (iii) the packages are pressed up to a desired height to achieve suitable density of packing; (iv) the carrier is loaded on the dyeing machine and the yarn is dyed; (v) after dyeing, the packages are unloaded from the carrier into a trolly; (vi) now the trolly is taken to hydro extractor where water is removed; (vii) the packages are hydro extracted to remove the maximum amount of water leaving the desired color into raw yarn; and (viii) the packages are then dried to achieve the final dyed package. After this process, the dyed yarn packages are packed and delivered. See also Dyeing. Yarn Dyeing is the dyeing of yarn before the fabric is woven or knit. Yarn can be dyed in the form of skeins, muff, packages, cheeses, cakes, chain-wraps, and beams. When dyeing is done after the fiber has been spun into yarn, it is called Yarn Dyeing. In this method, the dyestuff penetrates the fibers to the core of the yarn. There are many forms of yarn dyeing:- Package Dyeing, Skein (Hank) Dyeing, Space Dyeing, and Warp-Beam Dyeing.

YARN DYEING DIFFERENCES = РАЗЛИЧИЯ В ОКРАШИВАНИИ ПРЯЖИ (или ОТЛИЧИЯ В ОКРАСКЕ ПРЯЖИ) – Yarn Dyeing Differences are the variations in take-up of dyes by yarns, resulting in streaks in finished fabrics.

YARN EVENNESS = РОВНОТА ПРЯЖИ – Yarn Evenness:- non-uniformity in variety of properties exists in yarns. There can be variation twist, bulk, strength, elongation, fineness etc. Yarn Evenness deals with the variation in yarn fineness. Thisis the property, commonly measured as the variation in mass per unit length along the yarn, is a basic and important one, since it can influence so samy other properties of the yarn and offabric made from it. Such variations are inevitable, because they arise from the fundamental nature of textile fibers and from their resulting arrangement. The spinner tries to produce a yarn with the highest possible degree of homogeneity. In this connection, the evenness of the yarn mass is of the greatest importance. In order to produce an absolutely regular yarn, all fiber characteristics would have to be uniformly distributed over the whole thread. However, that is ruled out by the inhomogeneity of the fiber material and by the mechanical constraints. Accordingly, there are limits to the achievable yarn eveness. Importance of Yarn Evenness:- irregularity can adversely affect many of the properties of textile materials. The most obvious consequence of yarn evenness is the variation of strength along the yarn. If the average mass per unitlength of two yarns is equal, but one yarn is less regular than the other, it is clear that the more even yarn will be the stronger of the two.The uneven one should have more thin regions than the even one as a result of irregularity, since the average linear density is the same. Thus, an irregular yarn will tend to break more easily during spinning, winding, weaving, knitting, or any other process where stress is applied. A second qality-related effect of uneven yarn is the presence of visible faults on the surface of fabrics. If a large amount of irregularity is present in the yarn, the variation in fineness can easily be detected in the finished cloth. The problem is particularly serious when a fault (i.e a thick or thin place) appears at precisely regular intervals along the length of the yarn. In such cases, fabric construction geometry ensures that the faults will be located in a pattern that is very clearly apparent to the eye, and defects such as streaks, stripes, barre, or other visual groupings develop in the cloth. Such defects are usually compounded when the fabric is dyed or finished, as a result of the twist variation accompanying them. Twist tends to be higher at thin places in a yarn. Thus, at such locations, the penetration of a dye or finish is likely to be lowe than at the thick regions of lower twist. In consequence, the thicker yarn region will tend to be deeper in shade than the thinner ones and, if a visual fault appears in a pattern on the fabric, the pattern will tend to be emphasized by the presence of color or by some variation in a visible property, such as crease-resistance controlled by a finish. Other fabric properties, such as abrasion or pill-resistance, soil retention, drape, absorbency, reflectance, or lustre, may also be directly influenced by yarn evenness. Thus, the effects of irregularity are widespread throughout all areas of the production and use of textiles, and the topic is an important one in any areas of the industry. Yarn Evenness deals with the variation in yarn fineness. This is the property, commonly measured as the variation in mass per unit length along the yarn, is a basic and important one, since it can influence so samy other properties of the yarn and of fabric made from it. Such variations are inevitable, because they arise from the fundamental nature of textile fibers and from their resulting arrangement. The spinner tries to produce a yarn with the highest possible degree of homogeneity. In this connection, the evenness of the yarn mass is of the greatest importance. In order to produce an absolutely regular yarn, all fiber characteristics would have to be uniformly distributed over the whole thread. However, that is ruled out by the inhomogeneity of the fiber material and by the mechanical constraints. Accordingly, there are limits to the achievable yarn eveness. Importance of Yarn Evenness:- irregularity can adversely affect many of the properties of textile materials. The most obvious consequence of yarn evenness is the variation of strength along the yarn. If the average mass per unitlength of two yarns is equal, but one yarn is less regular than the other, it is clear that the more even yarn will be the stronger of the two.The uneven one should have more thin regions than the even one as a result of irregularity, since the average linear density is the same. Thus, an irregular yarn will tend to break more easily during spinning, winding, weaving, knitting, or any other process where stress is applied. Yarn Evenness is a measure of the level of variation in yarn linear density or mass per unit length of yarn. In other words, it refers to the variation in yarn count along its length. It is the evenness of staple spun yarn that is of concern here. Continuously filament yarns have virtually no variation in linear density so evenness is not an issue for those yarns. A yarn with poor evenness will have thick and thin places along yarn length, while an even yarn will have little variation in mass or thickness along length. While a yarn may vary in many properties, evenness is the most important quality aspect of a yarn, because variations in other yarn properties are often a direct result of yarn count irregularity. We already know that twist tends to accumulate in the thin places in yarn, so irregularity in yarn linear density will cause variations in twist along yarn length. This preferential concentration of twist in thin places along a yarn also exacerbates the variations in yarn diameter or thickness, which often adversely affects the appearance of the resultant fabrics. An irregular yarn will also vary in strength along the yarn. The 'weakest link' theory says a chain is only as strong as its weakest link. Similarly a yarn is only as strong as its weakest spot. When there are large variations in yarn linear density, there will be many thin spots in the yarn, which are often the weak spots (despite its relatively high twist concentration). / пятна. Прочие свойства ткани, такие как устойчивость к истиранию или скатыванию, . Порок или дефект. высокая крутка .

YARN FROM FILAMENT TOW = ПРЯЖА ИЗ ЖГУТА ЭЛЕМЕНТАРНЫХ НИТЕЙ – Yarn From Filament Tow:- is the formation of a yarn from filament tow by a combination of cutting or breaking, drafting, and twisting in a single series of operations. Also known as Converting.

YARN FROM LEAF AND BAST FIBER = ПРЯЖА ИЗ ЛИСТОВОГО И ЛУБЯНОГО ВОЛОКНА – Yarn From Leaf And Bast Fiber:- in the manufacture of leaf and bast fiber yarns, the terms ‘wet spinning’ and ‘dry spinning’ refer to the spinning of fibers in the wet state and in the air-dry state, respectively.

YARN FROM STAPLE FIBER = ПРЯЖА ИЗ ШТАПЕЛЬНОГО ВОЛОКНА – Yarn From Staple Fiber:- the formation of a yarn by a combination of drawing or drafting and twisting prepared strands of fibers, such as rovings.

YARN IMPERFECTIONS = НЕДОСТАТКИ ПРЯЖИ – A term ‘Yarn Imperfections’ refers to yarn defects that usually either cause thick or thin places in the thread that can cause sewing problems. Some of these yarn imperfections include:- knots, slubs, neps, dropped ply, dropped filament, singles kinks, etc.

YARN INTERMEDIATE = ПОЛУФАБРИКАТ ПРЯЖИ (или ПРЯЖНЫЙ ПОЛУФАБРИКАТ) – Yarn Intermediate is a generic term for products obtained during the conversion of fibers to yarn, including card webs, laps, slivers, rovings, and tops. / Цель и сущность процесса прядения – получение пряжи, нити из полуфабрикатов (ленты и ровницы) на прядильных машинах.

YARN KNOTS = УЗЛЫ ПРЯЖИ – Yarn Knots:- joint of broken threads:- (i) avoid more re-winding as it leads to more knots and adds to yarn hairiness also; (ii) smaller package at rewinding should be avoided; (iii) knot failure should be avoided; (iv) package quality should be checked at rewinding; and (v) use same quality of yarn that is required for warping. These are the reasons of most spinning faults as explained in details. Spinning defect. / Порок или дефект прядения.

YARN LENGTH = ДЛИНА ПРЯЖИ – Yarn Length is the length of yarn wound on a support measured under defined conditions. / Длина Пряжи в мотке:- публикуется фактическая, измеренная длина пряжи в метрах. Допустимое отклонение длины ±5%. Значение длины пряжи используется для подсчёта количества мотков пряжи, необходимых для вязания.

YARN MIXING = СМЕШЕНИЕ ПРЯЖИ – Spinning defect. Yarn Mixing:- mix up of different color, count, twist direction, blend and shade:- (i) material movement should be checked as (lot, shade, blend, count and dyeing plan wise); (ii) marking and labels given during each process; (iii) not to run similar shade side by side; (iv) all shades to be referred with standard shades; (v) remove all ramnant yarn from package; (vi) cutting of bottoms on cops; (vii) mixing of parallel winding and TFO bobbins should be avoided; (viii) non-removable tails; (ix) wrong practices should be avoided; (x) negligence of worker at every stage and avoid wrong marking; and (xi) avoid QC checked material mixing. / Порок или дефект прядения.

YARN NUMBER = НОМЕР ПРЯЖИ – Yarn Number is a relative measure of the fineness of yarns. Two classes of systems are in use:- (i) direct yarn number (equal to linear density) is the mass per unit length of yarn. This system is used for silk and manufactured filament yarns. (ii) Indirect yarn number (equal to the reciprocal of linear density) is the length per unit mass of yarn. This system is used for cotton, linen, and wool-type spun yarns. See also Cotton Count. Cotton yarn is measured in terms of length per unit of weight. N 1 cotton has 840 yards per pound. N 10 has 8 400 yards per pound. The count is inversely proportionate to the size of the yarn. Therefore, N 100 yarn is ten times finer than N 10, etc. Yarn Number is the standard measure of the fineness of yarn, either calculated by number of specified lengths per specified weight, as for cotton, wool or linen (thus, the higher the yarn number, the finer the yarn); or calculated by number of specified weights per specified length, as rayon, silk, or nylon (thus, the higher the number the thicker the yarn). Measures of cotton yarn follow:- 54 inches equals one thread – the circumference of the warp reel; 80 thread equals one lea, 1 lea equals 120 yards; 7 leas equal one hank or 840 yards, the standard yardage for a Number One’s cotton yarn. A bundle equals 10 pounds. Cotton yarn is measured by yarn English number, based on how many hanks (840 yards) there are in 1 pound (lb) of yarn. The higher the number the finer the thread. Yarn measurements are expressed as yarn number, count, or size, and describe the relationship of length and weight (or approximate diameter). Because methods of measurement were developed in various areas of the world, there has been a lack of uniformity in such systems. Indirect measuring systems are those employing higher number to describe finer yarns, and are based on length per unit weight. Most countries measure yarns made from staple fibers according to the weight of a length of yarn. If one pound is used as a standard unit, for example, a very fine yarn will have to be much longer than a coarser yarn to weigh a pound, so higher counts indicate finer yarns. The size number is an indication of the length of yarn needed to reach a weight of one pound. In the United States, the system is based on the number of hanks per pound, with a hank of 840 yards for cotton and spun silk, 300 yards (a lea) for linen, 256 yards for woollen yarns, and 560 yards for worsted yarns. A widely used continental system is based on the number of hanks of 1 000 meters (one kilometer) required to reach a weight of one kilogram. / Найлан^{T3} (Nylon^{TM}). филаментная (комплексная) пряжа (filament yarn). мотовило основы (warp reel). Хлопковая пряжа характеризуется Английским номером (N_E) пряжи, который определяется как количество початков (мотков) пряжи (по 840 ярдов), весящее 1 фунт. Более высокий номер соответствует более тонкой нити. Прядильная способность волокна в большей мере характеризуется прядильным номером. Прядильный номер – это наивысший номер пряжи, которая может быть произведена из данного волокна конкретным оборудованием. шёлк, или Найлан^{T3} (Nylon^{TM}). Номер Пряжи – стандартная сравнительная мера тонины пряжи. Толщина пряжи:- На этикетке мотка фабричного производства часто указывается номер пряжи, выраженный дробным числом, например, № 32/2. Цифры до черты указывают Метрический номер (N_M) пряжи:- чем больше число, тем тоньше нить. Метрический номер выражает длину одного грамма пряжи в метрах (м/г). Цифра после черты показывает, из скольких нитей скручена пряжа. Толщина пряжи в системе текс (tex) численно равна количеству граммов в одном километре пряжи (г/км). Если пряжа скручена из нескольких нитей, это обозначается произведением, например, 100 х 2 текс соответствует № 10/2. Публикация толщины пряжи на мотке не является обязательной. Основными свойствами и показателями качества пряжи и нитей являются:- толщина (тонина), крутка, прочность, растяжимость и ровнота. Толщина пряжи и нитей, так же как и волокон, характеризуется единицами текс, миллитекс и килотекс соответственно в г/км, мг/км и кг/км. Одновременно продолжают пользоваться старой системой характеристики толщины пряжи и нитей, выраженной номером в м/г, мм/мг и км/кг. Толщину пряжи и нитей определяют взвешиванием пасмы (мотка пряжи длиной 100 или 50 м). Предварительно пасму выдерживают не менее 10 часов в стандартных атмосферных условиях. Вес пасмы определяют, пользуясь весами или весовыми квадрантами. Толщину пряжи и нитей можно определить и по коротким отрезкам. В этом случае взвешивание производят на торсионных или аналитических весах. Толщину пряжи и нити, определённую опытно-лабораторным способом, называют фактической толщиной. Толщину кручёной пряжи и нити обозначают произведением, величины текс на число скрученных нитей или дробью, в числителе которой указывают толщину одиночной нити, а в знаменателе – число скрученных нитей. Например, кручёную пряжу, состоящую из двух нитей 18.7 текс (№ 54), обозначают 18.7 текс х 2 (№ 54/2). Номинально-расчётную толщину (тонину) кручёной нити, то есть толщину, определённую расчётным путём без учёта укрутки нитей, устанавливают соответственно умножением величины текса или делением номера на число сложений. Для указанной выше кручёной пряжи она будет 37.4 текс (№ 27). Если кручёная пряжа состоит из двух нитей разной толщины (тонины), например хлопчатобумажная пряжа 25 текс (№ 40) скручена с вискозным шелком 16.6 текс (№ 60), толщину кручёной нити обозначают следующим образом:- х/б 25 текс + ВШ 16.6 текс (№ 40 х/б/60 ВШ). Номинально-расчётная толщина (тонина) такой нити будет составлять 41.6 текс (№ 24). Метрический номер пряжи Nm характеризует тонину пряжи отношением её длины l к весу G. При этом длину выражают в мм, м или км, а вес, соответственно, 0.001 сН, сН или 10 Н. Фактический номер кручёной пряжи, а

также и целлюлозных волокон определяют этим же соотношением. Если номер кручёной пряжи необходимо рассчитать по характеристикам исходном однониточной пряжи, то, кроме номера последней и числа сложений, необходимо знать величину так называемой укрутки относительного укорочения пряжи в процессе кручения. Метрический номер исходной пряжи (номинальный номер), количество и порядок сложений определяют структуру пряжи. Например, для корда обычной является структура 37/5 x 3, гда цифра 5 показывает количество нитей номера 37 в стренге, а цифра 3 – количество стренг в нити корда. Перевод из номерной системы в систему текс следует из зависимости T = 1 000 / Nm. В ряде случаев производители употребляют метрическую систему нумерации, в скобках указывая толщину в текс, например, № 20 (50 текс). Тонину непрерывной нити (шёлк, натуральное, вискозное и синтетические волокна) принято определять весовым номером или титром T, показывающим отношение веса к длине нити. Весовой номер представляет вес (в сН) мотка длиной 9 000 м или вес в Денье (Денье равно 0.05 сН) мотка длиной 450 м, то есть весовой номер нити (или волокна) – это количество Денье в 450 м длины.

YARN NUMBER, EQUIVALENT SINGLE = НОМЕР ПРЯЖИ, ЭКВИВАЛЕНТНЫЙ ОДИНОЧНОЙ – Yarn Number, Equivalent Single is the number of a plied yarn or cord determined by the standard methods used for singles yarns.

YARN QUALITY = КАЧЕСТВО ПРЯЖИ – Yarn Quality:- many modern textile organizations test product quality at every major stage of processing. Yarns are tested for uniform thickness and other characteristics. Various grades of yarn designated by the producer with respect to performance characteristics, e.g., first quality, second quality, etc.

YARN SIZE = РАЗМЕР ПРЯЖИ (или НОМЕР ПРЯЖИ) – Yarn Size:- yarns, or threads, are numbered according to weight. The higher numbers denote fiber fineness. A '1's' cotton yarn has 840 yards in a pound; a '30s' cotton yarn has 25 200 yards in a pound. A '30/2' is a two-ply yarn containing two strands of 30's. Also known as Count. Yarn Size is equal to the equivalent size times the number of ply (20/1 equivalent size = 40/2 or 60/3 yarn size). The cotton count system is used on most spun and corespun sewing threads. This is an indirect numbering system where the larger the number, the smaller the size. 45/2 is finer than a 28/2 yarn size. / Пряжа или нити нумеруются исходя из их веса. Чем выше номер пряжи или нити, тем тоньше волокно, из которого она производится. В одном фунте хлопковой пряжи Английского номера (Ne) 1's содержится 840 ярдов; в одном фунте хлопковой пряжи номера 30's содержится 25 200 ярдов. Английский номер 30/2 соответствует пряже в два сложения, то есть состоящей из двух нитей пряжи 30's. Известен также как Номер (Count).

YARN–TO–CORD CONVERSION EFFICIENCY = ЭФФЕКТИВНОСТЬ КОНВЕРСИИ ПРЯЖИ В КОРД – In tire cord, Yarn-Top-Cord Conversion Efficiency is a measurement relating tensile strength of untwisted yarn to tensile strength of cord. Increasing cord twist or increasing yarn diameter lowers conversion efficiency.

YARN VARIATION = ВАРИАЦИЯ ПРЯЖИ – Yarn Variation:- variation of yarn parameters such as diameter, mass, twist, strength, etc is unavoidable, especially for staple yarns, but this situation is not desired in most cases. See also Ring. The variation of the yarn count (CV count or Coefficient of Variation count) is the variation from one bobbin to the other. If this variation is more than 2% the difference in the fabric is visible with bare eyes.

YARN WASTE = ОТХОД ПРЯЖИ – Cotton Yarn Waste is obtained from 100% cotton yarn and is also called as Hard Waste. Hard Waste has a property of free contamination which makes it desirable in several industries like automotive, car manufacturers, printing, marine, hardware, textile Industry and heavy machinery manufactures and mining industries for cleaning machinery. Hard Waste is 100% cotton; contamination free and is packed in highest order in fully pressed bales. Besides usage of cleaning, Highly water-absorbent, soft and affordable, cotton yarn it is widely used for making mats, mops, wiping cloth, wiping material and cotton dolls and toys. Kinds Of Yarn Waste:- (1) Mill Yarn Waste (Hard Waste); (2) Size Yarn Waste (Sizing Waste); (3) Loom Yarn Waste; and (4) Scaling yarn waste.

Y/A RULES = YORK–ANTWERP RULES

YASHMAK = ЯШМАК (или ЧАДРА) – Yashmak is a veil worn by Muslim women around the upper and lower parts of the face so that only the eyes are visible. Yashmak:- also spelled Yaşmak, long, narrow face screen or veil traditionally worn in public by Muslim women. The yashmak can consist of a piece of black horsehair attached near the temples and sloping down like an awning to cover the face, or it can be a veil covered with pieces of lace, with slits for the eyes, tied behind the head by strings and sometimes supported over the nose by a small piece of gold, ivory, or silver. The yashmak is usually worn with an enveloping garment most frequently called a Chador. The custom of wearing the costume is centuries old, but in the XX century it was slowly abandoned except in the most traditional Islamic societies. Its use spread once again late in the XX century owing to the resurgence of Islam in Middle Eastern and other countries. / Под Чадрой понимается лёгкое белое, синее, реже чёрное покрывало, в которое с головы до ног закутывались женщины-мусульманки при выходе из дома, оставляя открытыми только глаза. Сохраняется частично в некоторых странах Востока, а также в Западно-Европейских странах, где выходцы из стран, где преобладает ислам в качестве религии, формируют некие общины и даже целые городские районы, в которых живут по своим обычаям, а не по законам данной страны.

YAW = РЫСКАТЬ – To Yaw:- to swing or steer off course, as when running with a quartering sea. To Yaw:- to steer wildly or out of line of course. / Рыскать – вести судно непредсказуемым образом или сходить с линии курса. О транспортных средствах:- двигаться, уклоняясь от курса то в одну, то в другую сторону. Идя по курсу, незначительно отклоняться от него в ту или другую сторону (о судне, самолете, автомобиле и тому подобном). Рыскать На Ходу – плыть по течению, маневрировать, применяя разные способы (шест, парус, якорь), чтобы удержаться на фарватере.

YAWL = ЯЛ (или ЙОЛ) – Yawl is a small oar-propelled open boat or skiff carried aboard a towboat for use as a utility boat. See also Skiff. Yawl is a vessel's small boat moved by one oar. Synonym:- a Jolly-Boat. A small sailboat rigged fore-and-aft, with a short mizzenmast astern of the cockpit; distinguished from ketch. Yawl is two-masted sailboat, usually rigged with one or more jibsails, a mainsail, and a mizzen. In common with the ketch, the forward (main) mast is higher than the mizzenmast, but the mizzenmast of a yawl is placed astern of the rudder post, while that of the ketch is closer amidships. Like most modern pleasure boats, yawls are rigged with fore-and-aft sails (in line with the keel), the most effective rigging in utilizing manpower. The word yawl is sometimes applied to a dinghy and to a light fishing vessel rigged with lugsails. / Под Ялом, от Голландского слова Jol, понимается 2–8 вёсельная относительно короткая и широкая судовая шлюпка с транцевой (плоской) кормой, приводимая в движение одним–четырьмя гребцами. Ял – одномачтовая рабочая или учебная корабельная шлюпка, короткая и широкая, имеющая от одной до нескольких пар вёсел.

YAWL PLAY = СОСТЯЗАНИЕ НА ЯЛАХ – Yawl Play is the use of a yawl to row lines or personnel between boat and bank.

Y AXIS = ОСЬ ИГРЭК. – The Y Axis is the vertical scale used in a graph. It serves as a reference line from which measurements are made on a coordinate plane. The distance from the Y axis and X axis describes the location of an item on that plane. On graphs, Y Axis is the vertical axis. Analysts generally use the Y axis for the dependent or variable information (total returns, prices, yields). They

generally use the X axis for the independent or fixed information (times, dates, numbers of securities). / На плоскости задаются две взаимно перпендикулярные прямые (координатные оси), пересекающиеся в точке 0, называемой началом координат. Одна из них – ось Икс. (X), или ось абсцисс, обычно выбирается горизонтальной, другая – ось Игрэк. (Y), или ось ординат, – вертикальной. Справа от 0 выбирается точка, у которой ставится отметка, например, 1. Если принять отрезок от 0 до 1 за единицу длины, то откладывая последовательно этот отрезок вдоль прямой, мы получаем числовую ось. Считается, что эта ось продолжается вправо до бесконечности. Точки на оси X слева от 0 помечаются отрицательными числами, как на шкале термометра. Например, точка –2 расположена от точки 0 слева на таком же расстоянии, как точка 2 справа. Аналогичным образом с той же единицей длины размечается и ось Y. Положительные числа располагаются выше точки 0, отрицательные – ниже.

YBS = YOU'LL BE SORRY

YBS = YOUNG, BEGINNING, AND SMALL

YCACT = YOUTH COALITION OF THE AUSTRALIAN CAPITAL TERRITORY

Y CHROMOSOME = ИГРЭК. ХРОМОСОМА (или Y ХРОМОСОМА) – Y Chromosome:- a sex chromosome that is characteristic of male zygotes (and cells) in species in which the male typically has two unlike sex chromosomes. / Игрэк. Хромосома – половая хромосома, половая хромосома, присутствующая исключительно в клетках мужского организма.

Y CHROMOSOME SHORT TANDEM REPEAT DNA = ИГРЭК. ХРОМОСОМА КОРОТКИЙ ТАНДЕМНЫЙ (или КОНЦЕВОЙ) ПОВТОР ДНК – Y Chromosome Short Tandem Repeat DNA (YSTR DNA) is a DNA found only in males (since they are the only humans with Y chromosome).

yd = YARD

YD = YELLOW DISCOLORATION

YE = YEMEN

YEAR 2000 = ГОД 2000 – Year 2000 (Y2K):- many systems, especially computers and equipment with embedded computer chips, are likely to fail on 01/01/2000. This is because such equipment stores years by the last 2 numbers (e.g., 1999 = 99, 2000 = 00) and many computers, etc, are programmed to understand the year 00 to be 1900, etc. See also Millenium Bug.

YEAR – BOOKED = ГОД – ЗАБРОНИРОВАННЫЙ (или XX) – Year – Booked:- in insurance, xxxxx. See also Entered Year.

YEAR – CALENDAR = ГОД – КАЛЕНДАРЬ (или XX) – Year – Calendar:- in insurance, premium and loss transactions occurring during the twelve calendar months.

YEAR – CLOSED = ГОД – ЗАКРЫТЫЙ (или XX) – Year – Closed:- the calendar year in which the premium is first advised to the company by a broker irrespective of the year or period time when the policy incepted. Also known as Closing Year.

YEAR CODES = ГОДИЧНЫЕ КОДЫ – Year Codes are the last two digits of the year are used to identify the individual contracts that are available on CQG Systems. The Year Code should be entered if contracts for more than one year are on the system. The system assumes the current year if a Year Code is not specified. The Year Code should be included when accessing an option to eliminate any confusion between the Year Code and the Strike Price. For example, USZ06 indicates the following:- (i) US = US Treasury Bond (Chicago Board of Trade); (ii) Z = December; and (iii) 06 = 2006. / Годичные Коды – это последние две цифры года, используемые для идентификации отдельных контрактов, которые доступны в системах Си.Кью.Дьжи. (CQG). Годичный код должен вводиться в тех случаях, когда в данной системе торгуются контракты более, чем по одному году. Если годичный код не специфицируется, то система по умолчанию предполагает текущий год. Годичный код должен вводится всегда, когда осуществляется доступ к опциону. Это делается с тем, чтобы исключить возможные разночтения между годичным кодом и сходной ценой (strike price). Например, USZ06 говорит о следующем:- (i) US = Облигация Казначейства США в Чикагской Палате Торговли (US Treasury Bond (Chicago Board of Trade; Чикагского Табло Торговли, если быть более точными)); (ii) Z = Декабрь; и (iii) 06 = 2006.

YEAR–END CLOSING = ЗАКРЫТИЕ НА КОНЕЦ ГОДА – Year-End Closing is an accounting procedure undertaken at the end of the year to close out business from the previous year, carry forward balances from the previous year, and open posting accounts for the upcoming year. Year-end closing is part of a company's closing operations, and is used to create a company's financial statements. See also Day-End Closing, and Month-End Closing.

YEAR–END DIVIDEND = ДИВИДЕНД В КОНЦЕ ГОДА – Year-End Dividend is an additional dividend beyond the regular, quarterly dividend that is given to stockholders based on the company's profit level at year end. In good years, the dividend may be large, and in bad years, no year-end dividend is paid out. The year-end dividend is discretionary, and many companies don't pay it. Year-End Dividend is a special dividend declared at the end of a fiscal year that usually represents distribution of higher-than-expected company profits. Year-End Dividend is an extra dividend paid at the end of the fiscal year depending on the amount of the profits. A company announces a year-end dividend especially if revised estimates show a greater than expected profit. A company waits until the end of the year to revise and attempt to verify these estimates before declaring the dividend. More broadly, it may refer to the last dividend declared in a year. Year-End Dividend is a payment to stockholders from Retained Earnings, declared at or near the end of the business year. Year-End Dividend is a dividend paid out to stockholders that is determined by how well the company performed during the previous year. Companies are not required to pay out year-end dividends regardless of how well or how poorly the company performs. / Привилегированные акции называются так потому, что дают акционерам, владельцам, право на получение фиксированного дивиденда в конце хозяйственного года. Этот дивиденд устанавливается в определённом проценте от номинала, скажем 3 процента, 5 процентов, то есть владелец такой акции твёрдо знает, что, если акционерное общество получит в конце года прибыль, он получит на свою акцию соответственно 3 или 5 процентов дивидендов. Дивиденд по привилегированным акциям выплачивается в первую очередь, и в этом то же привилегия привилегированных акций. Уже после выплаты дивидендов по привилегированным, выплачивается дивиденд по простым, если прибыли хватает. Может получиться так, что после выплаты по всем привилегированным акциям, простым акционерам ничего не достанется. Но во всех странах привилегированные акции – это акции не голосующие (безголосые). Дивиденд По Итогам Года – дополнительный или специальный дивиденд, объявляемый на основе прибыли компании за весь финансовый год. Дивиденд В Конце Года – специальный или дополнительный дивиденд, объявленный советом директоров корпорации в конце финансового года корпорации.

YEAR – ENTERED = ГОД – ПОСТУПИВШИЙ (или XX) – Year – Entered:- year during which premiums are entered on the company's books. Losses are recorded within the same year. (Booked, Closed and Signed are all synonymous).

YEAR FREE OF PREMIUM = ГОД, СВОБОДНЫЙ ОТ ПРЕМИИ (или ГОД БЕЗ ПРЕМИИ) – Year Free Of Premium:- some insurers offer insurance, especially household, under which a free year is granted from time to time, usually as a no claims bonus.

YEAR – INCEPTION = ГОД – ВОЗНИКНОВЕНИЕ (или XX) – Year – Inception:- the calendar year in which a risk commences to run.

YEARLING = ГОДОВАЛЫЙ – Yearling is a sheep or goat that is 12–18 months of age. The meat of sheep between 12 and 20 months old may be called yearling mutton. Yearling is an animal that is more than one year old, but less than two. See also Long Yearling, and Short Yearling. / Мясо годовалой овцы курдючной. Мягкостью, изысканным и насыщенным вкусом отличается молодая баранина – это мясо ягнёнка, не достигшего годовалого возраста. Обычная баранина – мясо барашков старше 2 лет. Покупайте мясо блестящее, влажное, но не липкое и не скользкое. Поверхностный жир должен быть белым, напоминающим воск. В зависимости от возраста животного цвет мяса может варьировать от розового до светло-красного.

YEARLY CHARTS = ПОГОДОВЫЕ ГРАФИКИ – In visual analysis, a term Yearly Charts is used to describe those charts that are constructed of yearly bars or candles. Each yearly bar or candle contains the Open, High, Low, and Close that occurred during each year. Yearly Charts are the graphical representation of price where the time interval is one year for each bar or candle. The term 'Tearly' or 'Annual' is used to describe those charts that are constructed of annual bars or candles. Each annual bar or candle contains the Open, High, Low, and Close that occurred during each one-year time interval. Also known as Annual Charts. / Термин Погодовой или По Годам используется для описания таких графиков, которые строятся на основе среднегодовых штрихов или свечей. Каждый погодовой штрих или свеча содержит цены Открытия, Максимума, Минимума и Закрытия, имевшие место в течение каждого года. Графическое отображение цены, где временным интервалом для каждого штриха или свечи служит один год. Термин 'Погодовой' или 'По Годам' используется для описания тех графиков, которые используют погодовые штрихи или свечи. Каждый погодовой штрих или свеча содержит цены Открытия (Open), Максимальную (High), Минимальную (Low) и Закрытия (Close), которые имели место в течение каждого одногодичного интервала. Известны также как Ежегодные Графики (Annual Charts). Погодовой График движения рынка – график движения рынка, на котором отражаются колебания цены за год. График – совокупность цен, наложенных на временной интервал. В математике и статистике, графиком можно назвать временной ряд. Если взять погодовой график, то окажется, что какой-то год был точкой абсолютного минимума, а какой-то – точкой абсолютного максимума.

YEARLY RENEWABLE TERM = ЕЖЕГОДНО ВОЗОБНОВЛЯЕМЫЙ СРОК – Yearly Renewable Term (YRT) or Risk Premium Reinsurance Basis:- reinsurance arrangements written on this basis transfer the mortality risk to the reinsurer. For every age, plan, and policy year, there is a certain reserve per USD1 000.00 of insurance. In calculating the insurer's available surplus capital, this is the liability that is deducted from assets to arrive at the insurer's available surplus capital. Since this reserve amount is already in the insurer's liabilities, it is clear that if the insurer is called upon to pay more than this amount, only the excess over the reserve needs to be taken from the insurer's available surplus capital. In the event of a death claim, assets are reduced by the face amount paid, liabilities are reduced by the reserve amount, and the excess of the face amount over the reserve comes from its available surplus capital. This excess is called the 'Policy Net Amount At Risk'. In the reinsurance agreement the ceding company and the reinsurer agree upon how the policy net amount at risk will be apportioned between them. The ceding company would prepare a schedule of the net amounts at risk for each policy year. The reinsurer would develop a schedule of yearly renewable term premium rates for reinsurance on the ceding company's schedule. The ceding insurer would pay the reinsurer the established premiums for the appropriate net amounts at risk each year. In the occurrence of a claim, the reinsurer would remit payment for the assumed potion of the policy's net amount at risk. Although the policy net amount at risk will decline over time as the policy reserves increase, it is common for the parties to agree to make adjustments only at agreed intervals to ease administration and lower processing costs. This reinsurance method is widely used because it reduces reinsurance to its fundamentals and provides a very flexible mechanism for satisfying the insurer's reinsurance needs. / Перестраховщик может разработать график ставок страховой премии с ежегодно возобновляемым сроком за перестрахование по .

YEARLY TERM REINSURANCE = ПЕРЕСТРАХОВАНИЕ НА ПОГОДИЧНЫЙ СРОК – Yearly Term Reinsurance:- xxxxx.

YEAR OF ACCOUNT = ГОД УЧЁТА (или ГОД ОТЧЁТА) – Year Of Account is the year in which an insurance or reinsurance contract that is underwritten by a syndicate is allocated for accounting purposes and into which all premiums and claims arising in respect of that contract are payable. Insurance or reinsurance contracts are generally allocated to years of account according to the calendar year of their inception date so that a contract that commences in 2005 will normally be allocated to the 2005 year of account. Historically syndicates have operated a three year accounting system which means that each calendar is normally left open for two further years before a profit or loss is determined. A year of account is normally closed by reinsurance to close at the end of 36 months. Year Of Account is the year to which a risk is allocated and to which all premiums and claims in respect of that risk are attributed. The year of account of a risk is usually determined by the calendar year in which the risk incepts. A year of account is normally closed by reinsurance at the end of 36 months. See also Open Year Of Account.

YEAR OF COMMERCIAL OPERATION = ГОД КОММЕРЧЕСКОЙ ОПЕРАЦИИ – Year Of Commercial Operation is the year in which the control of the loading of a generating unit is turned over to the system dispatcher.

YEAR OF CONSTRUCTION = ГОД ПОСТРОЙКИ – Year Of Construction is the year the structure was originally completed or the year any part of the structure was first occupied. For mobile homes year of construction is the model year. Year of Construction refers to the original year the structure was built.

YEAR OF CONSTRUCTION OF VESSEL = ГОД ПОСТРОЙКИ СУДНА – Year Of Construction Of Vessel (for inland waterways transport) is a year of original construction of the hull. Year of Construction of Vessel is the year of original construction of the hull.

YEAR OF ORIGIN = ГОД ПРОИСХОЖДЕНИЯ (или XX) – Year Of Origin:- the financial year in which a claim made against a company is known to have originated.

YEAR–ON–YEAR CHANGES = ИЗМЕНЕНИЯ ЗА ГОД (или ИЗМЕНЕНИЯ ОТ ГОДА К ГОДУ) – An Year-On-Year (YoY):- year-on-year comparison is made between the results for a period and the same period in the previous year. This means that it is not usually distorted by an seasonal effects. Using year on year comparisons is not an infallible way of eliminating seasonal effects because some seasonal effects are not firmly fixed to calendar dates. For example Easter has an effect on retail sales, but Easter days changes from year to year. Some companies provide estimates of the impact of changes in the date of Easter, but this, like all such non-standard estimates, needs to be regarded with a little scepticism. Changes in the weather are even worse:- no fixed dates, unpredictable, and not purely seasonal. If the structure of a company's businesses has changed (e.g., though acquisitions), then it may be preferable to do year on year comparisons on pro-forma and organic numbers. Year-On-Year (YoY) Changes are changes in levels expressed over the corresponding period (month or quarter in relation to the frequency of the data) of the previous year. Also often referred to as Year-Over-Year Changes, or Year-To-Year Changes. Year Over Year (YOY) is a method of evaluating two or more measured events to

compare the results at one time period with those from another time period (or series of time periods), on an annualized basis. Year-over-year comparisons are a popular way to evaluate the performance of investments. Any measurable events that recur annually can be compared on a year-over-year basis – from annual performance, to quarterly performance, to daily performance. Year-over-year performance is frequently used by investors seeking to gauge whether a company's financial performance is improving or worsening. For example, a business may report that its revenues have increased for the third quarter on a year-over-year basis for the last three years. This means that revenues at that company in the third quarter of year three were higher than revenues in the third quarter in year two, which were higher than revenues in the third quarter of year one. As another example, a mutual fund that returned 50% last year may have a YOY return of 12%, as the year-over-year return takes into account each annual return since the fund's inception.

YEAR–ON–YEAR GROWTH RATES = СТАВКИ РОСТА (или ПРИРОСТА) ЗА ГОД (или ОТ ГОДА К ГОДУ) – Year-On-Year (YoY) Growth Rates:- this method calculates quarterly growth rates as the percentage change in real Gross Domestic Product (GDP) from the corresponding quarter in the previous year. It yields the y-o-y (year-on-year) or nsa (nonseasonally adjusted) growth rate and is used in most European and Asian countries, including Singapore. The merits of this method are its ease of comparison with annual growth rates and its implicit seasonal adjustment. For example, the seasonally higher 4th quarter (which includes the Christmas and yearend festive period) is compared with the 4th quarter of the previous year. Thus, y-o-y growth rates display an underlying trend but remains sensitive to irregular effects and deviations from expected seasonal behaviour. Y-o-y growth rates do have some disadvantages. First, no correction is made for differences in the number of working days arising from leap year or moving holidays such as Hari Raya. More working days could, for example, result in a higher growth rate even when the underlying trend is declining. Second, the sensitivity to irregular effects could result in an inappropriate interpretation in a subsequent year. For example, if economic activity declines sharply in a particular quarter because of an unexpected shock, a 'normal' quarter in the subsequent year will show an exceptionally strong growth. This is often referred to as a Base Effect. To illustrate the base effect, consider Chart 1 which shows the growth rates in the real value-added of hotels and restaurants from 1990 to 1992. Because of the Gulf War, tourist arrivals declined sharply resulting in a decline of 5.3 per cent in the real value-added of hotels and restaurants in 1Q91. Hotels and restaurants grew strongly by 16.4 per cent in 1Q92 when the underlying trend returned to normal. Third, y-o-y growth rates are slower in identifying turning points. Chart 2, for example, shows that real GDP contracted sharply by 6.1 per cent in 4Q01 on a y-o-y basis. Growth momentum, however, has already improved, as reflected in the positive q-o-q (quarter-on-quarter) change in the seasonally adjusted real GDP in 4Q01. Year-On-Year (YoY) Growth Rates are rates of change expressed over the corresponding period (month or quarter in relation to the frequency of the data) of the previous year. Also often referred to as Year-Over-Year Growth Rates, Year-To-Year Growth Rate, Rate Of Change From The Previous Year, or 12-Month Rate Of Change. / Хари Рая (Hari Raya). гостиниц и ресторанов с 1990 по 1992.

YEAR – OPEN = ГОД – ОТКРЫТЫЙ (или XX) – Year – Open:- an insurance year of account which is not closed or finalised, common with Lloyds who keep a year of account open until the 36th month.

YEAR–OVER–YEAR = ГОД–СПУСТЯ–ГОД – Year-Over-Year (YOY) is a comparison of a company's current earnings or other financial performance with the same data for the previous year. Compare Last Fiscal Year (LFY); Most Recent Quarter (MRQ); Trailing 12 Months (TTM).

YEAR PLAN = ГОДОВОЙ ПЛАН – Year Plan is a calendar, policy, or fiscal year on which the records of the plan are kept. / Календарный, полисный, или фискальный год, по которому поддерживаются записи в плане.

YEAR – POLICY = ГОД – ПОЛИС (или XX) – Year – Policy:- the year commencing with the effective date of the policy or with an anniversary of that date.

YEAR – SIGNED = ГОД – ПОДПИСАННЫЙ (или XX) – Year – Signed:- xxxxx. See also Entered Year.

YEAR SPREAD = КУРСОВАЯ РАЗНИЦА ПО ГОДАМ (или СПРЭД ПО ГОДАМ) – Year Spread is a spread between two-year contracts.

YEARS PURCHASE = ГОДЫ ПРИОБРЕТЕНИЕ – Years Purchase:- the present value of unit annual rental income from a property. Years purchase factors can be in respect of rent received in perpetuity (in which case they are the reciprocal of the yield), or they can be for a specified term (equivalent to an annuity certain).

YEAR'S REVISION RATIO = ПЕРЕСМОТРЕННОЕ СООТНОШЕНИЕ ПО ГОДУ – Year's Revision Ratio:- xxxxx. / Пересмотренное Соотношение По Году (Year's Revision Ratio):- среднегодовой коэффициент переоценки запасов. Коэффициент изменения доказанных запасов в результате их переоценки по мере доразведки месторождений и изменения коэффициентов извлечения полезного ископаемого.

YEARS TO MATURITY = ЛЕТ ДО ПОГАШЕНИЯ – Years To Maturity:- the remaining term of a security, excluding any options or prepayment features.

YEAR–TO–DATE = С НАЧАЛА ГОДА К ДАННОЙ ДАТЕ – Year-To-Date (YTD) often appears on financial statements indicating income and expenses for a certain point in the year in a budget cycle. It is a very useful tool to measure actual numbers against those projected. Year-To-Date (YTD) is the period beginning at the start of the calendar year up to the current date. Year-To-Date (YTD) is a period, starting on a date which depends upon the country and the purpose, which is not more than one calendar year ago and ending on the day in question, e.g., today. Dates on which a year is deemed to start for this purpose include January 01 (calendar year), July 01, 01 April (UK corporation tax and government financial statements), and 06 April (UK fiscal year for personal tax and benefits). Year-to-date is used in many contexts, mainly for recording results of an activity in the time between a date (exclusive, since this day may not yet be 'complete') and the beginning of either the calendar or fiscal year. In the context of finance, YTD is often provided in financial statements detailing the performance of a business entity. Providing current YTD results, as well as YTD results for one or more past years as of the same date, allows owners, managers, investors, and other stakeholders to compare the company's current performance to that of past periods. Employees' income tax may be based on total earnings in the tax year to date. YTD describes the return so far this year. For example:- the year to date (YTD) return for the stock is 8%. This means from 01 January of current year to date, stock has appreciated by 8%. Another example: the year to date (ytd) rental income of a property (whose Fiscal Year End is 03/31/09) is USD1 000.00 as of 06/30/08 (2008-June-30). This means that the property brought in USD1 000.00 of rental income during the period 04/01/08 through 06/30/08 (= the YTD period for the property). Comparing YTD measures can be misleading if not much of the year has occurred, or the date is not clear. YTD measures are more sensitive to early changes than late changes. Contrast YTD with the concept of 12-months-ending (or Year-ending), which are more resistant to seasonal influences. If an employee is taxed based on pay during the year to date, the total tax due as of the end of week 33 of the tax year is calculated on total pay from the beginning of week 1 until the end of week 33; tax payable for that week will be this total tax minus tax already paid. Year-To-Date (YTD):- based on the beginning of the calendar year to a specified date. / Период от начала фискального года (fiscal year, FY) до

даты отчётности. Например, результаты деятельности компании за третий квартал в отчётности следует отражать только как квартальные или на дату от начала года, которая составляет девять месяцев.

YEAR–TO–DATE DATA = ДАННЫЕ С НАЧАЛА ГОДА К ДАННОЙ ДАТЕ – Year-To-Date Data are the data expressed in cumulative terms from the beginning of the year; sometimes referred to as Cumulative Data. YTD is short for Year-to-Date; meaning the period beginning of the calendar year, January 1st of the current year, or the fiscal year up until today's date.

YEAR TO DATE NET INCOME = С НАЧАЛА ГОДА К ДАННОЙ ДАТЕ – Year-To-Date Net Income is a company's net income from the start of the current accounting year until a specified date. For example, the year-to-date net income at May 31, 2012 for a calendar year company is the net income from January 01, 2012 until May 31, 2012. For a company with a fiscal year beginning on July 01, 2011 the year-to-date net income at May 31, 2012 is the net income for the 11-month period from July 01, 2011 through May 31, 2012. Year To Date Net Income is the revenue recognized for a company from the beginning of the calendar year to a specified date. Year-To-Date Net Income is the after-tax earnings from the beginning of an entity's fiscal year to the present reporting date. For example, if the fiscal year of a business is the same as its calendar year and it has released an income statement through July 31, then the income statement should contain year-to-date net income that spans the period from January 01 to July 31.

YEAR–TO–DATE PRICE CHANGE = ИЗМЕНЕНИЕ ЦЕНЫ С НАЧАЛА ГОДА К ДАННОЙ ДАТЕ – Year-To-Date Price Change is the price difference of a security between the end of last year and the price displayed. Price Change is the difference in the cost of an asset or security from one period to another. While it can be computed for any length of time, the most commonly cited price change in the financial media is the 'daily price change', which is the change in the price of a stock or security from the previous trading day's close to the current day's close. Price change over a period of time such as year-to-date or past 12 months are also commonly used time periods, and is generally computed as a percentage change. Percentage price change is generally the norm for computing asset performance. For shorter intra day periods, absolute price change may be used by momentum and algorithmic traders as the basis for trading and arbitrage strategies. Price change forms one of the two elements that comprise the total returns from an investment over a period of time, the other being dividends or distributions obtained from the investment.

YEAR–TO–YEAR = В ОТНОШЕНИИ К ПРЕДШЕСТВУЮЩЕМУ ГОДУ (или ГОД К ГОДУ) – Year-To-Year:- being compared with those of a previous year (of annual statistics).

YEAST = ДРОЖЖИ – Yeast is a unicellular Ascomycete that typically multiplies by a budding process, although some yeasts (e.g., Sacharomyces Pombe) multiply by symmetrical division. Sacharomyces species are important mediators of the commercial fermentation of carbohydrates to alcohol. Yeast is a fungus of the Family Saccharomycetaceae. Yeast is a tiny plant-like microorganism that serves as a catalyst in the process of fermentation. The organism is used to ferment sugars (primarily glucose) to ethanol. / Дрожжи – одноклеточные Аскомицеты (сумчатые грибы), которые размножаются преимущественно посредством процесса почкования, хотя некоторые дрожжи (например, Сачаромицэс Помбэ (Sacharomyces Pombe)) размножаются симметрическим делением. Сачаромицэс виды являются важными медиаторами (или посредниками, или переносчиками) коммерческой ферментации (брожения) углеводов в спирт. Под Дрожжами понимается сборная группа одноклеточных грибов из различных классов (базидиальные, несовершенные, сумчатые). Широко распространены в природе. Размножаются преимущественно почкованием. Многие вызывают спиртовое брожение. Богаты белком, витаминами группы В. Используются в виноделии, пивоварении, хлебопечении, сельском хозяйстве (дрожжи кормовые) и другом; пивные дрожжи – в медицине при гиповитаминозе B_1, нарушениях обмена веществ, фурункулёзе и другом. Под Кормовыми Дрожжами понимаются дрожжи, получаемые специально на корм сельскохозяйственным животным. Для их производства используют дрожжи видов Torula utilis, Monilia murmanica и другие. Выращивают их на отходах древисины, кукурузных стержнях, лузге Подсолнечника, соломе, а также на отходах сульфитно-целлюлозного и спиртового производств. Из 1 тонны (т) древесины можно получить 200–250 килограммов (кг) кормовых дрожжей, из 1 т кукурузных стержней 200–280 кг. Кормовые дрожжи – ценный белково-витаминный корм для сельскохозяйственных животных всех видов, в 100 кг сухих кормовых дрожжей 119 кормовых единиц и 41.9 кг переваримого протеина. Белок отличается высокой переваримостью и биологической полноценностью. В кормовых дрожжах содержатся витамины группы В, провитамин D_2 (эргостерин), минеральные вещества, ферменты, гормоны, способствующие усвоению белков и углеводов. Скармливают кормовые дрожжи с концентрированными кормами или в составе комбикормов. В рационах животных кормовые дрожжи могут составлять 2–3% по питательности. Дрожжи – грибы, семейства Saccharomycetaceae, использующиеся человеком в виноделии и хлебопечении.

YEAST ARTIFICIAL CHROMOSOME = ДРОЖЖЕВАЯ ИСКУССТВЕННАЯ ХРОМОСОМА – Yeast Artificial Chromosome (YAC):- pieces of DNA (usually human DNA) that have been cloned (made) inside living yeast cells. While most bacterial vectors cannot carry DNA pieces that are larger than 50 base pairs, YACs can typically carry DNA pieces that are as large as several hundred base pairs. / Дрожжевая Искусственная Хромосома – участок ДНК (обычно хромосома человека), клонируемый в геноме дрожжей.

YEAST EPISOMAL PLASMID = ДРОЖЖЕВАЯ ЭПИСОМАЛЬНАЯ ПЛАЗМИДА – Yeast Episomal Plasmid (YEP) is a cloning vehicle used for introduction of constructions (i.e. genes and pieces of genetic material) into certain yeast strains at high copy number. YEP can replicate in both Escherichia Coli and certain yeast strains. / Дрожжевая Эписомальная Плазмида – плазмида, использующаяся для клонирования генов в клетках дрожжей.

YEAST TWO–HYBRID SYSTEM = ДРОЖЖЕВАЯ ДВУГИБРИДНАЯ СИСТЕМА – Yeast Two-Hybrid System is a valuable tool used to identify interacting proteins. The protein of interest is expressed in yeast as a fusion to the DNA-binding domain of a transcription factor lacking a transcription activation domain. The DNA-binding fusion protein is generally called the bait. The yeast strain also contains one or more reporter genes with binding sites for the DNA-binding domain. To identify proteins that interact with the bait, a plasmid library that expresses cDNA-encoded proteins fused to a transcription activation domain is introduced into the strain. Interaction of a cDNA-encoded protein with the bait results in activation of the reporter genes, allowing cells containing the interactors to be identified. / Дрожжевая Двугибридная Система – система, использующаяся для изучения белок-белкового взаимодействия.

YEF = YEAR END FORECAST

YEL = YOUNGEST FULLY EMERGED LEAF BLADE

YELLING MARKETS = РЫНКИ ОГЛАШЕНИЙ (или РЫНКИ ВЫКРИКОВ) – Yelling Markets refers to markets where transactions involve the yelling of prices and quantities during the transaction. Yelling Markets:- also referred to as 'Public Outcry', refers to markets where transactions involve the yelling of prices and quantities, just as in the movies. / Рынки Оглашений или Рынки Выкриков относятся к рынкам, на которых осуществление операций сопряжено с оглашением или выкриком цен и количеств в процессе заключения сделок.

YELLOW = ЖЁЛТОЕ – Yellow:- a color whose hue resembles that of ripe lemons or sunflowers or is that of the portion of the spectrum lying between green and orange.

YELLOW BOOK = ЖЁЛТАЯ КНИГА – (1) In the United States, Yellow Book is written by the General Accounting Office; the yellow book sets forth standards to be followed in auditing the financial statements of entities that receive federal financial assistance. 'Yellow Book' is the name given to 'Government Auditing Standards' issued by the Comptroller General of the United States which contains standards for audits of government organizations, programs, activities and functions, and of government assistance received by contractors, non-profit organizations, and other non-government organizations. / В Соединённых Штатах Америки Жёлтая Книга, написанная Генеральным Управлением по Бухгалтерскому Учёту (the General Accounting Office). Она излагает стандарты, в соответствии с которыми должен осуществляться аудит финансовых отчётов юридических лиц, получающих федеральную финансовую поддержку. Фактически термин Жёлтая Книга является названием, данным Стандартам Государственного Аудита (Government Auditing Standards), выпускаемым Генеральным Контролёром Соединённых Штатов (the Comptroller General of the United States). Жёлтая Книга содержит стандарты для аудита правительственных организаций, программ, видов деятельности и функций, и государственной поддержки, получаемой подрядчиками, некоммерческими организациями и иными неправительственными организациями.

(2) In the United Kingdom, the Yellow Book is short-lived but influential illustrated quarterly magazine devoted to aesthetics, literature, and art. It was published in London from 1894 to 1897. From its initial visually arresting issue, for which Aubrey Beardsley was art editor and for which Max Beerbohm wrote an essay, 'In Defense of Cosmetics', The Yellow Book attained immediate notoriety. Published by John Lane and edited by Henry Harland, The Yellow Book attracted many outstanding writers and artists of the era, such as Arnold Bennett, Charlotte Mew, Henry James, Edmund Gosse, Richard Le Gallienne, and Walter Sickert. / Обри Бэадсли (Aubrey Beardsley) Мэкс Биабём (Max Beerbohm). Дьжон Лэйн (John Lane), Хэнри Алэнд (Henry Harland), Анолд Бэнэт (Arnold Bennett), Шарлот Мью (Charlotte Mew), Хэнри Дьжеймз (Henry James), Эдмэнд Госс (Edmund Gosse), Ришар Лё Гяльенн (Richard Le Gallienne), и Волтё Сикёт (Walter Sickert). Жёлтая Книга – свод правил Британской фондовой биржи для включения в официальный котировочный лист Лондонского рынка акций. В Соединённом Королевстве Жёлтая Книга – обиходное название справочника Условия Включения Ценных Бумаг в Котировочный Лист – книги, издаваемой Советом Лондонской Фондовой Биржи, содержащей свод правил включения в официальный котировочный лист (Official List) и перечень обязательств, налагаемых на компании, у которых есть ценные бумаги, включённые в котировочный лист.

YELLOWCAKE = ЖЁЛТЫЙ ТОРТИК – Slang in energy industries. 'Yellowcake' is another name for Uranium Oxide, named for its color and texture. After uranium is mined and separated from ore, it is made into 'yellowcake' and shipped to a conversion plant for more processing. Uranium must first be converted into a gaseous form and then go through a long process of 'enrichment' before it can be used by a nuclear power plant. Nuclear power plants generate around 20 percent of the electricity produced in the United States. Yellowcake is a natural uranium concentrate that takes its name from its color and texture. Yellowcake typically contains 70 to 90 percent U_3O_8 (uranium oxide) by weight. It is used as feedstock for uranium fuel enrichment and fuel pellet fabrication. / Урановый концентрат U_3O_8 это продукт, получаемый при переработке урановой руды, и который характеризуется высоким содержанием оксида урана U_3O_8.

YELLOW CORN = ЖЁЛТОЗЁРНАЯ КУКУРУЗА (или ЖЁЛТАЯ КУКУРУЗА) – Yellow Corn is a Corn that is yellow-kerneled and contains not more than five percent of Corn of other colors. Yellow kernels of Corn with a slight tinge of red are considered yellow Corn. See also Corn Classes. Yellow Corn is a variety of sweet Corn. Its ears are wrapped in tightly bound lime hued husks with silks and a tassel that extend out from the tip. The yellow kernels are packed in tight almost uniform rows. A single ear of Corn can contain up to 400 kernels. Freshly harvested yellow Corn at its peak ripeness is sweet, offering flavors of almond and sugar, the kernels so succulent, the skin pops as you bite into it. As the Corn matures, the kernels lose their milky consistency giving way to a starchy and doughy consistency. At this point, the Corn is considered a grain crop and is best suited for processing or feedstock. Seasons/Availability:- Yellow Corn is available year-round. Current Facts:- Corn, scientific name Zea mays and known outside of English languages as simply Maize, is a member of the grass family Gramineae. It is technically classified as a grain crop, though when harvested young it is treated as a vegetable. Its stalks produce a cob of seeds, which are better known as the kernels, though by botanical definition they are the individual fruits of the plant. Yellow Corn is just one cultivar among thousands of Corn Varieties, heirloom, hybrid or genetically modified. Yellow Corn is an evolutionary mutation of White Corn. Most yellow Corn in the commercial marketplace is a hybrid Variety developed in the XX century. The first hybrid yellow sweet Corn, 'Redgreen' was released by the Connecticut Agricultural Experimental program in 1924. Nutritional Value:- Yellow Corn is a significant resource of Vitamin A. As Corn kernels mutated from white to yellow, they acquired chemicals called Cartenoids. Of these cartenoids is beta carotene, which produces Vitamin A. Very little attention has been emphasized on yellow Corn's significant beta carotene levels until the early XXI century. Yellow Corn, easy to grow in developing regions of Africa and Latin America, where Corn is heavily relied upon as a food source, could actually keep millions of children from going blind. Yellow Corn is now being bred to have at least 10 times higher the amount of beta carotene than average sweet Corn Varieties. Applications:- the less sweet Corn is cooked, the better the flavor and texture. Yellow Corn can be roasted, grilled, blanched, steamed, or pureed. Its bright and sweet flavors lend well to pastas and salads. It pairs well with tomatoes, basil cilantro, lobster, pork, chiles, truffles, shelling beans, cream, nutty cheeses, peas, summer squashes, fennel, citrus and scallops. Yellow Corn is dried and ground into flour for baked goods, tortillas, cereals and used as a crust/crisping agent for dishes both savory and sweet. Corn is also used for oil, as a sweetener in foods and beverages and as a base for beverage alcohol. Ethnic/Cultural Info:- Maize was the single most important crop of pre-Columbian North America. It formed the identities of the Mesoamericans & North Americans as a staple food source. The very first domesticated variety was white, though Corn now grows in a variety of colors, including orange, red, and multi-colored Corn. The ancestral source of sweet Corn is an Andean Corn, named Chullpi. This Corn contains the quintessential sugary gene that identifies sweet Corn as the best fresh eating Corn. Though white Corn is preferred for fresh eating eating in Latin cultures, yellow Corn is most often used for masa and tortilla making. Yellow Corn is the ubiquitous fresh eating and grain crop variety in Midwest and Northeast America. Geography/History:- Corn is native to the Americas, specifically Mexico. Wild Corn was domesticated by indigenous Mesoamericans in prehistoric times. A wild grass, Teosinte (Zea Mexicana) is considered the ancestor of all known Species of Corn. Teosinte grows wild in remote areas of Mexico and Guatemala. The oldest known remains of Corn were discovered in Mexico's Valley of Tehuacan, and dated 2750 BC, approximately 7 000 years old. Corn is still the number one grain crop grown in the Americas. It continues to be a significant source of food and now fuel security, providing at least 12 billion bushels annually for agricultural and industrial use. Not all Corn is grown for fresh eating. Corn varieties are classified essentially by their purpose. The amount of starch in any given Corn variety will determine if it is used for sweet Corn, feedstock Corn, popping Corn, flour Corn or biofuel Corn among other designations. / Жёлтозёрная Кукуруза содержит жирорастворимый витамин, необходимый для нормального роста и развития человека и животных. В 1920-е многие учёные-животноводы доказали, что свиньи, содержавшиеся в загонах для откорма и получавшие жёлтозёрную Кукурузу, быстрее прибавляли в весе, чем получавшие белозёрную Кукурузу. Это открытие приобрело широкую известность. В результате животноводы стали

значительно шире использовать жёлтозёрные сорта. Сигфрэд Эм. Хойге (Sigfred M. Hauge) и Дьжон Эф. Тчрост (John F. Trost) сообщали о существовании у Кукурузы связи между жёлтым эндоспермом и витамином А. Американский ботаник и агроном Пол Кристоф Мэнгэлздорф (Paul Christoph Mangelsdorf; 1899–1989) и Дьжодьж Стронэк Фрапс (George Stronach Fraps; 1876–1955) обнаружили прямую количественную зависимость между витамином А и рядом генов, контролирующих жёлтый пигмент в эндосперме. Триплоидная природа эндосперма позволяет производить четыре класса семян, различающихся по соотношению доминантных и рецессивных генов. По-видимому, гены жёлтого эндосперма оказывали арифметическое, кумулятивное действие – каждый ген добавлял 2.5 единицы витамина А на 1 г веса зерна. По сообщению Асо Эм. Брансэна (Arthur M. Brunson) и Форэста Дабл.Ю. Квакенбоша (Forrest W. Quackenbush), содержание провитамина А у жёлтозёрных инбредных линий с высоким содержанием каротина в среднем было в 4.4 раза больше, чем у жёлтозёрных инбредных линий с низким содержанием каротина. Гибриды между этими крайними формами содержали промежуточное количество провитамина А при слабой доминантности. Простые гибриды содержали обычно больше провитамина А, чем их родительские инбредные линии. Авторы пришли к заключению, что можно получать гибриды Кукурузы с повышенным содержанием провитамина, которые будут давать лучшие результаты при кормлении ими скота. По данным Эс.Эй. Ватсэна (S.A. Watson), самая высокая концентрация жёлтых пигментов в зерновке Кукурузы обнаружена в роговидной части эндосперма. Жёлтый пигмент Кукурузы представляет собой смесь 6–8 химически различных, но близкородственных соединений, относящихся к семейству естественных пигментов, известных под названием каротиноидов. В поступающей на рынок Кукурузе содержание пигмента в зерне различается на 50–100%, в зависимости от условий года выращивания. Третьим важным фактором, влияющим на концентрацию каротиноидов, является наследственность. Комбинированные воздействия этих трёх факторов вызывают колебания концентрации пигментов в Кукурузе, поступающей на рынок, на 5–30 мг/кг веса зерна. Си.Оу. Грогэн (C.O. Grogan) и Си.Дабл.Ю. Блэсин (C.W. Blessin) подчёркивали, что жёлтую окраску Кукурузы определяют в основном два главных класса каротиноидных пигментов – каротины и ксантофиллы. Содержание ксантофилла в зерне и листьях значительно превышает содержание в них каротина. В средней товарной Кукурузе ксантофилла содержится примерно в 10 раз больше, чем каротина. Содержание каротина и ксантофилла во всей зерновке можно предсказать в семенах F_1 реципрокных скрещиваний, учитывая относительный вклад геномов мужского и женского родителей. Гроган и другие установили, что содержание каротина и ксантофилла в семенах растений можно предсказать с большой точностью на основании среднего их содержания у родителей, участвующих в данном скрещивании. Это обобщение можно распространить и на поколение беккросса с различными соотношениями мужских и женских родителей. Фактическое и предсказанное содержание каротиноидов может быть механически восстановлено, используя для этой цели относительные соотношения (по весу) родительских форм, участвующих в скрещиваниях. Грогэн и другие пришли к выводу, что каротины и ксантофиллы наследуются по аддитивному типу в жёлтозёрных формах. Однако для ксантофилла было обнаружено геометрическое действие гена в семенах F_1 от скрещивания белозёрных и жёлтозёрных линий, и поэтому невозможно предсказать их содержание на основе аддитивного действия гена. У гибридов высококсантофилловых жёлтозёрных и белозёрных линий содержание ксантофилла было примерно на 10 – 15 мг/кг меньше, чем ожидалось на основании аддитивного действия в семенах F_1 и примерно на 10 мг/кг меньше, чем в поколении F_1. Михаилович и другие исследовали содержание провитамина А у некоторых из своих гибридов Кукурузы. Они обнаружили у гибридов также сильную изменчивость общего содержания провитамина А и содержания каротина и ‘криптоксантина’. Белозёрные гибриды не содержали измеримых количеств каротиноидов. Кабулеа занимался изучением метаболизма каротиноидов в зерне Кукурузы. Он показал, что биосинтез каротиноидов в зёрнах Кукурузы управляется равновесной генетической системой, представленной двумя группами генов. Одна группа определяет цепочку каротинов, другая – цепочку ксантофиллов. Он разработал модель, демонстрирующую взаимосвязи генетического контроля метаболизма каротиноидов в зерне Кукурузы. Из селекционных программ следует исключать инбредные линии Кукурузы с низким содержанием каротиноидов. В настоящее время появились новые обогащённые и устойчивые источники витамина А и В-каротина, поступившие в продажу по относительно низкой цене. Однако наличие гибридов с высоким содержанием провитамина А обеспечило бы экономию концентратов витамина А. Грогэн составил сводку материалов по селекции высококсантофилловой Кукурузы. Интерес к Кукурузе с высоким содержанием ксантофилла стимулировался потенциальными возможностями вывозного (или экспортного) рынка для избыточных товаров. Высококсантофилловая Кукуруза придаёт желательную пигментацию коже и ножкам бройлеров и желтку яиц при условии одновременного скармливания высокоэнергетических кормов. Ксантофиллы Кукурузы были бы идеальным кормом для домашней птицы с точки зрения биологической эффективности, диетических соображений, стоимости и эффективности. Очень большой прогресс достигнут в области выведения высокоурожайных гибридов с высоким содержанием ксантофилла. Однако остаётся ещё бесчисленное множество факторов, связанных с наследованием, методами селекции и способами уборки и хранения, о которых мы ещё имеем мало сведений. Дополнительные исследования в этой области провели Рэтклиф (Ratcliff) и другие, Грогэн и другие. Другой шаг вперед по пути улучшения питательной ценности Кукурузы стал возможен в связи с недавним открытием генов, ответственных за необычно толстый алейроновый слой. В алейроновом слое непосредственно под семенной оболочкой сосредоточены витамины группы В и высококачественный белок. Учёные установили, что у малоизвестной примитивной расы Кукурузы, называемой Короико (Coroico Corn (Zea Mays L.)), алейроновый слой на 2–5 клеток толще, чем у современных промышленных гибридов. Короико была найдена в Южной Америке на восточных склонах Анд. Этот генетический материал совершенно не использовался при выведении современных промышленных сортов Кукурузы. Хотя до осуществления этого ещё очень далеко, тем не менее перспективность Кукурузы с толстым алейроновым слоем заключается в повышенной питательной ценности, которую он мог бы придать современным сортам. Содержание сырого белка в алейроновом слое Короико составляет 35–38%, а в алейроне зубовидной Кукурузы – 20–22%. Кроме того, Кукуруза Короико содержит больше незаменимых аминокислот – лизина, аргинина, метионина и треонина. Хотя содержание витаминов у Короико ещё не анализировали, но известно, что алейроновый слой хлебных злаков отличается высокой концентрацией витаминов группы В, особенно ниацина. Множественные алейроновые слои обнаружили у Кукурузы Короико химик Майкэл Дьжей. Волф (Michael J. Wolf) и ботаник Ухенг Кхоо (Uheng Khoo) из Северной Лаборатории Изучения Продуктов Питания и Их Сбыта Министерства Сельского Хозяйства США, Пеория, Штат Иллинойс.

YELLOW DWARF = ЖЁЛТАЯ КАРЛИКОВОСТЬ – Yellow Dwarf is a viral disease transmitted by green Leafhoppers (Nephotettix Sp.). The first symptom of yellow dwarf is general chlorosis, especially on the newly emerged and young leaves. The color varies from yellowish to green. As the disease progresses, the infected plants become severely stunted, tillering increases markedly, and leaves become soft and droopy. The infected plants produce either no panicles or a few small panicles, which bear mostly unfilled spikelets. Yellow Dwarf is any of several virus diseases of plants characterized by stunting and yellowing of the leaves. / Вирус Жёлтой Карликовости встречается у зерновых колосовых, Кукурузы и многих злаковых трав. На практике недобор урожая зерна Пшеницы и Ячменя от этой болезни может достигать 30–40%. С Апреля у озимого и с середины Июня у ярового Ячменя появляются очаги болезни в виде окрашенных в золотисто-жёлтый и оранжевый цвет кончиков листьев. Рост листьев сильно замедлен, направление роста листьев – строго вверх. Корневая система развита слабо. Колошения или образования колоса может не произойти. У Овса наблюдается покраснение листьев. Болезнь переносится Тлёй, которая в течение всей жизни

является переносчиком вирусных болезней. Источником инфекции считают злаковые травы, растущие на границах полевых угодий, служащих одновременно и постоянным хранилищем для вирусов. В частности, поражение осенью озимых зерновых ранних сроков сева, вызванное главным образом овсяной тлей, наносит большой хозяйственный ущерб. Жёлтая Карликовость:- поражаются основные зерновые культуры – Пшеница, Ячмень, Овёс, а также злаковые травы. Вирус передаётся не менее 23 Видами Тлей. Сохраняется в зимующих растениях. Характерный признак жёлтой карликовости – появление на листьях Ячменя и Пшеницы интенсивной золотисто-жёлтой и даже оранжевой окраски, которая распространяется от верхушки вниз, чаще по краям листовой пластинки. Со временем листья становятся жёсткими. Мозаичность и крапчатость отсутствуют. При поражении молодых растений наблюдается интенсивное кущение и карликовость:- они едва достигают половины нормальной высоты, корневая система слабо развита. Колосья часто не образуются, или они короткие и дают незначительный урожай. Если заражение происходит после кущения, молодые листья желтеют, значительной задержки роста не происходит. Для растений Овса характерно покраснение листьев. Факторы, способствующие развитию болезни:- (i) ранние посевы озимых; (ii) затяжная влажная осень; (iii) морозная зима; и (iv) избыток азота (способствует размножению тлей). Меры борьбы:- (i) создание устойчивых (или толерантных) сортов; (ii) борьба с тлями-переносчиками путём инсектицидных обработок семян, обработка озимых ранних сроков сева и инсектицидные обработки в течение вегетации; (iii) оптимальные сроки сева (в зависимости от массового лёта тлей); (iv) борьба с сорняками-резерваторами вируса и переносчиками (злаковые Сорняки, всходы падалицы); и (v) применение сбалансированных доз удобрений.

YELLOWING = ПОЖЕЛТЕНИЕ – Yellowing Of Fabric:- this is a phenomenon which causes light colored fabric to yellow over time. All yellowing should be considered defective. Yellowing is a white fleece can yellow for a variety of reasons. Yellow stains can be caused by urine or feces, and by Bacteria or Fungus. Alkali and light can also cause yellowing in wool. Most stains cannot be removed by washing. Bleaching will probably damage the fleece. / развод (или потёк (stain)). Щёлочь (Alkali). Жёлтые разводы могут быть вызваны . Флис – материал, который изготавливают на основе сложного полиэфира. Технология производства флиса такова, что он получается ‘ворсистым’, похожим на замшу, сохраняя при этом все положительные свойства сложного полиэфира. Флис бывает нескольких видов:- одно- и двусторонний, тонкий, плотный, толстый; с добавлением других полимеров, для придания особенных свойств.

YELLOWING BRASSIERES = ПОЖЕЛТЕВШИЕ БЮСТГАЛЬТЕРЫ – Yellowing Brassieres:- Garment:- white satin brassiere; Fabric Construction:- (i) Count:- 218 x 00; (ii) Warp:- 55/20 bright acetate rayon; (iii) Filling:- 75/24 dull acetate rayon. Complaint:- fabric turned yellow when made into brassieres. Analysis:- it was found that in the manufacture of the brassieres a rubber laminated fabric was attached to the lower portion, to provide a firm support. Laboratory tests showed that the yellowing of the fabric took place only in areas where it was in contact with the rubber laminate. Further experiments proved that a rubber accelerator compound was responsible for the discoloration of the acetate rayon and that even the cotton backing which adhered to the rubber yellowed in time. The manufacturer was advised to try to obtain some other backing product for making these garments. / Уточина:- 75/24 .

YELLOWING OF COTTON = ПОЖЕЛТЕНИЕ ХЛОПКА – Yellowing Of Cotton:- Fabric:- print cloth; Construction:- (i) Count:- 64 x 60; (ii) Warp:- 28/1 carded cotton; (iii) Filling:- 40/1 carded cotton; Finish:- gray goods. Defect:- certain pieces of all-cotton print cloth gray goods were found to yellow on being subjected to heat in connection with their use for special industrial purposes by a rubber company. Analysis:- laboratory tests showed that, although any of this cotton fabric tended to yellow when subjected to high temperatures in the gray state, some pieces which yellowed more than others came from a different mill and had been sized with a slightly different formula. The pronounced discoloration on heating was attributed to the tendency for certain warp-sizing ingredients to yellow more readily than others when too much heat was applied. Since the warp-sizing materials were considered of good quality and had no harmful effect on the goods when desized and used for other purposes, the gray mill felt justified in not assuming any responsibility for color change which took place in this particular application. When a customer’s requirements are such that special precautions must be taken in the selection of warp-sizing compounds, specifications should be indicated on the purchase order. / Уточина:- 40/1 кардная хлопковая.

YELLOWING OF GARMENT SECTIONS = ПОЖЕЛТЕНИЕ ДЕТАЛЕЙ ШВЕЙНОГО ИЗДЕЛИЯ – Yellowing Of Garment Sections:- Garments:- white broadcloth shirts; Fabric Construction:- (i) Count:- 112 x 60; (ii) Warp:- 30/1 50% cotton 50% l’li-in. 1^4-den. bright viscose rayon; (iii) Filling:- 40/1, same as warp. Complaint:- sections of white shirts turned yellow after laundering. Analysis:- analysis of the fabric in the yellowed sections showed that it was of the same composition as parts of the shirt which had remained white. Chemical tests, however, revealed the presence of melamine formaldehyde resin in the colored portions. On the tracing of a shipment of the goods to the cutter, it was learned that he had purchased an odd lot of shirtings, some pieces of which had resin finish to obtain dimensional stability in laundering. Evidently the cutter had been careless in making the garments and had used pieces from different lots of goods. When the shirts were laundered by the consumer and given a chlorine bleach, those parts of the shirts which were made from the pieces containing the resin turned yellow. Since the manufacturer had no way of knowing how many new shirts might yellow after they were worn, laundered, and chlorine-bleached, he enlisted the aid of the laboratory to try to separate the good garments from those which he would have been obliged to sell as ‘seconds’. Fortunately, it was found that under the ultraviolet lamp the resin-finished fabric fluoresced in a distinctive manner. This permitted rapid examination and classification without damage. / Уточина:- такая же как основа.

YELLOW KERNELS = ПОЖЕЛТЕВШАЯ ЗЕРНОВКА (или ПОЖЕЛТЕВШИЕ ЯДРА) – Yellow Kernels mean Rice kernels that have some parts of the kernels turn yellow obviously. This includes parboiled Rice kernels that are light brown partly or wholly. / Под Пожелтевшей Зерновкой (или Пожелтевшими Ядрами) понимаются ядра Риса, имеющие чётко выраженные пожелтевшие части. Это относится к пропаренной зерновке (пропаренным ядрам) Риса, имеющей частичную или полную окраску светлокоричневого цвета. Зерно Риса с эндоспермом жёлтого цвета различной интенсивности. В России, к Пожелтевшим относят зёрна Риса с ядром жёлтого цвета различной интенсивности. Пожелтевшая Зерновка (или Пожелтевшие Ядра):- так официально называют целые или дроблёные зёрна Риса, которые сверху и на разрезе имеют жёлтый цвет различной интенсивности. Это испорченный Рис, пожелтевший в результате самосогревания. Так бывает, когда ещё достаточно влажные зёрна неправильно хранят в больших кучах, – в них активируются бактерии и грибки, повышающие температуру. Рис как бы пропаривается – в нём образуются пигменты меланоидины, придающие ему желтоватый цвет. А самое главное, грибки вырабатывают вредные микотоксины, загрязняющие зёрна.

YELLOW KNIGHT = ЖЁЛТЫЙ РЫЦАРЬ – A Yellow Knight is a company that backs out of an attempt to take over another company. How It Works/Example:- let’s assume Company XYZ wants to acquire Company ABC. Company ABC feels that Company XYZ is a hostile bidder and will ruin the company. As a result, Company ABC’s directors go on the offensive and tell the shareholders that a sale to Company XYZ would not be a good thing. Company XYZ, fearing a legal battle and little support from shareholders on both sides, backs off. That is, it becomes a yellow knight. Instead, Company XYZ comes back to Company ABC on more friendly terms and

proposes a merger. Why It Matters:- Yellow Knights are yellow because the color is associated with cowardice. Yellow Knight is a company that offered a hostile takeover but has since changed its mind and decided to discuss a merger. A yellow knight's management may decide that a hostile takeover would be too expensive or otherwise difficult but still believes that the target company would be advantageous. The term is derogatory and implies that the acquiring company (who would have been a black knight) has cold feet or has gone 'yellow'. One would expect the term to be used by the board, management, or even employees, rather than shareholders. Yellow Knight is a company that was once making a takeover attempt but ends up discussing a merger with the target company. Yellow knights have various reasons for backing out of the takeover attempt, but frequently are attributable to the target company's ability to fend off takeover. The 'Yellow' in 'Yellow Knight' may refer to the color's association with cowardice. Since a yellow knight backs down from a takeover attempt and retreats to merger discussions, a yellow knight may be viewed as weak. In mergers and acquisitions (M&A), various colored knights are used to identify the nature of a takeover or potential takeover. A Black Knight is a company that makes a hostile takeover offer for the target company. A White Knight makes a friendly takeover offer to a target company that is being faced with a hostile takeover. A Gray Knight (sometimes spelled Grey Knight) is a second unsolicited bidder in a corporate takeover. Yellow Knight is a corporation with plans to takeover a company in hostile manner. A term Yellow Knight refers to a company that attempted a hostile takeover of another company, but opted to merge the company instead as a result of a change in strategy. The color yellow implies cowardice, which in this case refers to the act of retreating from the attempted takeover. There might be several reasons why an acquiring company is discouraged from proceeding with its hostile takeover. The business initiating the takeover may have come to a decision that their approach is no longer possible. For example, perhaps the acquiring party realizes partway through the takeover that more resources than initially anticipated are needed to close the deal. In such cases, the targeted company may have already manipulated its strategic plan in order for the takeover not to happen. If, in any case, there is a valid rationale to continue with the takeover, the method of taking over the targeted company may involve a gentler approach that's favorable to both parties. / Жёлтый Рыцарь:- так называют ситуацию обсуждения слияния двух фирм, когда первоначально одна из них пытается поглотить другую. Сравните Белый Рыцарь (White Knight), Серый Рыцарь (Gray Knight), и Чёрный Рыцарь (Black Knight).

YELLOW LEAF(Y) = ПОЖЕЛТЕВШИЙ ЛИСТ – Yellow Leaf(y):- seedlings which have pale yellow leaves, but this condition is non-lethal.

YELLOW MOTTLE = ЖЁЛТАЯ КРАПЧАТОСТЬ – Yellow Mottle is a disease caused by Rice yellow mottle virus. The virus disease can be transmitted by mechanical inoculation or vectored by the adult Beetle Sesselia Pusilla. It is characterized by stunting and reduced tillering of the infected Rice Plant; crinkling, mottling, and yellowish streaking of the leaves; malformation and partial emergence of the panicles and sterility. / Жёлтая Пятнистость или Пиренофороз (Pyrenophora spp.) пшеницы:- возбудителем жёлтой (жёлто-коричневой) пятнистости (пиренофороза) листьев пшеницы является гомоталличный Гриб Pyrenophora Tritici-repentis (Died.) Drechsler. Гриб зимует на растительных остатках Пшеницы. Осенью на стеблях и листовых влагалищах формируются мелкие, чёрные, часто обильные, приподнимающиеся над поверхностью стебля псевдотеции. Ранней весной в них образуются аски с 8 аскоспорами. Такая болезнь, как вирус жёлтой крапчатости Риса (ВЖКР), может погубить до 100 процентов молодых растений и сделать подросшие растения восприимчивыми к вторичным грибковым инфекциям.

YELLOWNESS = ЖЕЛТИЗНА – (1) Yellowness (+b); the yellowness of the light that is reflected by the cotton fibers. The Yellowness of the cotton fibers is expressed as +b determined by the CIELab system (the second of two systems adopted by the Comission Internationale de l'Eclairage (CIE; the International Commission on Illumination) in 1976 as models that better showed uniform color spacing in their values):- a positive increase in +b represents an increase in the degree of yellowness. See also Color. / Степень жёлтой составляющей цвета в испытуемой пробе. Комисьо Этэрнасьёналь дё л'Эклераж (Сэ.И.Е.; Commission Internationale de l'Eclairage (CIE)).

(2) Yellowness:- attribute of color perception by which an object color is judged to depart from colorless or a preferred white toward yellow.

YELLOWNESS COEFFICIENT = КОЭФФИЦИЕНТ ЖЕЛТИЗНЫ – Yellowness Coefficient is a measure of the color of a molded acetate disc or dope solution. $Cy = 1–T_{4400}/T_{6400}$ where Cy is the yellowness coefficient; T_{4400} is the transmission at 4400A (blue); and T_{6400} is the transmission at 6400A (orange).

YELLOWNESS INDEX = ПОКАЗАТЕЛЬ ЖЕЛТИЗНЫ – Yellowness Index is a number, computed by a given procedure from colorimetric or spectrophotometric data that indicates the degree of departure of an object color from colorless, or from a preferred white, toward yellow.

YELLOW SHEETS = ЖЁЛТЫЕ ЛИСТКИ – Yellow Sheets:- the National Quotation Bureau is a company that provides quotes for over-the-counter stocks and corporate bonds. The National Quotation Bureau provides information such as the bids, asks, and the market makers giving them. Because stocks and bonds listed by the National Quotation Bureau are over-the-counter, they do not have to meet any listing requirements and may, therefore, come from quite small issuers. The Bureau provides all quotes in real time and publishes a review each week. Its quotes are divided into Yellow Sheets (for bonds) and Pink Sheets (for stocks). Yellow Sheets are sheets published by the National Quotation Bureau (NQB) that detail bid and ask prices, plus those firms that are making a market in over-the-counter corporate bonds. Yellow Sheets:- the National Quotation Bureau (NQB) is a privately-owned company that was established in New York in 1913 to provide investors with information on stocks and bonds traded over the counter (OTC). The company now mainly offers electronic services, including data access, on its website. NQB changed its name to Pink Sheets LLC in 2000 and then to Pink OTC Markets Inc in 2008. It is considered a non-exclusive securities information provider by the Securities and Exchange Commission (SEC). NQB published information on OTC stocks and bonds for decades in the Pink Sheets and Yellow Sheets, which were named for the color of paper on which they were printed. Stock quotes were published on the Pink Sheets, while corporate bonds were quoted on the Yellow Sheets. Pink Sheet stocks include penny stocks and other companies that are not traded on exchanges. These stocks can pose added risk for investors, because they may not be current on filing financial statements, may not file at all, or, in extreme cases, may not even be legitimate companies. Information sources, such as Pink OTC Markets, help investors find information on these less liquid and less regulated stocks. / Жёлтые Листки – ежедневные публикации Национального Бюро Котировок с детальной информацией о ценах покупателей и продавцов и фирмах, которые 'делают рынок' облигаций корпораций в сделках на внеучётном рынке. Смотрите также Белые Листки (White Sheets), и Розовые Листки (Pink Sheets). Жёлтые Листки – бюллетень в США, который постоянно публикует информацию о курсах покупки и продажи, а так же как другую информацию об облигациях, торгуемых на внеучётном или, так называемом, внебиржевом рынке. Как и Розовые Листки, которые отслеживают торговлю внебиржевыми акциями компаний с микрокапитализацией, Жёлтые Листки являются основным источником информации для инвесторов, которые отслеживают внебиржевые облигации или ценные бумаги с фиксированной процентной ставкой. Жёлтые Листки – ежедневная публикация Национального Бюро Котировок (National Quotation Bureau), в которой содержится детальная информация относительно цен спроса и предложения и компаний, которые создают этот рынок,

корпоративных облигаций (corporate bonds), продающихся на внеучётном рынке (over the counter, OTC). Большая часть этой информации не приводится в ежедневно публикуемых в газетах таблицах котировок внебиржевого рынка. Жёлтые Листки называются так из-за своего цвета. Выпуски ценных бумаг, продающихся на внебиржевом рынке, перечисляются отдельно на Розовых Листках (Pink Sheets), а региональные выпуски ценных бумаг обеих классов, продающихся на внебиржевом рынке, на Белых Листках (White Sheets).

YELLOW SOYBEANS = ЖЁЛТЫЕ СОЕВЫЕ БОБЫ – Yellow Soybeans are the Soybeans that have yellow or green seed coats, that in cross section are yellow or have a yellow tinge, and may include not more than 10 percent of soybeans of other colors.

YELLOW STAINS = ЖЁЛТЫЕ РАЗВОДЫ (или ЖЁЛТЫЕ ПОТЁКИ) – Yellow Stain:- termeric, oil, stains on fabric, looks like yellow stain. Finishing defect. Yellow Stains:- Garments:- new white cotton-broadcloth shirts; Fabric Construction:- (i) Count:- 136 x 60; (ii) Warp:- 40/1 combed cotton; (ii) Filling:- same as warp. Complaint:- slight yellow discoloration was detected in sections of the garments after the shirts were cut and sewed. Analysis:- laboratory tests indicated that the fabric discoloration was not due to any fault of the garment manufacturer. It was possible to remove this yellow color by laboratory bleaching. The conclusion was reached that the goods as delivered to the cutter had contained some pieces or some portions of pieces that were not so white as the standard. Although it was impossible to determine from the few shirts submitted the exact cause of the condition, it is very probable that it was due to kier stains, or 'channeling' of the liquor during the kier-boiling operations. When this takes place, some sections of the cotton fabric do not receive adequate solution contact to cause destruction of the natural cotton coloring matter. Also, in some instances a yellowing of the fabric after bleaching may be due to the presence of unremoved cotton wax. / Порок или дефект заключительной отделки. Уточина:- такая же как основа.

YELLOW STEM BORER = ЖЁЛТЫЙ СТЕБЛЕВОЙ ТОЧИЛЬЩИК – Yellow Stem Borer is the Borer which attacks Rice throughout its growth period. It lays its eggs near the tip of the leaf blade in oval masses of 50–200 eggs each, which hatch in 8 days. The larva is cream-colored and the head capsule is reddish brown. The pupa is yellowish white with a tinge of green, but turns dark brown just before emergence. The male moth is light brown with numerous small brownish dots along the subterminal area and near the tip of the forewing. The female adult is yellow, the color deepening toward the tip, and there is a very distinct black spot in the center of each forewing. The hindwings are pale and straw-colored. Scientific name:- Scirpophaga Incertulas. / Против Стеблевых Точильщиков (личинок различных бабочек) – основных вредителей Кукурузы в тропиках применяют 1–2 обработки химическими препаратами типа эндрина, севина, фурадана, токса-фена, эндосульфана и другими.

YELLOW STRIP = ЖЁЛТАЯ ПОЛОСКА (или ЖЁЛТАЯ ПОЛОСА) – Yellow Strip:- certain London Stock Exchange (LSE) trading screens show market makers' quotes in two columns. One column shows bid prices, the other column shows offer prices. Both columns show the best quotes (highest bid and lowest offer) at the top. A yellow strip runs through the top line of both columns, highlighting the best bid and offer prices. The best bid and offer prices are therefore known as 'Yellow Strip' Prices. Yellow Strip Price or Touch Price is a term used in the UK stock market (LSE (short for the London Stock Exchange)) by market makers for the highest bid price or lowest offer price, shown on the SEAQ (short for the Stock Exchange Automated Quotation system) or SETS (short for the Stock Exchange Electronic Trading Services) screen in a yellow strip. The difference between the lowest (offer) and highest (bidding) price is known as the Bid-Offer Spread.

YELLOW WARP STREAKS = ЖЁЛТЫЕ ОСНОВНЫЕ ЗАТАСКИ (или ЖЁЛТЫЕ ПОЛОСКИ ПО ОСНОВЕ, или ЖЁЛТЫЕ ОСНОВНЫЕ ЧЕРТЫ) – Yellow Warp Streaks:- Fabric:- crêpe-backed satin dress goods; Construction:- (i) Count:- 264 x 70; (ii) Warp:- 75/40 semidull viscose rayon; (iii) Filling:- 125/60 bright viscose rayon crêpe, 2 S and 2 Z; Finish:- plain dyed black. Defect:- numerous short yellow warp streaks. Analysis:- examination showed that the short yellow threads began and ended at knots. It was found that they were lengths of 75-denier acetate yarn which were apparently pieced in on the loom by mistake. In the dyeing of the viscose rayon black, the acetate became stained a bright yellow. / Уточина:- 125/60 .

YEMENI RIAL = ЙЕМЕНСКИЙ РИАЛ – emeni Rials (YER):- YER is the three-letter currency ISO code representing the currency of Yemen which is commonly known as the Rial.

YEN = ЙЕНА (или ИЕНА) – Yen is the currency of Japan. Its subdivisions are 100 sen and 1 000 rin. ISO 4217 Currency Code:- JPY/392. Yen is the monetary unit of Japan. It was divided into 100 sen and into 1 000 rin until 1954, when these tiny denominations were removed from circulation. The Yen's symbol is ¥, or Y. First minted in 1869, after the Meiji Restoration, the Yen was officially adopted as the basic unit in the monetary reform of 1871. In that year, the government suspended the exchange of clan notes, paper money that feudal lords had issued and circulated since the late XVI century. (According to a Ministry of Finance survey of 1868, a total of 1 694 denominations of clan money had been issued by 244 clans, 14 magistrates' offices, and 9 shogunate retainers during the Tokugawa regime.) By 1879 the replacement of clan notes by the Yen-based government notes had been completed. The term Yen derives from an ancient term for Chinese round money (Yüan). / Йена или Иена – денежная единица (или валюта) Японии, равная 100 Сенам, а до 1954 – 1 000 Ринам, когда эти крошечные деноминации были выведены из обращения. Символ Йены – ¥ или Y. Впервые введённая в обращение в 1869, после Восстановления Мейзи (Meiji Restoration), Йена была официально адаптирована в качестве базовой единицы в монетарной реформе 1871. В тот год правительство приостановило обмен клановых нот, бумажных денег, которые выпустили феодальные владельцы и которые находились в обращении с конца XVI века. (Согласно исследованию Министерства Финансов от 1868, всего из 1 694 деноминаций клановых денег было выпущено 244 кланами, 14 конторами судей и 9 слугами щёгуната за время существования режима Токугавы). К 1879 замена клановых нот нотами правительства, основанными на Йене, было завершено. Термин Йена (или Иена) происходит от древнего термина для Китайских круглых денег – Юаней (Yüan). Иена, денежная единица Японии, равная 100 Сенам. Иенами назывались старинные золотая и серебряная монеты Японии, равные 1.5 грамма (г) чистого золота и 24.3 г чистого серебра. Золотое содержание Иены составляло 0.002 657 г чистого золота (до Декабря 1971). По курсу Госбанка СССР на 01 Января 1972 1 000 Иен = 2 Рубля 69 Копеек. Йенами назывались старинные золотые и серебряные монеты Японии, чеканившееся с 1870 по массе и пробе Доллара США. С 1933 обращается только в виде банкнот.

YEN BOND = ЙЕНОВАЯ ОБЛИГАЦИЯ (или ОБЛИГАЦИЯ В ИЕНАХ) – In general terms, Yen Bond is any bond issue denominated in Japanese Yen. International bankers using the term are usually referring to Yen-Denominated Bonds issued or held outside Japan. Yen Bond is a bond denominated in Japanese Yen. A Yen bond is usually issued by a Japanese entity and is traded in Japan, but this is not always the case. For example, a Yen bond may be issued in Japan by a foreign company or even issued outside Japan. See also Euroyen Bond. / Йеновая Облигация:- деноминированные в Йенах облигации. В целом – любой выпуск облигаций, деноминированных в Японских Йенах. Международные банкиры, использующие этот термин, обычно употребляют его по отношению к облигациям, деноминированным в Японских Йенах, но выпущенным или удерживаемым за пределами Японии. Йеновая Облигация – любая облигация, деноминированная в Японской валюте – Йене. Йеновая облигация обычно выпускается Японским юридическим лицом и торгуется в Японии, но это не всегда так. Например, Йеновая облигация может

быть выпущено в Японии иностранной компанией или даже выпущена за пределами Японии. Смотрите также Евройеновая Облигация (Euroyen Bond). В Японии Йеновые облигации не Японского эмитента называются Самураями.

YEN–LINKED BOND = ОБЛИГАЦИЯ С УВЯЗКОЙ К ЙЕНЕ (или УВЯЗАННАЯ К ИЕНЕ ОБЛИГАЦИЯ) – Yen-Linked Bond is a bond expressed in US Dollars or Swiss Francs, whose face value is also indicated in Yen (parity fixed at issuance). Issuance and redemption are in Yen, which are converted into the original currency at the parity of the payment date.

YIELD = ВЫХОД – (1) Yield is the amount of a specified substance produced.

(2) Yield (economic maximum) is the most that can be produced on full, efficient application of technology presently known by all producers. It assumes there are no limitations on management, materials, equipment, capital, and experience. Yield is the proportion of heavy or light products which can be derived from a given barrel of crude oil. / Под Выходом понимается пропорция тяжёлых и лёгких нефтепродуктов, которые могут быть получены из одного барреля нефти определённого качества. Выход Продукции Из Единицы Сырья – это технико-экономический показатель использования сырья в производстве готовой продукции. Рассчитывается как отношение выпуска готовой продукции определённого вида к количеству затраченного на её производство основного сырья или полуфабриката; чем лучше используется сырьё, тем больше выпуск продукции из единицы сырья и тем меньше его удельный расход. Выпуск продукции из единицы сырья – это показатель, обратный показателю удельного расхода сырья на единицу продукции, он применяется чаше всего в отраслях переработки продуктов сельского хозяйства.

(3) Yield is the amount of scoured wool obtained from a definite amount of grease wool. The amount of usable fiber after the processes of washing, drying, and removing guard hairs. A 'high yield' fleece would have a low percentage of grease. Yield (wool) is:- (i) the amount of clean wool that is derived from grease wool in the scouring process; expressed as a percentage; or (ii) the amount of usable fiber after processing.

(4) Yield is a number of linear or square yards of fabric per pound of fiber or yarn. / Выход – число погонных или квадратных ярдов ткани на фунт волокна или пряжи.

(5) Yield is the number of finished square yards per pound of greige fabric. / Выход – число квадратных ярдов готовой ткани на фунт суровой ткани.

(6) Yield is the amount of fabric delivered off a knitting machine in terms of its weight per unit length or area, or the number of linear units delivered per unit weight. For example, ounces per yard, or ounces per square yard or yards per pound.

YIELD = ДОХОДНОСТЬ – (1) Yield:- rate expressing the present value, for a given period, of the relationship between the effective cost of a loan (or the effective yield of a loan) and the principal amount. Gross yield does not take into account the effect of taxes, which varies depending on the individual taxpayer's situation. Net yield (net of taxes) is adjusted for taxes. Also known as Net Present Rate of Return. Yield is the return on a loan or investment, stated as a percentage of price. Yield is a measure of the return on an investment expressed as a percentage. A stock yield is calculated by dividing the annual dividend by the current market price of the stock. E.g., a stock selling at USD100.00 with an annual dividend of USD10.00 per share has a yield of 10% (assuming a redemption price of USD100.00). For Bonds, the Yield calculation is a little more complicated because you have to take into account the discounted value of the redemption amount at maturity. So, if a USD100.00 Bond is purchased at USD90.00, with a coupon of 10% (amount paid on the USD100.00 face value), the yield is calculated by taking into account the USD10.00 annual payment and the USD10.00 gain at maturity. The Yield is the net present rate of return on an investment. For a bond the current yield is the coupon rate of interest divided by the purchase price. A yield is inversely related to the price of a bond, such that as the price of the bond goes up, its yield declines. Yield is the total income produced by a capital investment expressed in percent. In the case of bonds, the yield to maturity or yield to the earliest possible redemption date is usually taken, the total return being calculated by dividing the annual interest payments and price changes to redemption by the number of years left to maturity. Yield is the percentage rate of return paid on a stock in the form of dividends, or the effective rate of interest paid on a bond or note. The most common meanings of the word 'Yield' in an investment context are:- (i) dividend yield; (ii) yield to maturity; and (iii) flat yield. Although they are superficially similar measures, there are important differences between them. The first is that yield to maturity is a measure of total return on an investment. On the other hand flat yield and dividend yield are measures of the income at a point in time relative to the price. Dividends are a very different income stream from interest. Bond yields are usually either fixed or floating and will be paid unless the issuer is in serious financial difficulty. Dividend yields depend on company profits and dividend policy. This usually means that dividend will grow. It also means that they tend to be far more risky than interest payments on bonds. This is why a yield gap exists. In general, Yield is a return on an investor's capital investment. A piece of real estate may yield a certain return, or a business deal may offer a particular yield. Yield is the rate of return on an investment, usually expressed as a percentage of the amount initially invested. Investment yield is a primary concern of the investor, along with the risk of loss associated with an investment. Yield is typically stated as an annualized number. Thus, if there is an actual return of USD100 on an investment of USD1 000 after three months, it is considered to have a yield of 40% on an annualized basis (the actual 10% return multiplied by four quarters). The yield calculation should include unrealized gains or losses on those investments that an investor continues to hold (such as bonds or stock); otherwise, the yield will only be based on dividends or interest payments, and so will not represent a complete picture of the return on investment. When an investment is in a fund, the yield is calculated as the income generated by the fund minus fund expenses, divided by the investment. Yield is the dividends or interest paid by a company expressed as a percentage of the current price. A stock with a current market value of USD40.00 a share paying dividends at the rate of USD3.20 is said to return 8% (USD3.20–USD40.00). The current yield on a bond is figured the same way. Also known as Return. Yield is the interest rate that will make the net present value of the cash flows from an investment equal to the price (or cost) of the investment. The net present value is the present value of future cash flows, discounted at the present cost of capital. The current yield relates the annual coupon yield to the market price by dividing the coupon by the price divided by 100, neglecting the time value of money or potential capital gains and losses. The simple yield-to-maturity takes into account the effect of the capital gained or lost at maturity, as well as the current yield. In general the Yield is the return on an investor's capital investment. For bonds, this is the coupon rate of interest divided by the purchase price of the bond which is called the Current Yield. The rate of return on a bond, taking into account the total of annual interest payments, the purchase price, the redemption value, and the amount of time remaining until maturity is also called the Yield. / Доходность – мера отдачи на вложения, выраженная в процентах. Доходность акции рассчитывается путём деления годового дивиденда на текущую рыночную цену данной акции. Например, продажа акции ценой USD100.00 с годовым дивидендом USD10.00 на акцию имеет доходность 10% (допуская цену выкупа (или погашения) (redemption price) в размере USD100.00). Для облигаций, расчёт доходности немного сложнее,

поскольку необходимо учитывать дисконтированную стоимость суммы выкупа (или погашения) (discounted value of the redemption amount) при погашении (maturity). Так, если облигация с лицевой стоимостью USD100.00 приобретается по цене USD90.00, с купоном (coupon) в 10% (сумма, уплаченная на лицевую стоимость USD100.00), доходность рассчитывается с учётом годового платежа в USD10.00 и прибылью при погашении (gain at maturity) в USD10.00. Доходность – дивиденды или процент, уплачиваемый компанией и выраженный в качестве процента от текущей цены. В отношении акции с текущей рыночной стоимостью в USD40.00 и дивидендами, уплачиваемыми по этой акции по ставке USD3.20, говорят, что она имеет отдачу в 8% (USD3.20–USD40.00). Текущая доходность по облигации вычисляется таким же образом. Известна также как Отдача (Return). Доходность – доход по ценной бумаге или иному финансовому активу, выраженный в виде процентной ставки. Ставка доходности по тому или иному финансовому активу определяется как годовой доход (дивиденд или сумма процентов) в процентном отношении к рыночной цене актива. Доходность инвестиций, выражаемая различными способами. Номинальная доходность (nominal yield) ценных бумаг с фиксированным процентом представляет собой выплачиваемый по этим бумагам процент, выраженный в процентах от их нарицательной стоимости (par value). Например, ценная бумага номиналом в 100 Фунтов Стерлингов, которая обеспечивает 8% годовых, принесёт доходность в 8 Фунтов Стерлингов в год. Однако Текущая Доходность (Current Yield), называемая также Набегающей Доходностью (Running Yield), Доходностью От Заработков (Earnings Yield) или Flat Доходностью (Flat Yield), зависит от рыночной стоимости ценной бумаги. Если ранее упомянутая 8-процентная ценная бумага номиналом в 100 Фунтов Стерлингов стоит на рынке 90 фунтов стерлингов, то текущая доходность по ней составит (100 / 90) x 8 = 8.9%. По мере роста процентных ставок рыночная стоимость ценных бумаг с фиксированным процентом (срок погашения которых ещё далёк) падает, так как иначе они не будут иметь конкурентоспособную текущую доходность. Прирост или потеря капитала в момент погашения ценной бумаги, которая обычно выкупается за 100 Фунтов Стерлингов, также может приниматься во внимание. Такая доходность называется Доходностью К Погашению (Yield To Redemption или Redemption Yield). Доходность ценной бумаги к её погашению состоит из суммы текущей доходности и прироста (или потери) капитала, разделённой на количество лет, остающихся до погашения. Таким образом, если вышеупомянутая ценная бумага должна погашаться через 9 лет, её доходность к погашению составит около 10% (8.9 + (10 / 9)). Доходность предполагаемых различных ценных бумаг обычно публикуется в коммерческой прессе, причём указываются текущая доходность и доходность к погашению, рассчитанные на основе текущих рыночных цен. Однако сам инвестор, реально владеющий ценными бумагами, рассчитывает свой доход не на основе рыночной цены, а исходя из той цены, по которой он приобрёл ценную бумагу. Годовая доходность ценной бумаги с фиксированным процентом, после того как она куплена, может быть указана абсолютно точно. Однако этого нельзя утверждать, имея дело с паями (equities), так как ни дивидендный доход, ни прирост (или потеря) капитала по ним не поддаются прогнозированию, что отражает более высокую степень риска инвестиций в паи. Доходы по ценным бумагам с фиксированным процентом и паям обычно калькулируются как валовые доходы, то есть как доходы до вычета налога. Доходность – сравнительная величина, характеризующая отношение полученного дохода к базовому показателю. Процентная величина, определяющая отношение полного годового дохода по ценной бумаге к её текущей рыночной цене. Процентная ставка дохода, выплачиваемого по акциям в форме дивидендов, или эффективная ставка процента, выплачиваемого по облигациям или векселям. Доходность:- (1) в общем смысле, прибыль или доход в результате инвестиций в собственность. (2) При инвестировании, норма прибыли, полученной на чьи-либо инвестиции в определённую ценную бумагу или определённую собственность; как правило, выражается в терминах, обозначающих ежегодную норму прибыли на инвестиции. Синоним термина Отдача (Return). Смотрите также Отдача По Инвестиции (Return On Investment). (3) В отношении облигаций, купонная процентная ставка, делённая на цену покупки. (4) В отношении облигаций, норма прибыли по облигации с учётом суммы ежегодных процентных платежей, цены покупки, выкупной стоимости и периода времени, остающегося до срока погашения. (5) В отношении ценных бумаг, норма прибыли, выраженная в процентах, уплаченная в виде дивидендов по обыкновенным или привилегированным акциям. (6) При кредитовании, общая сумма денег, полученная по ссуде. Доходность представляет собой сумму годовых процентов, которую, как ожидается, принесёт конкретная инвестиция с учётом фактов, имеющих отношение к делу, то есть какой она должна быть с точки зрения рынка. Таким образом, оценка инвестиции будет нуждаться в выборе подходящего процента в виде доходности, и такая доходность используется при капитализации (фактического или расчётного) дохода.

(2) In the case of bonds, the yield to maturity or yield to the earliest possible redemption date is usually taken, the total return being calculated by dividing the annual interest payments and price changes to redemption by the number of years left to maturity. In the case of stock, the ratio of dividends per share to the purchase price per share. In stocks and bonds, the amount of money returned to investors on their investments. Also known as Effective Yield, and Rate Of Return. Yield is a rate of return on a bond, taking into account the total of annual interest payments, the purchase price, the redemption value, and the amount of time remaining until maturity. Also called Maturity Yield, or Yield To Maturity. / В случае с облигациями доходность при погашении или доходность к . Отношение ежегодного дохода по облигации к её рыночной цене. Это фактическая норма прибыли, а не курс облигационного купона. Известна также как Эффективная Доходность (Effective Yield), и Ставка Отдачи (Rate Of Return).

(3) Yield is the annual return on an investment, expressed as a percentage. The yield to redemption or maturity (the same thing) combines the running yield with the ‘pull to redemption’; thus a bond which has a 10% coupon and exactly one year of remaining life will sell at USD98.2% when interest rates are at 12.0%, that 12.0% being composed of 10.2% running yield and 1.8% pull to redemption (USD100.0 – 98.2%). Yield is the return on a loan or investment, stated as a percentage of price. Yield is the interest rate that will make the present value of the cashflows from an investment equal to the price (or cost) of the investment. Also called the Internal Rate Of Return. The current yield relates the annual coupon yield to the market price by dividing the coupon by the price divided by 100 and ignores the time value of money or potential capital gains or losses. Simple yield to maturity takes into account the effect of the capital gain or loss on maturity of a bond in addition to the current yield. Yield is the total income produced by a capital investment expressed in percent. A Yield is the effective annual rate of return expressed as a percentage; the discount rate which, if applied to each cash flow, sets the sum of the present value of the cash flows equal to the price (internal rate of return). Yield is a measure of the annual return on an investment expressed as a percentage. Yield is the interest rate that will make the net present value of the cashflows from an investment equal to the price (or cost) of the investment. The net present value is the present value of future cashflows, discounted at the present cost of capital. The current yield relates the annual coupon yield to the market price by dividing the coupon by the price divided by 100, neglecting the time value of money or potential capital gains and losses. The simple yield-to-maturity takes into account the effect of the capital gained or lost at maturity, as well as the current yield. See also Dividend Yield. Yield is a return on an investment an investor receives from dividends or interest expressed as a percentage of the cost of the security. Yield is a coupon rate of interest divided by the purchase price, called Current Yield. For example, a bond selling for USD1 000 with a 10% coupon offers a 10% current yield. If that same bond were selling for USD500, however, it would offer a 20% yield to an investor who bought it for USD500. As a bond’s price falls, its yield rises and vice versa. Yield is the annual income earned from an investment, expressed usually as a percentage of the money invested. / Доходность – мера годовой отдачи по инвестированию, выраженная в процентах. Выраженный в процентах совокупный доход, полученный от вложений капитала.

Доход по ценной бумаге или иному финансовому активу, выраженный в виде процентной ставки. В общем случае определяется как годовой доход в процентном отношении к рыночной цене актива. Ставка процента по купону (coupon), делённая на цену покупки, называется текущим доходом (current yield). Например, облигация, продающаяся за 1 000 Долларов с купоном в 10%, предлагает текущий доход в 10%. Однако, если бы та же самая облигация продавалась за 500 Долларов, то по ней предлагался бы доход в 20% для инвестора, купившего облигацию за 500 Долларов (по мере того как цена падает, доход по облигации растёт, и наоборот).

(4) In the case of stocks, Yield is a percentage rate of return paid on a common or preferred stock in dividends. For example, a stock that sells for USD20.00 and pays an annual dividend of USD2.00 per share has a yield, also called a Dividend Yield, of 10%.

(5) In lending, Yield is a total money earned on a loan – that is, the annual percentage rate of interest multiplied by the term of the loan.

(6) In taxes, Yield in an amount of revenue received by a governmental entity as a result of a tax. / В налогообложении под Доходностью понимается сумма выручки, полученной правительственным учреждением в качестве налога.

(7) Yield:- airline revenue as measured in units of aggregated weight and distance, e.g., revenue per tonne-kilometer. Inclusion of surcharges, usually security or fuel or both, varies by the carrier reporting. Yield is a revenue, not necessarily profitable, per unit of traffic. / Под Доходностью понимается выручка, необязательно прибыльная, за единицу движения.

YIELD = УРОЖАЙНОСТЬ (или ПРОДУКТИВНОСТЬ) – In agriculture, Yield is the agricultural output in terms of quantity of a crop. The output of something in a season. The total yield of such produce in a particular season or place. Yield is the amount of a specified substance produced. Yield is measurable produce of economic value, related to a specified crop or animal, or to a defied area, and to a period of time. Yield is the return of crop material intended for growth obtained by humans harvesting the plant crop. Yield (economic maximum) is the most that can be produced on full, efficient application of technology presently known by all producers. It assumes there are no limitations on management, materials, equipment, capital, and experience. / Урожайность (продуктивность) земельного участка в отношении сбора с него хлопка-сырца, хотя многие международные организации используют этот термин в отношении полученного с этого участка хлопкового волокна. Под Урожайностью понимается количество растениеводческой продукции, получаемой с единицы площади – 1 га или 1 м^3 (в парниках, теплицах) в тоннах, центнерах. Под Урожайностью понимается количество продукции растениеводства с единицы посевной площади. Урожайность рассчитывают в центнерах с одного гектара (ц/га), в теплично-парниковом производстве – в килограммах с одного кубического метра (кг/м^3). В планировании, учёте и экономическом анализе используют несколько показателей урожайности. (1) Потенциальная Урожайность (Potential Yield) – максимальное количество продукции, которое можно получить с 1 га при полной реализации продуктивных возможностей сельскохозяйственной культуры (сорта). Исчисляется (применительно к идеальным и обычным условиям) главным образом сельскохозяйственными научно-исследовательскими и опытными учреждениями. Показатель используют для определения рациональной структуры земледельческих отраслей, набора сортов и сельскохозяйственных культур в хозяйстве, области, зоне. (2) Плановая Урожайность – количество продукции, которое можно получить с 1 га в конкретных хозяйственных условиях. Определяется до посева с учётом потенциальных возможностей сорта, достигнутого уровня урожайности, плодородия почвы, обеспеченности хозяйства техникой, минеральными удобрениями и тому подобного. Показатель производственно-финансового плана сельскохозяйственного предприятия. (3) Ожидаемая Урожайность (виды на урожай) – предполагаемый сбор продукции. Определяется в центнерах с одного гектара (ц/га) или условно (высокая, средняя, низкая, на уровне прошлого года) в отдельные периоды роста и развития сельскохозяйственных культур (по густоте стеблестоя и общему состоянию растений). Показатель используют для планирования агротехнических мероприятий. (4) Урожайность На Корню (Биологическая Урожайность) – количество выращенной продукции. Устанавливается выборочно следующими методами:- глазомерно-оценочным, методом взятия проб (до уборки урожая) или расчётно-балансовым (после уборки – по данным о фактическом намолоте и потерях в процессе уборки). Показатель используют в экономическом анализе для изыскания резервов снижения потерь урожая при уборке. (5) Фактический Сбор С 1 Га – собранная и учтённая продукция. Определяется различными способами:- в первоначально оприходованной или чистой (после обработки) массе в расчёте на 1 га посевной, весенней продуктивной или убранной площади (в зависимости от сельскохозяйственной культуры). Учитывается сельскохозяйственными предприятиями и органами Центрального Статистического Управления (ЦСУ) в 2 срока:- (i) предварительно – по оперативным сведениям о ходе уборки урожая; и (ii) окончательно – по данным бухгалтерского учёта (показатель отражается в статистических справочниках и характеризует развитие земледельческих отраслей). Уровень урожайности зависит от многих условий:- климатических, географических, почвенных, микробиологических, биологических, агротехнических, организационно-экономических и других. Повышению урожайности способствует возделывание сельскохозяйственных культур по интенсивной технологии. Урожайность – это производительность земельного участка, например, с его земли собрали урожай в 100 бушелей на акр.

YIELD ADJUSTMENT = ПЕРЕОЦЕНКА УРОЖАЙНОСТИ – Yield Adjustment:- under former programs for program yield purposes, the Farm Service Agency had the authority to adjust any farm program payment yield for any program crop on a farm if the yield did not accurately reflect the productive potential of the farm. Under the Farm Security and Rural Investment Act of 2002 (Sec. 1102(e)), payment yields for use in calculating counter-cyclical payments can be upgraded. See also Partial County Yield Average, and Program Yield.

YIELD ADVANTAGE = ВЫГОДА В ДОХОДНОСТИ (или ПРЕИМУЩЕСТВО В ДОХОДНОСТИ) – Yield Advantage is the advantage gained by purchasing convertible securities instead of common stock, which equals the difference between the rates of return of the convertible security and the common shares. The yield on a corporation's convertible securities minus the dividend yield on its common stock. The relationship between convertible securities and the dividend yield of the common stock of the same issuing corporation. The yield advantage is the additional amount of return an investor can expect to earn if a convertible security is purchased instead of the common stock. The yield advantage is calculated by subtracting the dividend yield of common stock from the rate of return on a convertible security. Determining this calculation helps investors decide if it is advantageous to retain the convertible security or exchange it for common stock. Yield Advantage is the percentage rate of return paid on a stock in the form of dividends, or the effective rate of interest paid on a bond or note. Yield Advantage is the extra amount of return an investor will earn if he or she purchases a convertible security instead of the common stock of the same issuing corporation. If an XYZ Corporation convertible yields 10% and an XYZ common share yields 5%, the yield advantage is 5%. / Выгода В Доходности – выгода, извлекаемая приобретением конвертируемых ценных бумаг вместо обыкновенных акций, которая равняется разнице между ставками отдачи по конвертируемой ценной бумаге и обыкновенной акции. Выгода В Доходности – доходность по конвертируемым ценным бумагам корпорации за вычетом дивидендной доходности по её обыкновенным акциям. Выгода В Доходности:- отношение между конвертируемыми ценными бумагами и дивидендной доходностью по обыкновенным акциям той же самой эмитирующей корпорации. Выгода в доходности представляет собой дополнительную сумму отдачи, которую инвестор может предположить в качестве заработка, если вместо обыкновенной акции приобретается конвертируемая ценная бумага. Выгода

в доходности рассчитывается посредством вычитания дивидендной доходности по обыкновенной акции из ставки отдачи по конвертируемой ценной бумаге. Определение этой калькуляции помогает инвесторам решить есть ли выгода для удерживания конвертируемой ценной бумаги или обмена её на обыкновенную акцию. Выгода В Доходности – процентная ставка отдачи, уплачиваемая по акции в форме дивидендов, или эффективная ставка по процентам, уплачиваемым по облигации или ноте. Выгода В Доходности – дополнительная сумма отдачи, которую заработает инвестор, если приобретёт конвертируемую ценную бумагу вместо обыкновенной акции той же самой эмитирующей корпорации. Если доходность конвертируемых ценных бумаг корпорации Эк.Уай.Зэд. составляет 10%, а доходность обыкновенных акций этой же корпорации – 5%, выгода в доходности составляет 5%. Выгода В Доходности – положительная разница в доходности между конвертируемой облигацией и обыкновенной акцией того же эмитента.

YIELD AUCTION = АУКЦИОН ПО ДОХОДНОСТИ – Yield Auction is the auction technique used in the US Treasury notes and bonds market in which buyers are asked to specify the yield they are prepared to lend out. / Аукцион По Доходности – аукционная техника, используемая на рынке нот и облигаций Казначейства США, в которой покупателей просят указать доходность, которую они подготовили для одалживания.

YIELD–BASED INSURANCE COVERAGE = СТРАХОВОЕ ПОКРЫТИЕ, ОСНОВАННОЕ НА УРОЖАЙНОСТИ (или СТРАХОВОЕ ПОКРЫТИЕ, ОСНОВАННОЕ НА ПРОДУКТИВНОСТИ) – Yield-Based Insurance Coverage is a crop insurance that pays an indemnity for low yields; as opposed to Revenue Insurance that insures a level of crop income, based both on yields and the prices that determine a crop's value. See also Dollar Plan, Group Risk Plan (GRP), and Multiperil Crop Insurance (MPCI). Yield Based Coverage (APH):- (i) Fall Crops (Oats, Rye); and (ii) Spring Crops (Sesame). APH (short for the actual production history or producer's actual yield history) is the yield based coverage available for the crops listed above. This is insurance coverage that provides protection against a production loss only. For sesame the price is set by contract with a processor. Each producer needs to have a contract with a processor before planting and Proof of Contract is required by Acerage Reporting Date.

YIELD BUCKET = БАДЬЯ ДОХОДНОСТИ – Yield Bucket is the remaining slot capacity for a trade/voyage in a certain port of loading after deduction of the allowance for specific contracts. Yield Bucket, 1 cu ft (28.3 liter):- non-ASTM measures are roll-formed heavy gauge steel, seam welded, water-tight with bail handle and are constructed to retain form. Shipping Weight:- 33 lbs. American Society for Testing and Materials (ASTM). / Американское Общество по Испытаниям и Материалам (АОИМ).

YIELD BURNING = ПРОЖИГАНИЕ ДОХОДНОСТИ – Yield Burning is a municipal bond financing method. Underwriters in advance refunding (prerefunding) add large markups on US Treasury bonds bought and held in escrow to compensate investors while waiting for repayment of old bonds after issuance of the new bonds. Since bond prices and yields move in opposite directions, when the bonds are marked up, they 'burn down' the yield, which may violate federal tax rules and diminishes tax revenues. Under the US IRS regulations, municipalities, not the underwriters, incur the tax liability. The US Securities and Exchange Commission (SEC), which was conductiong a wideranging probe of alleged yield-burning abuses by Wall Street firms in the late 1990s, favors making the underwriters responsible, not the municipalities. Yield Burning:- the advantage gained by purchasing convertible securities instead of common stock, which equals the difference between the rates of return of the convertible security and the common shares. Yield Burning is the illegal practice of underwriters marking up the prices on bonds for the purpose of reducing the yield on the bond. This practice, referred to as 'Burning The Yield', is done after the bond is placed in escrow for an investor who is awaiting repayment. Yield burning is attempted in order to reduce the amount of tax that is incurred on fixed-income investments. However, this practice violates federal tax laws. It is not legally possible for an investor to earn a given yield on a fixed-income investment and use yield-burning activities to evade the full extent of the tax obligations incurred on that investment. / фирмами с Вол Стрит (Wall Street) в конце 1990-х, .

YIELD COMPONENTS = КОМПОНЕНТЫ УРОЖАЙНОСТИ – Yield Components are the factors that contribute to grain yield – number of panicles per square meter, spikelets per panicle, percentage of fertile spikelets, and weight of each single grain. Yield Components are the individual plant parts directly contributing to yield based on their number, size and/or weight.

YIELD CURB = СУЖЕНИЕ ДОХОДНОСТИ – Yield Curb:- a municipal bond financing method. Underwriters in advance refundings add large markups on US Treasury bonds bought and held in escrow to compensate investors while waiting for repayment of old bonds after issuance of the new bonds. Since bond prices and yields move in opposite directions, when the bonds are marked up, they 'burn down' the yield, which may violate federal tax rules and diminishes tax revenues. Yield Curb applies mainly to convertible securities. Difference in current yield between the convertible and the underlying common. / Сужение Доходности применяется главным образом к конвертируемым ценным бумагам. Разница в текущей доходности между конвертируемой и соответствующей обыкновенной акциями.

YIELD CURVE = КРИВАЯ ДОХОДНОСТИ – In the United States, the Treasury's Yield Curve is derived using a quasi-cubic hermite spline function. Our inputs are the Close of Business (COB) bid yields for the on-the-run securities. Because the on-the-run securities typically trade close to par, those securities are designated as the knot points in the quasi-cubic hermite spline algorithm and the resulting yield curve is considered a par curve. However, Treasury reserves the option to input additional bid yields if there is no on-the-run security available for a given maturity range that we deem necessary for deriving a good fit for the quasi-cubic hermite spline curve. For example, we are using composites of off-the-run bonds in the 20-year range reflecting market yields available in that time tranche. Previously, a rolled-down 10-year note with a remaining maturity nearest to 7 years was also used as an additional input. That input was discontinued on 2005-May-26. More specifically, the current inputs are the most recently auctioned 4-, 13-, 26-, and 52-week bills, plus the most recently auctioned 2-, 3-, 5-, 7-, and 10-year notes and the most recently auctioned 30-year bond, plus the composite rate in the 20-year maturity range. The quotes for these securities are obtained at or near the 03:30 pm close each trading day. The inputs for the four bills are their bond equivalent yields. Between 2004-August-06 and 2008-June-02, to reduce volatility in the 1-year Treasury Constant Maturity (CMT) rate, and due to the fact that there were no on-the-run issues between 6-months and 2-years, Treasury used an additional input to insure that the 1-year CMT rate was consistent with on-the-run yields on either side of it's maturity range. Thus, Treasury interpolated between the secondary bond equivalent yield on the most recently auctioned 26-week bill and the secondary market yield on the most recently auctioned 2-year note and inputted the resulting yield as an additional knot point for the derivation of the daily Treasury Yield Curve. The result of that step was that the 1-year CMT was generally the same as the interpolated rate during that time period. As of 2008-June-03, the interpolated yield was dropped as a yield curve input and the on-the-run 52-week bill was added as an input knot point in the quasi-cubic hermite spline algorithm and resulting yield curve. Between 2007-December-03 and 2008-November-07, due to Treasury's discontinuance of 3-year notes, we added a composite rate in the 3-year range based on an average of off-the-run securities in that time tranche. This composite was replaced on 2008-November-10 with the on-the-run 3-year note upon its reintroduction. Treasury does not provide the computer formulation of our quasi-cubic hermite spline yield curve derivation program. However, we have found that most researchers have been able to reasonably match our results using alternative cubic spline formulas. Treasury reviews its yield curve derivation methodology on a regular basis and reserves the right to modify, adjust or improve the methodology at its option. If Treasury determines that the methodology needs to be changed or updated,

Treasury will revise the above description to reflect such changes. Yield curve rates are usually available at Treasury's interest rate web sites by 06:00 pm Eastern Time each trading day, but may be delayed due to system problems or other issues. Every attempt is made to make this data available as soon as possible. Yield Curve is the graph showing changes in yield on instruments depending on time to maturity. A system originally developed in the bond markets is now broadly applied to various financial futures. A positive sloping curve has lower interest rates at the shorter maturities and higher at the longer maturities. A negative sloping curve has higher interest rates at the shorter maturities. The Yield Curve is a chart in which the yield level is plotted on the vertical axis, and the term to maturity of debt instruments of similar creditworthiness is plotted on the horizontal axis. The yield curve is positive when long-term rates are higher than short-term rates. However, when short-term rates are higher than yields on long-term investments, the yield curve is negative or inverted. Yield Curve is a graphic representation of market yield for a fixed income security plotted against the maturity of the security. Yield Curve is a plot of treasury yields across the various maturities at a specific point in time. At the front (left) of the yield curve are T-Bills with maturities of 12, 26 and 52 weeks. In the middle are Treasury Notes with maturities of 2, 5 and 10 years. At the end (right) of the yield curve are Treasury Bonds with maturities of 20 and 30 years. In a normal yield curve, yields rise as the maturities increase. If the yield on shorter maturities is higher than that of longer maturities, then an inverted yield curve exists. An inverted yield curve is a sign of tight money and is bearish for stocks. Yield Curve is a graphic chart (of yield vs maturity) that shows interest rates at a specific point for all securities having equal risk, but different maturity dates. For bonds, it typically compares the 2 or 5 year treasury bonds with 30 year bonds. The Yield Curve is a curve that traces yields on securities with varying maturities. The slope of the yield curve is an indication of the stance of monetary policy. Under normal conditions, interest rates for long term rates are likely to be higher than short-term rates, resulting in an upward sloping yield curve. An inverted yield curve occurs when short-term interest rates rise above long-term rates, usually due to the central bank raising short-term interest rates to prevent the economy from overheating. A graph that shows the relationship between yield and maturity for a set of securities. In Bridge applications, the US Treasury market's on-the-run yield curve is the default benchmark. Yield Curve is a graph of the term structure of interest rates. It is usually given in terms of the spot yields on bonds with different maturities but the same risk factors (such as creditworthiness of issuer), plotted against maturity. In general, yields will increase with maturity and with the riskiness of the debt. Yield curves can be plotted for default-free bonds; bonds that may default will fall on another yield curve at some spread to the default-free curve. Yield Curve is the graphical depiction of the relationship between the yield on bonds of the same credit quality but different maturities. Related:- term structure of interest rates. Yield curve is a chart in which yield level is plotted on the vertical axis, and the term to maturity of debt instruments of similar creditworthiness is plotted on the horizontal axis. The term structure of interest rates is the variation of interest rates with time – for example, it is usual for a government bond with 10 years to run till maturity to have a different YTM from one which is only one year from maturity. The term structure, especially when depicted as a graph, is also called the Yield Curve. It is usual for interest rates to increase with time; the longer the time till maturity of a zero coupon bond the higher the rate of return on it. When the term structure shows this behaviour, the yield curve, when drawn as a graph, slopes upward. A yield curve that is downward sloping is called an inverted yield curve. There are a number of explanations for the upward sloping yield curve. The most important is liquidity preference, that investors need compensation for the potentially lower liquidity of long term bonds. Another explanation is that higher duration means greater exposures to interest rate risk and inflation risk. The Fisher hypothesis suggests that inflation and interest rates move together, so the risks are linked. Yield Curve:- depiction of the yield of bonds depending on the final maturity. The Yield Curve is a graphical representation of the term structure of interest rates. It is usually depicted as the spot yields on bonds with different maturities but the same risk factors (such as creditworthiness of issuer), plotted against maturity. The usual features of a spot yield curve are higher long-term yields than short-term yields and a curve for default-free bonds that is lower at each point than the equivalent curve for riskier debt. It is possible to construct variants of the yield curve from this basic form. The par yield curve is found by calculating the coupons that would be necessary for bonds of each maturity to be priced at par; the forward yield curve is found by extrapolating the spot yield curve point-by-point, based on the implied forward interest rates. Yield Curve is the relationship between interest rate yields and maturity lengths. The yield curve normally has a positive slope (i.e. upwards) because yields on long-term interest rates usually exceed short-term yields. An investor expects a higher return for holding an asset for a longer time, hence yields normally increase with maturity length. Yield Curve is the graph showing the term structure of interest rates by plotting the yields of all bonds of the same quality with maturities ranging from the shortest to the longest available. The resulting curve shows of short-term interest rates are higher or lower than long-term rates. If short-term rates are lower, it is called a Positive Yield Curve. If short-term rates are higher, it is called a Negative (or Inverted) Yield Curve. If there is little difference between short-term and long-term rates, it is called a Flat Yield Curve. For the most part, the yiled curve is positive, since investors who are willing to tie up their money for a longer period of time usually are compensated for the extra risk they are taking by receiving a higher yield. The most common version of the yield curve graph plots Treasury securities, showing the range of yields from a three-month Treasury Bill to a 20- or 30-year Treasury Bond. Fixed-income analysts study the yield curve carefully in order to make judgments about the direction of interest rates. See also Duration. Yield Curve is a curve describing the relationship between the interest rate or yield and the maturity at a given point in time for debt securities with the same credit risk but different maturity dates. The slope of the yield curve can be measured as the difference between the interest rates at two selected maturities. Yield Curve is a graph of the term structure of interest rates. It is usually given in terms of the spot yields on bonds with different maturities but the same risk factors (such as creditworthiness of issuer), plotted against maturity. In general, yields will increase with maturity and with the riskiness of the debt. Yield curves can be plotted for default-free bonds. Bonds that may default will fall on another yield curve at some spread to the default-free curve. Yield Curve is a plot of yield against term to redemption. Usually the yield plotted is the gross redemption yield on coupon paying bonds but other yields can be used. The Yield Curve is the relation between the interest rate (or cost of borrowing) and the time to maturity of the debt for a given borrower in a given currency. For example, the United States dollar interest rates paid on Treasury securities for various maturities are commonly plotted on a chart which is called 'the Yield Curve'. More formal mathematical descriptions of this relation are often called the term structure of interest rates. Yield curves are usually upward sloping showing that the longer the maturity the higher the yield. This is because investors demand a higher yield for the higher risk associated with long term investments. An Inverted Yield Curve is less common and happens when investors think that the economy may be slowing down and that interest rates will decline in the future. / Кривая Доходности – график взаимосвязи между доходностью и сроком до погашения ценных бумаг. Кривая Доходности – график, отражающий временную структуру процентных ставок путём изображения доходов по всем облигациям аналогичного качества со сроками погашения, варьирующими от самого короткого до самого длительного. Получившаяся в результате кривая показывает, являются ли процентные ставки по краткосрочным кредитам более высокими

или более низкими, чем долгосрочные процентные ставки. Если краткосрочные ставки ниже, то такая ситуация называется Позитивной Кривой Доходности (Positive Yield Curve). Если краткосрочные ставки выше, то такая ситуация называется Негативной (Перевёрнутой) Кривой Доходности (Negative (Inverted) Yield Curve). Если существует лишь незначительное расхождение между краткосрочными и долгосрочными процентными ставками, подобная ситуация называется 'Плоской' Кривой Доходности (Flat Yield Curve). В большинстве случаев кривая доходности является позитивной, поскольку инвесторы, желающие вложить свои средства на более длительный период, обычно получают компенсацию за более высокий риск в виде более высокого дохода. Наиболее известный вариант кривой доходности отражает доходы по казначейским ценным бумагам и показывает разброс возможных доходов от 3-месячных Казначейских векселей (Treasury bill) до 20- или 30-летних Казначейских облигаций (Treasury bond). Аналитики по ценным бумагам с фиксированным доходом внимательно изучают кривые доходности для того, чтобы оценить направление динамики процентных ставок. Кривая Доходности представляет собой графическую кривую, отображающую доходность ценных бумаг с фиксированным процентом в зависимости от срока, остающегося до даты их погашения. Кривая доходности обычно поднимается, указывая на то, что инвесторы рассчитывают получить премию на долгосрочные ценные бумаги. Однако, когда ожидаются изменения процентных ставок, направленность кривой доходности может измениться.

YIELD CURVE OPTION = ОПЦИОН НА КРИВУЮ ДОХОДНОСТИ – Yield Curve Option is an option whose underlying is the shape of the yield curve, normally defined as the yield of a longer-maturity bond minus the yield of a shorter-maturity bond. This allows investors to take a view on interest rates without taking a view on the bond market's direction. The value of a call yield curve option appreciates as the curve flattens, whereas a put's value decreases.

YIELD CURVE OPTION–PRICING MODELS = МОДЕЛИ ЦЕНООБРАЗОВАНИЯ ОПЦИОНОВ НА ОСНОВЕ КРИВОЙ ДОХОДНОСТИ – Yield Curve Option-Pricing Models:- any formula or theory for mathematically determining the correct price for an option contract that considers the yield curve of a bond at different levels of volatility. An example is the Black-Derman-Toy Model. Yield Curve Option-Pricing Models are the models that can incorporate different volatility assumptions along the yield curve, such as the Black-Derman-Toy model. Also known as Arbitrage-Free Option-Pricing Models. / Модели Ценообразования Опционов На Базе Кривой Доходности – модели, включающие различные допущения колебаний кривой доходности, в том числе модель Блэка-Дэрмана-Тоя (Black-Derman-Toy Model).

YIELD CURVE RISK = РИСК КРИВОЙ ДОХОДНОСТИ – Yield Curve Risk results from changing rate relationships between different maturities of the same index. For example, a 30-year Treasury bond's yield may change by 200 basis points, but a three-year Treasury note's yield may change by only 50 basis points during the same time period. Yield Curve Risk is the risk of experiencing an adverse shift in market interest rates associated with investing in a fixed income instrument. The risk is associated with either a flattening or steepening of the yield curve, which is a result of changing yields among comparable bonds with different maturities. When market yields change, this will impact the price of a fixed-income instrument. When market interest rates, or yields, increase, the price of a bond will decrease and vice versa. When the yield curve shifts, the price of the bond, which was initially priced based on the initial yield curve, will change in price. If the yield curve flattens, then the yield spread between long- and short-term interest rates narrows, and the price of the bond will change accordingly. If the bond is a short-term bond maturing in three years and the three-year yield decreases, the price of this bond will increase. If the yield curve steepens, this means that the spread between long- and short-term interest rates increases. Therefore, long-term bond prices will decrease relative to short-term bonds. Changes in the yield curve are based on bond risk premiums and expectations of future interest rates. Yield Curve Risk is risk attributed to changes in the relationship between short term bond yields and long term bond yields as expressed by the yield curves. The widening and narrowing of the yield curve caused by disparate changes in the prices or interest rates among bonds of varying maturities. The Yield Curve Risk is how your portfolio will react with different exposures based on how the yield curve shifts:- (i) investors portfolios tend to move in a parallel shift on the yield curve. This happens when all maturities on the yield curve move by an equal amount. The yield curve encompasses all maturities in the fixed income market. In a parallel shift, the investor would see an increase or decrease in all maturities by, for example, 25 basis points. (ii) In the real world, however, the yield curve does not move this way. The curve tends to steepen, or yield an increase in the long end of the curve compared to shorter issues. The curve can also flatten, with yield on the long end decreasing at a faster rate than at the short end of the curve. (iii) Because any measure of interest-rate risk assumes an equal amount of basis point moves on the yield curve, anything will be an approximation of how an investor's portfolio will react. The risk involved here is the degree to which this approximation will not match of the actual yield curve movement.

YIELD CURVE STRATEGIES = СТРАТЕГИИ В ОТНОШЕНИИ КРИВОЙ ДОХОДНОСТИ – Yield Curve Strategies are investments that position a portfolio to capitalize on expected changes in the shape of the Treasury yield curve. Yield Curve Strategies:- positioning a portfolio to capitalize on expected changes in the shape of the Treasury yield curve. Several Yield Curve Strategies have been developed in an attempt to boost returns in different interest-rate environments. Three yield curve strategies focus on spacing the maturity of bonds in a portfolio. In a bullet strategy, a portfolio is structured so that the maturities of the securities are highly concentrated at one point on the yield curve. For example, most of the bonds in a portfolio may mature in 10 years. In a barbell strategy, the maturities of the securities in a portfolio are concentrated at two extremes, such as five years and 20 years. In a ladder strategy, the portfolio has equal amounts of securities maturing periodically, usually every year. In general, a bullet strategy outperforms when the yield curve steepens, while a barbell outperforms when the curve flattens. Investors typically use the laddered approach to match a steady liability stream and to reduce the risk of having to reinvest a significant portion of their money in a low interest-rate environment. Using the yield curve, investors may also attempt to identify bonds that appear cheap or expensive at any given time. The price of a bond is based on the present value of its expected cash flows, or the value of its future interest and principal payments discounted to the present at a specified interest rate or rates. If investors apply different interest-rate forecasts, they will arrive at different values for a given bond. In this way, investors judge whether particular bonds appear cheap or expensive in the marketplace and attempt to buy and sell those bonds to earn extra profits. Fixed-income managers can also seek extra return with a bond investment strategy known as Riding The Yield Curve, or Rolling Down The Yield Curve. When the yield curve slopes upward, as a bond approaches maturity or 'Rolls Down The Yield Curve', it is valued at successively lower yields and higher prices. Using this strategy, a bond is held for a period of time as it appreciates in price and is sold before maturity to realize the gain. As long as the yield curve remains normal, or in an upward slope, this strategy can continuously add to total return on a bond portfolio. / Стратегия Кривой Доходности (Yield Curve Strategy) – позиционирование портфеля ценных бумаг таким образом, чтобы капитализировать его за счёт ожидаемых изменений кривой доходности Казначейских обязательств.

YIELD CURVE SWAP = СВОП НА КРИВУЮ ДОХОДНОСТИ – Yield Curve Swap is a swap in which two interest rate streams are exchanged, reflecting different points on the yield curve.

YIELD DECLINE = СНИЖЕНИЕ УРОЖАЙНОСТИ – Yield Decline is a decrease in grain yields over a period of at least several years. / Снижение Урожайности – уменьшение урожайности зерновых за период по крайней мере нескольких лет.

YIELD DIFFERENTIAL/PICKUP = ДИФФЕРЕНЦИАЛ/ПОПРАВКА ПО ДОХОДНОСТИ – Yield Differential/Pickup:- mainly applies to convertible securities. Graph showing the term structure of interest rates by plotting the yield of all bonds of the same quality with maturities ranging from the shortest to the longest available. Yield Differential-Pickup:- investments that position a portfolio to capitalize on expected changes in the shape of the Treasury yield curve. Yield Pickup is the additional interest rate an investor receives when selling a lower-yielding bond in exchange for a higher-yielding bond. The bond with the lower yield generally has a shorter maturity, while the bond with the higher yield will typically have a longer maturity. A certain amount of risk is involved since the bond with a higher yield is often of a lower credit quality. Additionally, the investor can be exposed to interest rate risk with the longer maturity bond. For example, an investor owns a bond issued by Company ABC that has a 4% yield. The investor can sell this bond in exchange for a bond issued by Company XYZ that has a yield of 6%. The investor's yield pickup is 2% (6% – 4% = 2%). Bonds that have a higher default risk often have higher yields, making a yield pickup play risky. Ideally, a yield pickup would involve bonds that have the same rating or credit risk, though this is not always the case.

YIELD DURATION = ДЛИТЕЛЬНОСТЬ ДОХОДНОСТИ (или ПРОДОЛЖИТЕЛЬНОСТЬ ДОХОДНОСТИ) – Yield Duration:- if the security has no options, the yield duration equals the modified duration. However, if the security does have options, the yield duration is the modified duration of the security as if it had no options. The yield duration is calculated as follows:- (i) the program adds the Dollar value of the option to the current price; and (ii) using this new price, and ignoring the original option, it calculates the modified duration.

YIELD EQUIVALENCE = ЭКВИВАЛЕНТНОСТЬ В ДОХОДНОСТИ (или РАВЕНСТВО В ДОХОДНОСТИ) – Yield Equivalence is the rate of interest at which a tax-exempt bond and a taxable security of similar quality provide the same return. In the day of the 50% tax bracket, for example, a tax-exempt bond paying 10% was the equivalent of a taxable corporate bond of 20%. To calculate the yield that must be provided by a taxable security to equal that of a tax-exempt bond for investors in different tax brackets, the tax exmplt yield is divided by the reciprocal of the tax bracket (100 less 28%, for example) to arrive at the taxable yield. Thus, a person in the 28% tax bracket who wished to figure the taxable equivalent of a 10% tax free municipal bond would divide 10% by 72% (100 minus 28%) to get 13.9% – the yield a corporate taxable bond would have to provide to be equivalent, after taxes, to the 10% municipal bond. To convert a taxable yield to a tax-exempt yield, the formule is reversed – that is, the tax exempt yield is equal to the taxable yield multiplied by the reciprocal of the tax bracket. Yield Equivalence is the interest rate at which a tax-exempt bond and a taxable security of similar quality give the investor the same rate of return. Yield Equivalence:- is the interest rate on a taxable security that would render a return equivalent to that of a tax-exempt security, and vice versa, calculated as follows:- (i) Taxable Yield Equivalence (YE):- YE = (Tax – Exempt Yield) / (1 – Tax Rate); and (ii) Tax-Exempt Yield Equivalence (YE):- YE = Taxable Yield x (1 – Tax Rate). In order to calculate yield equivalence, divide the tax-exempt yield by 1 minus the investor's tax rate. For example, say you were considering a 6% tax-exempt municipal bond, but you would like to calculate what the interest rate on a taxable investment would have to be to give you the same return. If you have a 20% rate of taxation, you would need a return of 7.5% on your taxable investment to match the 6% return on the tax-exempt investment (6% / (1 – 0.20) = 7.5%). Conversely, if you know your taxable rate of return, you can calculate the equivalent rate on a tax-exempt investment. This is done by multiplying the taxable rate by 1 minus your tax rate. If your taxable return is 6% and your rate of taxation is 20%, you need a 4.8% return on a tax-exempt security to match the after-tax return on a taxable security (6% x (1 – 0.20) = 4.8%). / Эквивалентность Доходности – ставка процента, при которой облигация, доход от которой освобождён от налогового обложения, и ценная бумага аналогичного качества, облагаемая налогом, приносят одинаковую прибыль. Равенство в Доходности:- процентная ставка, при которой не облагаемая налогом облигация и облагаемые налогом ценные бумаги аналогичного качества приносят одинаковый доход. В день, когда налогообложение (tax bracket) составляет 50%, например, не облагаемая налогом облигация, приносящая 10% доход, эквивалентна облагаемой налогом корпоративной облигации с доходом в 20%. Для подсчёта дохода, который должны приносить облагаемые налогом ценные бумаги, чтобы он был эквивалентен доходу от необлагаемых налогом облигаций, входящих в различные классы налогообложения, не облагаемый налогом доход делится на величину, обратную норме налогообложения данного класса налогообложения (100 минус 28%, например) для подсчёта облагаемого налогом дохода. Таким образом, лицу, уплачивающему налог по ставке 28% и желающему подсчитать облагаемый налогом эквивалент для 10% муниципальных облигаций, следует разделить 10% на 72% (100 минус 28) для получения 13.9% – дохода по корпоративным облагаемым налогом облигациям, который оказался эквивалентным после уплаты налогов доходу от 10% муниципальной облигации. Для конвертации облагаемого налогом дохода в необлагаемый надо применить обратную формулу, то есть не облагаемый налогом доход равен облагаемому налогом доходу, умноженному на величину, обратную норме налогообложения. Равенство В Доходности – процентная ставка, при которой доходность не облагаемой налогом ценной бумаги равна доходности другой облагаемой налогом ценной бумаги.

YIELD FROM ISSUE DATE = ДОХОДНОСТЬ С ДАТЫ ЭМИССИИ (или ДОХОДНОСТЬ С ДАТЫ ВЫПУСКА) – Yield From Issue Date:- this is a percentage expressed as an annual rate that describes the overall increase in an investment's value and is a measurement of the gain from the time the investment was made or started. Such a percentage is the result of computations using the amount of the initial investment, what the investment is worth on some later date – today or in the future – and the amount of time from when the investment was made to the later date.

YIELD GAP = РАЗРЫВ В ДОХОДНОСТИ – The Yield Gap is the difference between the average dividend yields in a market and the bond yields in the same market. By 'market' we would usually mean either a national market or the global markets for shares and bonds. The yield gap is a useful measure of the valuation of a stock market and can be an indicator that a market is over or under valued. An unusual yield gap can be justified by higher or lower growth expectations. The yield gap is also changes over time in response to changing conditions. For example, if companies commonly choose to increase share-buy backs rather than dividends, the yield on shares will fall. There are a number of reasons why companies might choose to do this, including tax structures, and the widespread tying of directors remuneration to share prices. Yield Gap, also known as Yield Ratio, is the yield gap compares the dividend yield on equities with the yield on long-term government bonds. It is used to assess whether equities are under or over-priced compared with government bonds. Yield Gap or Yield Ratio is the ratio of the dividend yield of an equity and the yield of a long-term government bond. Typically equities have a higher yield (as a percentage of the market price of the equity thus reflecting the higher risk of holding an equity. Formula:- Yield Gap = Yield Ratio Of Equity / Yield Ratio Of Bond. The purpose of calculating the yield gap is to assess whether the equity is over or under priced as compared to bonds. For a given equity, the following cases may be considered:- (i) if the yield gap is numerically small, then equity yield is lower than bond yield implying that the equity is overpriced; and (ii) if the yield gap is numerically large, then equity yield is higher than bond yield implying that the equity is cheap. Yield Gap is the difference between yield on equities and corresponding yield on long dated fixed interest bonds. Yield Gap (in the United Kingdom):- difference between the average yield on stocks constituting the Financial Times Industrial Share Index, and on 2.5% Consols. / Под Разрывом В Доходности понимается разница между средними значениями доходности дивидендов на рынке и доходностей облигаций на том же самом рынке. Под 'Рынком' в данном контексте обычно понимается либо национальный рынок либо глобальные рынки акций и облигаций. Разрыв в доходности является полезной мерой стоимостной оценки фондового рынка и может быть индикатором того, что рынок переоценён или недооценён. Необычный разрыв в доходности может быть оправдан более

высокими или более низкими ожиданиями роста. Разрыв в доходности со временем изменяется в ответ на изменяющиеся условия. Например, если компании обычно решают увеличить share-buy backs, а не дивиденды, доходность по акциям будет падать. Имеется ряд причин, почему компании могут пойти на это, включая налоговые структуры и распространённое увязывание вознаграждения директоров с ценами на акции.

YIELD GOAL = ЦЕЛЬ ПО УРОЖАЙНОСТИ (или ОЖИДАЕМАЯ УРОЖАЙНОСТЬ) – Yield Goal is the yield per acre you hope to grow. They further noted that what you hope to grow and what you end up with are two different things. Yield goals can vary all the way from past average yield to potential yield. They define Potential Yield as the highest possible yield obtainable with ideal management, soil, and weather. In our work, what they define as potential yield would be Maximum Yield, since 'potential' yield is associated with specific soil and weather conditions that can change. The practical range for a yield goal should be somewhere between above average to near maximum yield obtained by you or a nearby neighbor on a similar type soil. For most farmers, North Dakota State University recommends that the yield goal is the best achievable yield in the last four to five years and that it is usually 30 to 33% higher than the average yield. Black and Bauer (1988) reported that the yield goal should be based on how much water is available to the winter wheat crop from stored soil water to a depth of 1.5 m in the spring plus the anticipated amount of growing season precipitation. Combining Yield Goal, soil test NO_3–N and a simple estimate of nitrogen use efficiency can be used to estimate N fertilization requirements. Oklahoma State University generally recommends that farmers apply 33 kg N/ha for every 1 Mg of wheat (2 lb N/ac for every bushel of Wheat) they hope to produce, minus the amount of NO_3–N in the surface (0–15 cm) soil profile. With a yield goal of 2 690 kg ha^{-1} (40 bu/ac) and an average grain N content of 2.36%, estimated total N removed would equal 63.6 kg N ha^{-1}. The nitrogen use (soil N + fertlizer N) efficiency would be 71% (63.6 kg N ha^{-1} removed /89.6 kg N ha^{-1} available using a yield goal of 40 bu/ac), which is far greater than the 33% reported for grain production by Olson and Swallow (1984). Even though some of the N-fertilizer needs of the crop can be met by fall applications, the best time to make final N fertilizer adjustments is in the spring before the winter wheat surpasses the 3-leaf stage. The use of realistic yield goals combined with soil testing have assisted farmers in estimating preplant and/or in-season fertilizer N needs. When yield goals are applied, it explicitly places the risk of predicting the environment (good or bad year) on the producer. University extension (e.g., soil testing), fertilizer dealers and private consulting organizations have historically used yield goals, due to the lack of a better alternative. See also Per-Acre Yield Goal, and Yield. / (Black and Bauer) . (Olson and Swallow) .

YIELD GRADE = СОРТ ПО ВЫХОДУ (или СОРТ ПО УРОЖАЙНОСТИ, или СОРТ ПО ПРОДУКТИВНОСТИ) – (1) Yield Grade is a grade assigned by a federal grader to predict carcass cutability. See also Yield Grade (beef), Yield Grade (lamb), and Yield Grade (pork).

(2) Yield Grade (beef) is the yield grade of a beef carcass is determined by considering four characteristics:- (i) amount of external fat, (ii) amount of kidney, pelvic, and heart fat, (iii) area of the ribeye muscle, and (iv) hot-carcass weight. Under US standards, there are five classes of yield grade.

(3) Yield Grade (lamb) is the yield grade of an ovine carcass is based on the amount of external fat present, maturity, color, firmness, and texture of the lean evaluated in terms of their relationship to the ultimate flavor and tenderness of the meat. USDA lamb grades are prime, choice, and good.

(4) Yield Grade (pork) is the yield grade for barrowsand gilts, with an acceptable quality grade, is determined by the expected carcass yields of four lean cuts and is graded US 1 through 4. See also Utility Grade.

YIELD GROWTH RATE DECLINE = СНИЖЕНИЕ УРОВНЯ РОСТА УРОЖАЙНОСТИ – Yield Growth Rate Decline is a slowdown in the (percentage) rate of increase of grain yield over time.

YIELD GUARANTEE = ГАРАНТИЯ УРОЖАЙНОСТИ (или ГАРАНТИЯ ПРОДУКТИВНОСТИ) – Yield Guarantee:- for crop insurance purposes, the per-bushel figure that is a percentage of actual production history yield. Indemnity payments occur when the actual yield is below the yield guarantee.

YIELDING ABILITY = СПОСОБНОСТЬ ПРИНОСИТЬ УРОЖАЙ – Yielding Ability is the expected capacity of the plant to produce a certain quantity of grain.

YIELD MAINTENANCE = ПОДДЕРЖАНИЕ ДОХОДНОСТИ – Yield Maintenance is a kind of prepayment fee that borrowers pay to banks to reimburse them for the loss of interest resulting from the prepayment of a loan. How It Works/Example:- the formula for the yield maintenance premium is:- Yield Maintenance = Present Value of Remaining Payments on the Mortgage x (Interest Rate – Treasury Rate). Note that the Treasury rate should be for bonds of the same duration as the mortgage in question. Let's assume John takes out a USD1 000 000 mortgage from ABC Bank at 7%. The borrower begins making monthly payments on the mortgage. Two years later, interest rates decline dramatically, and John chooses to refinance the loan. To do so, John repays the USD1 000 000 loan by taking out a similar loan at a lower interest rate from a different lender and paying off the first loan. As a result, ABC Bank loses eight years of interest payments that it would have otherwise gotten had interest rates not declined enough to induce the borrower to go elsewhere. The bank calculates yield maintenance based on current interest rates and projected rates over the course of the life of the mortgage. Why It Matters:- yield maintenance helps lenders make the same yield regardless of whether all the mortgage payments are made until maturity. The idea behind yield maintenance is that it enables lenders to be indifferent to prepayment. Yield maintenance is most common in the commercial mortgage industry. Yield Maintenance:- the extra money a prepaying borrower would have to pay to make the yield the same for the lender if the borrower made all, regularly scheduled payments until maturity. When a borrower prepays a loan or other debt investment, the lender loses the interest the borrower otherwise would have paid. The lender may charge the yield maintenance as a prepayment penalty to ensure that it makes the yield regardless of whether or not the borrower prepays. This has the effect of making prepayment or refinancing unattractive to the borrower. Yield Maintenance is the type of prepayment fee that is based on the movement of interest rates. The fee is charged by the lender to the borrower, and the borrower pays the fee in the hope that the mortgage-backed investment will provide a higher yield. The yield maintenance formula is the present value of remaining payments multiplied by the difference between the bond interest rate and the rate on a Treasury note of the same duration. It is often used in the commercial mortgage market in the valuation of securities. Yield Maintenance is a prepayment premium that allows investors to attain the same yield as if the borrower made all scheduled mortgage payments until maturity. Yield maintenance premiums are designed to make investors indifferent to prepayment. Furthermore, It also makes refinancing unattractive and uneconomical to borrowers. / Поддержание Доходности – корректировка цены на ценную бумагу Правительственной Национальной Ипотечной Ассоциации или других закладных, купленных согласно фьючерсному контракту или резервному обязательству, при их поставке с целью обеспечения той же самой доходности для покупателя, как и той, что была установлена в первоначальном соглашении.

YIELD MANAGEMENT = УПРАВЛЕНИЕ ДОХОДНОСТЬЮ – Yield Management (transportation) is the process of managing the usage price of a transport asset, such as the fare paid by users, in view of changes in the demand. The goal of such an approach is to

maximize profit in the context where the transport supply is fixed. Commonly used in air transportation. Yield Management is the process of examining and factoring in consumer behavior to achieve the maximum amount of profit from a perishable good. Consumer behavior is examined to determine the correct price level to make the item enticing to the consumer. The idea is to coordinate timing, price, and consumer buying patterns to achieve the best return. The issue with yield management is that it can often result in unfair pricing for consumers. For instance, Joe may book a flight to California for USD500 during the morning and Jane may book the same flight for USD800 that evening. Joe was able to receive the better price because the flight still had plenty of open seats and the airline was trying harder to entice customers to purchase a ticket. Yield Management is the process of maximizing the contribution of every slot, vessel, trade and network. Basically it should be seen as the process of allocating the right type of capacity to the right kind of customer at the right price as to maximize revenue or yield. The concept should be used in combination with load factor management. Yield Management is the process of understanding, anticipating and influencing consumer behavior in order to maximize yield or profits from a fixed, perishable resource (such as airline seats or hotel room reservations or advertising inventory). As a specific, inventory-focused branch of revenue management, yield management involves strategic control of inventory to sell it to the right customer at the right time for the right price. This process can result in price discrimination, where a firm charges customers consuming otherwise identical goods or services a different price for doing so. Yield management is a large revenue generator for several major industries; Robert Crandall, former Chairman and CEO of American Airlines, gave Yield Management its name and has called it 'the single most important technical development in transportation management since we entered deregulation'. Yield management has become part of mainstream business theory and practice over the last fifteen to twenty years. Whether an emerging discipline or a new management science (it has been called both), yield management is a set of yield maximization strategies and tactics meant to improve the profitability of certain businesses that focus on yield. It is complex because it involves several aspects of management control, including rate management, revenue streams management, and distribution channel management, just to name a few of them. Yield management is multidisciplinary because it blends elements of marketing, operations, and financial management into a highly successful new approach. Yield management strategists frequently must work with one or more other departments when designing and implementing yield management strategies. History:- deregulation is generally regarded as the catalyst for yield management in the airline industry, but this tends to overlook the role of Global Distribution Systems (GDSs). It is arguable that the fixed pricing paradigm occurs as a result of decentralized consumption. With mass production, pricing became a centralized management activity and customer contact staff focused on customer service exclusively. Electronic commerce, of which the GDSs were the first wave, created an environment where large volumes of sales could be managed without large numbers of customer service staff. They also gave management staff direct access to price at time of consumption and rich data capture for future decision-making. On January 17, 1985, American Airlines launched Ultimate Super Saver fares in an effort to compete with low cost carrier PEOPLExpress. Donald Burr, the CEO of PEOPLExpress, is quoted as saying 'We were a vibrant, profitable company from 1981 to 1985, and then we tipped right over into losing USD50 million a month ... We had been profitable from the day we started until American came at us with Ultimate Super Savers'. in the book 'Revenue Management' by Robert G. Cross, Chairman and CEO of Revenue Analytics. The Yield management systems developed at American Airlines were recognized by the Edelman Prize committee of INFORMS for contributing USD1.4 billion in a three-year period at the airline. Yield management spread to other travel and transportation companies in the early 1990s. Notable was implementation of Yield management at National Car Rental. In 1993, General Motors Corporation was forced to take a USD744 million charge against earnings related to its ownership of National Car Rental Systems. In response, National's program expanded the definition of Yield management to include capacity management, pricing and reservations control. As a result of this program, General Motors was able to sell National Car Rental Systems for an estimated USD1.2 billion. Yield Management gave way to the more general practice of Revenue Management. Whereas Revenue Management involves predicting consumer behavior by segmenting markets, forecasting demand, and optimizing prices for several different types of products, Yield Management refers specifically to maximizing revenue through inventory control. Some notable Revenue Management implementations include the NBC which credits its system with USD200 million in improved ad sales from 1996 to 2000, the Target Pricing initiative at UPS, and Revenue management at Texas Children's Hospital. Since 2000, much of the dynamic pricing, promotions management and dynamic packaging that underlie ecommerce sites leverage Revenue management techniques. In 2002 GMAC launched an early implementation of web based revenue management in the financial services industry. There have also been high profile failures and faux pas. Amazon.com was criticized for irrational price changes that resulted from a Revenue management software bug. The Coca-Cola Company's plans for a dynamic pricing vending machine were put on hold as a result of negative consumer reactions. Revenue management is also blamed for much of the financial difficulty currently experienced by legacy carriers. The reliance of the major carriers on high fares in captive markets arguably created the conditions for low cost carriers to thrive. Use By Industry:- there are three essential conditions for yield management to be applicable:- (i) that there is a fixed amount of resources available for sale; (ii) that the resources sold are perishable (there is a time limit to selling the resources, after which they cease to be of value); and (iii) that different customers are willing to pay a different price for using the same amount of resources. If the resources available are not fixed or not perishable, the problem is limited to logistics, i.e. inventory or production management. If all customers would pay the same price for using the same amount of resources, the challenge would perhaps be limited to selling as quickly as possible, e.g., if there are costs for holding inventory. Yield management is of especially high relevance in cases where the constant costs are relatively high compared to the variable costs. The less variable cost there is, the more the additional revenue earned will contribute to the overall profit. This is because it focuses on maximizing expected marginal revenue for a given operation and planning horizon. It optimizes resource utilization by ensuring inventory availability to customers with the highest expected net revenue contribution and extracting the greatest level of 'willingness to pay' from the entire customer base. Yield management practitioners typically claim 3% to 7% incremental revenue gains. In many industries this can equate to over 100% increase in profits. Yield management has significantly altered the travel and hospitality industry since its inception in the mid-1980s. It requires analysts with detailed market knowledge and advanced computing systems who implement sophisticated mathematical techniques to analyze market behavior and capture revenue opportunities. It has evolved from the system airlines invented as a response to deregulation and quickly spread to hotels, car rental firms, cruise lines, media, telecommunications and energy to name a few. Its effectiveness in generating incremental revenues from an existing operation and customer base has made it particularly attractive to business leaders that prefer to generate return from revenue growth and enhanced capability rather than downsizing and cost cutting. / Кокэ-Кола Кампэни (Coca-Cola Company). YIELD ON COST = ДОХОДНОСТЬ ПО ЗАТРАТАМ (или ДОХОДНОСТЬ ПО ЦЕНЕ) – Yield On Cost (YOC) is the annual dividend rate of a security divided by the average cost basis of the investments. It shows the dividend yield of the original investment. If the number of shares owned by the investor does not change, the yield on cost will increase if the company increases the dividend it pays to shareholders; otherwise it will remain the same. To calculate yield on cost for a stock, an investor must divide the stock's annual dividend by the average cost basis per share and multiple the resulting number by 100 (to get a percentage). For example, an investor who purchased 10 shares of stock at USD15 and 20 shares at USD18 would have an average cost basis of USD17/share (USD15*10

+ USD18*20) / (10 + 20). If the annual dividend is USD0.90 per share, the yield on cost would be 5.29% (USD0.90 / USD17 * 100). Because the yield on cost depends on the price paid for the investment, the same stock portfolio can have a different yield on cost if shares are purchased over a period of time. Many investors focus instead on current yield when comparing the dividends of different stocks. Yield On Cost (YOC) represents the amount of dividends that will yield above the cost of the total investment.

YIELD ON MUNICIPALS = ДОХОДНОСТЬ ПО МУНИЦИПАЛКАМ – Yields On Municipal bonds are often lower than corporate or Treasury bonds with comparable maturities, because of the important advantage of not being taxed at the federal level. In general, municipal bonds are considered safer than corporate bonds, since a municipality is far less likely to go bankrupt than a company. Some municipal bonds can also be insured by outside agencies. These companies will promise to pay the interest and principal if the issuer defaults. Both issuers and bondholders can carry this insurance, though a bondholder would need to have a large stake to get the coverage. Municipal bond yields vary according to local economic factors, the issuer's perceived ability to repay, and the security's quality rating assigned by one of the bondrating agencies. / Доходность По Муниципалкам или Доходность По Муниципальным Облигациям варьируется в соответствии с местными экономическими факторами, ощущаемой способностью эмитента к оплате и рэйтиньгу качества ценной бумаги, присвоенного одним из агентств, осуществляющих рэйтиньги облигаций.

YIELD POINT = ТОЧКА ТЕКУЧЕСТИ (или ПРЕДЕЛ ТЕКУЧЕСТИ) – Yield Point:- it is important to note that the straight part of the curve gives way to a bend beyond which the material no longer behaves like a spring – or elastic. Relatively small increases in stress produce large extensions. And most of the stretch is irrecoverable. This bending or yielding region which is determined geometrically is known as Yield Point. This is the point at which the tangent to the curve is parallel to the line joining the origin and the breaking point. Point on the stress-strain curve where the load and elongation stop being directly proportional. See also Elastic Limit. In mechanical engineering, Yield Point is a load at which a solid material that is being stretched begins to flow, or change shape permanently, divided by its original cross-sectional area; or the amount of stress in a solid at the onset of permanent deformation. The yield point, alternatively called the Elastic Limit, marks the end of elastic behaviour and the beginning of plastic behaviour. When stresses less than the yield point are removed, the material returns to its original shape. For many materials that do not have a well-defined yield point, a quantity called Yield Strength is substituted. Yield strength is the stress at which a material has undergone some arbitrarily chosen amount of permanent deformation, often 0.2 percent. A few materials start to yield, or flow plastically, at a fairly well-defined stress (upper yield point) that falls rapidly to a lower steady value (lower yield point) as deformation continues. Any increase in the stress beyond the yield point causes greater permanent deformation and eventually fracture. / Предел Упругости (Elastic Limit). Прочность Текучести или Предел Текучести (Yield Strength).

YIELD POTENTIAL = ПОТЕНЦИАЛ УРОЖАЙНОСТИ – Yield Potential is the maximum grain yield of a given variety in a given environment without constraints involving water, nutrients, competition, pests, diseases, or climatic conditions. Yield Potential is defined as the yield of a crop cultivar when grown in environments to which it is adapted, with nutrients and water non-limiting, and pests and diseases effectively controlled. Hence, for a given crop variety or hybrid in a specific growth environment, yield potential is determined by the amount of incident solar radiation, temperature, and plant density – the latter determining the rate at which the leaf canopy develops under a given solar radiation and temperature regime. The difference between yield potential and the actual yield represents the exploitable yield gap. Hence, genotype, solar radiation, temperature, plant population, and degree of water deficit determine water-limited yield potential. In addition to yield reduction from limited water supply, actual farm yields are determined by the magnitude of yield reduction or loss from other factors such as nutrient deficiencies or imbalances, poor soil quality, root and/or shoot diseases, insect pests, weed competition, water logging, and lodging. Management decisions such as hybrid selection, planting date, and plant density can affect the yield potential at a given site by influencing the utilization of available solar radiation and soil moisture reserves during the growing season. Yield potential also fluctuates somewhat from year to year (typically ±10–15%) because of normal variation in solar radiation and temperature regime. To achieve yield potential, the crop must be optimally supplied with water and nutrients and completely protected against weeds, pests, diseases, and other factors that may reduce growth. Such conditions are rarely achieved under field conditions, nor is it likely to be cost-effective for farmers to strive for such perfection in management. Instead, understanding site yield potential and its normal year-to-year variation can help identify management options and input requirements that combine to reduce the size of the exploitable yield gap while maintaining profitable and highly efficient production practices. For much of the US Corn Belt, available moisture is the most important growth-limiting factor. The water deficit is determined by factors such as soil water holding capacity, rainfall, irrigation, and evapotranspiration, which vary from site to site and year to year. Because irrigation can help ensure adequate water supply in the face of suboptimal rainfall, differences between yield potential and water-limited yield are smaller and less variable in irrigated systems compared to rainfed maize systems. In well-managed irrigated maize, the attainable water-limited yield is close to the yield potential ceiling and relatively stable from year to year because irrigation is provided during key growth stages to make up for water deficits. Management can therefore focus on providing sufficient nutrients to fully exploit attainable yield and on minimizing yield-reducing factors that determine yield gap 2 (shown in Fig. 1.1). In rainfed maize, the attainable water-limited yield is typically less than that for irrigated maize, but fluctuates widely, depending on the initial soil moisture status, soil water holding capacity, planting date, plant density, evapotranspiration, and rainfall during the growing season. Therefore, setting a realistic yield goal is more difficult in rainfed (also called Dryland Agriculture) than under irrigated conditions because both yield gaps 1 and 2 can vary greatly from site to site or year to year. Maximum yields obtained in yield contests or in well-managed research experiments provide the best estimates of yield potential because maize is grown at high plant density with optimal water and nutrient supply, and effective control of weeds, diseases, and insect pests. For example, in the past 20 years yield levels achieved by winners of the irrigated maize contest in Nebraska have averaged 300 bu/acre (18.8 Mg/ha), with a standard deviation of ±38 bu/acre among years (13%), which indicates the effect of growing season weather on the yield potential. The extremes in yield potential are represented by low-yield years of 1993 (210 bu/acre, wet and cold) and 1988 (228 bu/acre, dry and hot) versus highest yields in 1986 (348 bu/acre) and 1998 (338 bu/acre) when temperatures and solar radiation supported high yield potential. During the same period, yields achieved by the winners of the rainfed maize contest in Nebraska have averaged 220 bu/acre (13.8 Mg/ha) but are steadily increasing such that maximum rainfed yields are now reaching 250 bu/acre in years with favorable weather. These numbers illustrate the typical upper limits of yield potential and waterlimited rainfed maize yield in Nebraska. The Hybrid-Maize model simulates maize growth on a daily basis from emergence to physiological maturity. This version of the program simulates maize yield potential and/or water limited yield, both assuming optimal nutrient supply and no yield losses from other factors. For simulation of yield potential, the model requires daily weather data for solar radiation and maximum and minimum temperatures. For simulation of the water-limited rainfed or irrigated yield at a given site with optimal nutrient supply, the model requires daily weather data for solar radiation, maximum and minimum temperature, rainfall, reference evapotranspiration, and relative air humidity, as well as basic soil information influencing available water status such as soil textural class and bulk density.

YIELD PROTECTION = ЗАЩИТА УРОЖАЙНОСТИ – Yield Protection (known as YP):- (i) Fall Crops (Wheat, Barley, Canola); and (ii) Spring Crops (Corn, Grain Sorghum, Soybeans, Cotton, Sunflowers). Insurance coverage that only provides protection against a production loss for crops for which revenue protection is available but was not elected. The Yield Protection (YP) Guarantee will be

determined by multiplying the production guarantee by the projected price. The projected price is also used to determine the premium, any replant payment or prevented planting payment, and to value the production to count. The harvest price is not used for the Yield Protection (YP) Plan of Coverage.

YIELD RATIO = СООТНОШЕНИЕ МЕЖДУ ДОХОДНОСТЯМИ – Yield Ratio:- a comparison of the expected yield of one bond to the expected yield of another. A yield ratio is important when deciding whether to invest in one bond or another; generally, the one with the higher yield wins out. However, it is important to take into account the after tax basis when taking the yield ratio of a corporate bond and a tax-exempt municipal bond. A corporate bond yields less than its stated interest rate because of taxation, whereas a tax-exempt municipal bond does not. Thus, a municipal bond paying a lower interest rate will often net the bondholder more than a corporate bond with a slightly higher interest rate, depending upon one's tax bracket. Yield Ratio is the quotient of two bond yields. Yield Ratio is an important aspect to determine your returns. Yield ratio is the correlation between expected yields of a bond with an expected yield of other bond. This is crucial ratio for deciding on which bond to invest. Higher yield bond wins the race. However, along with this some factors are there like after tax-basis while finding the yield ratios of tax-exempt municipal bond and corporate bond. A corporate bond has lesser yield than the interest rate that is stated, but the tax exempt-municipal bond has higher yield rate. Therefore, the municipal bond that is paying low interest rates will gain more with the bond-holder as compared to the corporate bond. One more term familiar to the topic is Bond Equity Earnings Yield Ratio (BEER), this is metric measurement of the bond yields and earning yield in the stock market. It has main two parts:- the top part is recognized as benchmark bond-yield and bottom are recognized as current earnings-yield. Yield is a return on the investment done by the capitalists. Like, yield of the bond is the coupon rate of the interest divided by the purchase price. There are two terms related to the yield ratio:- first, is the debt yield ratio and the second is the dividend yield ratio. (i) Debt Yield Ratio:- it is the inherited risk on loan. With the fall in debt yield & debt services, the coverage ratio is now an essential aspect for commercial mortgage lenders considering whether to make an investment in a property or not. The debt yield ratio represents NOI (net operating income); this is a percentage of the total loan amounts. Example, a loan of USD10 million & NOI of USD1 will produce a debt yield ratio of 10 million being divided by 1 million. Higher the debt yield ratio, the investment would be more attractive to the lender. Many mortgages provide 10% of minimum debt yield ratios. (ii) Dividend Yield Ratio:- this is a ratio of the amount paid by the company from the dividends being divided by the current share price of the stock. It is a measure of the investor return. Dividend yield ratios help investors to determine the total cash inflow, on their stock-investment, in a business. Dividend yield is a method of comparing unrelated income, producing stocks that determine the relative value. Dividend yield gives you the measure of cash flow provided by the stock. It is an effective way to compare the dividends, from different companies with varying stock prices. A comparison can be done between dividend yield ratio and interest rate, on higher-grade debt-securities paying interest. The dividend yield ratio is defined as the ratio of the Dividend per share with current share price. Formula:- Dividend Yield = Dividend Per Share / Current Share Price. / Соотношение Доходности (Yield Ratio) – показатель соотношения доходности двух облигаций.

YIELD SPREAD = КУРСОВАЯ РАЗНИЦА В ДОХОДНОСТИ (или СПРЭД В ДОХОДНОСТИ) – In finance, the Yield Spread is the difference between the quoted rates of return on two different investments, usually of different credit quality. It is a compound of yield and spread. The 'yield spread of X over Y' is simply the percentage return on investment (ROI) from financial instrument X minus the percentage return on investment from financial instrument Y (per annum). The yield spread is a way of comparing any two financial products. In simple terms, it is an indication of the risk premium for investing in one investment product over another. When spreads widen between bonds with different quality ratings it implies that the market is factoring more risk of default on lower grade bonds. For example, if a risk free 10 year Treasury note is currently yielding 5% while junk bonds with the same duration are averaging 7%, the spread between Treasuries and junk bonds is 2%. If that spread widens to 4% (increasing the junk bond yield to 9%), the market is forecasting a greater risk of default which implies a slowing economy. A narrowing of spreads (between bonds of different risk ratings) implies that the market is factoring in less risk (due to an expanding economy). There are several measures of yield spread, including Z-spread and option-adjusted spread. In US consumer loans, particularly home mortgages, a yield spread is the difference between the interest rate actually paid by the borrower on a particular loan and the (lower) interest rate that the borrower's credit would allow that borrower to pay. For example, if a borrower's credit is good enough for a lender to make a loan at 6.0%, but the borrower actually takes out a loan at 6.5%, the 0.5% difference in the interest rates is the yield spread. As the lender earns additional interest on the loan without assuming additional risk (the borrower's credit is the same), this is a source of additional profit for the lender. In order to encourage loan brokers to find borrowers who will pay yield spreads, lenders typically offer yield spread premiums to the brokers who bring them loans with yield spreads. The difference between the yield on a particular bond and the yield on an otherwise comparable bond that is considered, like a US Treasury bill, to have essentially zero risk. The spread is an indicator of the risk of the bond and thus, as in the case of bonds issued by emerging market governments, the economic strength of those governments. Yield Spread is the difference between yields on differing debt instruments, calculated by deducting the yield of one instrument from another. The higher the yield spread, the greater the difference between the yields offered by each instrument. The spread can be measured between debt instruments of differing maturities, credit ratings and risk. Looking at the yield spread, often with historical spreads, can give investors ideas for potential investment opportunities. For example, if the five-year Treasury bond is at 5% and the 30-year Treasury bond is at 6%, the yield spread between the two debt instruments is 1% (6–5%). If the yield spread has historically been closer to 5%, the investor is much more likely to invest in the five-year bond compared to the 30-year bond (as it should be trading around 1% instead of 6%). In other words, if the 30-year bond is trading at 6%, then based on the historical yield spread, the five-year should be trading at around 1%, making it very attractive at its current yield of 5%. The difference in yield between two bonds or bond indexes. Yield Spread is the difference in yield between various issues of securities. In comparing bonds, it usually refers to issues of different credit quality since issues of the same maturity and quality would normally have the same yields, as with Treasury securities, for example. Yield spread also refers to the differential between dividend yield on stocks and the current yield on bonds. The comparison might be made, for example, between the Standard & Poor's Index (of 500 stocks) dividend yield and the current yield of an index of corporate bonds. A significant difference in bond and stock yields, assuming similar quality, is known as a Yiled Gap. Yield Spread is the difference in yield between different security issues usually securities of different credit quality. The Yield Spread is the difference between the yield on a bond and the yield on a similar risk free debt instrument. It is the amount by which the yield on a bond exceeds the risk free rate for the same cash flows. This means that the yield spread represents the risk premium a particular instrument pays. It therefore reflects the credit risk taken. Yield spreads can also sometimes usefully be calculated for a sector, or between a particular bond and a basket of other bonds such as its sector. The differences in yields on different types of debt securities, a function of supply and demand, credit rating, and anticipated interest rate changes. / Казначейки (Treasuries). Стэндод Энд Поз (Standard & Poor's). Курсовая Разница В Доходности – разница в доходности по различным ценным бумагам. Концепция, используемая управляющими портфелями. Спрэд В Доходности – стандартная статическая мера измерения разности в доходности ипотечных ценных бумаг и принимаемых в качестве базиса государственных ценных бумаг. Спрэд В Доходности:- разница в доходности между различными выпусками ценных бумаг. При сравнении облигаций этот термин обычно относится к различному качеству кредита, поскольку выпуски с одним и тем же сроком погашения и имеющие одно и то же качество, как правило, имеют один и тот же доход, как, например, казначейские облигации. Разница в доходе также может относиться к разнице между

дивидендным доходом по акциям и текущим доходом (current yield) по облигациям. сравнение может производиться, например, между дивидендным доходом от акций, входящих в Индекс по 500 от Стэндод Энд Поз по стоимости акций, и текущим доходом по индексу корпоративных облигаций. Значительная разница между доходом по акциям и облигациям, при условии одинакового качества, известна как разрыв в доходности (yield gap).

YIELD SPREAD STRATEGIES = СТРАТЕГИИ В ОТНОШЕНИИ КУРСОВОЙ РАЗНОСТИ В ДОХОДНОСТИ – Yield Spread Strategies are strategies that involve positioning a portfolio to capitalize on expected changes in yield spreads between sectors of the bond market. Yield Spread Strategies:- investments that position a portfolio to capitalize on expected changes in yield spreads between sectors of the bond market. In bonds, Yield Spread Strategy is an investment strategy in which one attempts take advantage of the yield spread of a particular bond. For example, one may take a short position on a bond with a low yield while taking a long position on a bond with a higher yield. See also Relative Yield Spread. / Стратегии Спрэда Доходности (Yield Spread Strategies) – стратегии, предполагающие позиционирование портфеля таким образом, чтобы капитализировать его за счёт ожидаемых изменений спрэдов доходности между различными секторами рынка облигаций.

YIELD SWAP = СВОП НА ДОХОДНОСТЬ – Yield Swap is a bond swap which aims to improve the yield. See also Bond Swap.

YIELD TO ADJUSTED MINIMUM MATURITY = ДОХОДНОСТЬ ДО ПЕРЕОЦЕНЕННОГО МИНИМАЛЬНОГО ПОГАШЕНИЯ – Yield To Adjusted Minimum Maturity:- US term for a measure designed to give the yield to the shortest possible life of a bond. It is based on the assumption of maximum sinking fund operation and call on the bond as early as possible. / Доходность До Переоцененного Минимального Погашения – мера, предназначенная для обеспечения доходности облигации, рассчитанной до самого короткого возможного срока погашения.

YIELD TO AVERAGE LIFE = ДОХОДНОСТЬ ДО УСРЕДНЁННОГО СРОКА ДЕЙСТВИЯ – Yield-To-Average Life:- the yield calculation of a bond that is systematically retired throughout its life. This yield replaces the stated final maturity with the average life maturity. The yield-to-average life calculation is often used in the case of a sinking fund where the issuer purchases its own bonds on the open market to fulfill its sinking fund obligations when the bonds are trading below par. The yield-to-average life allows investors to determine the expected return when a bond is not held to maturity either because of sinking fund obligations or, in the case of mortgage-backed securities (MBS), because of the prepayment of the underlying mortgage debt. The yield-to-average life metric is used in regard to the pricing of mortgage-backed securities, such as collateralized mortgage obligations (CMOs) issued by the Federal Home Loan Mortgage Corporation and private issuers. Because an MBS generally repays principal throughout the life of the investment, the prepayment of the underlying mortgage debt can affect the investor's return (depending on whether the MBS was purchased at a discount or at a premium). Yield To Average Life is a yield calculation used, in lieu of yield to maturity or yield to call, where bonds are retired systematically during the life of the issue, as in the case of a sinking fund with contractual requirements. Because the issuer will buy its own bonds on the open market to satisfy its sinking fund requirements if the bonds are …. Yield To Average Life is the yield on a fixed-income security when the average maturity is substituted for the maturity date of the issue. It is particularly useful when a bond has a sinking-fund feature, as average life in this case may be significantly less than the actual number of years until maturity. Yield to average life enables the investor to estimate the actual return from a bond investment, regardless of the actual maturity. The yield to average life calculation assumes that the bond matures on the day given by its average life and at the average redemption price instead of the par price. Yield To Average Life is the yield assuming that all sinks (mandatory and voluntary) are taken at par. This results in a faster paydown of debt; the yield is then calculated to the average life date. Yield To Average Life:- companies that want to raise capital may elect to sell bonds. Sinking funds are bond funds designed so that the company regularly repurchases or retires a portion of the outstanding bonds throughout the life of the issue. As such, the yield of bonds in a sinking fund will not be equal to yield to maturity, since some of the bonds will be retired early. The yield-to-average life calculates the expected yield of a fund by using the average number of years that a bond will be outstanding. By using the yield-to-average life, a bond investor can anticipate more accurately his return on a bond investment with a sinking fund requirement. For example, imagine a company issues bonds to raise USD100 000 with a par value of USD100 and a five-percent coupon that is payable annually. A sinking fund is incorporated into the terms of the bond with a fixed redemption schedule of 20 percent per year at the par value over five years. Armed with this information, an investor can determine that the yield-to-average life for this investment is four percent annually with an average life of three years. The yield-to-average life falls short of the yield to maturity due to the 20 percent early retirement each year. To perform the calculation for yield-to-average life, the investor first multiplies the percentage redeemed each year by the redemption payment and the number of years invested. At the end of the each year, the corporation redeems 20 percent of the bonds for USD105 (USD100 principal + USD5 interest). According to the formula, percent redeemed X redemption payment X years, the values obtained for each year are 21, 42, 63, 84, and 105 for a total of 315. This total is divided by (21 X five years), or 105, to produce an average duration of three years. At a coupon rate of five percent for three years, bearing in mind the 20 percent reduction in principal per year, the total yield-to-average life is 12 percent or four percent per year. Yield-to-maturity is the most common form of earnings calculation. A major drawback to yield-to-maturity formula is that it assumes that the principal will be invested at the same interest rate as the redemptions become due. In actuality, this is rarely true. Even if a conventional bond is held to maturity, the actual yield may differ from the yield-to-maturity. The yield-to-maturity, just like the yield-to-average life, is only an anticipated outcome that depends on interest rate fluctuations. Yield to Average Life:- a calculation of the yield of a bond assuming the bond's average life. The yield to average life is useful if a bond is likely to be retired before maturity because of sinking fund requirements. This method helps the investor determine how much he/she is likely to make from a given bond investment, regardless of its actual maturity. See also Yield To Worst. Yield To Average Life is a yield calculation in which bonds are retired routinely during the life of the issue. Since the issuer buys its own bonds on the open market because of sinking fund requirements, if the bonds are trading below par, this action provides automatic price support for these bonds and they will usually trade on a yield to average life basis. / Доходность До Усреднённого Срока Действия или Доходность До Среднего Срока Погашения – рассчитанный доход до наступления среднего срока погашения, когда средний срок погашения облигации заменяется окончательной датой погашения эмиссии. Доходность За Средний Срок Погашения:- подсчёт доходности за средний срок погашения используется вместо дохода при погашении (yield to maturity) или доходности до первой даты погашения (yield to call), когда происходит систематическое погашение облигаций в течение срока выпуска, как, например, в случае погашения облигаций из резервного фонда (sinking fund), согласно контрактным обязательствам. Поскольку выпустившая сторона будет приобретать собственные облигации на открытом рынке для того, чтобы удовлетворить требования к резервному фонду, если облигации продаются по цене ниже номинальной (par), то возникает автоматическая поддержка цен, поэтому такие облигации, как правило, продаются и покупаются на основе доходности за средний срок погашения актива.

YIELD TO BEST PUT = ДОХОДНОСТЬ ДО ЛУЧШЕГО ВЫКУПА (или ДОХОДНОСТЬ ДО ЛУЧШЕЙ ПРОДАЖИ) – Yield To Best Put is the highest yield to all possible put dates, including maturity. Put date is the next date on which the holder can redeem the security. The list of valid put dates is determined using the notification periods. Put dates that occur after a valid call date are not

included. Yield To Best Put:- for a bond with a put option, it is the yield that would be realized on a callable bond if it was redeemed on the put date that would result in the highest yield.

YIELD TO CALL = ДОХОДНОСТЬ ДО ОТЗЫВА (или ДОХОДНОСТЬ ДО ПОКУПКИ) – Yield To Call (YTC):- the annual return on a bond, assuming the security will be redeemed at the call price on the first date permitted. This measure of yield includes interest payments and price depreciation because bonds are quoted in this way only if they sell above the call price. Yield to call is more relevant than yield to maturity when interest rates are declining and you are concerned about the yield on a premium-priced bond. What you really want to know is how much you will make on an investment that is going to pay you an above-market rate of income for some period of time but then may produce only a partial return of your original principal at a later date when the bond is called. If the income flow to you is sufficiently above the going rate for par-priced bonds, and if it lasts long enough, then the loss of principal that might result from a bond being called is not a problem. In any case, the yield to call formula takes this principal loss into account:- the shorter the time period a premium-priced bond has before its first call date versus its maturity date, the greater the disparity between the bond's yield to call and its yield to maturity. Yield To Call (YTC) is a rate of return measuring the performance of a callable bond, from the time of purchase to its call date. Similar to Yield to Maturity, but calculated using the call date instead of the maturity date, and the call price instead of the par value. For example, say you own a Company XYZ bond with a USD1 000.00 par value and a 5% zero-coupon bonds that matures in three years. Also suppose this bond is callable in two years at 105% of par. To calculate the yield to call, you simply pretend that the bond matures in two years rather than three, and calculate the yield accordingly. You should also consider the call price (105% of USD1 000.00, or USD1 050.00) as the principal at maturity. Thus, if this Company XYZ bond is selling for USD980.00 today, using the special formula we can calculate that the yield to call is 4.23%. The percentage rate of a bond or note if the investor buys and holds the security until the call date. This yield is valid only if the security is called prior to maturity. Generally bonds are callable over several years and normally are called at a slight premium. The calculation of yield to call is based on coupon rate, length of time to call, and market price. While the yield on most bonds is measured by their yield to maturity, there are two other measurements for yield:- yield to call and yield to worst. Yield to Call:- to understand yield to call, or YTC, it's necessary to first understand what a callable bond is. A callable bond is a bond that an issuer (usually a corporation or municipality) can redeem – or 'call away' – (in other words, pay off) prior to the bond's maturity date. Some callable bonds can be called at any time, while others can be redeemed after a fixed period; for instance, a 30-year bond could be callable after ten years has elapsed. Callable bonds typically carry higher yields than non-callable bonds since the bond can be called away from an investor if interest rates fall. The advantage to the issuer is that it has the ability to refinance the bond at a lower rate when rates are dropping. Yield-to-call is the estimated yield an investor would receive if the bond is called by the issuer prior to its maturity. When a bond is likely to be called away, an investor would want to judge the bond based on its yield to call, rather than its yield to maturity, for the simple reason that it is unlikely to continue trading until its maturity. The question is, how do you know which yield figure to use? Yield to Worst:- the rule of thumb when evaluating a bond is always to use the lowest possible yield. This figure is known as the 'Yield To Worst'. This leads to the next, question, how do you tell which is lower – yield to maturity, or yield to call? Here's the simple rule of thumb:- if a bond is ...:- (i) callable; (ii) trading at a premium to its par value (for instance, its price is USD105 but its par value is USD100); and (iii) the yield-to-call is lower than the yield to maturity. … then yield to call is the appropriate figure to use. An example:- a bond is maturing in ten years and its yield to maturity is 3.75%. The bond has a call provision that allows the issuer to call the bond away in five years. The yield, when calculated for the bond maturing on the call date, is 3.65%. In this case, 3.65% is the yield-to-worst – and the figure investors should use. Conversely, if the yield to maturity were lower of the two, that would be the yield-to-worst. Yield To Call:- for a bond that may be called prior to maturity, the yield to the first call date. The Yield To Call (YTC) is the yield on callable bond, on the assumption that it will be called on the earliest possible date. The calculation of YTC is similar to the yield to maturity:- it is, in fact the same calculation, except that the final cashflow is the call price and it only includes coupon payments prior to the next call date. There may be more than one call date, in which case there will be more than one yield to call number. These are usually distinguished by calling them Yield To First Call, Yield To Second Call etc. Yield To Call is the expected yield to maturity of a bond if it is called on the scheduled exercise date. Yield To Call is the yield that would be realized on a callable bond in the event that the bond was redeemed by the issuer on the next available call date. / Доходность До Отзыва (ДкО) – доходность облигации, рассчитанная к первому сроку погашения. Измеряет доходность инвестирования в облигацию, которую инвестор может получить от даты покупки до даты первого срока погашения. Показатель рассчитывается на уровне средней годовой прибыли. Доходность До Отзыва – доход от облигации при условии, что облигация будет погашена выпустившей стороной при отзыве, дата которого указана в контракте на выпуск облигаций (indenture). Для подсчёта доходности до отзыва используется тот же подход, что и для подсчёта доходности до погашения (yield to maturity), за исключением того, что основная сумма облигации в момент погашения заменяется ценой на момент отзыва (call price), а дата погашения заменяется датой отзыва – при условии, что выпустившая сторона поставит интересы компании выше интересов инвесторов и отзовёт облигации при наличии благоприятных обстоятельств. В этом случае низший показатель доходности до отзыва и доходности до погашения следует рассматривать как более реалистичную норму прибыли для инвесторов. Доходность До Покупки (Yield To Call (YTC)) – процентная ставка дохода, выплачиваемого по ценной бумаге с фиксированной процентной ставкой в предположении, что бумага удерживается до наступления срока её покупки. Доходность до покупки действительна только при покупке ценной бумаги до наступления срока погашения. Расчёт доходности до покупки основан на ставке купона, длительности периода до покупки и рыночной цене.

YIELD TO CRASH = ДОХОДНОСТЬ ДО КРАХА – Yield To Crash:- xxxxx. See also Yield To Adjusted Minimum Maturity. / Доходность До Краха:- . Смотрите также Доходность До Переоцененного Минимального Погашения (Yield To Adjusted Minimum Maturity).

YIELD TO EFFECTIVE DATE = ДОХОДНОСТЬ ДО ЭФФЕКТИВНОЙ ДАТЫ – Yield To Effective Date means different things for different types of securities:- For securities with call but no put options, yield to effective date is yield to worst call. For securities with puts, it is yield to best put. Note that Bridge applications ignore the refund date when looking for a callable security's yield to worst call, since most callable securities are traded to the next call date, not to the refund date. Only utility securities are traded to the refund date, although there may be exceptions even here. To analyze a security that actually is traded to the refund date, use yield to refund date. Also known as Yield To Effective Redemption Date.

YIELD TO FASTEST SINK = ДОХОДНОСТЬ ДО САМОГО БЫСТРОГО ПАДЕНИЯ – Yield To Fastest Sink is a bullet yield to the average-life date. This yield type incorporates the exercise of all options (which accelerates the sink).

YIELD TO LONGEST AVERAGE LIFE = ДОХОДНОСТЬ ДО САМОГО ДЛИТЕЛЬНОГО УСРЕДНЁННОГО СРОКА ДЕЙСТВИЯ – Yield To Longest Average Life is a bullet yield to the longest average-life date. To find this date, the program compares the sink schedule to the amount outstanding. If the comparison shows that principal payments are ahead of schedule, the program assumes that no further payments are made until the amount outstanding 'catches up' to the schedule. Yield to Longest Average Life is the yield assuming only mandatory sinks are taken. This results in a lower paydown of debt; the yield is then calculated to the final payment date.

YIELD TO MATURITY = ДОХОДНОСТЬ ДО ПОГАШЕНИЯ – Yield to Maturity:- When investing in bonds, the yield to maturity is the calculated return on investment that an investor will get if they hold the bond to maturity. It takes into account the present value of all future cash flows, as well as any premium or discount to par that the investor pays. If the investor is calculating the value of a Zero Coupon Bond then there will be no cash flows and only a single redemption at maturity. In this case the yield to maturity will be calculated based on the discount to par and the par value of the bond. Yield To Maturity (YTM) is the yield of a bond to maturity takes into account the price discount from or premium over the face amount. It is greater than the current yield when the bond is selling at a discount and less than the current yield when the bond is selling at a premium. Yield To Maturity is the rate of return expected on a bond if it is held until its maturity date. The concept is used by investors to evaluate the returns on different bond investments that may have a range of maturities and different coupon amounts. The rate of return is based on the stream of future coupon payments, the eventual return of principal, and the initial purchase price. The specific inputs to the calculation are:- (i) par value of the bond; (ii) market value of the bond; (iii) annual interest rate; (iv) maturity of the bond in years; and (v) timing of the coupon payments (such as quarterly, semi-annually, or annually). If a bond holder sells the bond prior to its maturity date, the yield to maturity on that investment may vary from the amount that would have been realized if it had been held to the maturity date. Several issues included in the yield to maturity topic are:- (i) it discounts cash flows to their present value; (ii) the concept is expressed as an annual rate of return; (iii) all coupon payments are assumed to be reinvested at the same rate of return as the current yield to maturity; (iv) all coupon payments are assumed to be paid on time; (v) there is no consideration of the transaction costs required to buy or sell a bond; and (vi) there is no consideration of the tax rate paid by the investor. The calculation of yield to maturity can be performed manually, but requires a series of trial and error estimates to gradually refine the result. A much easier approach is to plug the necessary information into a formula in an electronic spreadsheet. The rate of return an investor receives if a fixed income security is held to maturity. Yield To Maturity is the yield of a bond to maturity takes into account the price discount from or premium over the face amount. It is greater than the current yield when the bond is selling at a discount and less than the current yield when the bond is selling at a premium. Yield To Maturity (YTM) is the rate of return the investor will earn if a bond is held to maturity. Also known as Yield. The discount rate, expressed as a percentage, that equates the net present value of all future cash flows of a security (as of the maturity date) to its current market price. Synonymous with Internal Rate of Return (IRR). Yield To Maturity is the interest rate that will make the present value of a bond's remaining cash flows (if held to maturity) equal to the price (plus accrued interest, if any). Yield To Maturity (YTM) is the percentage rate of return paid on a bond, note, or other fixed income security if the investor buys and holds it to its maturity date. The calculation for YTM is based on the coupon rate, length of time to maturity, and market price. It assumes that coupon interest paid over the life of the bond will be reinvested at the same rate. Yield To Maturity (YTM) is the expected rate of return of a bond if it is held to its maturity date; calculated by taking into account the current market price, stated redemption value, coupon payments and time to maturity and assuming all coupons are reinvested at the same rate; equivalent to the Internal Rate of Return (IRR). The Yield To Maturity (YTM) of a bond is the Internal Rate of Return (IRR) that a buyer would receive if they purchased the bond at the current market price. This is also called the Redemption Yield. As an IRR measure, YTM suffers from the same flaws. The flaws are less serious in this case, because of the characteristics of bonds:- cash flows are always positive, and the variation in the rates at which income can be re-invested is lower. YTM is, nonetheless, generally a much better measure than flat yield, and is probably the most accurate of the commonly used measures of bond yield. A full evaluation of a bond needs to consider whether the yield spread is sufficient compensation for risk, and how it compares with alternatives over the same term. YTM is also needs to be adjusted for callable bonds. The calculation of yield to maturity for index linked government bonds is made more complex by the need to make assumptions about inflation in order to make the YTM comparable with other bonds. Any other type of bond that has uncertain cash flows will need similar adjustments. / Ставка отдачи, которую получает инвестор в тех случаях, когда ценная бумага с фиксированным доходом удерживается им до её погашения. Доходность До Погашения измеряет реальную эффективность инвестиций в виде готовой ставки сложных процентов. При расчёте учитывается ставка купона, величина процентного периода, покупная цена, цена при погашении, срок до погашения. Фактически доходность до погашения равна ставке дисконтирования, при которой будущие доходы будут эквивалентны текущей стоимости финансового инструмента. Доходность до погашения учитывает как купонный доход, так и прирост/потерю капитала к концу срока, поэтому наиболее пригодна для сравнения доходности инвестиций в инструменты с фиксированной доходностью. Может называться также как Внутренняя Ставка Отдачи (BCO; Internal Rate of Return (IRR)). Доходность До Погашения – доходность, рассчитанная до срока погашения. Норма прибыли по инвестициям, когда они сохраняются до срока погашения, рассчитанная в процентах. Доходность До Погашения – понятие, использующееся для определения нормы прибыли, которую инвестор получит в том случае, если долгосрочные, приносящие процентный доход инвестиции, такие, как облигации, сохраняются до даты погашения (maturity date). При этом принимаются во внимание цена покупки, стоимость выкупа (redemption value), срок до даты погашения, купонный доход и интервал времени между выплатой процентов. С учётом срочной стоимости опциона подсчитывается ставка дисконта (discount rate), при которой текущая оценка (present value) всех будущих платежей равна текущей цене облигации, что также известно как внутренняя норма отдачи (internal rate of return). Имплицидно предполагается, что доход по купонам реинвестируется по ставке YTM. Ставка YTM может быть приблизительно подсчитана с помощью таблицы оценки облигаций (называемой также Таблицей Доходности Облигаций (Bond Yield Table)), или с помощью калькулятора, в который введены формулы расчёта доходности облигаций. Ставка дохода по облигации с учётом совокупных годовых процентных платежей, цены покупки, стоимости погашения и срока, остающегося до погашения, называется Доходностью При Погашении (Maturity Yield) или Доходностью До Погашения (Yield To Maturity). Доходность До Погашения (Yield To Maturity (YTM)) – ставка доходности по облигации, учитывающая всю величину полученных по ней доходов, равную сумме выплаченных процентов и выкупной стоимости за вычетом продажной цены.

YIELD TO MATURITY SPREAD = КУРСОВАЯ РАЗНОСТЬ В ДОХОДНОСТИ ДО ПОГАШЕНИЯ – Yield To Maturity Spread, also known as YTM Spread and Index Spread, is a spread off an index – LIBOR (short for the London Interbank Offered Rate), COFI (short for the 11th District Cost of Funds Index), etc – rather than off the Treasury curve. Used to analyze floating-rate notes and floating-rate tranches. According to the Public Securities Association (PSA) Uniform Practices (p. SF-25, 6/1/90), the YTM spread is 'the difference between (1) the yield of a floating-rate security and (2) the yield of the index rate itself, assuming in both cases that the index rate takes on a certain fixed value for the indefinite future. Unless otherwise specified, this should be the current level of the index rate'. YTM-spread cash flows can be compared easily because compounding and calendar assumptions are converted, as needed, to semi-annual compounding and actual/360 (CD) or 30/360 (bond-equivalent) calendars. However, keep in mind that the discount margin allows for varying interest-rate scenarios while the YTM spread does not. / (более известная в Англоязычном звучании как ЛАЙБО или ЛИБО (LIBOR)).

YIELD TO NEXT CALL = ДОХОДНОСТЬ ДО СЛЕДУЮЩЕГО ОТЗЫВА (или ДОХОДНОСТЬ ДО СЛЕДУЮЩЕЙ ПОКУПКИ) – Yield To Next Call is the yield to the next possible call, refundable or otherwise (including continuous calls). If the bond is continuously callable, the next call date is today's date plus the notification period. The redemption price is the price corresponding to the last or current call date. Note that the program ignores refund date restrictions, if any, since most callable securities are traded to the next call date, not to the refund date.

YIELD TO NEXT PUT = ДОХОДНОСТЬ ДО СЛЕДУЮЩЕГО ВЫКУПА (или ДОХОДНОСТЬ ДО СЛЕДУЮЩЕЙ ПРОДАЖИ) – Yield To Next Put is the yield to the next put date.

YIELD TO NEXT REFUND = ДОХОДНОСТЬ ДО СЛЕДУЮЩЕГО РЕФИНАНСИРОВАНИЯ (или ДОХОДНОСТЬ ДО СЛЕДУЮЩЕГО ВОЗВРАТА) – Yield To Next Refund (Sinking Fund Bonds) is the yield assuming all bonds are redeemed at the next refund date at the redemption price.

YIELD TO PUT = ДОХОДНОСТЬ ДО ВЫКУПА (или ДОХОДНОСТЬ ДО ПРОДАЖИ) – Yield To Put (YTP) is the annual yield on a bond, assuming the security will be put (sold back to the issuer) on the first permissible date after purchase. Bonds are quoted in this manner only if they sell at a price below the put price. Therefore, the yield includes interest and price appreciation. Compare Premium Put. See also Yield To Call. What is the difference between a yield to call and a yield to put? Yield To Call is the yield a bondholder gets by holding it until the next call date. It's calculated based on the number of years, months or days to the next call date. Investors in callable bonds typically receive a higher coupon rate or yield to call, because the issuer has the option of calling it back at a pre-determined time and above a pre-determined threshold (Price). Yield To Put is the yield a bondholder gets by holding it until it is able to sell it back to the issuer. Bondholders in this type of bonds receive a lower expected coupon rate or yield to put, because they are able to sell it back to the issuer and reinvest their capital elsewhere (at higher rates). Pricing Of Callable Bond = Price Of Straight Bond – Price Of Call Option (Investor receives discount because the price of the call is deducted). Benefit of Holder:- Higher Coupon Rate. Benefit of Issuer:- Able to Call back if interest rate are expected to decrease and issue at lower coupon rates. Price Of Puttable Bond = Price Of Straight Bond + Price Of Put Option (Investor pays a premium because the price of the put is added). Benefit of Holder:- Able to Sell Back to issuer if interest rates go up, and reinvest proceedings in higher yielding securities. Benefit of Issuer:- Decrease interest costs, in a event of liquidity crisis. / Доходность До Продажи – доходность облигации, рассчитанная до её продажи компании эмитенту. Получаемая по облигации доходность при условии, что она (облигация) сохраняется до определённой даты и тогда продаётся по сделке 'пут' её компании эмитенту по определённой цене (цене 'пут').

YIELD TO REFUND DATE = ДОХОДНОСТЬ ДО ДАТЫ РЕФИНАНСИРОВАНИЯ (или ДОХОДНОСТЬ ДО ДАТЫ ВОЗВРАТА) – Yield To Refund Date is the yield to the next refundable call (including continuous calls). If the refund date does not match a date in the call schedule, the redemption price is the call price for the call date immediately before the refund date.

YIELD TO SCHEDULED SINK = ДОХОДНОСТЬ ДО НАМЕЧЕННОГО ПАДЕНИЯ – Yield To Scheduled Sink is a bullet yield to the average-life date. This yield type incorporates all scheduled mandatory sinks at par. A bond sink date will have a corresponding amount. This is the amount of the bond issue that will be paid down by the issuer on that date. The bonds that will be 'sunk' (refunded) are usually chosen randomly.

YIELD TO SHORTEST AVERAGE LIFE = ДОХОДНОСТЬ ДО САМОГО КОРОТКОГО УСРЕДНЁННОГО СРОКА ДЕЙСТВИЯ – Yield To Shortest Average Life is a bullet yield to the average-life date. This yield type incorporates the exercise of all sink options and the first call. Yield To Average Life is a yield calculation in which bonds are retired routinely during the life of the issue. Since the issuer buys its own bonds on the open market because of sinking fund requirements, if the bonds are trading below par, this action provides automatic price support for these bonds and they will usually trade on a yield to average life basis. Yield To Average Life is the average yield on a fixed-income security assuming an average life for the security. In the case of bonds, average life may be significantly less than the number of years until maturity because of sinking fund requirements. Thus, the investor may be forced to sell the bond back before maturity. Yield To Average Life is the yield on a fixed-income security when the average maturity is substituted for the maturity date of the issue. It is particularly useful when a bond has a sinking-fund feature, as average life in this case may be significantly less than the actual number of years until maturity. Yield to average life enables the investor to estimate the actual return from a bond investment, regardless of the actual maturity. The yield to average life calculation assumes that the bond matures on the day given by its average life and at the average redemption price instead of the par price. Yield to Average Life is a calculation of the yield of a bond assuming the bond's average life. The yield to average life is useful if a bond is likely to be retired before maturity because of sinking fund requirements. This method helps the investor determine how much he/she is likely to make from a given bond investment, regardless of its actual maturity. See also Yield To Worst (YTW).

YIELD TO SLOWEST SINK = ДОХОДНОСТЬ ДО САМОГО МЕДЛЕННОГО ПАДЕНИЯ – Yield To Slowest Sink is a bullet yield to the average-life date. This yield type incorporates the sinking-fund schedule and a delay based on the amount overfunded (if any).

YIELD TO WARRANT CALL = ДОХОДНОСТЬ ДО ПОКУПКИ ВАРРАНТА (или ДОХОДНОСТЬ ДО ОТЗЫВА ВАРРАНТА) – Yield To Warrant Call applies mainly to convertible securities. Effective yield of usable or synthetic convertible bonds determined against the first date at which the warrants can be called. A term Yield to Warrant Call refers to the effective yield of usable convertible bonds based on the earliest date when the warrants can be called.

YIELD TO WARRANT EXPIRATION = ДОХОДНОСТЬ ДО ПРЕКРАЩЕНИЯ ПРИЗНАНИЯ ВАРРАНТА (или ДОХОДНОСТЬ ДО ЭКСПИРАЦИИ ВАРРАНТА) – Yield To Warrant Expiration applies mainly to convertible securities. Effective yield of usable convertible bonds determined by the expiration date of the applicable warrants. Yield To Warrant Expiration applies mainly to convertible securities. Effective yield of usable or synthetic convertible bonds determined against the first date at which the warrants can be called.

YIELD TO WEIGHTED AVERAGE MATURITY = ДОХОДНОСТЬ ДО ВЗВЕШЕННОГО УСРЕДНЁННОГО ПОГАШЕНИЯ – Yield To Weighted Average Maturity is the rate, expressed as a percentage, that equates the net present value of all future cash flows of a security to its current market price, assuming principal is prematurely redeemed at an assumed rate. See also Weighted Average Maturity.

YIELD TO WORST = ДОХОДНОСТЬ ДО НАИХУДШЕГО (или ДОХОДНОСТЬ ДО НАИХУДШЕГО СЛУЧАЯ) – Yield To Worst (YTW) is the expected yield to maturity in the worst possible bond repayment scenario – typically used with reference to a callable bond, where the lower of the bond's yield-tocall and the yield-to-maturity would be the yield-to-worst. Yield To Worst:- The bond yield computer by always using the lower of either the yield to maturity or the yield to call on every possible call date. Yield To Worst (YTW) is the lowest cash-flow yield that accounts for all calls and optional sinks. Note that Bridge applications ignore the refund date when looking for a callable security's yield to worst, since most callable securities are traded to the next call date, not to the refund date. Only utility securities are traded to the refund date, although there may be exceptions even here. To analyze a security that actually is traded to the refund date, use yield to refund date. Yield To Worst:- a bond may have more than one yield measure such as yield to maturity and yield to call. A callable bond may have more than one call date. The yield to worst is the lowest of all these numbers. In order to calculate the yield to worst it is necessary to calculate all yields to different call dates as well as the Yield to Maturity (YTM). Yield To Worst (YTW) is the lowest potential yield that can be received on a bond without the issuer actually defaulting. The yield to worst is calculated by making worst-case scenario assumptions on the issue by calculating the returns that would be received if provisions, including prepayment, call or sinking fund, are used by the issuer. This metric is used to evaluate the worst-case scenario for yield to

help investors manage risks and ensure that specific income requirements will still be met even in the worst scenarios. Yield to worst is calculated on all possible call dates. It is assumed that prepayment occurs if the bond has call or put provisions and the issuer can offer a lower coupon rate based on current market rates. If market rates are higher than the current yield of a bond, the yield to worst calculation will assume no prepayments are made, and yield to worst will equal the yield to maturity. The assumption is made that prevailing rates are static when making the calculation. The yield to worst will be the lowest of yield to maturity or yield to call (if the bond has prepayment provisions); yield to worst may be the same as yield to maturity but never higher. / Доходность До Наступления Самого Худшего – доходность, получаемая до скорректированного минимального срока погашения. Наименьшая Доходность (Yield To Worst (YTW)) – доходность облигации, при расчёте которой используется меньшая из доходностей к погашению или доходностей до срока выкупа на каждую возможную дату.

YIELD TO WORST CALL = ДОХОДНОСТЬ ДО ХУДШЕЙ ПОКУПКИ (или ДОХОДНОСТЬ ДО ХУДШЕГО ОТЗЫВА) – Yield To Worst Call is the lowest yield to all possible call dates, including maturity and continuous-call notification dates. Note that Bridge applications ignore the refund date when looking for a callable security's yield to worst call, since most callable securities are traded to the next call date, not to the refund date. Only utility securities are traded to the refund date, although there may be exceptions even here. To analyze a security that actually is traded to the refund date, use yield to refund date. / Доходность До Худшей Покупки:- самая низкая доходность для всех возможных дат покупок, включая даты погашения и даты нотификации о постоянных покупках. Имейте ввиду, что приложения Брыдьж (Bridge) игнорируют дату возврата (refund date) при поиске доходности до худшей покупки покупаемой ценной бумаги, так как большинство покупаемых ценных бумаг торгуется до следующей даты покупки, а не до даты возрата. Только ценные бумаги коммунальных компаний торгуются до даты возврата, хотя они могут стать исключениями даже в этом случае. Для анализа того, как ценная бумага торгуется фактически до даты возврата, используйте доходность до даты возврата.

YIELD TRIALS = ИСПЫТАНИЯ НА УРОЖАЙНОСТЬ – Yield Trials are the trials in which the main objective is to determine and compare the yields of a cultivar against a check. Yield Trials are an important way for producers to look at a hybrid's performance in several locations, over several years and environments. Yield is one component of the trials.

YIELD VALUE OF A 32ND = ВЕЛИЧИНА ДОХОДНОСТИ В 32–Х – Yield Value Of A 32^{nd} is the amount by which the yield to maturity (YTM) value changes for a 1/32nd change in the price of the issue. Yield Value Of A 32^{nd} or YV32 is an estimate of the change in the yield of a bond for a 1/32 change in the full price. Yield Value Of A 32^{nd} (YV32) is a measure of Dollar price volatility of a Treasury security that calculates the Treasury security's yield in response to a price increase or decrease of one tick, i.e. 32^{nd} or 1/32. In other words, it tells us how much the yield to maturity of a bond varies given a price change of one thirty-second of one point. This measure is figured out by calculating the security's yield if the price is increased or decreased by a 32^{nd}. Then, we calculate the difference between the initial yield (before the change) and the new yield (after the change). The smaller this yield, the greater the Dollar price volatility of a given security, and vice versa. The yield value of a 32^{nd} is known for short as YV1/32 or YV32.

YOKE = УПРЯЖКА (или УПРЯЖЬ, или СБРУЯ) – Yoke:- wooden bar or frame used to join draft animals at the heads or necks so that they pull together. In the early Middle East and in Greece and Rome, oxen and onagers were yoked across the horns or necks. Control of a team of yoked beasts was difficult. Furthermore, ancient yokes pressed against a hard-pulling animal's windpipe, choking it. The invention of the horse collar solved this problem and led to the replacement of oxen by horses. In some areas of the world, however, oxen still are yoked together much as they were in medieval Europe. / Упряжь (Сбруя) – приспособление для управления лошадью, волом, оленем, собакой и другими животными и для использования их силы на работах (под седлом, вьюком, в повозке, с сельскохозяйственными орудиями). Одноконная дуговая упряжь состоит из хомута, дуги, седёлки с подпругой, чересседельника, шлеи, узды и вожжей. Основная часть сбруи верховой лошади – седло.

YOKE (SELF) = КОКЕТКА (или ЯРМО, или КОРОМЫСЛО, или ХОМУТ, или ЗАЖИМ, или СВЯЗЬ, или ЗАКРЕПА, или ОБОЙМА, или СКОБА) – Yoke is a fitted or shaped piece of fabric fullness principally designed to control fullness from gathers, pleats, or darts. Sometimes a yoke is used strictly as a decorative design element. Yokes are gener ally found in the shoulder area of shirts, blouses, and dresses, but are also used in the waist and hip areas of skirts and slacks. Yoke (self):- the entire back of a garment is one piece and has a single yoke superimposed on the outside.

YOKE (TWO–PIERCE) = ХХ КОКЕТКА (или ХХ ЯРМО) – Yoke (Two-Pierce):- two identical pieces of fabric are joined to a shortened back piece to produce the total back. / два одинаковых куска ткани, .

YOKELESS SHIRT = БЛУЗКА БЕЗ КОКЕТКИ – Yokeless Shirt:- the front and backs of a shirt are joined without a yoke facing.

YOLK = ЖЕЛТОК – Yolk:- also called Deutoplasm, the nutritive material of an egg, used as food by a developing, embryonic animal. Eggs with relatively little, uniformly distributed yolk are termed Isolecithal. This condition occurs in invertebrates and in all but the lowest mammals. Eggs with abundant yolk concentrated in one hemisphere of the egg are termed Telolecithal. This occurs in many invertebrates and in all vertebrates lower than marsupial mammals. In arthropods, the yolk is massed near the centre of the egg; such eggs are termed Centrolecithal. Yolk:- The yellow, spherical part of an egg that is surrounded by the white albumen, and serves as nutriment for the growing young. To make meringue, you have to separate the white from the yolk. Yolk:- the yellow internal part of a bird's egg, which is surrounded by the white, is rich in protein and fat, and nourishes the developing embryo; e.g., 'two yolks' or 'a mass of yolk'. In zoology:- The part corresponding to the yolk in the ovum or larva of all egg-laying vertebrates and many invertebrates. / Желток или Дейтоплазма, питательные вещества, накапливающиеся в яйцеклетке животных и человека в виде зёрен или пластинок, которые иногда сливаются в сплошную желточную массу (у Насекомых, костистых Рыб, Птиц и других). Желток обнаружен в яйцеклетках всех животных и человека, но его количество и распределение значительно варьируют. В яйцах с малым количеством желтка желточные зёрна распределяются в цитоплазме равномерно (изолецитальные яйца). В яйцах с большим количеством желтка желточные зёрна скапливаются либо в вегетативной части яйца (телолецитальные яйца), либо в центральной части цитоплазмы – вокруг ядра (центролецитальные яйца). От количества и распределения желтка зависит тип дробления яиц. По химической природе различают три главных разновидности желтка:- белковый, жировой и углеводный, однако у большинства животных зёрна желтка имеют сложный химический состав и содержат белки, жиры, углеводы, рибонуклеиновую кислоту, пигменты и минеральные вещества. Например, в завершившем рост курином яйце желток содержит 23% нейтрального жира, 16% белка, 11% фосфолипидов, 1.5% холестерина и 3% минеральных веществ. В синтезе и накоплении желтка принимают участие различные органоиды яйцеклетки:- Комплекс Гольджи, эндоплазматическая сеть, митохондрии. У многих животных белковый компонент желтка синтезируется вне яичника и поступает в растущую яйцеклетку

путём пиноцитоза. У некоторых беспозвоночных животных желток может накапливаться также в специальных клетках яичника – желточных клетках, за счёт которых питается развивающийся зародыш.

YOLK = ЖИРОПОТ (или XX) – (1) Yolk is the natural grease and suint covering on the wool fibers of the unscoured fleece, and excreted from glands in the sheep's skin. Usually the finer the wool, the more abundant the yolk. Yolk serves to prevent entanglement of the wool fibers and damage during growth of the fleece. Yolk:- the grease in a Sheep's fleece. Yolk or Lanolin is not to be confused with Canary stain. Yolk or Lanolin is the natural substance on the wool that provides lubrication for the wool fibers as well as cleans and protects the fiber from degradation from sun and rain. It gives a soft creamy yellow color to the wool as opposed to the bright yellow color of Canary stain. Yolk:- The sebaceous and sudoriferous (sweat) glands associated with the wool follicles coat the fibers with their secretions as the new, growing fiber is pushed along the follicle shaft to the skin surface. Wool follicles do not all possess sweat glands, and sebaceous glands may vary both in number and size from follicle to follicle (Sutton, 1931). A variation in yolk over the body of the Merino was noted by Bonsma & Starke (1934). They pointed out that the yolk in wool is an inherent characteristic. Bonsma (1930) stated that the wool yolk comprises all the impurities of animal origin adhering to the fiber. This description of the term is hardly satisfactory, since it fails to distinguish between wool fat (grease or wax) and suint. Bonsma & Starke (1934), however, showed that wool fat and suint were in no way correlated, but that wool fat is negatively correlated with yield. According to Lang (1945), the appraiser and wool buyer do not place a value directly on the yolk itself, although they take note of its nature and use it as a guide in assessing certain characteristics of wool as well as the clean yield. It was established by Winson (1929) that yolk influences the characteristics of the fiber, viz. wool of more greasy samples of the same quality being distinctly finer and more uniform in fineness, i.e. showing less variation in size of cross-section and a more circular cross-section. Sutton (1931) postulated that the products of the sebaceous glands and sweat glands might have some influence on the fiber while still within the follicle. There is a popular belief that the yolk nourishes the fiber. The penetration of liquids into the capillary cavities of the wool fiber has been shown by Speakman (according to Sutton, 1931) to influence the pliability and elasticity of the fiber and that yolk functions in a similar manner. However, the yolk may simply have a protective function, serving to prevent weathering of the fiber after it has emerged from the follicles. Yolk is regarded as a substance, which cements the fibers closely together, so keeping the fleece closed on the sheep (Le Roux, 1958; Louw, Swart & Mellet, 1963; Kruger, 1964). Uys (1966) and Van Rensburg (1966), however, could find no significant difference in grease content in large and small staples of fleeces. Truter and Woodford (1955) stated that wool grease has to increase about tenfold to be of any significance in preventing the fleece from falling open on the sheep's back. Sutton (1931) stated that, whatever the true relationship between yolk and fiber may be, it would seem that empirically, at least, a plentiful supply of fluid (mobile) yolk is desirable, if only as an indication of the good health of the sheep. Daly & Carter (1955) pointed out that wax production was positively related to an increase in feed intake and negatively to a rise in atmospheric temperature. Suint production was positively related to both feed intake and fleece weight. Further, wool wax and suint production per unit feed intake decreased with an increase in feed intake. Wax per unit feed intake decreased with a rise in temperature and suint per unit feed intake increased with increase in fleece weight. A negative regression of wax production and atmospheric temperature was found by Bowstead & Larose (1938). No definite relation between suint production and average atmospheric temperature was found. In New Zealand Romney Marsh sheep under local climatic conditions, Sutton (1931) found that the effect of sheep covers on yolk production was quite insignificant as compared with the normal variations between individual animals. According to Bonsma & Starke (1934) the feeding of ordinary maintenance production rations, either high or low in protein, did not seem to have any influence upon the secretion of yolk. Raymond & Mandell (1955) postulated that the quantity of grease not only increases with the fineness of the wool, ranging from 5 to 20 percent of its grease weight, but also varies in the wool of sheep of different ages, and also depends on the breed and the climate and to a lesser extent on the age and sex. There is even a substantial difference in the amount of grease found in wool on different parts of the body. Venter (1966), however, found that the percentage of wool wax in Merino wool under ad lib conditions remained practically constant up to the age of 3 1/2 years. From 3 1/2 to 6 1/2 years a gradual increase was noted in the percentage of wool wax in the wool of wethers and ewes, but a sharp increase was noted in the wool of rams, consequently affecting the yield percentage of the wool. The increase in the wool wax in the wool of the rams with increasing age was accompanied by a decrease in the percentage of suint. Venter, Steenkamp & Edwards (1973) found that wool produced on a ration low in protein but with adequate energy had markedly more wool wax than wool produced on a ration high in protein but low in energy or wool produced on a ration with sufficient protein and energy. A comparative study was undertaken by Venter, Cloete & Edwards (1969) on the productivity of Merino sheep kept under different climatic and nutritional conditions on three sites differing largely in altitude, topography, geology, vegetation and veld type. Climatic and environmental factors, in terms of the penned groups receiving the same ad lib feeding on each site, had no influence on wool wax, fluidity and suint content of the wool. The wool of the sheep on the open veld, and particularly those at a higher altitude and whose grazing was deficient in protein during both the growing and dry season, had less suint and a lower pH than normal. The penned groups had more suint and a generally high pH value. Bonsma & Starke (1934) stressed that it is futile to try to influence the yolk content of a sheep through feeding. In attempting to increase yolk secretion by feeding, there is a possibility of overheating the body and thus causing an undesirably golden discoloration of the fleece in individuals with a natural tendency to discoloration. Contrasting statements were found in respect of the stimulating effect of shearing and the use of sheep blankets on the secretion of yolk in wool. Since 1931 sheep blankets were used as a protection for sheep against cold and it was noted indirectly that the wool was cleaner and less weathered (Sutton, 1931; Austin, 1936; Duncan, 1938, 1939; Montgomery, 1938; Lipson, Ellingworth & Sinclair, 1970). Although the amount of yolk in the wool does not appear to be the main factor contributing to protection against weathering, a sufficient amount of yolk is still essential. It must however be fluid and spread over the entire fiber in order to cement the fibers together within the staples. It is also responsible for a good color. A deficiency of yolk is associated with a dull appearance and the falling open of tips, which again is responsible for greater weathering. Excessive yolk in wool, on the other hand, affects the handle by increasing its harshness, and the appearance by causing an undesirable discoloration, and also results in a lower yield. It is therefore evident that either extreme in yolk content will have a detrimental effect on the price obtained for wool. / развод (или потёк (stain)). Сатэн (Sutton, 1931). Отличается от других восков высоким содержанием стеринов (в частности, холестерина). Ланолин хорошо всасывается в кожу и обладает смягчающим действием; широко применяется в составе различных косметических средств – кремов и тому подобного, в медицине используется как основа для различных мазей, а также для смягчения кожи (в смеси с равным количеством вазелина).

YORK–ANTWERP RULES = ЙОРК–АНТВЕРПЕНСКИЕ ПРАВИЛА – York-Antwerp Rules 2004 (2004-December):- General Average is a mechanism for allocating the costs of dealing with a maritime casualty among those parties who benefit from the ship and cargo being saved. To ensure a uniform approach the principles for General Average are codified in the York-Antwerp Rules. The rules were first agreed in 1890 but from time to time have been reviewed and amended. The most recent review was 1994 (York-Antwerp Rules of 1994) and prior to that, 1974 (York-Antwerp Rules of 1974). Rule A of the York Antwerp Rules sets out when there is a 'General Average Act'. There are two categories:- (1) losses and sacrifices incurred for the common safety of ship, cargo and other property involved in the common maritime adventure; and (2) expenses incurred for the common benefit to safely complete the voyage. Since shortly after the 1994 revision of the York Antwerp Rules cargo underwriters, through the International Union of Marine Insurers (IUMI) had been pressing for a further review. In particular, the restriction of General Average to common safety issues and excluding allowances for General Average in respect of the common benefit approach. Reform of the York Antwerp Rules 1994 was discussed at the June 2004 meeting of the Comité Maritime International (CMI). Prior to the June Conference, and in the face of opposition from the shipping industry through the International Chamber of Shipping, IUMI amended its position from radical change to one of incremental change. The following changes were agreed and the revised rules will be known as the York Antwerp Rules 2004. Rule VI – Salvage Remuneration:- the York Antwerp Rules 1974 and 1994 provide for salvage claims to be recoverable in General Average. York Antwerp Rules 2004 will exclude salvage from allowable General Average recoveries. Rule XI – Wages and Maintenance of Crew and Other Expenses putting into a Port of Refuge:- these costs will no longer be allowed during the period the vessel is in port or place of refuge undergoing repairs recoverable in General Average. Fuel and stores consumed will continue to be allowable expenses. Rule XIV(b) – Temporary Repairs:- a new clause will be introduced to restrict the advantage to the shipowner where temporary repairs make it possible to effect permanent repairs at a place where such repairs can be made more cheaply than at or near the place of refuge. Rule XX:- the payment of a commission of 2% on General Average disbursements will be abolished. Rule XXI:- interest will no longer accrue at a fixed rate of 7% but will be set on an annual basis by the CMI. Rule XXIII:- if permitted by domestic law a time bar provision will be inserted extinguishing rights to claim General Average contributions one year after an adjustment has been issued, or six years after the termination of the 'Common Maritime Adventure'. The York Antwerp Rules 2004 are not mandatory but (i) may be incorporated into contracts of affreightment, and therefore applied to the adjustment of claims in General Average, from 31st December, 2004, and (ii) are a new set of rules and not merely an amendment to the 1994 Rules. Therefore, specific reference to the new rules must be set out in a bill of lading if the York Antwep Rules 2004 are to apply. Bills of lading that refer to '... York Antwerp Rules 1994 and amendments thereto ...', or use similar words, will apply the York Antwerp Rules 1994. See also General Average Act. In water transportation, York-Antwerp Rules of 1974 is the deliberate sacrifice of cargo to make the vessel safe for the remaining cargo. York-Antwerp Rules (Y/A Rules) are a code of rules adopted by an international convention in 1890, amended in 1924 and again in 1950, for the purpose of establishing a uniform basis for adjusting general average. Certain nationalities decline to observe certain of the rules adopted. United States shipping interests generally abide by general rule 'F' and numbered rules 1 to 15 and 17 to 22, inclusive and specifically set this forth in a Bill Of Lading Clause. Voluntary code, drawn up in 1877, for those involved in shipping cargo by sea. York-Antwerp Rules is a set of internationally accepted rules for application to general average circumstances. Most contracts of affreightment provide for general average to be adjusted in accordance with these rules. In the absence of such agreement adjustment is made in accordance with the law of the place where the adventure is terminated. A set of rules adopted by the representatives of all the leading maritime nations to govern the method of applying General Average. York-Antwerp Rules is a set of internationally-accepted rules, first published in 1890, proposing points of detail in the application of the maritime law principle of general average. The rules first came out in 1890 and allow all parties to the voyage during which the general average act occurred, to calculate, fairly, points of detail such as the relative proportions and interest. The Comité Maritime International has undertaken to house and administer the York-Antwerp Rules and the name continues upon subsequent versions of the Rules, including those of 1974, 1994 and of 2004. York-Antwerp Rules of 1974 established the standard basis for adjusting general average and stated the rules for adjusting claims. Йорк-Антверпенские Правила – совокупность упорядоченных правил, относящихся к урегулированию претензий при общей аварии. Первоначально они были провозглашены мировыми судоходными компаниями. Эти правила не обладают формальным статусом закона, но их включают практически во все коносаменты. Йорк-Антверпенские Правила – свод норм, регулирующих взаимоотношения сторон и расчёты по общей аварии. Правила не имеют силы закона и их применение оговаривается в договорах морской перевозки в каждом отдельном случае. Действующая в настоящее время редакция текста Правил была принята на 30-й конференции Международного Морского Комитета 05 Апреля 1974 (Йорк-Антверпенские Правила 1974). Йорк-Антверпенские Правила, свод общепринятых в международном торговом мореплавании правил, регулирующих распределение между судовладельцем и грузовладельцем пропорционально стоимости судна, груза и фрахта убытков, понесённых каким-либо из этих лиц, вследствие расходов и пожертвований, произведённых во время морской перевозки намеренно для спасения судна, груза и фрахта от общей для них опасности. Йорк-Антверпенские Правила были выработаны международной конференцией представителей торговых палат, судовладельцев, грузовладельцев и страховых компаний ряда стран, ведущих морскую торговлю, в 1864 в Йорке (Великобритания), в 1877 существенные изменения в них были внесены на конференции в Антверпене. Наибольшее распространение имеет современная редакция Йорк-Антверпенских Правил, принятая на конференции Международного Морского Комитета в Амстердаме в 1950. Хотя Йорк-Антверпенские Правила не являются ни законом, ни международным соглашением и применение их в каждом отдельном случае основывается на соглашении перевозчика с грузовладельцем, большинство стандартных форм чартеров и коносаментов, в том числе и тех, которые

применялись Советскими пароходствами, содержат условие о применении Йорк-Антверпенских Правил. Йорк-Антверпенские Правила подразделяются на литерные (от 'A' до 'C') и цифровые (I–XXII) правила. Цифровые правила содержат положения, относящиеся к отдельным случаям общей аварии (распределение убытков от выбрасывания за борт части груза в целях спасения судна и остального груза, от тушения пожара на судне и тому подобного), а также к определению размера отдельных видов убытков и стоимости спасённого имущества. В литерных правилах содержится определение общей аварии (правило 'A') и ряд других положений общего характера. Йорк-Антверпенские Правила оказали значительное влияние на законодательство об общей аварии большого числа стран; с некоторыми уточнениями и изменениями они были воспроизведены в Кодексе Торгового Мореплавания бывшего Союза Советских Социалистических Республик (СССР).

YOUNG, BEGINNING, AND SMALL = МОЛОДОЙ, НАЧИНАЮЩИЙ, И МАЛЫЙ – Young, Beginning, And Small (YBS) is a Farm Credit System initiative to encourage newer and younger producers to enter farming and ranching and to provide increased credit opportunities for small farmers. The goals of this initiative are to be balanced with the requirement to minimize undue credit risks. See also Beginning; Beginning Farmer and Rancher (Qualified), Small (Farmer and Rancher), and Young; Young Farmer.

YOUNG INDEX = ИНДЕКС ОТ ЯНГА – Young Index is a quarterly gauge of market sentiment within the private rented sector, polling Young Group® EURs client base of around 500 active investors/landlords who hold UK residential investment property. Since 2007, we have been tracking investor sentiment within the Private Rented Sector (PRS) through our Young Index research. Each quarter, we poll 500 active landlords seeking their opinions on a host of elements including their appetite to acquire investments, attitude to the mortgage market and financing, intended hold period, income and capital growth expectations and attitudes towards other investment classes and the practicalities of day-to-day asset management. The results provide valuable insight into investors' likely future behaviour and an indicator of the strength of the sector. The results are clearly influenced by the prevailing economic sentiment but without question investors see the PRS as an asset class for the long term. By Neil Young, CEO, Young Group®. Young Lettings Limited (trading as Young Group®) headquartered in London, the United Kingdom. Each quarter, through Young Index, Young Group polls investor sentiment among 500 of its Private Rented Sector (PRS) investment clients who hold UK property assets. Young Group is actively shaping the Private Rented Sector (PRS) through research, investment, finance and asset management. Young Index is an index defined as a weighted arithmetic average of the price relatives. It is a weighted version of the Carli Index. A Lowe or Young Indices use price reference periods and weight reference periods that differ, while in the Laspeyres index the price and weight reference period are one and the same. Typically the weight reference period precedes the price reference period in the version of the Young and Lowe indices used by statistical offices owing to the time it takes to develop weights from administrative sources and establishment surveys in earlier periods. / Арсо Янг. YOUNG PLAN = ПЛАН ЯНГА – The Young Plan was a program for settlement of German reparations debts after World War I written in 1929 and formally adopted in 1930. It was presented by the committee headed (1929–30) by American Owen D. Young. After the Dawes Plan was put into operation (1924), it became apparent that Germany could not meet the huge annual payments, especially over an indefinite period of time. Young Plan, program for settlement of German reparations debts after World War I. It was presented by the committee headed (1929–30) by Owen D. Young. After the Dawes Plan was put into operation (1924), it became apparent that Germany could not meet the huge annual payments, especially over an indefinite period of time. The Young Plan – which set the total reparations at USD26 350 000 000.00 to be paid over a period of 58 1–2 years – was thus adopted by the Allied Powers in 1930 to supersede the Dawes Plan. Designed to substitute a definite settlement under which Germany would know the exact extent of German obligations and to reduce the payments appreciably, the Young Plan divided the annual payment, set at about USD473 million, into two elements – an unconditional part (one third of the sum) and a postponable part (the remainder). The annuities were to be raised through a transportation tax and from the budget. No sooner had the plan gone into effect than Germany felt the full impact of economic depression, and a moratorium was called for the fiscal year 1931–32. When Adolf Hitler took over Germany, he defaulted on the unpaid reparations debt. After Germany's defeat in World War II, an international conference decided (1953) that Germany would pay the remaining debt only after the country was reunified. Nonetheless, West Germany paid off the principal by 1980; then in 1995, after reunification, the new German government announced it would resume payments of the interest. The Young Plan (1929) and Dawes Plan (1924) were international arrangements to help European nations pay their war debts to the United States and help Germany pay is reparations obligations. The onset of the depression in the 1930s ruined chances that either war debts or reparations would continue to be paid. Young Plan is the second reparations plan for Germany, replacing the Dawes Plan. Drawn up by a committee of financial experts from several countries under the chairmanship of the American banker Owen D. Young, the plan was adopted, with some modifications, at the Hague Conference on Reparations of 1929–30. The creation of the Young Plan was dictated to a considerable extent by the interests of the private, mostly American, creditors of Germany, whose solvency was being undermined by the enormous reparations it was required to pay. The new plan retained the anti-Soviet character of the Dawes Plan. It provided for a slight reduction in the amount of annual payments (by an average of up to two billion marks), the abolition of the reparations tax on industry, a reduction of taxation on transportation, and the elimination of foreign controls. One of the most important consequences of the adoption of the Young Plan was the early withdrawal of occupation troops from the Rhineland. The Young Plan remained in effect only until July 1931; it was officially abolished in 1932. The burdens imposed by the plan, however, were made use of by reactionary forces in Germany to incite a spirit of chauvinism in the country. Dawes Plan is a reparations plan for Germany worked out by an international committee of experts under the chairmanship of the American banker Charles G. Dawes; it was approved on 1924-August-16, at a London conference of representatives of the victorious powers in World War I and was accepted by Germany. Young Plan:- (1929), second renegotiation of Germany's World War I reparation payments. A new committee, chaired by the American Owen D. Young, met in Paris on 1929-February-11, to revise the Dawes Plan of 1924. Its report (1929-June-07), accepted with minor changes, went into effect on 1930-September-01. It reduced the amount due from Germany to 121 000 000 000 Reichsmarks in 59 annuities, set up the Bank for International Settlements to handle the transfer of funds, and ended foreign controls on German economic life. However, hardly had the Young Plan started operation than the world depression of the 1930s began, and Germany's ability to pay dwindled to the vanishing point. In 1932 the Lausanne Conference proposed to reduce reparations to the token sum of 3 000 000 000 Marks, but the proposal was never ratified. Adolf Hitler came to power in 1933, and within a few years all important obligations under the Treaty of Versailles – political as well as economic – were repudiated. / План Янга. YOUNG'S MODULUS = МОДУЛЬ ЯНГА (или МОДУЛЬ ПРОДОЛЬНОЙ УПРУГОСТИ) – Young's Modulus is meaningful only in the range in which the stress is proportional to the strain, and the material returns to its original dimensions when the external force is removed. As stresses increase, Young's modulus may no longer remain constant but decrease, or the material may either flow, undergoing permanent deformation, or finally break. Young's Modulus:- numerical constant, named for the XVIII century English physician and physicist Thomas Young, that describes the elastic properties of a solid undergoing tension or compression in only one direction, as in the case of a metal rod that after being stretched or compressed lengthwise returns to its original length. Young's

modulus is a measure of the ability of a material to withstand changes in length when under lengthwise tension or compression. Sometimes referred to as the Modulus Of Elasticity, Young's modulus is equal to the longitudinal stress divided by the strain. Stress and strain may be described as follows in the case of a metal bar under tension. If a metal bar of cross-sectional area A is pulled by a force F at each end, the bar stretches from its original length L_o to a new length L_n. (Simultaneously the cross section decreases.) The stress is the quotient of the tensile force divided by the cross-sectional area, or F/A. (Its units in the English system are pounds per square inch, usually abbreviated psi.) The strain or relative deformation is the change in length, $L_n - L_o$, divided by the original length, or $(L_n - L_o) / L_o$. (Strain is dimensionless.) Thus Young's modulus may be expressed mathematically as:- Young's Modulus = Strainstress = $(L_n - L_o) / L_oF / A$. Young's Modulus is a property of perfectly elastic materials, it is the ratio of change in stress to change in strain within the elastic limits of the material. The ratio is calculated from the stress expressed in force per unit cross sectional area, and the strain expressed as a fraction of the original length. Modulus so calculated is equivalent to the force required to strain the sample 100% of its original length, at the rate prevailing below the elastic limit. Young's Modulus, also known as the Tensile Modulus or Elastic Modulus or Modulus of Elasticity, is a measure of the stiffness of an elastic material and is a quantity used to characterize materials. It is defined as the ratio of the stress along an axis over the strain along that axis in the range of stress in which Hooke's law holds. In solid mechanics, the slope of the stress-strain curve at any point is called the Tangent Modulus. The tangent modulus of the initial, linear portion of a stress-strain curve is called Young's Modulus. It can be experimentally determined from the slope of a stress-strain curve created during tensile tests conducted on a sample of the material. In anisotropic materials, Young's modulus may have different values depending on the direction of the applied force with respect to the material's structure. Young's modulus is the most common elastic modulus, sometimes called the Modulus Of Elasticity, but there are other elastic moduli measured, too, such as the bulk modulus and the shear modulus. It is named after Thomas Young, the XIX century British scientist. However, the concept was developed in 1727 by Leonhard Euler, and the first experiments that used the concept of Young's modulus in its current form were performed by the Italian scientist Giordano Riccati in 1782, predating Young's work by 25 years. Young's modulus is the ratio of stress, which has units of pressure, to strain, which is dimensionless; therefore, Young's modulus has units of pressure. The SI unit of modulus of elasticity (E, or less commonly Y) is the Pascal (Pa or N/m^2 or $m^{-1}\cdot kg\cdot s^{-2}$). The practical units used are MegaPascals (MPa or N/mm^2) or gigapascals (GPa or kN/mm^2). In United States customary units, it is expressed as pounds (force) per square inch (psi). The abbreviation ksi refers to thousands of psi. The Young's modulus enables the calculation of the change in the dimension of a bar made of an isotropic elastic material under tensile or compressive loads. For instance, it predicts how much a material sample extends under tension or shortens under compression. Young's modulus is used in order to predict the deflection that will occur in a statically determinate beam when a load is applied at a point in between the beam's supports. Some calculations also require the use of other material properties, such as the shear modulus, density, or Poisson's ratio. / Швейцарский математик, физик, астроном, логик и инженер Лионхард Ойля (Leonhard Euler; 1707–1783), Итальянский механик экспериментатор Дьжордано Рикати (Giordano Riccati; 1709–1790). Томэс Ян (Thomas Young; родился в Милвертоне (Графство Сомерсет) 13 Июня 1773; умер Янг в Лондоне 10 Мая 1829), Английский физик, врач, египтолог, один из выдающихся представителей мира науки, искусства и медицины начала XIX века. В теории упругости Янгу принадлежат исследования деформации сдвига. Он же ввёл характеристику упругости – модуль растяжения (модуль Янга, который в России почему-то называют Модулем Юнга). Модуль Янга или Модуль Юнга – то же что, Модуль Продольной Упругости E. Смотрите также Модули Упругости. Модуль Янга (модуль упругости) – коэффициент, характеризующий сопротивление материала растяжению/сжатию при упругой деформации. Назван в честь Английского физика XIX века Томэса Янга. В динамических задачах механики модуль Янга рассматривается в более общем смысле – как функционал среды и процесса. площадь поверхности, по которой распределено действие силы. длина деформируемого стержня. сила в Ньютонах. Модуль Янга зависит только от свойств материала и не зависит от размеров и формы тела. Модуль Янга показывает напряжение, которое необходимо приложить к телу, чтобы удлинить его в 2 раза. Для различных материалов модуль Янга меняется в широких пределах. Для стали, например, $E \approx 2\cdot10^{11}$ Н/м^2, а для резины $E \approx 2\cdot10^6$ Н/м^2. Через Модуль Янга вычисляется скорость распространения звука в веществе.

YOUNG TURKEY = МОЛОДАЯ ИНДЕЙКА – Young Turkey is a Turkey of either sex that is less than eight months of age. / Индейка – красивая, крупная и внушительная по своим размерам птица, которая в показателе веса может достигать даже 35 килограммов (кг). И утончённые по своей конституции тела самки, и, самцы обладают длинными и крепкими ногами, мощными и раскидистыми крыльями. Домашние птицы настоящие и полноправные хозяева всего домашнего птичника, где содержат несколько разновидностей. Индейка отличается спокойным и уравновешенным характером, поэтому способна запросто ужиться с утками, курами, перепёлками. Отличить же домашнего индюка от индейки в самом раннем возрасте легче, чем петуха от курочки. Методы различия:- борода и шпоры; масса; гребешок; перья; помёт; поведение. Борода И Острые Шпоры:- Заводчик способен чётко отличить самочку от предполагаемого самца по природному наличию небольшой бородки, острых шпор. Данный метод разумно использовать только в возрасте двух месяцев. У самочки встретить шпоры можно довольно редко. Небольшая, но заметная бородка на голове груба, перья на грудной клетке птицы жёсткие у самца, а вот у индюшки перышки мягкие, растут таки не очень густо. Масса:- Индюк отличается большой массой, выглядит внушительнее, чем индейка. Самка выглядит мельче, изящнее, а вес меньше. Метод идеально подойдет для раннего и четкого определения пола птиц, потому что после непосредственного появления все представители мужского пола сразу выглядят крупнее и намного крепче. Хвостовые Перья И Гребешок:- Индейка обладает гребнем небольшого размера, он отличается блеклым оттенком. У самца гребешок ярко блестит, отличается ярким окрасом и непосредственно важен в очень теплое время года, особенно при наступлении весны. Хвост у самочки не очень пышный, а вот у самца он привлекателен и внушителен. У мужской особи в хвостике есть плотные, красивые и абсолютно ровные перья. Особенная Железа:- У самца этой птицы есть достаточно выраженная железа, которую можно прощупать. Вы можете полностью прощупать и обследовать пальпацией эту железу, когда домашней птице исполняется примерно пять месяцев. Метод относят к распространённому народному, но не к научному направлению. Но всё же работает технология всегда и безотказно. Определить пол можно, когда индейка и индюк обладают одинаковым весом – происходит в возрасте полугода. Перья На Крыльях:- Метод используется, когда индейка достигла суточного возраста. Когда перышки в крайнем ряду на крыле птенца отличаются одной длиной, это точно мальчик. Различие пола птицы таким способом работает просто безотказно. Приём давно зарекомендовал себя, но, когда птенец старше, технология теряет свою актуальность и точность. Случается так по той причине, что вместе с крылышками растёт и длина оперения. Индейка отличается активностью развития и роста, поэтому обращайте внимание на особенности оперения ещё в самом раннем возрасте птенцов. Метод позволяет визуально понять, какого пола птенец или подросшая птица находится перед вами. Количество Помёта:- Так вы поймёте, где индейка, а где индюк. Метод определения пола неординарный, но эффективный. Используется активно среди Американских фермеров. Они обратили внимание, что у самки количество помёта обильнее, чем у самца, он более плотный. Помёт каждой индюшки схож с помётом курицы:- образовывает горку и отличается повышенным количеством. Поведение И Характер:- Самка отличается коллективной манерой своего поведения, она стремится находиться в компании других птиц. Индюшки активно собираются мелкими или же крупными группами в зависимости от самой численности в птичнике. Довольно странно, но дамы отличаются агрессивностью, а вот кавалеры их спокойнее. Индюшки позволяют себе заклёвывать других домашних птиц, курицу или же петуха, если соберутся группой.

Различия в поведении и характеры присущи для подростков и более взрослых представителей индюков. Да, методов точного определения пола и отличия домашней индюшки от индюка не так уж и много, но всё же в соответствии с определёнными советами вы сможете легко определять, кто находится перед вами – самка или же самец. Но стоит практиковаться в тесном обращении и общении с птицами. Присматривайтесь к своей домашней птице – так вы научитесь отличать индеек от индюков. Обилие научного контента помогает повысить квалификацию и практичные навыки заводчиков. Молодой Индюк топчет индюшку, но не оплодотворяет, то есть ногами потоптал, а сперму на пол слил.

YoY = YEAR–ON–YEAR

YO–YO OPTION = ОПЦИОН Ё–Ё – Yo-Yo Option:- xxxxx. Yo-Yo is slang for a very volatile market. The name comes from the movements of a yo-yo, where security prices continually go up and down. A yo-yo market has no distinguishing features of either an up or down market, taking on characteristics of both. Security prices in a yo-yo market swing very high to low over a given period of time, making it difficult for buy and hold investors to profit. Breaking Down Yo-Yo:- Yo-yo markets can, however, be profitable environments for astute traders who are able to recognize buy and sell points and make trades before the market reverses. These markets are characterized by steep up and down movements in share prices that can occur within a short timeframe, such as weeks, days or even hours. The movements are often abrupt, without warning, and they usually involve a majority of the stocks moving in unison. Traders on Wall Street also refer to this kind of activity as 'all or nothing' when everything about the market is either good or bad. Since the market crash of 2008, the stock market has become more volatile, driven in some part by its hypersensitivity to macro events. A Recent Example Of A Yo-Yo Market:- The occurrence of yo-yo markets is still rare, especially those that last for several days or more. They are more likely to occur when market volatility picks up following a protracted rise in stock prices, which can tend to make investors nervous. For example, during the first six months of 2015, the Dow Jones Industrial Average (DJIA) never fluctuated up or down more than 3.5% as it rose to record heights. Then, in August, a convergence of macro issues, such as China's slowing economy, crashing oil prices and the prospect of higher interest rates, sent the stock market in a steep decline. From August 20, 2015, to September 01, 2015, the market experienced eight trading days in which the Standard & Poor's 500 Index advance/decline reading was either above 400 or below 400, meaning 400 of the 500 stocks in the index were either advancing or declining at the same time. Within just two days, the DJIA had its worst and best days of the year. Prior to August 20, there had been only 13 days when that occurred. The last time the market experienced an extended number of yo-yo days was during the stock market crash of 2008. During a 15-day period from August 20, 2008, to September 09, 2008, there were 11 occurrences, which is unprecedented. Xxxxx. Yo-Yo is slang describing volatility in the market. How It Works (Example):- In a mathematical sense, standard deviation is a measure of how much an investment's returns can vary from its average return. That is, it is a measure of how much the market for a stock is yo-yo-ing. The less a market or investment yo-yos, the less risk there is that its value will deviate from the expected value. Why It Matters:- Yo-yos famously go up and down, though their owners usually think that is fun. In the trading world, yo-yo markets are rarely fun – they create a lot of stress for investors, who worry their investments are going to lose value suddenly. However, yo-yo markets also present tremendous opportunity, because what goes down often comes back up, just like a yo-yo (unless, of course, the string comes off or gets tangled, which euphemistically can happen in the trading world, too). / Опцион Ё-Ё – опцион на акции с неустойчивым курсом. Характерная черта повышения стоимости акций в программах опциона на акции тех фирм, где цена опциона на акции для руководителей понижается на один Доллар каждый раз, когда курс акций компании повышается на один Доллар.

YO–YO STOCK = АКЦИЯ Ё–Ё – Yo-Yo Stock:- informal, a stock that moves upwards and downward in price frequently and with little pattern. Yo-yo stocks are highly volatile and, as such, can be very risky. Yo-Yo is slang for a stupid and easily manipulated person. Yo-Yo Stock is a highly volatile stock that moves up and down like a yo-yo. Yo-Yo Stock is a stock that is considered volatile because the price of the stock goes up and down sporadically without a justified reason. Yo-yo stocks are considered a risky investment due to an investor's inability to gauge how the stock will perform. Yo-Yo Stock is a stock whose price rises and drops often and quickly. / Американский жаргон:- Ё-Ё – флюгер, беспринципный человек. Акции Ё-Ё – акции с крайне неустойчивым курсом. Эти акции являются специальными эмиссиями ценных бумаг с высокой ценой, привлекающими внимание спекулянтов как потенциальный источник спекулятивной прибыли благодаря тому, что они очень резко колеблются в цене. Неустойчивые Ценные Бумаги – акции, цены на которые подвержены значительным колебаниям, неустойчивые акции (volatile); цены быстро поднимаются и опускаются, как игрушка ё-ё (детская игрушка – диск или шар на верёвочке или резинке).

ZAIBATSU = ЗАИБАЦУ – Zaibatsu (in Japanese:- 'Wealthy Clique'), any of the large capitalist enterprises of Japan before World War II, similar to cartels or trusts but usually organized around a single family. One zaibatsu might operate companies in nearly all important areas of economic activity. The Mitsui combine, for example, owned or had large investments in companies engaged in banking, foreign trade, mining, insurance, textiles, sugar, food processing, machinery, and many other fields as well. All zaibatsu owned banks, which they used as a means for mobilizing capital. The four main zaibatsu were Mitsui, Mitsubishi, Sumitomo, and Yasuda, but there were many smaller concerns as well. All of them developed after the Meiji Restoration (1868), at which time the government began encouraging economic growth. The zaibatsu had grown large before 1900, but their most rapid growth occurred in the XX century, particularly during World War I, when Japan's limited engagement in the war gave it great industrial and commercial advantages. In 1946, after the end of World War II, the Allied occupation authorities ordered the zaibatsu dissolved. Stock owned by the parent companies was put up for sale, and individual companies of the zaibatsu empires were freed from the control of parent companies. The management of the individual companies, however, was not radically changed, and to some extent the coordination and control of the previous organization remained. After the signing of the peace treaty in 1951, many companies began associating into what became known as Enterprise Groups (Kigyō Shūdan). Those created with companies that were formerly part of the big zaibatsu – Mitsubishi group, Mitsui group, and Sumitomo group – were more loosely organized around leading companies or major banks; they differed most significantly from the old, centrally controlled zaibatsu in the informal manner that characterized each group's policy coordination and in the limited degree of financial interdependency between member companies. The cooperative nature of these groups became a major factor in Japan's tremendous postwar economic growth, because, in the pooling of resources, the investments made by these groups in developing industries were large enough to make these industries competitive worldwide. Large family-owned conglomerates that controlled much of the economy of Japan prior to World War II. Zaibatsu (property) is a Japanese term referring to the 'Financial Cliques', 'Wealth Cliques', or business conglomerates, whose influence and size allowed for control over significant parts of the Japanese economy throughout the Edo and Meiji periods. The term was commonly used up until the end of World War II. Zaibatsu were usually organized around a single family, and might operate companies in all the major areas of economic activity. All zaibatsu owned banks, which they used to mobilize capital. The zaibatsu used their contacts in the government to secure lucrative monopolies, subsidies, and tax concessions. In return, the zaibatsu helped to finance strategic semiofficial enterprises in Japan and abroad, particularly in Taiwan and Korea. The tightly-organized control of the zaibatsu over large areas of the economy was responsible for Japan's successful industrialization and rapid growth as an economic power. By 1937, the four leading zaibatsu directly controlled one third of Japanese bank deposits, one third of all foreign trade, one half of Japan's shipbuilding and maritime shipping, and most of the heavy industries in Japan. After Japan's surrender (1945) in World War II, the breakup of the zaibatsu was announced as a major aim of the Allied occupation. Assets were seized, holding companies were eliminated, interlocking directorships were outlawed, and the individual companies that made up the zaibatsu were made independent entities. Complete dissolution of the zaibatsu was never achieved by Allied reformers, mostly because, in an effort to reindustrialize Japan as a bulwark against Communism in Asia, the US government rescinded the SCAP (Supreme Commander of the Allied Powers) orders to deconcentrate Japan's large companies. Individual companies began associating in 'enterprise groups' (kigyo shudan), organized around leading companies or major banks. The cooperative nature of these groups became a major factor in the rapid economic growth of postwar Japan, as they pooled their

resources to invest in developing industries. Though large industrial conglomerates continue to exist in Japan, the vertically-integrated chain of command of the zaibatsu, has now widely been displaced by the horizontal relationships of association and coordination characteristic of ‘Keiretsu’ (meaning ‘Series’ or ‘Subsidiary’). History And Significance:- the term Zaibatsu was used in the XIX century and the first half of the XX century to refer to large family-controlled banking and industrial conglomerates in Japan. While the term was used arbitrarily in the United States throughout the 1980s to refer to any large Japanese corporation, it is not used by native Japanese speakers for anything other than historical discussions in reference to Edo- and Meiji-era zaibatsu. A zaibatsu was usually organized around a single family, and might operate companies in all the major areas of economic activity. All zaibatsu owned banks, which they used to mobilize capital. The Mitsui zaibatsu, for example, owned companies or invested in banking, food processing, foreign trade, mining, insurance, textiles, sugar, machinery, and many other areas. The leading zaibatsu were Mitsui, Mitsubishi, Dai Ichi Kangyo, Sumitomo, Sanwa, and Fuyo. Historical Influence:- the ‘Big Four’ Zaibatsu (Shidai Zaibatsu) of Mitsubishi, Mitsui, Sumitomo and Yasuda are the most historically significant zaibatsu groups, with roots stemming from the Edo period of Japanese history, but there were also many smaller concerns. During the Edo and into the Meiji periods, the Tokugawa shogunate made use of their services and financial power, often free of charge, to carry out various endeavors, in exchange for the privilege of using government funds. The oldest zaibatsu, the house of Mitsui, had been run by merchants since 1616, when its samurai founder began brewing sake and soy sauce. Most of the other zaibatsu developed after the Meiji Restoration of 1868, when the government began to actively encourage economic growth and industrialization with subsidies, privileges and favorable tax policies. The zaibatsu founders were not wealthy merchants, but samurai bureaucrats with long-established contacts in the government, which enabled them to secure lucrative monopolies, subsidies, and greatly undervalued state assets when the government sold off state industrial properties during the 1870s. The zaibatsu helped to finance strategic semiofficial enterprises in Japan and abroad, particularly in Taiwan and Korea. For example, Yataro Iwasaki, founder of Mitsubishi, was given a subsidised shipping monopoly in return for his help ferrying troops to Taiwan during a military expedition in 1874. In the early 1930s, an attempt by the military clique to break the economic power of the zaibatsu failed. By 1937, the four leading zaibatsu directly controlled one third of Japanese bank deposits, one third of all foreign trade, one half of Japan’s shipbuilding and maritime shipping, and most of the heavy industries in Japan. They maintained close relationships with the major political parties. After the Russo-Japanese War, a number of ‘second-tier’ zaibatsu also emerged, mostly as the result of business conglomerations. Some more famous second-tier zaibatsu included the Okura, Furukawa, Nakajima Aircraft Company, and Nissan groups, among several others. The zaibatsu grew most rapidly during the early XX century, particularly during World War I when Japan’s limited involvement in the war gave it industrial and commercial advantages. Postwar Dissolution:- after Japan’s surrender (1945) in World War II, the breakup of the zaibatsu was announced as a major aim of the Allied occupation. Their controlling families’ assets were seized, holding companies (the previous ‘heads’ of the zaibatsu conglomerates) eliminated, and interlocking directorships, essential to the old system of intercompany collaboration, were outlawed. Stock owned by the parent companies was sold, and the individual companies that made up the zaibatsu were made independent entities, although the management within each company remained largely unchanged. Among the zaibatsu that were targeted by the Supreme Commander of the Allied Powers (SCAP) for dissolution in 1946 were Asano, Furukawa, Nakajima, Nissan, Nomura, and Okura. Matsushita Electric Industrial Co., Ltd., though not a zaibatsu, was originally targeted for breakup, but was saved by a petition signed by 15 000 of its trade union workers and their families. After the signing of the peace treaty in 1951, individual companies began associating in ‘enterprise groups’ (kigyo shudan), organized around leading companies or major banks. They differed from the previous centralized zaibatsu in that their collaboration was more informal, and the financial interdependency among the member companies was limited. The cooperative nature of these groups became a major factor in the rapid economic growth of postwar Japan, as they pooled their resources to invest in developing industries. Complete dissolution of the zaibatsu was never achieved by Allied reformers or SCAP, mostly because, in an effort to reindustrialize Japan as a bulwark against Communism in Asia, the US government rescinded the SCAP orders to deconcentrate Japan’s large companies Zaibatsu as a whole were widely considered to be beneficial to the Japanese economy and government. The Japanese public, zaibatsu workers and management, and the entrenched bureaucracy were unenthusiastic and disapproving of plans to dissolve the zaibatsu. The change in the political focus of the Occupation during the reverse course crippled efforts to eliminate the zaibatsu. Modern Influence:- today, the influence of the zaibatsu can still be seen in the financial groups, institutions, and larger companies whose origins reach back to the original zaibatsu, often sharing the same original family names (for example, Sumitomo Mitsui Banking Corporation). However, some argue that the ‘old mechanisms of financial and administrative control’ that zaibatsu once enjoyed have been destroyed. Though large industrial conglomerates continue to exist in Japan, the vertically-integrated chain of command of the zaibatsu, culminating in control by a single family, has now widely been displaced by the horizontal relationships of association and coordination characteristic of keiretsu (meaning ‘series’ or ‘subsidiary’). / заибацу (zaibatsu). Крупные конгломераты, основанные и поддерживаемые на семейных началах, которые контролировали до Второй Мировой Войны большую часть экономики Японии. Под термином Заибацу, дословно переводимо с Японского языка как Состоятельная Клика (Wealthy Clique), понимались крупнейшие монополии и финансовая олигархия современной Японии. До её поражения во Второй Мировой Войне (1939–45) они выступали в форме концернов, объединявших каждый десятки разнообразных компаний под контролем головной семейной компании (главные из концернов – Мицуи (Mitsui), Мицубищи (Mitsubishi), Сумитомо (Sumitomo), Ясуда (Yasuda)). Заибацу контролировали основные отрасли экономики, способствуя милитаризации Японии, выступали как вдохновители агрессии. После Второй Мировой Войны прежние концерны были реорганизованы по принципам современных Американских и Западно-Европейских монополий – со свободной куплей-продажей акций, широким привлечением внешнего капитала. Это способствовало усилению концентрации производства и капитала, особенно в 1960. Заибацу выступают в форме финансово-монополистических групп (основные из них – Мицубищи (Mitsubishi), Сумитомо (Sumitomo), Мицуи (Mitsui), Фудзи (Fuji), Дайити-Кангё (Daiichi-Kangyo), Санва (Sanwa)), объединяющих самые крупные банки, страховые, промышленные и торговые компании страны. После войны заибацу ещё более укрепили свои позиции в качестве ведущей силы правящего реакционного лагеря. Этому исскуству не одна сотня лет. Пришло оно в Индию вместе с Великими Моголами, которые позаимствовали его у Персов. Само слово Зардози состоит из друх Персидских слов Зар (Zar) и Дози (Douzi), означающими соответственно Золото и Вышивка. Первоначально в вышивке зодози исользовались только золотые и серебряные нити, поэтому такие изделия могли позволить себе только очень богатые. Вышивка зодози украшала наряды придворных, ковры, покрывала, тенты. В настоящее время в вышивке используют также разноцветные металлические нити. Для зодози подходит дорогая качественная ткань – шёлк, вельвет, парча. Искусство вышивки зодози требует огромного терпения и мастерства. Помимо металлических нитей, для создания дизайна используют стразы, бусины, а также драгоценные и полу-драгоценные камни. Вышивка зодози особенно популярна в свадебных нарядах, а также ею украшают покрывала, подушки, занавески, скатерти, сумки и туфли.

ZAYCHIK = ЗАЙЧИК – Zaychik:- The slang term for the Belarusian Rouble (BYR), literally means ‘Rabbit’ after the first post-communist Roubles in the early 1990s had pictures of animals on them, one of which was a hare. The currency has subsequently defenestrated the animals and now lists national monuments on the banknotes, but alongside parallel denominations has lost much of its value. While at a high of 2 150 Roubles to USD1 in 2006, the value of the Belarusian Rouble to USD1, after a 56% devaluation in May 2011, now has decreased to more than 5 000 BYR.

Z BOND = ОБЛИГАЦИЯ ЗИ. (или ОБЛИГАЦИЯ ЗЭД.) – A Z Bond is a type of bond used in some collateralized mortgage obligations (CMOs). It is often the last bond to mature. It pays no interest while principal is being paid down on earlier bonds. Instead, interest that would have been paid to the Z bond is instead used to more rapidly pay down principal on the earlier bonds. Because it accrues interest rather than pay it out, the Z bond is analogous to a zero-coupon bond. Note that interest payments made by mortgagors during the early years of the CMO are treated as principal payments to the A, B and C bonds. Principal payments made by mortgagors during the later years of the CMO are treated as payments of accrued interest to the Z bond. Z bonds can be incorporated into a variety of CMO structures. Some CMOs have multiple Z bonds that mature one after another. Multiple Z bonds do not need to be consecutive. A CMO might have an intermediate Z bond and a long maturity Z bond with intervening sequential pay tranches. A CMO might consist entirely of Z bonds. Also known as Accrual Bond. Z Bond is a bond on which interest accrues but is not currently paid to the investor but rather is added to the principal balance of the Z bond and becoming payable upon satisfaction of all prior bond classes. A Z Bond (also called an Accrual Bond) is a type of bond used in some collateralized mortgage obligations (CMOs). It is often the last bond to mature. It pays no interest while principal is being paid down on earlier bonds. Instead, interest that would have been paid to the Z bond is instead used to more rapidly pay down principal on the earlier bonds. Because it accrues interest rather than pay it out, the Z bond is analogous to a zero-coupon bond. Cash flows for a CMO with three sequential pay bonds followed by a single Z bond are depicted in Exhibit 1. Note that interest payments made by mortgagors during the early years of the CMO are treated as principal payments to the A, B and C bonds. Principal payments made by mortgagors during the later years of the CMO are treated as payments of accrued interest to the Z bond. A Z bond pays no interest while principal is being paid down on earlier bonds. Z bonds can be incorporated into a variety of CMO structures. Some CMOs have multiple Z bonds that mature one after another. Multiple Z bonds do not need to be consecutive. A CMO might have an intermediate Z bond and a long maturity Z bond with intervening sequential pay tranches. A CMO might consist entirely of Z bonds. Z-Bond:- the fourth (Z) tranche of bonds in the structure of a typical collateralized mortgage obligation (CMO). Combining features of zero-coupon securities and mortgage pass-through securities, Z bonds receive no coupon payments until the earlier A (fast-pay), B (medium-pay), and C (slow-pay) classes have been paid off. Z holders then receive all the remaining cash flow, although interest has been added to principal as cash was used to repay earlier tranches. Some CMOs have been issued with multiple Z and Y tranches, incorporating sinking-fund schedules. Z-Bond:- the final tranche in a series of mortgage-backed securities that is the last one to receive payment. Used in some collateralized mortgage obligations (CMO), Z-bonds pay no coupon payments while principal is being paid on earlier bonds. Interest that would have been paid on Z-bonds is used instead to pay down principal more rapidly on the earlier series of bonds. Interest payable on a Z-bond is added to the principal balance and becomes payable once claims on all prior bond classes have been satisfied. A Z-bond is similar to a zero-coupon bond, since it accrues interest rather than paying it out. Therefore, the final tranche is considered the most risky for the CMO class structures. / Облигация, процент по которой начисляется, но не выплачивается инвестору в текущий момент. Бескупонная Облигация Зи. сочетает свойства бескупонных ценных бумаг и ценных бумаг, обеспеченных пулом (pass-through securities) ипотек. Облигации Зи. не обеспечивают никаких купонных платежей до тех пор, пока не будут произведены выплаты по облигациям класса А (первая выплата), В (последующая выплата) и С (последняя выплата). Владелец облигаций Зи. получает все оставшиеся выплаты и основную сумму облигации самым последним, хотя основная часть процентов уже была выплачена по облигациям более ранних траншей. Некоторые CMO были выпущены с многочисленными Зи. или Зэд. (Z) и Уай. (Y) траншами, объединёнными общей схемой погашения через выкупной фонд (sinking fund).

Z–CERTIFICATE = ЗИ.–СВИДЕТЕЛЬСТВО (или СЕРТИФИКАТ–ЗЭД.) – Z-Certificate is a certificate issued by the Bank Of England used as a substitute for stock certificates for the purpose of improving liquidity and short-term transactions. The purpose of the Z-Certificate is to prove ownership of a stock which would only be held for a short period of time. A Z-Certificate is a certificate issued by the Bank of England. It is used instead of stock certificates to improve short term transactions. In fact a Z-Certificate is a proof of ownership of stocks, when the investor is intending to keep them for a short time. Z-Certificates are not available to all kinds of stocks, they can even expire after a limited time. This is to prevent inventors of miss-using them, as there is a higher rate of interest associated with this stock. The restrictions on this certificate helps preserve the integrity of the document, keeping it a good document for short term transactions. / Зи.-Свидетельство или Сертификат-Зэд. – свидетельство, выданное Банком Англии учётным домам вместо акционерных сертификатов для содействия их сделкам с краткосрочными первоклассными ценными бумагами.

Z–DNA = ЗИ.–ДНК (или ЗЭД.–ДНК, или ДНК–ЗЭД.–КОНФОРМАЦИЯ) – Z-DNA is a left-handed helix (molecular structure) of DNA, in contrast to A-DNA and B-DNA which are right-handed helix structures. The difference is in the direction of the double-helix twist. Z-DNA has the most base pairs per turn (in the helix), and so has the least twisted structure; it is very 'skinny' and its name is taken from the zigzag path that the sugar-phosphate 'backbone' follows along the helix. This is quite different from the smoothly curving path of the backbone of B-DNA. The Z-form of DNA has been found in polymers that have an alternating purine-pyrimidine sequence. / ДНК Z-Конформация – левозакрученная форма молекулы ДНК.

ZEARALENONE = ЗЕАРОЛЕНОН – Zearalenone is one of the mycotoxins (i.e. toxins produced by a Fungus), it causes reproductive difficulties in swine (e.g., reduced sperm production, halting of estrus, etc) when consumed by animals (e.g., in contaminated grain such as Corn/Maize). It causes a variety of adverse health impacts when consumed by some other Species of Animals. Zearalenone is produced by certain strains of Fusarium Fungi (e.g., Fusarium Culmorum, Fusarium Graminearum, Fusarium Crookwellense, Fusarium oxysporum, etc) when climate (e.g., moisture and temperature) conditions during the grain growing season, combined with entry points (e.g., holes chewed into the grain plants by insects) facilitate growth of those Fusarium strains in grain. / Зеароленон – токсин, выделяемый Грибами (Fusarium Culmorum, Fusarium Graminearum), препятствующий репродукции Свиней.

ZEAXANTHIN = ЗЕАКСАНТИН – Zeaxanthin is a carotenoid (i.e. 'light harvesting' compound utilized in photosynthesis) that is naturally produced in Brussels sprouts, summer squash, maize, avocado, green beans, and dark green leafy vegetables. Zeaxanthin is also naturally present within the retina of the human eye. Zeaxanthin is a phytochemical/nutraceutical whose consumption by humans has been shown to reduce risk of the disease age-related macular degeneration, a leading cause of blindness in older people. / Зеаксантин – каратинойд, синтезируемый некоторыми растениями (Авокадо, Брюссельская Капуста и Тыква) положительно влияющий на зрение человека. Под Зеаксантином, от Латинского слова Zea, означающее Кукуруза, и Греческого слова Xanthós, означающее Жёлтый, понимается жёлтый пигмент из группы ксантофиллов, содержащийся в хромопластах зёрен Кукурузы и плодов Облепихи.

ZEBRA FISH = ЗЕБРОВАЯ РЫБКА – Zebra Fish is the Fish Danio Rerio. / Зебровая Рыбка – Рыбка Данио Рэрио (Danio Rerio). Классификация:- Царство Животные, Тип Хордовые, Класс Костные Рыбы, Отряд Карпообразные, Семейство Карповые, Род Данио, Вид Данио Рэрио. Рыбка Данио Рэрио относится к так называемым модельным организмам биологии развития. Благодаря простоте содержания, размножения, высокой скорости развития эмбриона она стала своего рода лабораторной белой мышью для ихтиологии. Это один из немногих живых организмов посетивших космическую орбиту. Рыбка Данио Рэрио – обитатель рек, ручьёв Восточного побережья Передней Индии, Пакистана, Бангладеш, Непала, Мьянмы, Бутана. Российские аквариумисты впервые увидели рыбу около 1905–06. Повторно на территорию бывшего Союза Советских Социалистических Республик (СССР) была ввезена около 1950. Помимо основного названия аквариумисты дали рыбке ряд других ласковых прозвищ таких как 'дамский чулочек', 'полосатики', 'данюшки', 'зебровый'. Описание:- Рыбка Данио Рэрио имеет продолговатую форму тела, вдоль которого идут жёлто-зелёные чередующиеся с тёмно-синими полосами. В своё время шли достаточно оживлённые споры – какой цвет основной, а какой дополнительный. Теперь считается, что окрас у рыбки жёлто-зелёный с металлическим блеском, а по телу идут 4–5 тёмно синих полосок. Это утверждение подтверждается существованием леопардового вариетета. У молодых представителей плавники короткие. Но по мере роста они становятся вуалевыми. Плавники придают их обладателям фееричный вид. Края вуалевых плавников могут иметь жёлтый окрас. На воле взрослые особи достигают 6–7 сантиметров (см). Аквариумные обитатели, как правило, 4.5–5 см. Желательно держать стайками не менее семи–десяти рыбок. Самцы несколько стройнее самочек, а так же имеют более насыщенные цвета. Самки имеют более округлое брюшко особенно после полового созревания. Держится большую часть времени в средних, верхних слоях. Продолжительность жизни около трёх лет. Иногда при хорошем содержании доживают до пяти лет. Половозрелыми становятся, достигнув шести- – восьмимесячного возраста.

ZEBRA MUSSEL = ЗЕБРОВАЯ МИДИЯ (или ЗЕБРОВАЯ ДВУСТВОРЧАТАЯ РАКУШКА) – Zebra Mussel (Dreissenna Polymorpha) can cause severe fouling of municipal drinking water, electric power generation, and industrial water systems; they are also harmful to aquatic ecosystems, boating and navigation, agricultural irrigation equipment, aquacultural equipment, and recreation beach use. This mussel was first discovered in the Great Lakes of the United States in 1988, and is believed to have arrived in North America in the ballast water of a cargo vessel. Since the first discovery of this exotic species, they have spread rapidly through North American surface waters, particularly throughout the Great Lakes and Mississippi River basins and their navigable tributaries. / Зебровая Мидия (Dreissenna Polymorpha).

ZEBRA STRIPE = ЗЕБРОВАЯ ПОЛОСАТОСТЬ (или ЗЕБРИСТОСТЬ) – Zebra Stripe:- transverse, alternating chlorotic bands on seedling leaves which later disappear. striped or zebra (transverse green and chlorotic bands). For Tomatos:- Symptoms:- (i) characterized as a series of dark green spots arranged in a line from the stem end to the bloom end; (ii) at times it seems the spots coalesce together and form elongated markings; and (iii) many times the dark green areas will disappear when fruit ripens. Causes:- (i) this problem seems to be variety related; (ii) it is probably a genetic defect that only shows up under certain environmental conditions; and (iii) zebra stripe may be linked to pox and fleck. Zebra stripe may be linked to pox and fleck.

ZEBRINIA = ЗЭБРИНИА (или ХХ) – Zebrinia:- with striped leaves.

ZEBRINUS = ЗЭБРИНУС (или ЗЕБРОВОЕ) – Zebrinus (-a, -um):- zebra-striped.

ZEIN FIBER = ЗЕИНОВОЕ ВОЛОКНО – Zein Fiber is a manufactured fiber of regenerated protein derived from maize. Zein is a class of prolamine protein found in maize. It is usually manufactured as a powder from corn gluten meal. Zein is one of the best understood plant proteins and has a variety of industrial and food uses. Historically, it has been used in the manufacture of a wide variety of commercial products, including coatings for paper cups, soda bottle cap linings, clothing fabric, buttons, adhesives, coatings and binders. The dominant historical use of zein was in the textile fibers market where it was produced under the name Vicara. With the development of synthetic alternatives, the use of zein in this market eventually disappeared. By using electrospinning, zein fibers have again been produced in the lab, where additional research will be performed to re-enter the fiber market. Pure zein is clear, odorless, tasteless, hard, water-insoluble, and edible, making it invaluable in processed foods and pharmaceuticals, in competition with insect shellac. It is now used as a coating for candy, nuts, fruit, pills, and other encapsulated foods and drugs. In the United States, it may be labeled as 'Confectioner's Glaze' (which may also refer to Shellac-Based Glazes) and used as a coating on bakery products or as 'Vegetable Protein'. It is classified as Generally Recognized as Safe (GRAS) by the US Food and Drug Administration. Zein can be further processed into resins and other bioplastic polymers, which can be extruded or rolled into a variety of plastic products. With increasing environmental concerns about synthetic coatings (such as PFOA) and the current higher prices of hydrocarbon-based petrochemicals, there is increased focus on zein as a raw material for a variety of nontoxic and renewable polymer applications, particularly in the paper industry. Other reasons for a renewed interest in zein include concern about the landfill costs of plastics, and

consumer interest in natural substances. There are also a number of potential new food industry applications. Researchers at the University of Illinois at Urbana-Champaign and at William Wrigley Jr. Company have recently been studying the possibility of using zein to replace some of the gum base in chewing gum. They are also studying medical applications such as using the zein molecule to 'carry biocompounds to targeted sites in the human body'. There are a number of potential food safety applications that may be possible for zein-based packaging according to several researchers. A military contractor is researching the use of zein to protect MRE food packages. Other packaging/food safety applications that have been researched include frozen foods, ready-to-eat chicken, and cheese and liquid eggs. Food researchers in Japan have noted the ability of the zein molecule to act as a water barrier. While there are numerous existing and potential uses for zein, the main barrier to greater commercial success has been its historic high cost until recently. Some believe the solution is to extract zein as a byproduct in the manufacturing process for ethanol or in new off-shore manufacture. Zein:- cornmeal from which protein is derived for synthetic fibers. Zein a corn protein obtained by treating corn gluten with alcohol. Used in making fibers. / Викора (Vicara). шеллак (shellac). Обэнэ-Шэмпэйн (Urbana-Champaign) Вилъйэм Ригли Дьжюниа Кампэни (William Wrigley Jr. Company). Зеиновое Волокно – это волокно выработанное из регенерированного протеина, полученного из Маиса. Под Зеином, от Латинского слова Зэа (Zea), означающее Кукуруза, понимается белок растительного происхождения, содержащийся в зёрнах Кукурузы. Молярная масса около 40 000. Кристаллы зеина по форме напоминают иглы или короткие нити. Зеин плохо растворим в воде; растворяется в 60–80% этиловом спирте. Занимает промежуточное положение между глобулярными и фибриллярными белками. В состав зеина входят 18 из 20 известных аминокислот (отсутствуют глицин и лизин). При гидролизе зеина образуется значительное количество глутаминовой кислоты (26.9%), лейцина (21.1%) и пролина (10.53%). Отсутствие в молекуле зеина незаменимой аминокислоты лизина снижает его пищевую ценность. К группе белковых волокон относятся казеиновое и зеиновое волокна. Исходными полимерами для производства белковых волокон является казеин и зеин. Белковые волокна обладают мягкостью, хорошими теплоизоляционными свойствами, по показателям растяжимости и гигроскопичности приближаются к шерстяным. Но характеризуются низкой термостойкостью (боятся горячей, особенно подщелочённой воды), недостаточной прочностью и значительным снижением прочности в мокром состоянии. Производство белковых волокон ограничено из-за их низких механических свойств и в связи с тем, что сырьём для них служит ценный пищевой продукт.

ZEN. = ZENITH

ZENITH = ЗЕНИТ – (1) Zenith is the point of the celestial sphere that is directly opposite the Nadir and vertically above the observer. When you reach the zenith, you're at the top, the pinnacle, the summit, the peak. Zenith developed from Arabic terms meaning 'the way over one's head', and then traveled through Old Spanish, Medieval Latin, and Middle French before arriving in English. As long ago as the 1300s, English speakers used Zenith to name the highest point in the celestial heavens, directly overhead. By the 1600s, Zenith was being used for other high points as well. The celestial term is often contrasted with Nadir, or the point that is vertically downward from the observer (imagine a line going through the earth from the observer's feet and out the other side into the sky). Figuratively, Nadir simply means 'the lowest point'. Zenith is the point on the celestial sphere vertically above a given position orobserver. Zenith is the imaginary point that is directly above a particular location on the celestial sphere. It is vertically opposite to the apparent gravitational force, i.e. directly opposite to the gravitational pull. It is the highest point on the sphere and thus, the farthest up from the gravitational force. Description:- the term Zenith is derived from an Arabic expression meaning direction of the head or path above the head. Zenith is sometimes also used to refer to the highest point that a celestial body reaches during its orbit at a given point of observation. The opposite of zenith, that is the direction of the gravitational pull, is called the Nadir, at 180 degrees. Zenith, in astronomy terms, is the point in the sky directly overhead. For example, when a person says that the Sun has reached its zenith, it is used to refer to the sun's position in the sky. According to astronomers, there is no zenith for a Sun's position but to any observer, the Sun has reached its zenith if it is directly overhead. The angular distance from the zenith to any celestial body, in space, is called the Zenith Distance. The nadir which is directly opposite the zenith, has a zenith distance of 180° and the celestial horizon has a zenith distance of 90°. Zenith means the high point – it comes from astronomy, where it describes the highest point in an arc traveled by a star or a planet or another celestial body. The sun reaches its zenith when it is as high in the sky as it is going to go on that day. / зенит – zenith. Под Зенитом, от Французского слова Zénith, от Арабского слова Земт, означающее буквально Направление или Путь, понимается точка небесной сферы, расположенная над головой наблюдателя; в зените небесную сферу пересекает линия, направленная из места наблюдений вертикально вверх. Точка небесной сферы, противоположная зениту, называется Надиром.

(2) Zenith is the best or most successful point or time:- e.g, in the 1860s, Aleksey Konstantinovich Tolstoy (1817–1875) was at the zenith of his achievement; or his career reached its zenith in the 1860s. Zenith is the time at which something is most powerful or successful:- 'in 1977, punk was at its zenith'.

ZEPHYR = ЗЕФИР – (1) Zephyr may refer to a light wind or west wind. Zephyr:- of the west. Zephyr is the name for any prevailing warm and gentle westerly breeze at the time of the summer solstice in the N hemisphere. The name derived from Zephyros was the Greek god of the west wind, which was considered the gentlest wind, especially if compared to the colder North wind, Boreas. The Greek mythology knows four winds:- Boreas, the North Wind; Favonius, the South Wind; Eurus, the East Wind; and Zephyr, the West Wind. Aeolus was the King of the Winds. Zephyros, was the kindliest of the four brothers. Like all winds, he was the son of Dawn and his father was Astreus. The West Wind came in springtime. He melted snow. He brought warm rain. And the waters of the melting snow and the warm rain sank into the Earth and brought up flowers and trees and all crops that fed mankind. / Зефир может относиться к лёгкому ветру или Западному ветру. Зефир:- с Запада. В древнегреческой мифологии под Зефиром подразумевался бог Западного ветра, первоначально представлявшийся в виде лошади. В переносном смысле Зефир – тёплый лёгкий ветер, приносящий дожди. Зефир – ветер, по мнению древних господствовавший в Восточной части Средиземного Моря, начиная с весны, и наибольшей интенсивности достигавший к летнему солнцестоянию. Здесь он, хотя и тёплый, но часто приносит с собою дожди и даже бури, тогда как в западной части Средиземного Моря Зефир является почти всегда лёгким, приятным ветром. Отсюда разница в представлениях о Зефире Греков, считавших его одним из самых сильных и стремительных ветров, и Римлян, соединявших с ним ныне вызываемое им представление – о ласкающем, лёгком ветре. Мифологически Зефир является сыном Астрея и Эос. Его возлюбленная – Хлорида, (в переводе с Латинского языка – Флора). Вследствие своей быстроты, он считался также вестником богов. О разнице в свойствах Зефира на Западе и на Востоке, по-видимому, имели уже понятие составители Гомеровских песен, которые заставляют Зефир дуть на островах блаженных, находящихся на крайнем западе и не знающих ни бурь, ни дождей, ни снега.

(2) Zephyr is any of various lightweight fabrics. / Зефир – бельевая хлопчатобумажная ткань из кручёной белёной пряжи, вырабатываемая полотняным переплетением. Предназначается главным образом для изготовления мужских рубашек. Для зефира характерно наличие вдоль основы узких полосок (просновок), состоящих частью из утолщённых белых нитей частью из тонких цветных, чередующихся между собой и с белыми нитями.

ZEPHYR HAUL = ЗЕФИРНЫЙ ПОДВОЗ (или НЕВЕСОМЫЙ ПОДВОЗ, или ДОСТАВКА ЛЁГКИХ ГРУЗОВ) – Zephyr Haul is a shipment of light weight cargo. / Зефирный Подвоз это термин, используемый для обозначения отгрузки легковесного груза.

ZEPHYR YARN = ЗЕФИРНАЯ ПРЯЖА – Zephyr Yarn is a fine, soft yarn with a low twist popular for hand knitting. Originally made from wool, zephyr is usually made of acrylic and often has other fibers such as silk added to it. / Зефирная Пряжа – тонкая, мягкая с низкой круткой, популярной для ручной вязки. Первоначально изготовлявшаяся из шерсти зефирная пряжа производится из акрила и часто имеет другие волокна, такие, как шёлк, добавляемые к нему. Пряжа из гребенной шерсти со слабой круткой.

ZERO–BALANCE ACCOUNT = СЧЁТ С НУЛЕВЫМ ОСТАТКОМ (или СЧЁТ С НУЛЕВЫМ БАЛАНСОМ, или СЧЁТ С НУЛЕВЫМ САЛЬДО) – A Zero Balance Account is any account that is maintained with a purposeful balance of zero. Businesses use them to make payments, only keeping enough in the account to cover pending debits. Since these accounts don't have a running balance, there's no interest earned on them. However, they're a useful method of keeping money liquid and separate from interest-earning balances. A zero balance account is also useful for controlling money as it flows in and out. There's less chance of money loss from bounced checks, theft and mistakes. Plus, banks do their best to expedite transfers between zero balance and other accounts, making funding fast and dependable. Although banks charge a fee for these accounts, medium to large businesses may find that they benefit from the time-saving separation of disbursement and interest monies. A zero balance account allows money to work for the investor, rather than sitting in a checking account that earns a fraction of the return. According to Sovereign Bank, the accounts are a hands-off method of money management; as long as the primary (interest-bearing account) is at the same bank, transfers can be automated from one account to another. In fact, many banks set up the transfers to happen overnight automatically, freeing up energy for other tasks. This is great for payroll and other regular expenditures. It also makes for easier bookkeeping, since there are no balances to juggle or tend to in the records. Most major and community banks offer zero balance accounts. However, any checking account can be a zero balance account, as long there's no standing balance. For personal banking customers, it would be difficult to set up a zero balance situation; personal savings accounts often charge for more than six withdrawals a month, so bookkeeping would have to be precise to avoid hitting any limits. Plus, there might not be enough of an interest benefit to warrant the effort. Business customers can speak to their bank about zero balance account options. A Zero-Balance Account (ZBA) is a checking account in which zero balance is maintained by transfers of funds from a master account in an amount only large enough to cover checks presented. A check account operated by a company by which checks are drawn against the account balance, which at the start of the day is always zero. At the end of the day the value of all checks drawn is totaled and the amount is transferred into the account, so that the account balance reverts from a debt to zero. Zero Balance Account (ZBA):- this account is maintained when a company handles endorsements with a large amount. A Zero-Balance Account is a checking account which always contains a balance of zero funds. When an entity makes a check payment, it transfers only enough funds into the account to maintain a zero balance once the check has been paid. By doing so, an entity can harbor its cash within a master account for investment purposes. This approach also reduces the risk of a fraudulent transfer out of the zero-balance account, since there is so little cash in it. Zero Balance Account (ZBA) is a checking account in which a balance of zero is maintained by automatically transferring funds from a master account in an amount only large enough to cover checks presented. A zero balance account is used by corporations to eliminate excess balances in separate accounts and maintain greater control over disbursements. / с головного счёта. Счёт С Нулевым Остатком – чековый счёт, используемый корпорациями для концентрации наличных поступлений и контроля за выплачиваемыми суммами; используются как промежуточные счета для централизованного контроля за поступлениями и платежами; в конце рабочего дня на них не остаётся средств.

ZERO–BALANCE MODEL = МОДЕЛЬ НУЛЕВОГО ОСТАТКА (или МОДЕЛЬ НУЛЕВОГО БАЛАНСА, или МОДЕЛЬ НУЛЕВОГО САЛЬДО) – Zero-Balance Model:- xxxxxx. Also known as Cost Recovery Basis. / Известна также как На Основе Покрытия Затрат (Cost Recovery Basis). В бухгалтерском учёте страхового дела Модели Нулевого Остатка, которые называются также моделями покрытия издержек, схожи с моделями открытого года в том, что и в тех, и в других прибыль не признаётся до тех пор, пока страховщик не получит возможности оценить размер премий, страховых выплат и расходов. Для того чтобы не объявлять прибыль, страховщик учитывает расходы по страховым выплатам как сумму, которая сводит страховую прибыль к нулю. (Если имеются основания полагать, что размер страховых выплат и расходов превысит размер премий, убыток признаётся незамедлительно.) После этого размер расходов на страховые выплаты корректируются в каком-то из будущих периодов. Некоторые страховые компании могут использовать модель 'открытого года' или модель нулевого остатка в качестве временной меры, переходя на периодическую модель, как только в их распоряжении оказывается необходимая информация. Другие могут принять модель 'открытого года' или модель нулевого остатка для конкретных видов страхования, используя фиксированный одногодичный или двухгодичный срок отсрочки.

ZERO–BASE BUDGETING = БЮДЖЕТИРОВАНИЕ НА НУЛЕВОЙ ОСНОВЕ (или СОСТАВЛЕНИЕ БЮДЖЕТА НА НЕИЗМЕНЁННОЙ БАЗЕ, или БЮДЖЕТИРОВАНИЕ С НУЛЕВОЙ БАЗОЙ) – Zero-Based Budgeting (ZBB) is a technique of planning and decision-making which reverses the working process of traditional budgeting. In traditional incremental budgeting, departmental managers justify only increases over the previous year budget and what has been already spent is automatically sanctioned. No reference is made to the previous level of expenditure. By contrast, in zero-based budgeting, every department function is reviewed comprehensively and all expenditures must be approved, rather than only increases. Zero-based budgeting requires the budget request be justified in complete detail by each division manager starting from the zero-base. The zero-base is indifferent to whether the total budget is increasing or decreasing. The term 'Zero-Based Budgeting' is sometimes used in personal finance to describe 'Zero-Sum Budgeting', the practice of budgeting every Dollar of income received, and then adjusting some part of the budget downward for every other part that needs to be adjusted upward. Zero based budgeting also refers to the identification of a task or tasks and then funding resources to complete the task independent of current resourcing. A Zero-Base Budgeting (ZBB) is a budgeting method that disregards the previous year's budget in setting a new budget, since circumstances may have changed. Each and every expense must be justified in this system. Zero Based Budgeting (ZBB) is an approach to budgeting that starts from the premise that no costs or activities should be factored into the plans for the coming budget period, just because they figured in the costs or activities for the current or previous periods. Rather, everything that is to be included in the budget must be considered and justified. This initially appears to be a very resource hungry approach, and if applied in this simplistic form, would quickly fall foul of the law of diminishing returns. However, the application of practical common sense to the ZBB concept quickly identifies potential gains, and it will be seen that ZBB also aligns closely to current initiatives, including the Efficiency Agenda, and to performance measurement. ZBB is not new – it first appeared in the 1960's – and indeed it is not surprising that dissatisfaction with a purely incremental approach to budgeting has been one of the main drivers in attempting to find budgeting models that actually serve the purposes and objectives of the organisation. In its pure form, ZBB involves the preparation of operating budgets on the assumption that the organisation is starting out afresh in the new planning period – it is as if the life of the organisation exists as a series of fixed term contracts. However, it is usually used most effectively where the activities involved are wholly or mainly discretionary in nature. But it is very easy to fall into the trap of assuming that something is non-discretionary, for no other reason than the activity has been carrying on at a similar level for a number of years.

ZBB can be applied usefully to budget heads such as repairs, maintenance or equipment costs. The traditional incremental approach often pays scant attention to these heads, perhaps at best looking at trends over 2 or 3 years, and very often simply taking 'last year plus x%'. But it is often possible for service priorities to be proposed, discussed and established without reference to previous years. If proposals for resource allocations are presented with options for service level and predicted outcome, funds can then be allocated on the basis of best value for money. ZBB is there to question set assumptions, and to provide a tool for systematically reviewing, reprioritising, and perhaps withdrawing from long term activities that no longer align properly with an organisation's objectives. Successful use of ZBB relies upon the effective involvement of all executive managers. Like all good budgeting processes, it requires that the organisation's objectives are determined and clearly stated. Where it differs from the traditional route, and adds value to the budget process is in the next stage, where different ways of achieving those objectives are explored and assessed, so that the resources associated with the preferred option can be actively justified. In the late 1970s many countries recognized that the steady growth in public expenditure was putting a strain on their economies, and they attempted to curtail the growth. The Jimmy Carter administration in the United States, although planning for a steep rise in expenditure as a proportion of gross domestic product (GDP), also attempted to introduce the concept of 'zero-base budgeting', whereby the entire government program, not just its incremental parts, was to be evaluated each year. This idea, which involved considerable changes to existing procedures, was applied to some programs on a selective basis but never had the impact its designers envisaged. A similar attempt was made in the United Kingdom in the introduction of program analysis reviews (PAR), but again attempts to evaluate systematically the whole of government expenditure were unsuccessful. The degree of inertia in the system and the vested interests of existing institutions have proved too entrenched to be overcome by administrative procedure. All countries have an annual program of public expenditure allocation, in which those responsible for individual programs argue for greater allocations for their activities and those responsible for raising the money attempt to control the amount allocated. In practice, the results of this process depend as much on the political weight of individuals in charge of a spending program as on an objective assessment of its desirability. The normal practice is to take as a base what each program spent the previous year and then argue about incremental changes, rather than (as under zero-base budgeting) to consider each program in its totality. This creates perverse incentives, in that departmental heads who have saved money in one area in a particular year have an incentive to spend more in other areas in order to protect next year's total budget. Zero-Based Budgeting (ZBB) is a method of setting budgets for corporations and government agencies that requires a justification of all expenditures, not only those that exceed the prior year's allocations. Thus all budget lines are said to begin at a zero base and are funded according to merit rather than according to the level approved for the preceding year, when circumstances probably differed. Zero-Based Budgeting (ZBB) is a method of budgeting in which all expenses must be justified for each new period. Zero-based budgeting starts from a 'zero base' and every function within an organization is analyzed for its needs and costs. Budgets are then built around what is needed for the upcoming period, regardless of whether the budget is higher or lower than the previous one. ZBB allows top-level strategic goals to be implemented into the budgeting process by tying them to specific functional areas of the organization, where costs can be first grouped, then measured against previous results and current expectations. Because of its detail-oriented nature, zero-based budgeting may be a rolling process done over several years, with only a few functional areas reviewed at a time by managers or group leadership. Zero-based budgeting can lower costs by avoiding blanket increases or decreases to a prior period's budget. It is, however, a time-consuming process that takes much longer than traditional, cost-based budgeting. The practice also favors areas that achieve direct revenues or production; their contributions are more easily justified than in departments such as client service and research and development. Zero Based Budgeting (ZBB) is a method for preparing cash flow budgets and operating plans which every year must start from scratch with no pre-authorized funds. Unlike the traditional (incremental) budgeting in which past sales and expenditure trends are assumed to continue, ZBB requires each activity to be justified on the basis of cost-benefit analysis, assumes that no present commitment exists, and that there is no balance to be carried forward. By forcing the activities to be ranked according to priority, ZBB provides a systematic basis for resource allocation. A Zero-Base Budget requires managers to justify all of their budgeted expenditures, rather than the more common approach of only requiring justification for incremental changes to the budget or the actual results from the preceding year. Thus, a manager is theoretically assumed to have an expenditure base line of zero (hence the name of the budgeting method). In reality, a manager is assumed to have a minimum amount of funding for basic departmental operations, above which additional funding must be justified. The intent of the process is to continually refocus funding on key business objectives, and terminate or scale back any activities no longer related to those objectives. The basic process flow under zero-base budgeting is:- (i) identify business objectives; (ii) create and evaluate alternative methods for accomplishing each objective; (iii) evaluate alternative funding levels, depending on planned performance levels; and (iv) set priorities. The concept of paring back expenses in layers can also be used in reverse, where you delineate the specific costs and capital investment that will be incurred if you add an additional service or function. Thus, management can make discrete determinations of the exact combination of incremental cost and service for their business. This process will typically result in at least a minimum service level, which establishes a cost baseline below which it is impossible for a business to go, along with various gradations of service above the minimum. Advantages of Zero-Base Budgeting:- there are a number of advantages to zero-base budgeting, which include:- (i) Alternatives Analysis:- zero-base budgeting requires that managers identify alternative ways to perform each activity (such as keeping it in-house or outsourcing it), as well as the effects of different levels of spending. By forcing the development of these alternatives, the process makes managers consider other ways to run the business. (ii) Budget Inflation:- since managers must tie expenditures to activities, it becomes less likely that they can artificially inflate their budgets – the change is too easy to spot. (iii) Communication:- the zero-base budget should spark a significant debate among the management team about the corporate mission and how it is to be achieved. (iv) Eliminate Non-Key Activities:- a zero-base budget review forces managers to decide which activities are most critical to the company. By doing so, they can target non-key activities for elimination or outsourcing. (v) Mission Focus:- since the zero-base budgeting concept requires managers to link expenditures to activities, they are forced to define the various missions of their departments – which might otherwise be poorly defined. (vi) Redundancy Identification:- the review may reveal that the same activities are being conducted by multiple departments, leading to the elimination of the activity outside of the area where management wants it to be centered. (vii) Required Review:- using zero-base budgeting on a regular basis makes it more likely that all aspects of a company will be examined periodically. (viii) Resource Allocation:- if the process is conducted with the overall corporate mission and objectives in mind, an organization should end up with strong targeting of funds in those areas where they are most needed. In short, many of the advantages of zero-base budgeting focus on a strong, introspective look at the mission of a business and exactly how the business is allocating its resources in order to achieve that mission. Disadvantages of Zero-Base Budgeting:- the main downside of zero-base budgeting is the exceptionally high level of effort required to investigate and document department activities; this is a difficult task even once a year, which causes some entities to only use the procedure once every few years, or when there are significant changes within the organization. Another alternative is to require the use of zero-base budgeting on a rolling basis through different parts of a company over several years, so that management can deal with fewer such reviews per year. Other drawbacks are:- (i) Bureaucracy:- creating a zero-base budget from the ground up on a continuing basis calls for an enormous amount of analysis, meetings, and reports, all of which requires additional staff to manage the process; (ii) Gamesmanship:- some managers may attempt to skew their budget reports to concentrate expenditures under the most vital activities, thereby ensuring that their budgets will not be reduced; (iii) Intangible Justifications:- it can be difficult to determine or

justify expenditure levels for areas of a business that do not produce 'concrete', tangible results; for example, what is the correct amount of marketing expense, and how much should be invested in research and development activities? (iv) Managerial Time:- the operational review mandated by zero-base budgeting requires a significant amount of management time; (v) Training:- managers require significant training in the zero-base budgeting process, which further increases the time required each year; and (vi) Update Speed:- the extra effort required to create a zero-base budget makes it even less likely that the management team will revise the budget on a continuous basis to make it more relevant to the competitive situation. / администрация Президента США Джими Катё (Jimmy Carter) (полное имя Джеймз Орл Катё Младший (James Earl Carter Jr.); 1924–20XX). Бюджетирование На Нулевой Основе или Бюджетирование С Нуля – метод планирования и бюджетирования, использующий анализ эффективности проектов и функций для улучшения распределения ресурсов в организации. Традиционное бюджетирование опирается на приростные изменения относительно предыдущего периода, предполагает, что избранные программы и деятельность будут продолжены. Бюджетирование с нуля требует, чтобы каждый элемент был обоснованно определён, как если бы деятельность осуществлялась в первый раз. Без такого обоснования бюджетный показатель считается равным нулю. Бюджетирование на Нулевой Основе (БНО) базируется на денежной оценке каждого выполняемого действия, жёстком обосновании необходимости расходования средств на его выполнение и, главное, размеров этих расходов. Любая программа, новая или старая, каждый год должна оправдывать своё существование, как 'каждый без исключения расход'. БНО разбивает организацию или процесс на отдельные виды деятельности и требует расположения видов деятельности и альтернативных способов их воплощения по ранжиру, основываясь на анализах затрат и результатов. Ресурсы выделяются в строгом соответствии с таким ранжированием, то есть более эффективным вариантам выделяется больше ресурсов. Данный подход можно рассматривать как обоснование:- (i) необходимости осуществления каждого отдельного вида деятельности внутри объекта управления, поскольку каждый из этих видов деятельности предполагает расходы на своё осуществление; и (ii) величины расходов на осуществление определённого вида деятельности, необходимость которого обоснована. Система Бюджетирования на Нулевой Основе (БНО; Zero-Based Budgeting (ZBB)) получила распространение в корпоративном управлении проектами и программами. Случаи её практического использования в России пока ещё редки из-за общего резкого отставания уровня нашего управления от минимально допустимых международных стандартов. Основанная на принципе 'распределение ресурсов на нулевой основе', получившем определённое распространение в Американской практике ещё в начале 1960-х, система БНО позволяет периодически (обычно один раз в год) переоценивать осуществляемые мероприятия и программы (строительства, НИОКР и тому подобное) в сопоставлении с вновь предлагаемыми проектами, исходя из экономических и финансовых критериев сопоставления будущих затрат и ожидаемых результатов. Смысл применения системы состоит в том, чтобы в случае повышенной неопределённости и хозяйственной нестабильности своевременно принимать решения о реструктуризации бизнеса исходя из максимально обоснованных финансовых расчётов и прогнозов, не продолжать финансирование тех проектов и программ, эффективность будущих результатов которых вызывают сомнения. Система бюджетирования на нулевой основе позволяет периодически переоценивать осуществляемые мероприятия и программы в сопоставлении с новыми проектами, исходя из критериев сопоставления будущих затрат и ожидаемых результатов. Смысл применения системы состоит в том, чтобы в случае повышенной неопределённости и хозяйственной нестабильности своевременно принимать решения о реструктуризации бизнеса исходя из максимально обоснованных финансовых расчётов, не продолжать финансирование тех проектов и программ, эффективность будущих результатов которых вызывает сомнения. Бюджетирование с Нулевой Базой:- подход к разработке бюджета для корпораций и государственных агентств, при котором требуется обоснование всех расходов, а не только превышающих ассигнования предшествующего года. Часто, говорят, что все строчки бюджета начинаются с нулевой основы и финансируются в соответствии с потребностями, а не с уровнем, одобренным для предшествующего года, когда обстоятельства, возможно, были иными.

ZERO BASED BUDGET = БЮДЖЕТ НА НУЛЕВОЙ ОСНОВЕ (или БЮДЖЕТ НА НЕИЗМЕННОЙ БАЗЕ, или БЮДЖЕТ С НУЛЕВОЙ БАЗОЙ) – Zero Based Budget is where the expenses or costs of the prior year are not taken into consideration when establishing expense or budgetary levels looking forward. Each expense category starts from zero. All expenses or cost levels within the budget must be justified or re-justified as being necessary; thus 'zero-base'. Zero Based Budget is a budget developed disregarding the expenses or costs of the prior year, requiring explicit justification for all expenditures. Zero Based Budgeting (ZBB):- is a method for preparing cash flow budgets and operating plans which every year must start from scratch with no pre-authorized funds. Unlike the traditional (incremental) budgeting in which past sales and expenditure trends are assumed to continue, ZBB requires each activity to be justified on the basis of cost-benefit analysis, assumes that no present commitment exists, and that there is no balance to be carried forward. By forcing the activities to be ranked according to priority, ZBB provides a systematic basis for resource allocation. / Бюджет, который составляется по принципу системы ЗББ (от zero-based budgeting), то есть, каждый раз заново, без учёта уже произведённых затрат по ранее принятым программам, их пропорций, приоритетов.

ZERO BASIS = НУЛЕВОЙ БАЗИС – Zero Basis:- xxxxx. The Zero Basis concept has been applied to debt securities, specifically, to notes of shareholders contributed by them to controlled corporations in exchange for stock. By extension, the concept can be applied when a partner contributes his note to a partnership in exchange for a partnership interest, when an individual makes a gift of his note, or in any other situation where the recipient of a newly issued interest or obligation has a transferred basis in it. / Нулевой Базис или Нулевая Основа:- положение, когда конвертируемая облигация так высоко оценивается инвесторами, что они покупают её с настолько высокой премией, что получаемый процент сводится на нет премией, уплаченной при покупке облигации. При этом говорят, что сделка с облигацией совершалась на нулевом базисе.

ZERO BASIS RISK SWAP = СВОП НА РИСК С НУЛЕВЫМ БАЗИСОМ – Zero Basis Risk Swap (ZEBRA) is a swap agreement between a municipality and a financial intermediary. Also known as a Perfect Swap or Actual Rate Swap. The municipality pays a fixed rate of interest to the financial intermediary and receives a floating rate of interest in return. The floating rate received is equal to the floating rate on the outstanding floating rate debt initially issued by the municipality to the public. Zero Basis Risk Swap, also referred to as a ZEBRA (abbreviation). These are agreements to transfer the risk of debts from usually a minicipality to a financial intermediary. Upon doing so the municipality pays a fixed given rate to the financial intermediary, and in return recieves a floating (changing) rate which is identical to the rate that they were paying to the public from the initial debt. Zero-Basis Risk Swap (ZEBRA):- when a municipal stock is traded for another financial security. A Zero Basis Risk Swap, or ZEBRA, is a specialized type of swap for municipalities. The zero basis risk swap is an agreement between a municipality and a financial intermediary. Also known as Perfect Swap or Actual Rate Swap, a zero basis risk swap has the municipality pay out fixed interest and take in floating interest. The floating rate the municipality receives on zero basis risk swap equals the rate on public outstanding floating-rate debt already issued by the municipality that engages in the zero basis risk swap. Basis risk is the risk factor of uncorrelated hedging, and in a zero basis risk swap this risk is zero because the zero basis risk swap's risk is perfectly correlated by definition. A zero basis risk swap can help cities plan annual budgets without worrying about changes in interest rates. / ЗЭБРА (ZEBRA).

ZERO–BETA PORTFOLIO = ПОРТФЕЛЬ С НУЛЕВОЙ БЕТОЙ – In one of the non-standard forms of Capital Asset Pricing Model (CAPM) a Zero Beta Portfolio is used to replace the risk free security. In fact, under the no riskless lending and borrowing assumption, it can be shown, both intuitively and mathematically, that a zero Beta portfolio lies on a straight line joining a risky portfolios with the market portfolio in an expected return-beta space. This is the so called Zero Beta Version of the CAPM. So Z is a portfolio which return is uncorrelated with the market portfolio, Z is the Zero-Beta Portfolio. Zero-Beta Portfolio is a portfolio constructed to have zero systematic risk, similar to the risk-free asset, that is, having a beta of zero. / Портфель, сформированный таким образом, чтобы иметь нулевой систематический риск. Он схож с безрисковым активом, у которого коэффициент бета равен нулю. Портфель С Нулевой Бетой – инвестиционный портфель, представляющий собой безрисковый актив, для которого значение коэффициента бета равно 0.

ZERO–BRACKET AMOUNT = СУММА НАЛОГОВОГО ВЫЧЕТА (или СУММА ПО НУЛЕВОЙ ШКАЛЕ, или СУММА, НЕ ОБЛАГАЕМАЯ НАЛОГОМ, или СУММА НУЛЕВОГО РАЗРЯДА) – In the United States, Zero-Bracket Amount is a lump-sum allowance of income that a taxpayer could receive without imposition of any federal income tax because it was considered equivalent to the standard amount of deductions usually taken by an average taxpayer. It was replaced by the standard deduction in the Tax Reform Act of 1986. 100 Stat. 2085, 26 USCA §§ 47, 1042 (26 USCA is short for the United States Code Annotated:- Title 26). The zero-bracket amount was so named because a zero rate of taxation was applied to it. Its financial value was determined by the filing status of the taxpayer. If a taxpayer had more deductions that qualified as itemized deductions than the zero-bracket amount, she could itemize deductions, but the itemized deductions were reduced by the zero bracket amount. That figure was subtracted from the taxpayer's adjusted gross income to find her taxable income, upon which the income tax liability was computed. Congress eliminated the zero-bracket amount in the Tax Reform Act of 1986, replacing it with the standard deduction. The standard deduction is a specific Dollar amount that can be deducted from income by those taxpayers who do not itemize their deductions because their deductions do not exceed the standard deduction assigned to them. The base amount of the standard deduction depends on the taxpayer's filing status (single, married filing jointly, married filing separately, head of household, or qualifying widow or widower). The standard deduction portion of income which is not taxed for taxpayers choosing not to itemize deductions. Zero-Bracket Amount:- until the US Tax Reform Act of 1986, the standard deduction, that is, the income automatically not subject to federal income tax for taxpayers choosing not to itemize deductions. The zero-bracket amount was built into the tax tables and schedules used to compute tax. The 1986 Act replaced the zero-bracket amount with an increased standard deduction, which was subtracted from income before computing taxes rather than being part of the rate tables. Current law indexes the standard deduction to inflation and contains special provisions for the blind and elderly. In the United States, Zero-Bracket Amount is the amount of income not taxed before the Tax Reform Act of 1986. Taxpayers who chose not to itemize deductions subtracted the zero-bracket amount from their adjusted gross income. The amount was indexed to inflation and therefore had the potential to change every tax year. It has since been replaced by the standard deduction. / В последнее время словосочетание 'налоговый вычет' всё чаще слышится в обществе. Привлекательность возможности вернуть часть затрат бесспорна. Однако далеко не все понимают, что такое налоговый вычет, в каких случаях он предоставляется, какие документы нужны для того, чтобы получить налоговый вычет и каков срок возврата? Налоговый вычет представляет собой уменьшение суммы, облагаемой налогом. Это особый вид налоговых льгот, дающих возможность в оговорённых законом случаях вернуть часть затрат. Законодательством Российской Федерации определены налоговые вычеты четырёх категорий:- (i) стандартный налоговый вычет; (ii) социальный налоговый вычет; (iii) профессиональный налоговый вычет; и (iv) имущественный налоговый вычет. При расчёте каждого из налоговых вычетов применяются определённые условия. Сумма дохода, не облагаемая налогом (zero-bracket amount). До принятия Акта о Налоговой Реформе от 1986 (Tax Reform Act of 1986) – стандартная сумма вычетов из налогообложения (standard deduction), иными словами, доход, автоматически не облагаемый федеральным подоходным налогом для налогоплательщиков, не желающих предоставлять постатейный перечень вычетов из налогообложения. Сумма дохода, не облагаемая налогом, была встроена в таблицы ставок налогообложения и графиков, используемых для расчёта налогов. Акт от 1986 заменил сумму дохода, не облагаемую налогом, увеличенной стандартной суммой вычетов из налогообложения, которая вычиталась из дохода до расчёта налогов, а не являлась частью таблицы ставок налогообложения. Нынешнее законодательство установило стандартные вычеты из налогообложения, индексированные в соответствии с инфляцией и содержащие специальные положения, касающиеся слепых и престарелых.

ZERO CERTIFICATION = СВОБОДА ОТ СЕРТИФИКАЦИИ – Zero Certification:- under former programs, producers who chose not to plant any acres to a program crop in any particular year could 'zero certify' such acreage and protect the base for historical purposes. The farm must have been enrolled in the program in order to be eligible to 'zero certify'.

ZERO CLEARANCE FIREPLACE = БЕЗДЫМНЫЙ КАМИН – A Zero Clearance Fireplace, whether wood or gas, refers to a manufactured fireplace that you can frame right up to. Think of it as a stove in a box with the purpose of the box being to contain and/or convect the heat into the room while maintaining a cool enough exterior skin temperature that wood framing can placed nearly against it. What differentiates the various zero clearance wood fireplaces? There are 3 basic categories:- air conditioners, pretty good heaters, and very good heaters. The air conditioners are characterized by pulling more air out of the house than they give back in heat so their net effect on the house as a system is to cool it. Glass doors are usually an option rather than a standard feature and they are not gasketed or sealed, nor should they be closed when the unit is burning. The optional outside air will not provide more than a quarter of the combustion air needs. The pretty good heaters are a big step up in terms of heating ability. They will generally have sealed, gasketed doors and outside air sufficient to provide all combustion air needs. They are not EPA (short for the US Environmental Protection Agency) certified. As exempt units, you cannot control the heat output other than by the fuel load. The primary difference between the pretty good and really good heaters is that the latter are EPA certified. What that means to you is that you can control the combustion air intake, thereby controlling the heat output and, consequently, the burn time. A factory built fireplace that is constructed so that it can be placed safely close to combustible materials. Zero Clearance refers to the firebox:- there are rules about the setback for protrusions at 90 degrees to the fireplace face, varies depending on model, should be in your owner's manual. / На протяжении многих веков и даже тысячелетий огонь помогал человеку в жизнедеятельности. Это не могло не сказаться на подсознательных инстинктах людей. Сегодня на пылающее пламя уже не возлагается столько ответственности за выживание, однако вид огня до сих пор является одним из наиболее завораживающих внимание процессов. Очень редко можно встретить человека, который абсолютно равнодушен к каминам. Хорошо тем, кому жилище позволяет иметь камин классической конструкции. Но, тем не менее, прогресс не стоит на месте, и в современных квартирах или офисах также имеется возможность наслаждаться гипнотическим видом пламени. Причём установка дымоходов и ухаживание за ними совершенно не требуется. Бездымные камины – это последняя инновация в мире каминов. Бездымные камины работают на экологически

чистом топливе. Под экологически чистым топливом в данном случае подразумевается – этиловый спирт или этанол. Биологическое топливо при сгорании выделяет в окружающую среду некоторое количество пара и немного диоксида углерода. Для того чтобы камин отапливал помещение, необходимо лишь наполнить бак. Камин будет работать на одной заливке топлива около 2 часов. Если обложить горелку бездымного камина полешками, то у стороннего наблюдателя возникнет ощущение, что камин настоящий, да еще и дровяной. Бездымные камины – это новое открытие для мира каминов. Бездымные камины – это декоративные камины, которые также изысканны и современны.

ZERO–COST OPTION = ОПЦИОН С НУЛЕВОЙ СТОИМОСТЬЮ (или НИЧЕГО НЕ СТОЯЩИЙ ОПЦИОН) – Zero Cost Collar or Zero Cost Option is an option technique applied to secure a return. Also called Equity Risk Reversal a zero cost collar is a type of positive carry collar. The zero cost collar is executed by buying a cap and a floor. Zero cost collar option strategies are employed for interest rates, commodities, options, and equities trading. An example of a zero cost collar option purchase is buying a put and selling a call at a lower strike price. The zero cost collar works because sale of the call will cap the return if the underlying falls in price and offsets the purchase of the put. Hedging with zero cost collar options meets Statement No. 133 – Financial Accounting Standards Board (FASB 133) derivatives hedging standards if the zero cost collar is written with a single underlying reference asset. Upside risk is still unlimited in a zero cost collar. Zero-Cost Option is an option strategy under that one option is purchased by simultaneously selling another option of equal value. Zero-Cost Option:- this investment strategy is sometimes used in relation to interest rates, commodities, options, and equities. Investors looking to secure a return will sell a cap and buy a floor, whereas borrowers will sell a floor and buy a cap. For investors, the cost of the cap is offset by the income received from the floor. An example of a zero cost option collar is the purchase of a put option and the sale of a call option with a lower strike price. The sale of the call will cap the return if the underlying falls in price, but it will also offset the purchase of the put. Obviously, upside risk is still unlimited. Zero Cost Collar means a type of positive-carry collar that secures a return through the purchase of a cap and sale of a floor. Also called Zero Cost Options, or Equity Risk Reversals. Zero-Cost Option is an option strategy under which one option is purchased by simultaneously selling another option of equal value. ZERO COUPON = БЕСКУПОННОЕ – Zero Coupon:- sometimes called Strip Bonds, these are government bonds in which some or all of the interest 'coupons' have been detached. The bond principal and any remaining coupons trade separately from the strip of detached coupons, both at substantial discounts from par. Zero Coupon refers to a debt instrument that does not make coupon payments, but, rather, is issued at a discount to par and redeemed at par at maturity. Zero Coupon or Strip Bonds are fixed income securities that are created from the cash flows that make up a normal bond. The cash flows of a normal bond consist of the regular interest or 'coupon' payments, that take place over the term of the bond, and the principal repayment that occurs at maturity of the bond. For example, the cash flows of the Government of Canada 8% bond with a maturity date of 2023-June-01 are:- (i) CAD4.00 every December and June 1st up to and including 2023-June-01, representing 4% of the CAD100.00 par value; and (ii) CAD100.00 on 2023-June-01, representing the repayment of the principal or par amount of the bond. Taken individually, each of these payments is an obligation of the issuer, in this case, the Government of Canada. The process of 'stripping' a bond involves deppositing bonds with a trustee and having the trustee separate the bond into its individual payment components. This allows the components to be registered and traded as individual securities. The interest payments are known as 'Coupons' after their source of cash flow, and the final payment at maturity is known as the 'Residual' since it is what is left over after the coupons are stripped off. Both coupons and residuals are known as 'Zero Coupon' Bonds or 'Zeros'. Initially, when this process first took place in the early 1980s, the individual coupons were 'physical', which meant that an actual paper certificate existed for each coupon and the residual. Now these securities are 'book based' which means that they are entries on a centralized financial registry system known as the Central Depository System (CDS). Once a bond has been stripped, a trustee directs the appropriate amount of the interest or maturity payment to the security holders. The holder of a zero coupon receives the par amount of the particular term of the zero that she holds. For example, an investor holding CAD100 000.00 par amount of the 2001-December-01 coupon would receive USD100 000.00 on that date. Conceptually, a zero coupon security is just like a Treasury Bill or T-Bill. The investor pays something up front in exchange for a promise to receive CAD100.00 on the maturity date. Take our example of the coupons and residual generated by stripping the Canada 8% of 2023. If we start on 1996-December-01 the first two payments are identical to a 6 month and 1 year T-Bill. An investor would receive CAD100.00 on June 01 and December 01 for each CAD100.00 par amount she purchased of these terms of coupons. The basic mathematics are easy. What should an investor pay for the 1 year coupon? If the investor demands a 4% return over a one year period, she should pay something around CAD96.00 for the CAD100.00 maturity value (actually CAD96.154 since we're starting at less than CAD100.00). The longer coupons get a bit more complicated. Take the coupon due on 2001-December-01, five years from 1996-December-01. What do we pay for this CAD100.00? First of all, we need to consider what interest rate would be appropriate. Reflecting on the term structure of interest rates, we know that we should use the yield on a similar term Government of Canada bond. Being bond market fans, we just happen to know that there is a Government of Canada issue the 9.75% of 2001-December-01. We also know that it currently yields 5.6% semiannually. As a rough cut, forgetting the compounding of interest (interest-on-interest) and the conversion to semiannual yields, we know that 5.6% for 5 years is 28%. This means if we pay something around CAD72.00 (100 – 28 = 72) on 1996-December-01 for the CAD100.00 coupon due on 2001-December-01, we will earn something around 30% over the period or 6% a year. Pulling out our trusty bond calculator, we can actually do the calculation. At a semiannual yield of 5.6%, the price works out to be CAD75.91. At a semiannual yield of 6%, the price works out to be CAD4.44. Of course, nothing is as easy as it seems. The yield of a zero coupon bond is different than the yield of a normal bond of the same issuer. This difference of 'spread' reflects the economics or profits available to investment dealers from 'stripping' activities and the supply and demand for zero coupon bonds. There is also a difference in yield between coupons and residuals which reflects the larger size of residuals and the economies of trading compared to many smaller coupon positions or 'lines'. / Данный Англоязычный термин при дословном переводе на Русский язык соответствовал бы термину С 0 Купонов, но для нас более привычен как Бескупонный. Он относится к долговому инструменту, не предусматривающему осуществление платежей по купонам, а ещё точнее, выпущенному с дисконтом к нарицательной стоимости и выкупаемому по нарицательной стоимости при погашении. Бескупонные облигации выпускаются компаниями и не предусматривают выплаты процентов, но взамен распродаются с большим дисконтом к номиналу. Бескупонная или С Нулевым Купоном – долговая ценная бумага, выпущенная со скидкой от её номинальной стоимости, подлежащая погашению по номинальной стоимости в течение срока, превышающего один год, и не предоставляющая других выплат наличными, кроме оплаты по номинальной стоимости при погашении. Ценная бумага может быть погашена до наступления срока погашения в зависимости от условий контракта. Обычно корпоративные бескупонные облигации покупаются инвесторами только по счетам, защищённым от налогов.

ZERO–COUPON BOND = БЕСКУПОННАЯ ОБЛИГАЦИЯ – Zero-Coupon Bond is a single-payment security that does not involve interest payments during the life of the bond. The bond is sold at a discount from par value, and the full return is paid at maturity. The difference between the discounted issue price and the face or redemption value reflects the market rate of interest at the time of issue and time to maturity. The longer the maturity of the bond and the higher the interest rate, the greater the discount against the face or

redemption value. Zero-coupon, and deep-discount bonds, have four particular advantages for investors:- (i) there may be some tax advantage in receiving a capital gain rather than an income payment; (ii) there is no or little (deep-discount bond) reinvestment risk (the possibility that when coupon payments fall due, and need to be reinvested, interest rates will be lower); (iii) the bond has a longer 'duration' than a bond of comparable maturity that pays fixed- or variable rate interest, so making the zero-coupon bond's price more sensitive to interest rate changes; and (iv) a zero-coupon bond is a leveraged investment in that a relatively small initial outlay gives exposure to a larger nominal amount. Zero-Coupon Bond is a bond that pays no interest. The bond is initially offered at a discount to its redemption value. Zero Coupon Bonds are bonds priced at a large discount from face value. The bonds mature at full face value so the difference between the original issue price and the face value represents interest income. The issuer of the zero coupon bond saves on cash flow since the interest isn't paid out until the end of the bond holding period. Bond that makes no regular interest payment, but is instead issued at a discount against full repayment at maturity. Zero bonds have been issued on the US capital market since 1981, but have also established a foothold in other major capital markets as an alternative to interest-bearing bonds. A Zero-Coupon Bond or deep discount bond is a debt security with no coupon (zero-coupon) or substantially lower coupon than current interest rates. The bonds are issued at a discount to their nominal value, with the discount reflecting the prevailing market interest rate. In the case of a zero-coupon bond, investors receive at maturity the difference between the purchase price and the nominal value of the bond (so called 'uplift'). The longer the maturity of the bond, the greater the discount against par value. There are three main advantages of zero-coupon bonds or deep discount bonds to the investor:- (i) in some countries there may be some tax advantage in receiving a capital gain rather than an income gain; (ii) there is no or significantly reduced reinvestment risk for the investor, i.e. the possibility that market interest rates may fall in the future; the bond has a longer 'duration' than a bond of comparable maturity which pays fixed or floating interest; and (iii) a zero-coupon bond is a leveraged investment:- because the bonds are sold at a discount a relatively small up-front payment gives the investor exposure to a larger nominal amount. A bond which pays no interest but is priced, at issue, at a discount from its redemption price. A Zero Coupon Bond is a bond with no stated interest rate. Investors purchase these bonds at a considerable discount to their face value in order to earn an effective interest rate. An example of a zero coupon bond is a US savings bond. Because payments are delayed to maturity, there is a greater chance of fluctuations in the price of a zero coupon bond over its lifespan that reflect changes in interest rates. A zero coupon convertible bond allows investors to convert to stock if the stock price reaches a level higher than its current price on the open market. A bond in which no periodic coupon is paid over the life of the contract. Instead, both the principal and the interest are paid at the maturity date. In the fixed income markets, there are a variety of instruments that defer the payment of interest. This article focuses on instruments that have terms greater than a year. Generally, the instruments are called Deferred-Interest Bonds (DIBs). They fall into three categories:- (i) accrued-coupon bonds are issued at some par value and have a stated nominal yield. Rather than pay coupons, they accrue them until maturity. (ii) Zero-coupon bonds have a par value that is their maturity value. They are issued at a discount from that par value. These are also called Zeros or Original Issue Discount (OID) Bonds. (iii) Deferred-coupon bonds (or split-coupon bonds) pay no coupons for their first few years but then pay a higher coupon than they otherwise would for the remainder of their term. Usually, they are issued below par. If the issuer's credit quality doesn't deteriorate and interest rates don't rise, they trade above par by the time they start paying coupons. They mature for their par value plus the final coupon. The instruments generally have terms of ten years or more. If they are issued with shorter terms, they may be called notes instead of bonds. While accrued-coupon and zero-coupon bonds only pay interest at maturity, for accounting and tax purposes, interest is generally recognized as income when it accrues. Treatment of deferred-coupon bonds depends upon the specific structure and jurisdiction. Paradoxically, you will hear of accrued-coupon and zero-coupon bonds being described as either safe, conservative investments or risky, speculative investments. It all depends on how you intend to use and account for them. For a buy-and-hold investor who accounts for them at book value, the bonds can be a safe investment, so long as the issuer is of good credit quality. They guarantee a specific yield until maturity. Because they don't pay coupons, they pose no reinvestment risk. On the other hand, for investors who may sell the bonds prior to maturity or account for them at market value, they can be quite risky. Their duration equals their time to maturity. Many of these bonds have terms of 20 or 30 years. With durations like that, their market values can be as volatile as those of common stocks. Examples of these types of bonds are municipal accrued-coupon bonds and Treasury zero-coupon bonds. Deferred-coupon bonds usually have considerable credit risk. This is because they tend to be issued by corporations that lack the cash flow to meet near-term coupon payments. Usually, they are junk bonds. Two variants of deferred-coupon bonds are:- (i) step-up bonds, which pay a low coupon for the first few years and a higher coupon after that; and (ii) payment-in-kind (PIK) bonds, which are like regular coupon bonds but give the issuer the option of paying coupons in cash or in more bonds. Securitizations are often structured with tranches that defer interest. In the context of collateralized mortgage obligations, these are called Z Bonds. A Zero-Coupon Bond is a bond that is issued without a coupon but at a deep discount. At maturity, it is redeemed at its face amount. A Zero Coupon Bond is one which does not pay interest. It is instead issued at a discount to its face value (which is what the holder will receive at maturity). Instead of interest payments, the holder receives a capital gain at maturity. The duration of a zero coupon bond is clearly longer than that of an otherwise similar bond that pays interest and it will be more sensitive to changes in interest rates. This is best understood by looking at how the present values of a zero coupon and an interest paying bond will be affected by changes in interest rates. The UK, and many other countries, treat some of the capital gain on a zero coupon bond as income for tax purposes. A Zero-Coupon Bond is a fixed income securities which do not pay a coupon and are instead issued at a discount. A Zero Coupon Bond is a bond that does not pay interest coupons (zero-coupon bond). Instead of periodic interest payments, the difference between the redemption price and the issue price is the yield to maturity. Accordingly, the investor receives only one payment: the amount realized in the case of a premature sale or the amount redeemed at maturity. In general, zero-coupon bonds are issued at a substantial discount (differential) and redeemed at maturity at a price of 100% (at par). Depending on the term, creditworthiness of the borrower and capital market rates, the issue price may be slightly or significantly below the redemption price. Zero Coupon Bond (Gilt Strip) is a bond that repays a fixed amount (the nominal amount) on one certain date. There are no coupons paid on the bond. Zero Coupon Bonds are bonds that do not have coupons attached and therefore do not pay a interest during the life of the bond. They are purchased at a discount to the maturity value. For example, you might pay USD900 today to get back USD1 000 a year later. The difference between what you pay now and what you receive in the future is your return. Zero Coupon Bonds are similar in concept to savings bonds. Zero Coupon Bonds have an accreted value (not the same as the market value) that increases in a mathematically linear fashion over the life of the bond. In the United States, a bearer bond that pays no dividend, but is issued at a substancial discount. A capital gain is made by the bearer when the bond matures, and so tax on the proceeds is paid at a lower rate than if the proceeds were in the form of dividends. Zero-coupon bonds are not issued in the United Kingdom. / выплата (repayment) . Бескупонная Облигация – облигация, проданная со значительной скидкой, и по которой начисляется полугодовой процент. Основная сумма и накопленный процент выплачиваются в момент погашения облигации; хотя процент по такой облигации выплачивается только по истечении срока облигации, весь начисленный процент, не полученный в данном году, облагается налогом как обычный доход. Бескупонная Облигация – разновидность облигаций, по которой не предусматривается выплата процентов. В действительности процент по ней закладывается в её стоимость погашения и выплачивается в момент погашения. Инвесторы иногда отдают предпочтение бескупонным облигациям, так как эти облигации могут давать некоторые преимущества при налогообложении. Бескупонные Облигации – ценные бумаги без выплаты процентов; выпускаются и обращаются по типу

векселей с дисконтом к номиналу; впервые выпущены в США в 1981. Дисконтная облигация, владелец которой получает доход за счёт того, что приобретает облигацию по цене ниже номинала, а в момент погашения получает номинальную стоимость. Других выплат (купонов) такая дисконтная облигация не предусматривает. Облигация, которая приносит владельцу доход в виде разницы в ценах, по которой он купил у эмитента облигацию и по которой её выкупят при погашении. Проценты по такой облигации не выплачиваются. Облигация, по которой не выплачиваются проценты, при её погашении цена выкупа назначается выше, чем цена выпуска. Бескупонная Облигация – это ценная бумага, которая не имеет купонов. Доход инвестора возникает за счёт разницы между ценой погашения облигации (номиналом) и ценой её приобретения. Бескупонные облигации привлекательны и для инвестора, если ему необходимо аккумулировать известную сумму денег к определённому времени. Купив необходимое количество облигаций, вкладчик уже не зависит от конъюнктуры, как в случае с купонной бумагой. Дословно Облигация С Нулевым Купоном – это такая облигация, по которой не выплачиваются проценты, но которая изначально продаётся по цене существенно ниже номинальной.

ZERO–COUPON CALLABLE BOND = БЕСКУПОННАЯ ОТЗЫВАЕМАЯ ОБЛИГАЦИЯ – A Zero-Coupon Callable Bond is a callable bond that pays no coupon; callable at varying prices that typically accrete to par by maturity; schedule of call prices determined from a single yield level. / Раньше Казначейство США выпускало Отзываемые Облигации (Callable Bonds). Дата погашения отзываемой облигации не была определёной. Казначейство имело право, но не было обязано отзывать, то есть выкупать, облигации после даты отзыва. В начале 1980-х, когда процентные ставки были очень высоки, Казначейство выпускало каждую новую долгосрочную облигацию с датой отзыва, которая наступала на 5 лет раньше конечного срока погашения. Дата отзыва давала Казначейству право рефинансировать часть долга, если процентные ставки снижаются. В настоящее время Казначейство не эмитирует отзываемые облигации.

ZERO–COUPON CONVERTIBLE COLLATERALIZED SECURITY = БЕСКУПОННАЯ ОБРАТИМАЯ ОБЕСПЕЧЕННАЯ ЦЕННАЯ БУМАГА (или БЕСКУПОННАЯ КОНВЕРТИРУЕМАЯ ЦЕННАЯ БУМАГА С ОБЕСПЕЧЕНИЕМ) – Zero-Coupon Convertible Collateralized Security:- xxxxx. / Конвертируемая Ценная Бумага С Обеспечением С Нулевым Купоном:- облигация с нулевым купоном с правом конвертирования в обыкновенные акции.

ZERO–COUPON CONVERTIBLE SECURITY = БЕСКУПОННАЯ ОБРАТИМАЯ ЦЕННАЯ БУМАГА (или БЕСКУПОННАЯ КОНВЕРТИРУЕМАЯ ЦЕННАЯ БУМАГА) – Zero-Coupon Convertible Security is a zero-coupon bond that has no coupon and is convertible into the common stock of the issuing company is referred to as a Zero-Coupon Convertible. A zero-coupon convertible is similar to a zero-coupon bond in that its value will fluctuate with changes in interest rates. A zero-coupon convertible differs from a zero-coupon bond in that its value increases as the share price of the issuing company increases. This occurs because the conversion feature of the zero-coupon convertible becomes more valuable with a rising share price. A zero-coupon convertible is sold at a discount to face value and matures at face value. As a result, reinvestment risk associated with zero-coupon convertible investments is minimal. An advantage associated with the zero-coupon convertible is the flexibility of choosing between accrued interest on the bond or recognizing capital gains on the conversion. The market for zero-coupon convertible securities is relatively illiquid so this security is seldom held by retail investors. Zero Coupon Convertible Security (or debenture) is a zero coupon bond that is convertible into the common stock of the issuing company after the common stock reaches a certain price. Zero-Coupon Convertible Security is:- (1) a zero-coupon bond convertible into the common stock of the issuing company when the stock reaches a predetermined price. Introduced as Liquid Yield Option Notes (LYONS), these securities have a put option that permits holders to redeem the bonds within three years after the initial offering. They tend to trade at a small premium over conversion value and provide a lower yield to maturity than their nonconvertible counterparts. (2) Zero-coupon bond, usually a municipal bond, convertible into an interest bearing bond at some time before maturity. For example, a zero-coupon (tax-free) municipal bond would automatically accumulate and compound interest for its first 15 years at which time it would convert to a regular income-paying bond. Thus, an investor is able to lock in a current interest rate with a small initial investment. Varieties are marketed under the acronyms GAINS (Growth and Income Securities) and FIGS (Future Income and Growth Secutities). A Zero-Coupon Convertible Security is a zero-coupon bond convertible into the common stock of the issuing company after the stock reaches a certain price, using a put option inherent in the security. Also refers to zero-coupon bonds, which are convertible into an interest bearing bonds at a certain time before maturity. Zero-Coupon Convertible Bond is:- (1) a bond that may be converted into common stock in the company issuing it. A zero-coupon convertible bond is sold at a discount from par and matures at par. They tend to be volatile in the secondary market because the convertible option may or may not become worthwhile, depending on how the company is performing. Additionally, like all zeros, they can fluctuate in price, sometimes dramatically, with changes in interest rates. (2) A municipal bond that may be converted into a corporate bond in the company issuing it. A zero-coupon convertible bond is sold at a discount from par and matures at par. They tend to be volatile in the secondary market because the convertible options may or may not become worthwhile, depending on how the companies they represent are performing. These zero-coupon convertibles are tax-exempt, but are convertible to other bonds that may yield more. / Бескупонная облигация, обратимая (конвертируемая) в обыкновенные акции эмитирующей компании после того, как данная акция достигнет определённой цены, и использующая опцион на продажу, свойственный данной ценной бумаге. Данный термин относится также к бескупонным облигациям (zero-coupon bonds), которые в определённое время перед погашением конвертируются в облигации, приносящие проценты (interest bearing bonds). Бескупонная Конвертируемая Ценная Бумага – ценная бумага без купона и опционом конверсии в обыкновенные акции эмитента при достижении ценой определённого уровня. Конвертируемая облигация в соответствии с условиями эмиссии может быть обменена на акции или другие облигации. Бескупонная Конвертируемая Ценная Бумага (zero coupon convertible security) – конвертируемая ценная бумага без купона:- (1) Бескупонные Облигации, конвертируемые в обыкновенные акции выпустившей их компании, когда акции достигают предварительно оговорённой цены. Впервые были введены как ликвидные доходные опционные векселя (Liquid Yield Option Notes (LYONs)). Эти ценные бумаги имели опцион на продажу в соответствии с которым владельцы имели право погасить облигации в течение трёх лет после их первоначального предложения. Они, как правило, имеют невысокую премию сверх конвертируемой стоимости (premium over conversion value) и предлагают меньшую доходность к дате погашения (yield to maturity), чем их неконвертируемые аналоги. (2) Бескупонные Облигации обычно муниципальные (municipal bond), конвертируемые в приносящие процентный доход облигации до наступления срока погашения. Например, бескупонные муниципальные облигации (не облагаемые налогом) автоматически накапливают и приумножают процентный доход в течение первых 15 лет, после чего они конвертируются в обычные облигации с выплачиваемым доходом. Таким образом, инвестор имеет возможность сохранить текущие процентные ставки при небольшом объёме первоначально вложенных средств. Различные виды таких ценных бумаг продаются под названиями GAINS (растущие доходные ценные бумаги (Growth and Income Securities)) и FIGS (ценные бумаги с ростом и доходом в будущем (Future Income and Growth Securities)). Бескупонная ценная бумага (zero-coupon security) – облигациия без купона. Ценные бумаги, не приносящие регулярного процентного дохода, но продающиеся со значительной скидкой против их нарицательной стоимости. Покупатель таких облигаций получает доход благодаря постепенному росту (appreciation) стоимости ценных бумаг, которые погашаются по нарицательной стоимости (face value) по наступлении указанной даты погашения. В целях налогообложения Служба Внутренних Доходов

(Internal Revenue Service) – налоговое управление США считает, что владелец облигаций без купона должен уплатить подоходный налог на проценты, которые были накоплены за каждый год, хотя он реально и не получает наличных денег до наступления даты погашения ценных бумаг. Налоговое управление называет такие проценты 'условно-начисленными', или расчётными или вменёнными (imputed interest). Многие финансовые консультанты рекомендуют использовать бескупонные ценные бумаги для индивидуальных пенсионных счетов (individual retirement accounts) или счетов Кио (Keogh accounts), где они защищены от налогообложения. Существует много различных видов ценных бумаг без купона. Большинство из них известно как бескупонные облигации, которые могут быть выпущены либо некоторой корпорацией с большой скидкой, либо брокерской компанией, которая открепляет купоны от облигации и продаёт основную сумму (corpus) и купоны отдельно. Этот метод часто используется по отношению к Казначейским облигациям; маркетинг купонных выпусков осуществляется под такими названиями, как CATS (Certificate of Accrual on Treasury Securities), TIGER (Treasury Investors Growth Rate), STRIPS (separate trading of registered interest and principal of securities). Бескупонные облигации выпускаются также и муниципалитетами. Покупка муниципальной бескупонной облигации освобождает её владельца от уплаты налогов на условно начисленный процент, поскольку этот процент исключён из налогообложения. Также существуют бескупонные депозитные сертификаты и бескупонные ипотечные ценные бумаги. Они работают по такому же принципу, что и бескупонные облигации – владелец депозитного сертификата или ипотечных ценных бумаг получает их нарицательную стоимость по наступлении срока погашения, а до тех пор не получает каких-либо выплат. Бескупонные ценные бумаги, базирующиеся на облигациях, обеспеченных пулом ипотек (collateralized mortgage obligation), называются Облигациями Z-Транша (Z-Tranche Bonds). Некоторые взаимные инвестиционные фонды приобретают только бескупонные ценные бумаги, предлагая своим клиентам диверсифицированный портфель, который подлежит погашению в намеченный год. Бескупонные ценные бумаги часто используются при планировании конкретных инвестиционных целей. Например, родители, ожидающие, что их ребенок поступит в колледж через 10 лет, могут приобрести бескупонную ценную бумагу, срок погашения которой наступит через 10 лет, и, таким образом, получить гарантию наличия средств, необходимых для оплаты обучения. Люди, собирающиеся уйти на пенсию через 20 лет, покупают 20-летние Z-купоны, будучи уверенными, что они получат деньги именно тогда, когда они им понадобятся. Поскольку по бескупонным ценным бумагам не выплачивается процентного дохода, они являются наиболее неустойчивыми (volatile) из всех ценных бумаг с фиксированным доходом. В случае роста процентных ставок бескупонные облигации падают быстрее, чем облигации, приносящие текущий процентный доход, поскольку владельцы бескупонных облигаций не получают процентных выплат. Однако, когда процентные ставки падают, стоимость бескупонных ценных бумаг растёт быстрее, поскольку такие облигации имеют фиксированную ставку реинвестиций, которая становится привлекательной по мере падения процентных ставок. Чем больше лет остаётся до погашения беспроцентных ценных бумаг, тем меньше инвестору приходится за неё платить и тем больше заёмных средств (leverage) начинает на него работать. Например, облигация, срок погашения которой наступает через 5 лет, может удвоиться, но облигация, срок погашения которой наступает через 25 лет, может вырасти в 10 раз – в зависимости от ставки процента по облигации.

ZERO COUPON EUROBOND = БЕСКУПОННЫЕ ЕВРООБЛИГАЦИИ – Zero Coupon Eurobond:- 1982-February-01, The New York Times, London, UK:- The international bond market is being swamped by a rash of American company issues that pay no interest but are sold at a steep discount. The zero-coupon Eurobonds, as such foreign issues are known, are modeled on a similar bond that first appeared in the United States last fall and became an immediate success. Since the first zero-coupon Eurobond appeared late last year, companies with such household names as General Motors, Du Pont and Sears, Roebuck have moved into the foreign market, bringing new life to a somnolent business. According to estimates by Salomon Brothers, USD1.15 billion has been raised by American companies thus far in 1982 on bonds with a face value of USD4.97 billion. 'After the first four deals, I thought this cannot last', said Nicholas Gold, a director of Morgan Grenfell & Company, a leading London merchant bank. 'But it's gone on and on'. Thus far, only two non-American entities have sold zero coupons. Typically, the investor pays just a fraction of the face value, but receives the full value at maturity, usually in seven to 12 years. 13.9% Rate of Return. A recent issue by General Electric Credit International was priced at USD260.80 for a bond worth USD1 000 in 10 years, a rate of return of 13.9 percent a year. Thus, the USD5 billion in zero coupons may have raised only USD1.5 billion or less in cash for companies. By comparison, the more conventional Eurobond market has all but dried up, in much the same way as the domestic bond market has suffered as a result of high interest rates. Last week, only one conventional issue was reported, a USD50 million financing by the McDonnell Douglas Finance Corporation. The yield will not be known until the issue is priced on February 10. 'At most there has been a smattering of issues, but nothing spectacular', said Viscount Chandos, a manager of international corporate finance at Kleinwort, Benson Ltd., a British merchant banking concern. Accordingly, the zero coupons have been greeted eagerly by underwriters who receive commissions based on the full face value. Advantages for the Borrower:- For the borrower, the advantage of zero coupons is lower rates. For example, the General Electric (GE) bond at 13.9 percent compares with a likely interest cost of 15 percent on a conventional issue, according to several estimates. Demand for the GE issue was so great that it was raised from USD200 million to USD800 million. Issuers receive a further saving because the Internal Revenue Service (IRS) permits deduction of interest payments each year as if they had been made. Thus, a tax saving occurs without any cash going out. One investment banker estimated privately that this provision could reduce borrowing costs for most companies by an additional one percentage point. Zero coupons have become more popular abroad than in the United States principally because of tax considerations. The first burst of foreign interest several weeks ago came from wealthy Japanese investors for whom the bond is tax-free because Japan has no capital gains tax. By comparison, the bonds had little popularity among individuals in the United States because the IRS decreed that a proportionate share of the prospective gain had to be declared as income each year, even though no cash was received. Most were bought by pension funds and other untaxed entities. Few Rulings in Europe:- in some countries in Europe, tax advantages are expected, but the major nations have yet to make tax rulings. In Britain, for example, the interest could be taxable yearly as unearned income, at rates up to 75 percent, or it might be considered a capital gain at maturity, which would mean tax at about half that rate. Zero coupons are attractive to buyers in Europe for other reasons. Instead of having to reinvest dividends every six months at prevailing rates, the investor has his dividends in effect reinvested by the borrowing company, and knows at the outset what the compound return will be. That was a particular attraction for American pension funds. Perhaps more significantly, the investor has the potential for more substantial gains if American interest rates fall, as many predict. Because zero coupons are so cheap, a given investment in them will ris e in value by a larger amount than would the same investment in conventional bonds. 'It is most people's expectation that American interest rates have reached their peak for this cycle', said Mr. Gold of Morgan Grenfell. However, if American interest rates rise further, owners of zero coupons would probably be hurt more t han owners of conventional bonds. Because of the great demand for zero coupons abroad, they are currently yielding less than similar bonds issued in the United States. According to one expert, the General Electric zero coupon would probably yield 14.6 percent in the domestic market, compared with the 13.9 percent in Europe, while a similar conventional issue would probably pay 15 percent, the same as in the Euromarket. Changes In Eurobond Market:- the zero coupons have already succeeded in pressing two significant changes in the Eurobond market. First, the zero coupons often have maturities as long as 12 years while conventional issues have not regularly gone beyond 10 years. Second, the new format has drawn top-rated companies into the Eurobond market. In the past, Eurobonds have been more frequently floated by lesser-rated companies that could get a better interest rate from less discriminating foreign purchasers. How extensive the

zero-coupon market will be overseas remains to be seen. Although many investment bankers are bullish, others find the buyers' motives so diffuse as to raise questions about the permanence of the interest. 'I don't think the market is all that deep', said Archibald Cox Jr., a Managing Director of Morgan Stanley International here. 'I think even today, you're starting to see the saturation point'. Zero-Coupon Eurobonds do not have interest payments. The investor in this type of Eurobond may be looking for some kind of tax advantage. ZERO–COUPON SECURITY = БЕСКУПОННАЯ ЦЕННАЯ БУМАГА – Zero-Coupon Security (ZR) is a security that makes no periodic interest payments but instead is sold at a deep discount from its face value. The buyer of such a bond receives the rate of return by the gradual appreciation of the security, which is redeemed at face value on a specified maturity date. For tax purposes, the Internal Revenue Service (IRS) maintains that the holder of a zero-coupon bond owes income tax on the interest that has accrued each year, even though the bondholder does not actually receive the cash until maturity. The IRS calls this interest Imputed Interest. Because of this interpretation, many financial advisers recommend that zero-coupon securities be used in Individual Retirement Account or Keogh accounts, where they remain tax-sheltered. There are many kinds of zero-coupon securities. The most commonly known is the zero-coupon bond, which either may be issued at a deep discount by a corporation or government entity or may be created by a brokerage firm when it strips the coupons off a bond and sells the corpus and the coupons separately. This technique is used frequently with Treasury bonds, and the zero-coupon issue is marketed under such names as CATS (Certificate of Accrual on Treasury Securities), Tiger (Treasury Investors Growth Receipt) or Strip (separate trading of registered interest and principal of securities). Zero-coupon bonds are also issued by municipalities. Buying a municipal zero frees its purchaser of the worry about paying taxes on imputed interest, since the interest is tax-exempt. Zero-coupon certificates of deposit and zero mortgages also exist; they work on the same principle as zero-coupon bonds-the CD holder or mortgage holder receives face value at maturity, and no payments until then. Zero-coupon securities based on Collateralized Mortgage Obligation bonds are called Z-Tranche Bonds. Some mutual funds buy exclusively zerocoupon securities, offering shareholders a diversified portfolio that will mature in a particular year. Zero-coupon securities are frequently used to plan for a specific investment goal. For example, parents knowing their child will enter college in 10 years can buy a zero that will mature in 10 years, and thus be assured of having money available for tuition. People planning for retirement in 20 years can buy 20-year zeros, assuring them that they will get the money when they need it. Because zero-coupon securities bear no interest, they are the most volatile of all fixed-income securities. Since zero-coupon bondholders do not receive interest payments, zeros fall more dramatically than bonds paying out interest on a current basis when interest rates rise. However, when interest rates fall, zero-coupon securities rise more rapidly in value than full-coupon bonds, because the bonds have locked in a particular rate of reinvestment that becomes more attractive the further rates fall. The greater the number of years that a zero-coupon security has until maturity, the less an investor has to pay for it, and the more leverage is at work for him. For instance, a bond maturing in 5 years may double, but one maturing in 25 years may increase in value 10 times, depending on the interest rate of the bond. Zero-Coupon Security is a security that makes no interest payments but instead is sold at a deep discount from its face value. A Zero-Coupon Security, or Stripped Bond, is basically a regular coupon-paying bond without the coupons. The process of 'Stripping' or 'Zeroing' a bond is usually done by a brokerage or a bank. The bank or broker stripping the bonds then registers and trades these zeros as individual securities. Once the bonds are stripped, there are two parts:- the principal and the coupons. The interest payments are known as 'Coupons', and the final payment at maturity is known as the 'Residual' since it is what is left over after the coupons are stripped off. Both coupons and residuals are bundled and referred to as Zero-Coupon Bonds or 'Zeros'. You can think of a zero-coupon security just like a T-bill. Basically, you pay a certain amount right now in exchange for the par value of the security at a future date, usually USD1 000. For example, you might pay USD800 for a zero-coupon bond today and in five years you will receive the par value of USD1 000. The longer the time to maturity, the cheaper you can buy the bond for. This predictability also makes zeros popular – when you buy the security, the yield is essentially locked in. Objectives and Risks:- the basic objective of a zero-coupon security is 'buy low, sell high'. You purchase the bond for a sum of money, and once it reaches maturity you will be paid an even larger sum of money. When interest rates are low, the price of the zero will be higher. The best time to buy a zero is when interest rates are high because the bond will be at a deeper discount. The one major problem with zeros is that the annual accumulated return is actually considered to be income, and while you don't actually collect that interest until the bond reaches maturity, you still have to pay income tax on it. In other words, the gains on a zero are not treated as capital gains, instead they are considered to be interest. How To Buy or Sell It? Zero-coupon securities can be bought through most full service or discount brokers, commercial banks, and some other financial intermediaries. Strengths:- (i) zeros can be bought at huge discounts; and (ii) once you buy a zero-coupon security, you essentially lock in the yield to maturity. Weaknesses:- (i) if the company issuing the zero goes bankrupt or defaults, then you have everything to lose. Whereas, with a regular coupon bond, you may have at least gotten some interest payments out of the investment; and (ii) interest earned on the zero-coupon bond is taxed as income (a higher rate) rather than capital gains. Three Main Uses:- (i) Capital Appreciation; (ii) Tax-Deferred Savings; and (iii) Predictability. Zero Coupon Security is the debt security on which no coupon interest is paid to the investor. Instead, the security is purchased at a deep discount and matures at par. The security's yield is based on the

difference between the original-issue-discount price and the par payment at maturity. / или счета Кио (Keogh accounts). ZERO–DAY = ДЕНЬ НОЛЬ – Zero-Day:- a new, unpatched vulnerability which is used to perform an attack. The name Zero-Day comes from the fact that no patch yet exists to mitigate the vulnerability being exploited. Zero-days are sometimes used in Trojan horses, rootkits, viruses, worms and other kinds of malware to help them spread to and infect additional computers. Also spelled as 'Zeroday', '0Day' and '0-Day'.

ZERO DISCHARGE PERMITS = РАЗРЕШЕНИЯ ПО НУЛЕВОМУ РАСХОДУ (или НУЛЕВОЙ РАЗРЯЖЕННОСТИ) – Zero Discharge Permits:- as authorized by the Clean Water Act of 1972, permits for feedlots requiring that the wastewater facilities be designed, constructed, and operated to keep wastewater from overflowing, except during the largest 24-hour rainfall that occurs on the average of once every 25 years (a 25-year, 24-hour storm event). In the United States, The Bureau of Water Pollution Control (BWPC) also issues Zero Discharge Permits where the potential for a discharge exists, but will most likely never occur, e.g., lined ponds and tanks. Proposed projects are evaluated to ensure that the background water quality is not degraded or that drinking water quality standards are not exceeded. Zero Discharge Systems (also called Closed-Loop Plating) use a combination of rinsing modifications, drag-out recovery, and wastewater treatment that allows a meta finishing or electroplating shop to reuse nearly 100 percent of all the water in a plating process line. In these systems, all wastewater is reclaimed and internally reused, so there is into discharge of wastewater. Are there really zero discharges? No. the 'Zero' refers only to the fact that no water is discharged. Often, there are air emissions (mostly water vapor) and solid wastes (spent filters, ion exchange resins. cathodes, etc). Metals in the solid wastes may be reclaimed.

ZERO DIVIDEND PREFERENCE SHARES = БЕЗДИВИДЕНДНЫЕ ПРИВИЛЕГИРОВАННЫЕ АКЦИИ – Zero Dividend Preference Shares, often called Zeros, are simply preference shares that do not pay an annual dividend. They instead simply redeemed for a lump sum at a fixed date. Zeros are similar to zero coupon bonds. They are more risky because they are shares and therefore rank lower than bonds for repayment if the issuer is wound up. To look at this another way, consider how the present value of a zero will change if the risk changes. With a single payment a long way off in the future, even a small change in the discount rate will have a large impact on the value. Therefore a small change in the risk premium will mean a large change in the value. Zeros gained something of a bad reputation due to problems at a number of British split capital investment trusts that come to light in 2002. This was due to the way in which those particular trusts were managed, and does not say much about the intrinsic qualities of zeros – except perhaps highlighting a need for transparency to allow proper valuation of different classes of share. Zero Dividend Preference Share is a share which receives a fixed lump sum on redemption and is not entitled to any periodic dividend. Zero-Dividend Preferred Stock is a preferred share that is not required to pay a dividend to its holder. The owner of a zero-dividend preferred share will earn income from capital appreciation and may receive a one-time payment at the end of the investment term. Also referred to as Capital Shares. Owners of zero-dividend preference shares will not receive a normal dividend. Often, they still maintain reimbursement priority over common shareholders in the event of bankruptcy. While a company may structure preferred shares however they choose, most preferred shares will not have voting rights.

ZERO DOWNTICK = ШАГ НОЛЬ ВНИЗ (или НУЛЕВОЙ ПОНИЖАТЕЛЬНЫЙ ШАГ, НОЛЬ СНИЗУ ТИКА, или НУЛЕВОЙ ПОНИЖАТЕЛЬНЫЙ ТИК) – Zero Downtick is a trade that occurs at the same price as the trade preceding it but lower than the last trade at a different price. A zero downtick is the opposite of a zero plus tick. How it works/Example:- Let's say the first trade of the day for Company XYZ stock is 1 000 shares at USD20 per share. The very next trade is 2 500 shares at USD18. The third trade is 1 500 shares at USD18 (the same price). The third trade is called a Zero Downtick because that USD18 trade is the same price as the previous trade but lower than the last trade that occurred at a different price (the USD20 trade). Although the term is usually used in reference to stocks, it can also apply to bonds, commodities and other traded securities. Why it Matters:- a zero downtick suggests that a stock is trending down and staying there. The US Securities and Exchange Commission (SEC) used to disallow shorting stocks on downticks in order to prevent traders from jumping on the bandwagon to destabilize a stock's price. Zero Downtick is a security sale that occurs at the same time as another sale of the same security but at a lower price. For instance, if a stock sells at USD35 and then USD34.50 and the next sale is still USD34.50, it is considered to be made at a zero downtick. Short sales can't occur on zero downticks. Also known as Zero-Minus Tick. / Нулевой Понижательный Тик (Zero Downtick) или сделка по цене с нулевым понижением. Синоним термина Ноль-Минус Тик или Нулевой Минусовой Тик (Zero-Minus Tick) или сделка по цене с нулевым понижением.

ZERO EMISSION VEHICLE = ТРАНСПОРТНОЕ СРЕДСТВО, НЕ ВЫДЕЛЯЮЩЕЕ ОТРАБОТАВШИХ ГАЗОВ – Zero Emissions Vehicle is a vehicle powered by hydrogen fuel cell (HFC) which emits virtually no harmful emissions into the environment – in effect a clean air vehicle. Zero-Emission Vehicle is a clean fuel vehicle meeting even more stringent zero-emission vehicle standards. A Zero-Emissions Vehicle, or ZEV a vehicle that emits no tailpipe pollutants from the onboard source of power. Harmful pollutants to the health and the environment include particulates (soot), hydrocarbons, carbon monoxide, ozone, lead, and various oxides of nitrogen. Although not considered emission pollutants by the original California Air Resources Board (CARB) or US Environmental Protection Agency (EPA) definitions, the most recent common use of the term also includes volatile organic compounds, several air toxics, and global pollutants such as carbon dioxide (CO_2) and other greenhouse gases. Examples of zero emission vehicles include muscle-powered vehicles such as bicycles; electric vehicles, which have no tailpipe; and fuel cell vehicles powered by hydrogen that only emit water. / Транспортное средство, не выделяющее отработавших газов.

ZERO GROWTH STOCK = АКЦИЯ БЕЗ РОСТА (или АКЦИЯ С НУЛЕВЫМ РОСТОМ) – Zero Growth Stock:- when a stock has a return of a definite amount until the stock reaches maturity. Zero Growth Stock is a stock that will return a set amount until it matures.

ZERO HOUR RULE = ПРАВИЛО НОЛЯ ЧАСОВ – Zero Hour Rule is a provision in the insolvency law of some countries whereby the transactions of a closed institution that have taken place after midnight on the date the institution is ordered closed may be retroactively rendered ineffective. The principle that the bankruptcy decision of the court has a retroactive effect, starting from the first hour of the day on which it was made ('Zero Hour Rule'). Zero Hour Rule is a provision in the insolvency law of some countries whereby the transactions of a closed institution that have taken place after midnight on the date the institution is ordered closed may be retroactively rendered ineffective. A law in some countries that allows a bankruptcy declared by a court during the day to be declared retroactive to 00:00 am of the same day. This law retroactively renders invalid all transactions of the bankrupt entity that took place after 00:00 am on that date. Zero-Hour Rule is a provision in the insolvency law of some countries whereby the transactions conducted by an insolvent

institution after midnight on the date the institution is declared insolvent are automatically ineffective by operation of law. ZEROING = ОБНУЛЕНИЕ – Zeroing:- an investigating authority usually calculates the dumping margin by getting the average of the differences between the export prices and the home market prices of the product in question. When it chooses to disregard or put a value of zero on instances when the export price is higher than the home market price, the practice is called 'Zeroing'. Critics claim this practice artificially inflates dumping margins.

ZERO–INTEREST BOND = БЕСПРОЦЕНТНАЯ ОБЛИГАЦИЯ – Zero-Interest Bond is an alternative term for Zero Coupon Bond. Zero-Interest Bond is a bond that pays no interest while the investor holds it. It is sold originally at a substantial discount from its eventual maturity value, paying the investor its full face value when it comes due, with the difference between what he paid initially and what he finally collected representing the interest he would have received over the years it was held. Zero Coupon Bond is thus issued at a discount to its face value, at which it will be redeemed. There are no intermittent payments of interest. When such a bond is issued for a very long tenor, the issue price is at a steep discount to the redemption value. Such a zero coupon bond is also called a Deep Discount Bond. The effective interest earned by the buyer is the difference between the face value and the discounted price at which the bond is bought. There are also instances of zero coupon bonds being issued at par, and redeemed with interest at a premium. The essential feature of this type of bonds is the absence of intermittent cash flows. A Zero-Coupon Bond is a corporate, Treasury, or municipal debt instrument that pays no periodic interest. Typically, the bond is redeemed at maturity for its full face value. It is a security issued at a discount from its face value, or it may be a coupon bond stripped of its coupons and repackaged as a zero-coupon bond. / Под Беспроцентной Облигацией понимается облигация, по которой не предусматривается процент, компенсация его осуществляется определёнными услугами.

ZERO INTEREST RATE POLICY = ПОЛИТИКА НУЛЕВОЙ ПРОЦЕНТНОЙ СТАВКИ – Zero Interest Rate Policy (ZIRP):- ZIRP stands for Zero Interest Rate Policy. This is a macroeconomic concept describing conditions with very low nominal interest rates. In recent history we have seen this in Japan. In the United States this has been observed since December 16, 2008. ZIRP is associated with slow economic growth. Under ZIRP, the central bank maintains a 0% nominal interest rate. The ZIRP is an important milestone in monetary policy because the central bank is no longer able to reduce nominal interest rates. Monetary policy is at its maximum potential to drive growth under ZIRP, because the central bank has no more tools left to stimulate borrowing. ZIRP is very closely related to the problem of a liquidity trap, where nominal interest rates cannot adjust downward at a time when the loanable funds market has not cleared. When monetary policy is already used to maximum effect, to create further jobs, governments must use fiscal policy. The fiscal multiplier of government spending is expected to be larger when nominal interest rates are zero than they would be when nominal interest rates are above zero. Keynesian economics holds that the multiplier is above one, meaning government spending effectively boosts output. In his paper on this topic, Michael Woodford finds that, in a ZIRP situation, the optimal policy for government is to spend enough in stimulus to cover the entire output gap. / Майкэл Вудфод (Michael Woodford).

ZERO INVENTORIES = НУЛЕВОЙ ИНВЕНТАРЬ – Zero Inventories (ZIN):- stage in just in time inventory control where all waste due to built-up inventories is eliminated by having only the required items on hand. The hottest buzzword in shipping these days is Zero Inventory. It's a cross between absolute zero and the speed of light. Neither is truly attainable. But while it may be the impossible dream, it's how close you can approach it that's got a host of big companies looking for the big new idea. 'In an ideal world, you want zero inventory if you want to maximize cash flow', says (on 2005-August-12) Andy Chatha the CEO of ARC Advisory Group, a prime analyst of manufacturing and the supply chain. And it's the escalating volume of goods that are coming all the way from China that have made the quest for the holy grail so desperately important. It is also the normal variables of seasonal demand and customer tastes. 'In the context of more global supply chains, we are seeing retailers having to stock more inventory as so many of the goods come from China', says Steve Banker, analyst for the ARC Advisory Group. 'To keep their lead-time, given such a distant source, they have to have more inventory. This in turn has led to more and more cross docking at US ports. There they sort the goods and make them up into units for retail centers'. Lean manufacturers like Dell, Toyota and other competitive automakers have very little inventory in the factory itself – approaching the ideal zero. But Banker says, 'To make their factories run that lean, they put the burden of carrying raw materials with inventory on their suppliers'. Turns – the amount of time and the period it takes to restock shelves – are certainly important and so viewed by supply-chain professionals. However, the supply-chain world is only now realizing that, 'They are only one indicator, and they can be a misleading indicator', says Banker. So there are two problems for companies seeking the ideal zero-sum world – China on the one hand, and the other, even more fundamental difficulty of measuring in-house inventory as against supplier inventory destined to be in-house within time. There have to be trade-off decisions to cope with market variations and global-supply networks. Even as companies increase their cash flow by raising the speed and number of inventory turns (the rate of replenishment of total stock per year), reality may dictate having some spare inventory for emergencies and using the best techniques to expedite shipping and gain on efficiency. 'The number of inventory turns varies by industry and by industry segments. The ratio is critical within industries facing tough pricing and competitive pressures, low margins and high levels of obsolescence', says Chatha. Wal-Mart Store's competitive advantage through increased inventory turns has been to a great extent accomplished through a combination of logistics techniques, called Cross Docking (or Flow Through), and transloading. These methods are made practical through well-positioned distribution centers, warehouses and terminals. They are core tools in a company's aim toward zero inventory, or as close as possible to zero. Cross docking is a method for the delivery of goods with minimal handling of stock in motion and maximum return on that stock with greater cash flow. / Стив Бэнькё (Steve Banker), аналитик для Эй.Ар.Си. ZERO INVENTORY PRODUCTION SYSTEM = СИСТЕМА С ОТСУТСТВИЕМ ИНВЕНТАРНОЙ ПРОДУКЦИИ – Zero Inventory Production System (ZIPS), also known as Just In Time (JIT):- JIT means goods are produced only when the orders are received, there by no storage of finished goods, can avoid costs of carrying finished goods. Zero Inventory Production (ZIP) System is an integrated merchandising and manufacturing system designed to enhance retail sales and store traffic through consumer choice. ZIP provides higher profit margins and reduced inventory risk throughout the supply chain using individualized digital manufacturing driven directly by consumer demand. The ZIP system supports the management of retail selling space rather than product inventory. The ZIP system manages the retail selling space by allowing the store buyer to choose the product based on a predetermined ZIP index calculated from product velocity and gross profit. What makes ZIP unique is that it reduces inventory risk and costs throughout the manufacturing value chain. Other just-in-time solutions reallocate risk away from retailers down the supply chain to contractors and manufacturers. This reallocation has accelerated the loss of apparel manufacturing in the US rather than its original intention to protect the trades. The basis of ZIP is to manufacture and replenish only the products sold at retail prices and to reduce excess high risk inventory. The promise of ZIP to the consumer is infinite choice at a fair price. To the retailer it is a ready supply of stock, no over stock and to provide a unique product to attract store traffic. The manufacturer now has an unlimited inventory with no stocking costs and the contractor has

a steady replenishment business as opposed to feast or famine production that the current mass production paradigm fosters. / Система Производства С Нулевым Уровнем Запасов.

ZERO–INVESTMENT PORTFOLIO = ПОРТФЕЛЬ С НУЛЕВЫМ ИНВЕСТИРОВАНИЕМ – Zero-Investment Portfolio is a group of investments which, when combined, create a zero net value. Zero-investment portfolios can be achieved by simultaneously purchasing securities and selling equivalent securities. This will achieve lower risk/gains compared to only purchasing or selling the same securities. Zero-Investment Portofolio is a portfolio of zero net value established by buying and shorting component securities, usually in the context of an arbitrage strategy. Zero-Investment Portfolios have many uses, including:- (i) reducing taxes, because they generate little or no interest income; (ii) reducing risk by protecting against unexpected shifts in the value of the held securities; (iii) protecting the overall value of the portfolio so that investment can be made at a later date; and (iv) determining if the average portfolio returns are statistically different from zero. For example, if John bought (that is, took a long position) one share of XYZ Corp., he would be fully exposed to the change in value of that stock. If, however, John sold the same stock (that is, took a short position), then any movement up or down would be canceled out. The combination of these two positions creates a zero-investment portfolio. / Корп. (Corp.). Если, онако же, Дьжон продал такую же долю (что значит – занял позицию продажи или так называемую короткую позицию), . Портфель с Нулевыми Инвестициями – портфель, чистая стоимость которого равна нулю, что достигается за счёт покупки и короткой продажи составляющих его ценных бумаг в рамках арбитражной стратегии. Безрисковость портфеля требует отсутствия систематического и несистематического риска.

ZERO–MINUS TICK = НОЛЬ МИНУС ШАГ (или НОЛЬ МИНУС ТИК) – Zero-Minus Tick:- a sale that takes place at the same price as the previous sale, but at a lower price than the last different price. Also called a Zero Downtick. For instance, stock trades may be executed consecutively at prices of USD52, USD51, and USD51. The final trade at USD51 was made at a zero-minus tick, because it was made at the same price as the previous trade, but at a lower price than the last different price. Zero Minus is American slang for unacceptable, impossible. Zero-Minus Tick:- a minus sign is displayed throughout the day next to the last price of each stock at the trading post on the floor of the New York Stock Exchange. Sale that takes place at the same price as the previous sale, but at a lower price than the last different price. The opposite of Zero-Plus Tick. Zero-Minus Tick is a securities trade executed on an exchange at the same price as the preceding trade, but at a lower price than the last trade of a different price. For example, if a succession of trades occur in the following order – USD10.25, USD10.00, and USD10.00 – the last trade would be considered a zero-minus tick or zero downtick trade. Until 2007, Securities And Exchange Commission (SEC) regulations prohibited against selling a stock short on a down tick or a zero-minus tick. As a result potential short sales would have to pass a tick test to make sure that the stock was trading up or flat before the short sale could go through. The restriction was eliminated after the SEC concluded that US markets functioned orderly enough that excessive short sales would not artificially drive down prices. The advent of decimalization also helped the rule get lifted because it reduced the average size of a tick move from fractions to pennies. A term Zero-Minus Tick is used for sale that takes place at the same price as the previous sale, but at a lower price than the last different price. Antithesis of Zero-Plus Tick. Zero-Minus Tick is a transaction of the exchange at a price equal to that of the preceding transaction but lower than the last different price. / Продажа, совершённая по такой же цене, как и у предыдущей продажи, но с небольшим изменением в сторону понижения цены в сравнении с предшествуюшей ей. Например, когда сделки были заключены последовательно по ценам 52, 51 и 51 Долларов, то последняя сделка, совершённая по цене 51 Долларов, была заключена по цене Ноль Минус Тик, поскольку цена, по которой она была совершена, равна цене предшествовавшей ей сделки, но выше, чем последняя отличная от неё цена.

ZERO–ONE INTEGER PROGRAMMING = ЦЕЛОЧИСЛЕННОЕ ПРОГРАММИРОВАНИЕ НОЛЬ–ЕДИНИЦА (или ДИСКРЕТНОЕ ПРОГРАММИРОВАНИЕ НОЛЬ–ЕДИНИЦА, или ИНТЕГРАЛЬНОЕ ПРОГРАММИРОВАНИЕ НОЛЬ–ЕДИНИЦА) – 0–1 Integer Programming or binary integer programming (BIP) is the special case of integer programming where variables are required to be 0 or 1 (rather than arbitrary integers). Zero-One Integer Programming is an analytical method that can be used to determine the solution to a capital rationing problem. Zero-One Integer Programming is an analytical method consisting of what amounts to a series of 'yes' (1) and 'no' (0) answers to arrive at a solution. In the world of finance, such programming is often used to provide answers to capital rationing problems, as well as to optimize investment returns and assist in planning, production, transportation and other issues. Although seemingly simple, using a 0–1 integer scale can be very powerful. A 0–1 scale also helps to identify inefficiencies by providing a linear problem-solving framework. / Целочисленное Программирование Ноль-Единица – метод анализа, который используется при поиске решения задачи нормирования капитала для инвестиций. Целочисленное Программирование – разновидность линейного программирования, подразумевающая, что искомые значения должны быть целыми числами. Иногда дискретное программирование называется целочисленным. Программирование Ноль–Единица:- этот термин используется в специальном случае целочисленного программирования, где все переменные являются целыми числами и могут принимать значения либо Ноль, либо Единица. Такая техника планирования успешно применяется для решения проблемы выбора проекта, в которой проекты являются взаимоисключающими и/или технологически взаимозависимыми.

ZERO OR NO–COST CLAIMS = НУЛЕВЫЕ ИЛИ НЕСТОИМОСТНЫЕ ТРЕБОВАНИЯ (или XX) – Zero Or No-Cost Claims:- Personal Lines – claims which are settled or closed without indemnity payment to the Insured or Claimant except for possible service fees. All other areas full in line with the DoT (FSA) definition that a no-cost claim or zero claim is where no payment has been made. No-Cost Claims is a term used in personal lines claims which are settled or closed without indemnity payment to the insured or the claimant, except for possible service fees. All other business classes fall within FSA (short for the UK Financial Conduct Authority) definition that a no-cost claim or zero claim is where no payment has been made. Also known as Zero Cost Claims.

ZERO–PLUS TICK = НОЛЬ ПЛЮС ШАГ (или НОЛЬ ПЛЮС ТИК) – A Zero-Plus Tick is a term used for a transaction at the same price as the preceding trade but higher than the preceding different price. A plus sign is displayed throughout the day next to the last price of each stock at the trading post on the floor of the New York Stock Exchange. Transaction at the same price as the preceding trade, but higher than the preceding trade at a different price. The opposite of Zero-Minus Tick. Zero-Plus Tick is a security trade that is executed at the same price as the preceding trade but at a higher price than the last trade of a different price. For more than 70 years there was an 'uptick rule' as established by the US Securities and Exchange Commission (SEC); the rule stated that stocks could be shorted only on an uptick or a zero-plus tick, not on a downtick. This rule was lifted in 2007. For example, if a succession of trades occurs at USD10, USD10.25 and USD10.25 again, the latter trade would be considered a zero-plus tick, or 'zero uptick', trade. It was

thought that short selling on downticks may have led to the stock market crash of 1929, but the uptick rule was lifted in 2007 after the SEC concluded that markets were advanced and orderly enough to not need the restriction. It is also believed that the advent of decimalization on the major stock exchanges helped to make the rule unnecessary. Zero-Plus Tick is a term that is used for listed equity securities. Transaction at the same price as the preceding trade, but higher than the preceding trade at a different price. A term Zero-Plus Tick refers to a transaction made at the same price as a preceding trade, but at a price higher than two transactions previous. Also know as Zero Uptick. Written descriptions of zero-plus ticks are far more complicated than the actual concept. As an example of a zero-plus tick, if trades are executed at 52, then 53 and then 53 again – then the last trade at 53 was a zero plus tick. One of the biggest disadvantages of speculating in the stock market is the rule that prevents shorting shares on a downtick. Share traders are not able to short a stock during a downtick or zero downtick – only after an up-tick of price in the share. Having to wait for the market to increase is may be costly for those looking to profit from a decline in price. Such restrictions on shorting and profiting from asset's decline do not exist in the FX Market. Zero-Plus Tick is a transaction on the exchange at a price equal to that of the preceding transaction but higher than the last different price. / Сделка, совершённая почти по такой же цене, как и у предыдущей, но с небольшим отклонением в сторону повышения цены. ZERO POPULATION GROWTH = НУЛЕВОЙ ПРИРОСТ НАСЕЛЕНИЯ – Zero Population Growth is a condition in which a population in a given location neither increases nor decreases over time. The increases due to births and immigration are balanced with decreases caused by deaths and emigration. Zero Population Growth (ZPG) is the absence of population growth in which equal birth and death rates create a stable human population. Zero Population Growth means that:- (a) the birth rate is zero; (b) the death rate is zero; (c) the birth rate and death rate are the same; (d) the population density is zero; and (e) both c and d are correct. / Нулевой Прирост Населения – это демографическое состояние, при котором число смертей в популяции приблизительно совпадает с числом рождений жизнеспособных детей так, что общее количество популяции остаётся неизменным в течение какого-то периода времени.

ZERO PREPAYMENT ASSUMPTION = ДОПУЩЕНИЕ ОБ ОТСУТСТВИИ ПРЕДОПЛАТЫ – Zero Prepayment Assumption is the assumption of payment of scheduled principal and interest with no payments. The investor does not have to make any prepayment of principle on the assumption that interest and principal will be paid on schedule. Zero Prepayment Assumption:- the supposition that scheduled principal and interest will be paid off with no installments. This is typically done as a means of providing a benchmark to gauge other, more complex assumptions. By determining what a product or service will cost without financing, individuals or companies can better budget their resources and plan for future expenditures and/or revenue growth. Prepayment assumptions are critical in valuing mortgage-backed securities with various models making assumptions about prepayment patterns under various interest rate changes. Thus, having an established standard can be helpful in determining the fair value of such investments.

ZERO–PROOF BOOKKEEPING = ВЕДЕНИЕ КНИГИ ПРИ НУЛЕВОМ ПОКРЫТИИ – Zero-Proof Bookkeeping is a manual bookkeeping procedure in which posted entries are systematically subtracted from an ending balance to check for errors. In zero-proof bookkeeping, a balance of zero when all entries have been subtracted is proof that the accounting entries have been entered correctly. This method may be used to reconcile accounting differences in situations where the number of entries or transactions is not overly large. A typical situation where zero-proof bookkeeping is used is by bank tellers to reconcile differences at the end of a day. Zero proof bookkeeping is not practical where large numbers of transactions are the norm and many of the figures are rounded. Zero-Proof Bookkeeping:- used in smaller businesses or for individual purposes, this method of keeping an eye on the books allows for the accounts to have a balance of zero at the end of the accounting period. Zero-Proof Bookkeeping is a bookkeeping method in which entries are subtracted from the ending balance on a systematic basis to see if there are any errors. This method is used when there aren't a very large number of transactions.

ZERO–RATE AND LOW–RATE MORTGAGE = ЗАКЛАДНАЯ С НУЛЕВОЙ СТАВКОЙ И НИЗКОЙ СТАВКОЙ – Zero-Rate and Low-Rate Mortgage:- here buyer makes a substantial down payment (for example, one-third of total price) and borrows remainder on a zero rate (or very low interest rate) mortgage, agreeing to pay a substantial finance charge (10 percent or more of amount borrowed) immediately, and to repay the loan over a short period (5 years, for example). Sales price may be increased to reflect costs of loan. Zero-Rate Mortgage is a kind of mortgage where a mortgagee pays higher down payment whereby s/he is exempted from paying the interest. The mortgagee pays the balance amount in equal installments. / Закладная С Нулевой Ставкой и Закладная С Низкой Ставкой – закладная на дом, которая совершенно или почти не имеет процентной ставки. Требует большего первоначального платежа и одноразового финансового сбора, затем ссуда погашается фиксированными ежемесячными платежами в течение короткого периода времени.

ZERO–RATED = ПО НУЛЕВОЙ СТАВКЕ – Zero Rated is a term relating to value added tax (VAT). It refers to goods (for example, food and books) which are taxable but at a zero rate. The significance of this rating is that businesses selling such goods may claim back their input tax (the VAT which they have paid to their suppliers). Businesses which provide goods and services which are VAT exempt (for example, stamps and postal services) are not able to reclaim input tax. A term Zero-Rated denotes goods on which the buyer pays no value-added tax although the seller can claim back any tax he/she has paid. Zero-Rated Goods are the products on which a value-added tax (VAT) is not levied in countries that use a VAT. Examples of goods that may be zero rated include many types of food and beverage, exported goods, donated goods sold by charity shops, equipment for the disabled, prescription medications, water and sewage services, books and other printed publications, children's clothing, and financial services. Zero-rated goods can save consumers a significant amount of money. In the United Kingdom, for example, the standard VAT rate levied on most goods is 17.5% and the reduced rate is 5%. However, because the VAT is a hidden tax, which means it is already included in the price of goods, the consumer may be unaware that a good is zero rated. A fourth category of goods – exempt goods – also carries no VAT. / Так называют продажу товаров и услуг, которые формально облагаются налогом на добавленную стоимость (НДС), однако ставка этого налога равна нулю. Разница между продажами товаров и услуг, освобождённых от НДС (например, почтовых марок) и товаров и услуг, облагаемых НДС по нулевой ставке (например, детской одежды, книг, продовольственных товаров), заключается в том, что освобождённые от налога товары и услуги не включаются в систему НДС и, следовательно, нет

возможности компенсировать этот входящий налог, тогда как товары и услуги, облагаемые НДС по нулевой ставке, входят в систему НДС, поэтому возникает возможность компенсации входящего налога.

ZERO–RATED SALES = ПРОДАЖИ ПО НУЛЕВОЙ СТАВКЕ – A Zero Rated Sales is one on which no output tax is payable but input tax credit is eligible. The difference between an exempt sale and a zero rated sale should be properly understood. An exempt dealer pays value-added tax (VAT) on his purchases, but is not entitled to claim input tax credit as he cannot charge VAT on his exempt sales. A dealer effecting zero rated sales claims refund of the VAT on his inputs but pays no tax on his output, e.g., exports. Zero-Rated Sales is when a sale is taxable at the rate of 0%, i.e. no sales tax. Some examples could be:- basic groceries, prescription drugs or certain medical devices. / Операции, облагаемые налогом по нулевой ставке. Продажи по Нулевой Ставке осуществляются в тех случаях, когда эти продажи облагаются налогом по ставке, равной 0%, то есть вовсе без налога на продажу. Примерами таких продаж могли бы служить:- продажи основных бакалейных товаров, выписанных лекарств и определённых медицинских приборов.

ZERO SUM GAME = ИГРА С НУЛЕВОЙ СУММОЙ – A Zero Sum Game is one in which the total pay-offs are the same for all possible combinations of players' strategies. This means that each player can only gain at the expense of others; any player's loss is balanced by an equal gain (or gains) made by other players. It does not actually matter much whether the sum of the pay-offs is zero (the strict requirement for the zero sum game) or another number, as long as the total is the same for all possible outcomes. For this reason, zero sum games are often called Constant Sum Games. A real life example of a zero sum game is gambling. If one player wins, other players (including the house, if any) must have lost the same amount. Financial markets offer many examples of zero sum games. For example the writer of an option can only gain what the holder loses and vice-versa. Although securities markets are expected to have an overall positive outcome, attempts to out-perform are zero-sum, in that all out-performance by winning investors must be balanced by out-performance by losers. Zero Sum Game is a game played by a number of persons in which the winner takes all the stakes provided by the losers so that the algebraic sum of gains at any stage is zero. It has been argued that many decision problems may be viewed as zero sum games between two persons. The simplest two-person Zero-Sum Games of imperfect information are those that have saddle points. All two-person zero-sum games of perfect information have saddle points. Such games have a predetermined outcome (assuming rational play), and each player can, by choosing the right strategy, obtain an amount at least equal to this outcome no matter what the other player does. This predetermined outcome is called the Value Of The Game. Zero-Sum Game is a type of game wherein one player can gain only at the expense of another player. Futures trading is often referred to as a Zero Sum Game. This is because in any given time period there is always a buyer and a seller for each contract that is traded and the net amount lost by the losers will always equal the net amount gained by the winners. The Zero Sum Game is only theoretical because operating costs will eat into the profits of the winners and add to the losses of the losers. Typical operating costs include commissions, charting software, computer hardware, trading platforms, trading indicators, subscriptions and services. Compare this to Negative Sum Game. / Игра с Нулевой Суммой – игра или пари двух и более лиц, при которой выигрыш одного равен проигрышу другого, то есть доходы минус убытки дают ноль. Примером игры с нулевой суммой является вопрос, кто платит за такси:- доход одного человека для другого является убытком. 'Дилемма заключённых' (prisoners' dilemma) – пример игры с ненулевой суммой, демонстрирующий преимущества кооперации. Игры с нулевой и ненулевой суммами нашли широкое применение в экономической науке. Игра с Нулевой Суммой – ситуация, при которой выигрыш победителя уравновешивается убытком проигравшего. Например, в области фьючерсной и опционной торговли действует игра с нулевой суммой, потому что на каждого инвестора с выигрышным контрактом приходится противоположная сторона по контракту – инвестор, который потерял ту же сумму денег. Общая сумма выигрыша, полученного всеми торговцами в игре с нулевой суммой, остаётся постоянной, но конкретные выигрыши переходят от одного торговца к другому.

ZERO TILLAGE = БЕЗ ЗАПАХИВАНИЯ – In Canada, Zero Tillage (also known as Zero Till or No-Till or Direct Seeding) is a method of plowing or tilling a field in which the soil is disturbed as little as possible by, essentially, not plowing the field. The crop is planted directly into a seedbed which has not been tilled since the harvest of the previous crop. Zero tillage is being used more every year in Nova Scotia as individual farms and farmers start to recognize its benefits, especially the money-saving benefit. Recent periods of less-than-normal levels of precipitation in Nova Scotia have shown the importance of increasing the water holding capacity of soils, and therefore conserve our natural soils, which is the goal of zero tillage practices. A common perception by farmers is that zero tilling doesn't work, that crop yields will be lower, and that crop quality is poorer. Some people think a zero tilled field is less aesthetically pleasing since the field is left alone with plant and weed residues over its surface, indicating the potential for increased pesticide or herbicide costs. However, these perceptions may be false. It takes approximately 5 years before a real benefit can be observed and demonstrated, and most people tend to ignore benefits that aren't readily seen. Benefits include reduced soil salinity, which is better for plant growth, and conservation of natural soil structure. The soil stays spongy and doesn't become compacted, which is bad for plant growth. Zero tillage practices in cool climates or poorly drained soils, such as those typical of Nova Scotia, do not reap as many benefits as in dry tropical soils. However, there are many benefits:- (i) conservation of soil moisture; (ii) reduction of soil erosion by the wind since the crop residue cover isn't plowed under the soil; (iii) reduction of farm labor (i.e. time actually spent tilling the field, fuel consumption) thereby reducing farm expenses; (iv) increased planting and harvesting timelines, since time spent tilling and preparing the field isn't required; (v) earthworms, and other biological organisms, are left alone to live and manipulate the soil by creating tunnels, which otherwise would be created by tilling. This allows for good movement of water and air throughout the soil for good plant growth; (vi) reduced soil compaction. Many years of tilling lead to a very hard, densely packed soil; (vii) increased soil organic matter which means better soil structure and more available nutrients for plant growth. Tilling 'burns' organic matter away; (viii) increasing soil organic matter, helps to sequester carbon as carbon dioxide, in the soil which helps Canada meet the Kyoto Protocol mandate by reducing agricultural greenhouse gas (GHG) emissions. Also known as No-Tillage. In agriculture, a tillage is the preparation of soil for planting and the cultivation of soil after planting. Zero Tillage is a tillage in which disks push aside residue of the previous crop just prior to planting. There is no seedbed preparation. Zero Tillage is a practice where planting or seeding is directly done in untilled land. / сохранение (conservation). Без Запахивания семян . ZERO TOLERANCE RULE = ПРАВИЛО НУЛЕВОГО ДОПУСКА – Zero Tolerance Rule (policy) is:- (1) a Food Safety and Inspection Service policy on visible fecal contamination of poultry, specifying that poultry carcasses contaminated with feces are not allowed to enter chilling tanks where contamination could spread to other carcasses. (2) A part of the FSIS Pathogen Reduction Program in which carcasses and carcass parts are closely scrutinized for any form of contamination, and when found, the contamination must be totally eliminated and discarded before that carcass or carcass part is able to be further processed.

ZERO–TWIST = НУЛЕВАЯ КРУТКА (или БЕЗ КРУТКИ, или НЕКРУЧЁНОЕ) – Zero-Twist:- twistless, devoid of twist.

ZERO UPTICK = ШАГ НОЛЬ ВВЕРХ (или НУЛЕВОЙ ПОВЫШАТЕЛЬНЫЙ ШАГ, или НОЛЬ СВЕРХ ТИКА, или НУЛЕВОЙ ПОВЫШАТЕЛЬНЫЙ ТИК) – Zero Uptick:- a transaction made at the same price as the one directly preceding it but at a higher price

than the one before that. See also Zero-Plus Tick. Zero Uptick:- if there is no change in the last trade price of the particular stock, the previous trade price must be higher than the trade price that preceded it. Zero Uptick:- a transaction executed at the same price as the trade immediately preceding it, but at a price higher than the transaction before that. For example, if shares are bought and sold at USD47, followed by USD48 and USD48, the last trade at USD48 is considered to be a zero uptick. This distinction can be important for short sellers trying to avoid shorting an ascending stock. Also known as a Zero-Plus Tick. The technique of shorting on a zero uptick is not applicable to all investment markets, due to various rules and regulations prohibiting or restricting such transactions. The forex market, which has limited restrictions on shorting, is among the markets in which the technique is more popular. / сделка, совершённая по той же самой цене, что и в сделке, непосредственно прешествовавшей ей, но немного дороже цены сделки, предшествовавшей предшествующей. / Нулевой Повышательный Тик или сделка по цене с нулевым повышением. ZERO–VOLATILITY OPTION–ADJUSTED SPREAD = БЕЗЛИХОРАДОЧНАЯ КУРСОВАЯ РАЗНИЦА, ПЕРЕОЦЕНИВАЕМАЯ ОПЦИОНОМ (или БЕЗЛИХОРАДОЧНЫЙ СПРЭД, ПЕРЕОЦЕНИВАЕМЫЙ ОПЦИОНОМ) – Zero-Volatility Option-Adjusted Spread (OAS) is a OAS calculated relative to a reference yield curve by assuming that the future prepayment schedule of a mortgage backed security is known in advance and fixed, e.g., not uncertain. Zero Volatility Spread (i.e. Static Spread or Z-Spread). Option adjusted spread (OAS) must have gone down (B) Consider market OAS is kept constant and volatility is increased Option cost is increased since volatility is increased. OAS is the average yield spread of a security, adjusted for the value of its embedded options. Option-Adjusted Spread is a methodology using option pricing techniques to value the imbedded options risk component of a bond's total spread. OAS is the weighted average spread over the various interest rate paths that discounts the cash flows back to the security's price. For mortgage-backed securities (MBS), the option-adjusted spread (OAS) is the additional return over term structure of returns implied from Treasuries for the value of the MBS to equal its market price. This additional return is largely explained by the embedded options, such as for prepayment, in the MBS. Option cost is the difference between the zero volatility spread and the option adjusted spread and is an indication of return lost due to uncertainty in interest rates. As prepayment accelerates the payback of principal, it reduces net present value; and the static net present value using a static discounting rate does note give very reliable returns. To be able to compute the Z spread, we take the Treasury rates for different maturities. The Z spreads at different prepayment speeds are:- (1) prepayment reate:- 0% – Z spread:- 139.617 10; (2) prepayment rate:- 5% – Z spread:- 144.649 77; (3) prepayment rate:- 10% – Z spread:- 149.868 61; (4) prepayment rate:- 20% – Z spread:- 160.737 20. The above analysis is consistent with the fact that, in an increasing interest rate scenario, if prepayment rates are increased, the Z spread will increase. In fact, in an increasing interest rate scenario (implicit in the Treasury rates going up over the longer term), prepayment rates should drop, causing the Z spread to come down. As we have noted earlier the option-adjusted spread (OAS) is an option with the borrower and will be exercised as per the option of the borrower, at his advantage; this means prepayment will increase when rates of interest decline, and prepayments will decrease when rates of interest increase. In either case, the exercise of the option by the borrowers will reduce the Z spread of investors. Therefore, investors may want to project different scenarios of prepayment and Z spreads under each scenario. An option-adjusted spread is the value of the Z spread weighted by the probabilities of each of the prepayment scenarios. In other words, the option-adjusted spread does not presume static prepayment rate, and so is no more zero-volatility (by definition, Z-Spread means Zero-Volatility Spread). The reason why this spread is called the Option-Adjusted Spread is because, by taking different scenarios of prepayment, we are trying to quantify the impact of the prepayment risk on the investors' spreads. As the prepayment option has thus been discounted, the spread that we are left is net of prepayment risk and hence is the term option-adjusted spread. Zero Volatility Option Adjusted Spread is a measure of cash flow spread of an Mortgage-Backed Securities (MBS; debt securities that represent a claim of the cash flows of a pool of mortgages) over the treasury yield curve that takes into account the prepayment risk of the MBS. Option Adjusted Spread (OAS) combines two important concepts:- (i) First is 'Spread' which is analogous to Internal Rate of Return (IRR) or yield. Spread is a constant difference between Treasury yield curve and the discounting needed to achieve a given market price. And (ii) Second component embodied in OAS methodology is the Option Adjustment. Option Adjustment is a measure of the return of the asset after adjusting for the uncertainty (volatility) of interest rates. OAS methodology calculates this spread by generating a series of interest rate paths. Expected cash flows are determined for each interest path using a prepayment model. / Казначейки (Treasuries). , расчитываемая относительно справочной кривой доходности допуская, что расписание осуществляемых в будущем предоплат по ценной бумаге, гарантированной закладной, известно заранее и зафиксировано, например, несомненный. Z FACTOR = ФАКТОР ЗИ. (или ФАКТОР ЗЭД.) – How to calculate Z Factor:- The Altman Z-score (Z factor) is used to predict how vulnerable a company is to bankruptcy. The lower the Z factor, the higher the likelihood that a company will soon go bankrupt. To calculate this factor, five variables are distilled from a company's financial statements. These variables are then multiplied by constants and added. Instructions:- (i) Obtain the latest balance sheet and income statement for the company you want to analyze. (ii) Calculate the first of five variables:- X1. Using the balance sheet, subtract the company's current liabilities from its current assets. Divide this number by total assets (i.e. current and long term) to get X1. (iii) Find the amount of retained earnings on the balance sheet. Divide this number by total assets to get X2. (iv) Find the amount of earnings before interest and taxes (EBIT is sometimes called Operating Income on an income statement) on the income statement. Divide this number by total assets to get X3. (v) Find the amount of stockholders' equity on the balance sheet. Divide this number by total liabilities to get X4. (vi) Find the amount of revenue on the income statement. Divide this number by the company's total assets to get X5. (vii) Plug all five variables into the Z factor formula:- Z = 0.012X1 + 0.014X2 + 0.033X3 + 0.006X4 + 0.999X5. A company's latest balance sheet and income statement can be found in its annual 10-K filing. Use the US Securities and Exchange Commission's (SEC) EDGAR database to search for these 10-K forms. Companies do not always directly list total liabilities. To calculate it, find the amount of total liabilities and stockholders' equity on the balance sheet. Subtract the total stockholders' equity from this value. Z Factor is the ratio of the outstanding accreted principal amount of a Z bond to its original principal amount. ZHENGZHOU COMMODITY EXCHANGE = ЧЖЭНЧЖОУСКАЯ СЫРЬЕВАЯ БИРЖА – Zhengzhou Commodity Exchange (ZCE), the first experimental futures market approved by the State Council of China, was established on 1990-October-12. It introduced futures trading on 1993-May-28, two years after the successful operation of cash forward contract trading. In August 1998, the ZCE was confirmed by the State Council as one of the three futures exchanges in China. Some history facts:- 1988 – Research Group of China Zhengzhou Grain and Oil Futures Market was set up. In July 1990, China Zhengzhou Grain Wholesale Market (CZGWM) was approved to run on an experimental basis by the State Council. In August 1990, Regulatory Commission of China Zhengzhou Grain Wholesale Market was established. On 1990-October-12, China Zhengzhou Grain Wholesale Market was opened at Huazhong Hotel, 22 Songshan Road, Zhengzhou, Henan Province. Li Jingmou held the post of Chairman of the market. Auction was adopted in cash grain and oil trading. In March 1991, China's first forward contract was signed under the organization and supervision of CZGWM. In October 1992, the Futures Trading Regulations of China Zhengzhou Commodity Exchange (CZCE), the first futures regulations in China, was worked out. In January 1993, China Zhengzhou Grain Wholesale Market moved to Hongfeng Building, 20 Huayuan Road, Zhengzhou 450005, Henan Province. In March 1993, Henan People's Government ratified CZGWM to start China Zhengzhou Commodity Exchange (CZCE) and agreed to put the Futures Trading Regulations of China Zhengzhou Commodity Exchange on trial. On 1993-May-28, CZCE launched futures contracts including Wheat, Corn, Soybean, green Bean (mung Bean) and Sesame. The first day saw the trading volume of 1 854 contracts. The screen-based trading system developed by CZCE was used. Thus the cash market and the futures market were coexisted and mutually promoted each other. On 1994-January-12, the contracts of peanut kernel, soybean meal, red bean were introduced, and afternoon session was opened. On 1994-January-17, sesame futures trading was suspended. On 1994-February-21, late polished round-grained non-glutinous rice contracts were listed. On 1994-March-18, the contracts of aluminum, cotton yarn, 92-3-year treasury note and 93-3-year treasury note were introduced. On 1994-September-01, 92-5-year treasury note and 94-2-year treasury note contracts were added for trading. On 1994-September-19, CZCE started to use the new version of computer system for trading and clearing. In October 1994, the China Securities Regulatory Commission (CSRC) issued a notice to rectify more than fifty futures markets in China and eleven futures markets including CZCE were approved to be experimental markets. In May 1995, CSRC dispatched a document to ratify green bean to be CZCE's listed contract, while contracts of Wheat, Corn, Peanut kernel, Soybean meal, Sesame, cotton yarn, 425# ordinary Portland cement, 5 mm colorless float glass and plywood were trial futures contracts. In June 1995, CZCE joined International Options Market Association (IOMA). In November 1995, the Zhengzhou Building Material Exchange was disbanded. Its futures contracts such as 425# ordinary Portland cement, 5mm colorless float glass and plywood were merged into CZCE. In June 1996, Jicheng Cash Net was established and put into use. National grain and oil wholesale price index were compiled and issued, which filled the gaps in this area in China. 1996 – Futures contracts of Soybean, red bean, aluminium and treasury notes were deleted from the Exchange. 1997 – the management of clearing data was computerized. In February 1997, CZCE supplied investors with telephone and facsimile inquiring system. In May 1997, CZCE announced to open the trading session for Wheat and Soybean meal futures from 01:30 to 02:50 pm. 1997 – CZCE moved to Weilai Manson, 69 Weilai Road, Zhengzhou 450008, Henan Province. In November 1997, the management of CZCE's warehouse receipts was computerized and all warehouse receipts can be exchanged. In August 1998, CSRC rectified futures markets in China. China Zhengzhou Commodity Exchange changed its name into Zhengzhou Commodity Exchange (ZCE) which was one of the three futures exchanges in China approved to remain operation. The contracts of Wheat, green Bean, red Bean and Peanut kernel were approved to be continuing listed. In December 1998, Cash Grain & Oil Trading Network of CZGWM was put into operation. In August 1999, ZCE signed Agreements on the Clearing of Futures Trading with the Industry and Commerce Bank of China and the Bank of Communications respectively. On 2000-February-01, ZCE launched hard white winter Wheat futures contracts, which standard complies with the new National Standard for Wheat. On 2001-January-01, ZCE and ZCGWM were separated into two independent organizations. In September 2001, the first physical delivery by exchange for physicals (EFPs) of hard white winter Wheat was carried out. In December 2002, ZCE introduced electronic system for capital management among member firms. On 2003-March-28, ZCE listed strong gluten Wheat contracts. The newly revised Constitution of Zhengzhou Commodity Exchange, Rules and Regulations of Zhengzhou Commodity Exchange and detailed rules were issued. On 2004-April-14, ZCE signed Agreement of Client Service for Futures E-payment with Bank of China, Henan Branch, in Zhengzhou. On 2004-June-01, cotton futures contracts were listed on ZCE. On 2004-June-28, ZCE transmitted the Implement Measure of Notarizing Cotton Testing for Futures Delivery, issued by China Fiber Testing Bureau on 2004-June-26, to its member firms and appointed cotton delivery warehouses. On 2005-March-23, ZCE announced to supply investors with mobile message service. Investors may inquire about market information such as prices, open interest, volume, and so on. On 2005-April-29, ZCE starts to use the new computer trading system which is the fourth generation of computer trading system developed by ZCE. On 2005-September-01, the Zhengzhou Commodity Exchange formally launched mock trading of options on futures. Zhengzhou, or Cheng-chou, or Chengxian city in central Honan Province (sheng), China. The provincial capital of Honan since 1954. The Zhengzhou Commodity Exchange (ZCE) is the first experimental futures market approved by the State Council. Being one of the four futures exchanges in China, the ZCE is under the vertical management of China Securities Regulatory Commission. The ZCE performs its functions according to Futures Trading Management Ordinance, Futures Exchanges Regulation and implements self-regulation in accordance with Zhengzhou Commodity Exchange Constitution, Zhengzhou Commodity Trading Rules. The ZCE abides by the principle of openness, fairness, justness and good faith, provides a marketplace with associated facilities and services for the futures trading and regulates the futures trading. The ZCE adopts membership system. The General Meeting is the governing body of the Exchange and consists of all members. Being the standing body of the General Meeting, the Board of Directors has seven special committees, including Supervision Committee, Trading Committee, Delivery Committee, Finance Committee, Intercession Committee, Member Qualification Examination Committee and Technology Committee. At the end of 2009, 215 members, coming from 27 provinces, municipalities and autonomous regions in China, had been registered. Among the total, futures company member (173) accounts for 80%, non-futures company (42) accounts for 20%. The General Manager is the legal representative of the Exchange. According to the needs of business, the ZCE sets up 16 inner departments, including General Office, R&D Department, Marketing Department, Marketing Department, Trading Department, Delivery Department, Clearing Department, Market Surveillance Department, Media Relations and Information Department, Legal Affairs Department, IT Department, IT Department, Finance Department, HR Department, Internal Audit Office and Administration Department. The ZCE adheres to standardized operation, strengthens the market surveillance, safely organizes the futures trading and deepens the market functions. At present, the functions and roles of the listed products on ZCE in promoting the economic development of the related industries have been recognized by all sectors of the society. The listed products on ZCE includes Wheat (involving strong gluten wheat and hard white winter Wheat), Cotton, white Sugar, pure terephthalic acid, Rapeseed oil and early long-grain nonglutinous Rice. The ZCE carries out some futures trading systems such as Margin Requirement System, Daily Price-limit System, Mark-to-the-market System, Physical Delivery System and so on. It actively adapts to market demands, Constantly optimizes system arrangements, updates regulatory philosophy, enriches regulatory means, controls and resolves market risks timely and ensures the market operates smoothly. The ZCE has fully functional electronic system, including trading, settling, delivery, risk control, news release, member services and so on. The transaction order may be directly input by the members and investors through the internet and the long-distance transaction system. The information of trading on ZCE has been released through Reuters, Bloomberg, Shihua and so on. The ZCE pays great attention to international communion and

cooperation with the foreign futures exchanges. It joined the International Options Market Association in 1995 and signed the Memorandum of Understanding successively with Kansai Agricultural Commodity Exchange, Chicago Mercantile Exchange, Tokyo Grain Exchange, Multi-commodity Exchange of India, Ltd., Montreal Exchange, Abuja Securities and Commodity Exchange and NYSE Euronext Group. The ZCE establishes information exchange mechanism with 8 exchanges and institutions, exchanges market information regularly, further expands influence of ZCE in international market. Adhering to the principle of openness, fairness and justness and unswervingly keeping to the road of scientific development as core concept, keeping honesty, aggressiveness, security and efficiency as basic purpose, bringing market functions serving real economy into full play as direction, ZCE will strengthen the construction of the market-based fundamental systems, perfect risk prevention mechanism, reinforce market front-line supervision, guarantee the safety of information technology systems, keep to improving the market performance quality and development quality and work hard to make ZCE an modernized futures exchange with importance and influence both in the internal and international markets. / Чжэнчжоу столица Провинции Хэнань, расположенной в Центральном Китае. ZIBELINE = ЗИБЭЛИН (или ЗИБЭЛАЙН, или ЗИБЕЛИН) – Zibeline is a heavily napped coating fabric with the long sleek nap brushed, steamed, and pressed in one direction, thus hiding the underlying satin weave. Zibeline is usually made of a combi nation of such fibers as camel hair or mohair with wool, cotton, or a man-made fiber as the largest percentage. Zibeline is:- (1) a thick lustrous soft fabric of wool and other animal hair, such as mohair, having a silky nap. (2) The sable or its fur. Zibeline:- wool from cross-bred yarns. A soft lustrous wool fabric with mohair, Alpaca, or Camel's hair. Satin weave. The fabric is napped then steamed and pressed. The nap is long and lies in one direction. It is very lustrous and sleek. It may or may not be given a soft finish and feel. It is usually strong colored and sometimes strippings (removal of color) is noted in the cloth. Named for the 'zibeline' a small animal found in Siberia. It belongs to the sable family and has fine black fur. Zibeline is a thick, soft fabric with a long nap. It is usually made of wool, such as mohair or alpaca, but can also be made from the hair of other animals, such as camels. Zibeline can also refer to either the sable (Martes zibellina) or its pelt, which zibeline was originally made from. Zibeline can also refer to a heavy silk fabric with a twill weave, very similar to Mikado. / Зибелин – шерстяная ткань с пышным ворсом. Zibeline = Соболь или Соболиный Мех. Торговое название ткани:- (1) с лоснящимся ворсом, сработанная из мериносовой основы и аппаратного утка с примесью верблюжьей шерсти; (2) с основой из гребенной шерсти и кашмирового утка; и (3) с хлопчатобумажной основой и кашмировым утком.

ZIG ZAG = ЗИГ ЗАГ – (1) In technical analysis Zig Zag is a filter that only shows moves of a predetermined percentage. Any moves of less than the set percentage are ignored. This is the same as Swing Charts. In technical analysis Zig Zag is a corrective three-wave pattern in Elliott Wave comprised of two five-wave moves separated by a three-wave move. / В техническом анализе биржевых рынков Зиг Заг является поправочной трёх волновой моделью на графике индикатора Волны Элиота, состоящей из двух пяти-волновых ходов, разделённых между собой трёх-волновым ходом. Зиг Заг – очерёдность коротких линий, следующих друг за другом под одинаковыми углами и в которой каждая вторая линия является параллельной. Зиг заг издавна является основным элементом многих орнаментов и узоров керамики и фарфора. Швейные машины в состоянии очень быстро накладывать зигзагообразные швы. Форму зигзага имеет лезвие пилы. Зигзаговыми элементами отличаются флаги Катара и Бахрейна.

(2) The Zig Zag (Basic) overlay is a collection of straight lines that connect significant tops and bottoms on a price graph. It takes a single parameter that specifies the percentage that the price must move in order for a new 'zig' or 'zag' to appear. Zig Zag does not predict trends and should not be used on its own.

ZIMBABWEAN DOLLAR = ЗИМБАБВИЙСКИЙ ДОЛЛАР – Zimbabwean Dollar (ZWD):- ZWD is the three-letter currency ISO code representing the currency of Zimbabwe which is commonly known as the Zimbabwean Dollar or Zim Dollar or Z$ for short. This currency was suspended on 12 April 2009. This was once one of the worlds strongest currencies when it replaced the Rhodesian Dollar in 1980 but due to economic mismanagement, hyperinflation and political turmoil it has become one of the world's least valued currency units. Inflation had risen from an annual rate of 32% in 1998 to an estimate (IMF) of 150 000% in December 2007. It reached an official estimated high of 231 000 000% in July 2008. This represented a state of hyperinflation, and the central bank introduced a new 100 billion Dollar note. As of November 2008, unofficial figures put Zimbabwe's annual inflation rate at 516 quintillion per cent, with prices doubling every 1.3 days. Zimbabwe's inflation crisis during 2009 was the second worst inflation spike in history. The only other country to exceed this was Hungary in 1946 when prices doubled every 15.6 hours. In an effort to combat inflation and foster economic growth the Zimbabwean Dollar was suspended indefinitely on 12 April 2009. Zimbabwe now allows trade in the United States Dollar and various other currencies such as the South African Rand, Euro, and Botswana Pula. The use of the US Dollar yielded enormous results within weeks as inflation actually fell below zero to –3 percent.

ZIMMER FLATBED PRINTING MACHINE = ЦИММАВСКАЯ ПЛОСКОПЕЧАТНАЯ МАШИНА – Zimmer Flatbed Printing Machine (Peter Zimmer) is a carpet printing machine that uses flat screens and dual, metal-roll squeegees. The squeegees are operated by electromagnets to control the pressure applied. The unit also has a steamer for dye fixation. The Zimmer flatbed machine is normally used for carpets of low to medium pile heights. Very precise designs are possible, but speeds are slower than with rotary screen printers. J. ZINC = ЦИНК – Zinc is a metallic chemical element, it has a white color with a bluish tinge. It has a high resistance to atmospheric corrosion and a major use is as a protective coating for iron and steel sheet and wire. Galvanised sheets are a prime example. The melting point of zinc is 419 °C. Zinc (from German:- Zink) is a chemical element in the periodic table that has the symbol Zn and atomic number 30. Zinc is the fourth most common metal in use, trailing only iron, aluminium, and copper in annual production. Zinc is chemical element, low-melting metal of Group IIb (zinc group) of the periodic table, essential to life, and one of the most widely used metals. Atomic number 30, atomic weight 65.39, melting point 420 °C (788 °F), boiling point 907 °C (1 665 °F), density 7.133 (25 °C), valence 2, and electronic config. 2-8-18-2 or (Ar)$3d^{10}4s^2$. Zinc was known in Roman times only in combination with copper as the alloy brass. The metallurgists of India seem to have isolated the individual metal as early as the XIII century, and those of China had achieved large-scale production of zinc by the XVI century. In the West, commercial zinc production got under way by the middle of the XVIII century in England under the leadership of William Champion. Occurrence, Uses, And Properties:- a little more abundant than copper, zinc makes up an average of 65 grams (2.3 ounces) of every ton of the Earth's crust. The chief zinc mineral is the sulfide sphalerite (zincblende), which, together with its oxidation products smithsonite and hemimorphite, constitute nearly all of the world's zinc ore. Native zinc has been reported from Australia, New Zealand, and the United States, but no occurrence is well authenticated. Zinc is an essential trace element in the human body, where it is found in high concentration in the red blood cells as an essential part of the enzyme carbonic anhydrase, which promotes many reactions relating to carbon dioxide metabolism. The zinc present in the pancreas may aid in the storage of insulin. Zinc is a component of some enzymes that digest protein in the gastrointestinal tract. Zinc deficiency in nut-bearing and fruit trees causes such diseases as pecan rosette, little leaf, and mottle leaf. Zinc functions in the hemosycotypsin of snails' blood to transport oxygen in a way analogous to iron in the hemoglobin of human blood. Metallic zinc is produced by roasting the sulfide ores and then either leaching the oxidized product in sulfuric acid or smelting it in a blast furnace. Zinc is won from the leach solution by electrolysis or is condensed from the blast furnace gas and then distilled of impurities. For specific information on the mining, recovery, and refining of zinc. The major uses of zinc metal are in galvanizing iron and steel and in making brasses and alloys for die-casting. The negative electrode (outside can) in one common type of electric dry cell is composed of zinc. Freshly cast zinc has a bluish silver surface but slowly oxidizes in air to form a grayish protective oxide film. Highly pure zinc (99.99 percent) is ductile; the so-called prime western grade (99.8 percent pure) is brittle when cold but above 100 °C (212 °F) can be rolled into sheets that remain flexible. Zinc crystallizes in the hexagonal close-packed structure. When iron and zinc together are exposed to a corrosive medium, they constitute an electrolytic cell, and the zinc is attacked (oxidized to the Zn^{2+} ion) preferentially because of its higher electrode potential. This so-called Sacrificial Protection, coupled with the much greater corrosion resistance of zinc under atmospheric conditions, is the basis for galvanizing. Natural zinc is a mixture of five stable isotopes:- ^{64}Zn (48.6 percent), ^{66}Zn (27.9 percent), ^{67}Zn (4.1 percent), ^{68}Zn (18.8 percent), and ^{70}Zn (0.6 percent). Compounds:- in chemical compounds, zinc exhibits almost exclusively a +2 oxidation state. A few zinc (I) compounds have been reported, but never any compounds of zinc (III) or higher. Zinc oxide, ZnO, is one of the most important zinc compounds. It can be prepared in a state of high purity and in a variety of crystal shapes and sizes by burning zinc vapor in air. Because of its high heat conductivity and capacity, zinc oxide is frequently incorporated into rubber as a heat dissipater. In the crystal of zinc oxide, the lattice (i.e. the orderly structure formed by the ions) is an open one in which the zinc and oxygen ions occupy only 44 percent of the volume. Defects can be created in the lattice by specific treatments such as the introduction of foreign atoms or of zinc atoms in the vacancies of the lattice. Such treatment of zinc oxide crystals produces various electrical, photoelectrical, and catalytic properties. As a result, zinc oxide is used as a semiconductor in the production of phosphors for television tubes and fluorescent lamps. Its effects on the reactivity of many compounds make it useful as a catalyst in such operations as the manufacture of synthetic rubber and methanol. It is also used in paints, cosmetics, plastics, pharmaceuticals, and printing inks. Because under the influence of light the electrical conductivity of zinc oxide can be increased many times, it is employed in certain photocopying processes. Zinc sulfate, $ZnSO_4$, is an intermediate compound in the production of zinc from its ores by the electrolytic process. It is used as a weed killer, in the manufacture of viscose rayon, and in dyeing, in which it functions as a mordant. Zinc chloride, $ZnCl_2$, can be prepared by a direct reaction or by evaporating the aqueous solution formed in various reactions. It is strongly deliquescent (water-absorbing) and is utilized as a drying agent and as a flux. In aqueous form it is used as a wood preservative. Zinc sulfide, ZnS, occurs in nature as the mineral sphalerite and may be prepared by treating solutions of zinc salts with hydrogen sulfide. It was long used as a white pigment but has been gradually replaced by titanium dioxide. Zinc sulfide has luminescent properties when activated by the addition of small quantities of copper, manganese, silver, or arsenic and so has been used in X-ray screens, in luminous dials for clocks and watches, and in fluorescent lights. / и крапчатый лист (mottle leaf). Цинк, на Латинском Zincum, обозначение:- Zn, является химическим элементом II Группы Периодической Системы Менделеева. Атомный номер 30, атомная масса 65.39. Серебристо-белый металл плотностью 7.133 г/$см^3$, $t_{пл}$ 419.5 °C. Содержание цинка в земной коре $8.3 \cdot 10^{-3}$%. На воздухе покрывается защитной плёнкой оксида. Образует 66 минералов – цинкит, сфалерит и другие. Важнейший минерал – сфалерит. Входит в состав полиметаллических руд. Применяют в щелочных аккумуляторах, для цинкования, получения многочисленных сплавов, например, латуни. Содержание цинка в почве около 50 мг/кг. В живых организмах входит в состав ферментов, участвующих в дыхании, белковом, углеводном и нуклеиновом обменах. Цинк необходим для развития яйцеклетки и зародыша растений (в его отсутствие не образуются семена). У животных цинк повышает жизнедеятельность половых желёз, влият на формирование скелета плода. В организм растений цинк поступает из почвы и воды, животных – с пищей. Среднее содержание цинка в живых организмах – тысячные доли процента. Недостаток цинка вызывает хлороз растений, розеточность листьев. Особенно чувствительны к недостатку цинка Плодовые культуры, Кукуруза, Сахарная Свёкла. На почвах, бедных цинком (карбонатных, переизвесткованных и других), применяют цинковые удобрения. В биогеохимических провинциях с недостатком цинка в рацион сельскохозяйственных животных включают сульфат цинка или сернокислый цинк ($ZnSO_4$; 0.15–0.25 мг цинка на 1 кг живой массы). Цинк (Латинское название Zincum), Zn, химический элемент II Группы Периодической Системы Менделеева; атомный номер 30, атомная масса 65.38, синевато-белый металл. Известно 5 стабильных изотопов с массовыми числами 64, 66, 67, 68 и 70; наиболее распространён ^{64}Zn (48.89%). Искусственно получены 9 радиоактивных изотопов, среди которых наиболее долгоживущий ^{65}Zn с периодом полураспада $T_{1/2}$ = 245 суток (сут); применяется как изотопный индикатор. Историческая Справка:- сплав цинка с медью – латунь – был известен ещё древним Грекам и Египтянам. Чистый цинк долгое время не удавалось выделить. В 1746 Немецкий химик Андреас Зигисмунд Маграф (Andreas Sigismund Marggraf; 1709-Март-03–1782-Август-07) разработал способ получения металла прокаливанием смеси его окиси с углём без доступа воздуха в глиняных огнеупорных ретортах с последующей конденсацией паров цинка в холодильниках. В промышленном масштабе выплавка цинка началась в XVII веке. Распространение В Природе:- среднее содержание цинка в земной коре (кларк) – $8.3 \cdot 10^{-3}$% по массе, в основных изверженных породах его несколько больше ($1.3 \cdot 10^{-2}$%), чем в кислых ($6 \cdot 10^{-3}$%). Известно 66 минералов цинка, важнейшие из них – цинкит, сфалерит, виллемит, каламин, смитсонит, франклинит $ZnFe_2O_4$. Цинк – энергичный водный мигрант; особенно характерна его миграция в термальных водах вместе с Pb; из этих вод осаждаются сульфиды цинка, имеющие важное промышленное значение. Цинк также энергично мигрирует в поверхностных и подземных водах; главным осадителем для него

является H_2S, меньшую роль играет сорбция глинами и другие процессы. Цинк – важный биогенный элемент; в живом веществе содержится в среднем $5 \cdot 10^{-4}$% цинка, но имеются и организмы-концентраторы (например, некоторые Фиалки). Физические И Химические Свойства:- цинк – металл средней твёрдости. В холодном состоянии хрупок, а при 100–150 °C весьма пластичен и легко прокатывается в листы и фольгу толщиной около сотых долей миллиметра. При 250 °C вновь становится хрупким. Полиморфных модификаций не имеет. Кристаллизуется в гексагональной решётке с параметрами a = 2.659 4Å, c = 4.937 0Å. Атомный радиус 1.37Å; ионный Zn^{2+} – 0.83Å. Плотность твёрдого цинка 7.133 г/см^3 (20 °C), жидкого 6.66 г/см^3 (419.5 °C); $t_{пл}$ 419.5 °C; $t_{кип}$ 906 °C. Температурный коэффициент линейного расширения $39.7 \cdot 10^{-6}$ (20–250 °C), коэффициент теплопроводности 110.950 Вт/(м·К) 0.265 кал/см·сек·°C (20 °C), удельное электросопротивление $5.9 \cdot 10^{-6}$ Ом·см (20 °C), удельная теплоёмкость цинка 25.433 кДж/(кг·К) [6.07 кал/г·°C)]. Предел прочности при растяжении 200–250 МН/м^2 (2 000–2 500 кгс/см^2), относительное удлинение 40–50%, твёрдость по Бринеллю 400–500 МН/м^2 (4 000–5 000 кгс/см^2). Цинк диамагнитен, его удельная магнитная восприимчивость – $0.175 \cdot 10^{-6}$. Внешняя электронная конфигурация атома Zn $3d^{10}4s^2$. Степень окисления в соединениях +2. Нормальный окислительно-восстановительный потенциал, равный 0.76 в, характеризует цинк как активный металл и энергичный восстановитель. На воздухе при температуре до 100 °C цинк быстро тускнеет, покрываясь поверхностной плёнкой основных карбонатов. Во влажном воздухе, особенно в присутствии CO_2, происходит разрушение металла даже при обычных температурах. При сильном нагревании на воздухе или в кислороде цинк интенсивно сгорает голубоватым пламенем с образованием белого дыма окиси цинка ZnO. Сухие фтор, хлор и бром не взаимодействуют с цинком на холоду, но в присутствии паров воды металл может воспламениться, образуя, например, $ZnCl_2$. Нагретая смесь порошка цинка с серой даёт сульфид цинка ZnS. Сульфид цинка выпадает в осадок при действии сероводорода на слабокислые или аммиачные водные растворы солей Zn. Гидрид ZnH_2 получается при взаимодействии $LiAlH_4$ с $Zn(CH_3)_2$ и другими соединениями цинка; металлоподобное вещество, разлагающееся при нагревании на элементы. Нитрид Zn_3N_2 – чёрный порошок, образуется при нагревании до 600 °C в токе аммиака; на воздухе устойчив до 750 °C, вода его разлагает. Карбид цинка ZnC_2 получен при нагревании цинка в токе ацетилена. Сильные минеральные кислоты энергично растворяют цинк, особенно при нагревании, с образованием соответствующих солей. При взаимодействии с разбавленными HCl и H_2SO_4 выделяется H_2, а с HNO_3 – кроме того, NO, NO_2, NH_3. С концентрированными HCl, H_2SO_4 и HNO_3 цинк реагирует, выделяя соответственно H_2, SO_2, NO и NO_2. Растворы и расплавы щёлочей окисляют цинк с выделением H_2 и образованием растворимых в воде цинкатов. Интенсивность действия кислот и щёлочей на цинк зависит от наличия в нём примесей. Чистый цинк менее реакционноспособен по отношению к этим реагентам из-за высокого перенапряжения на нём водорода. В воде соли цинк при нагревании гидролизуются, выделяя белый осадок гидроокиси $Zn(OH)_2$. Известны комплексные соединения, содержащие цинк, например, $[Zn(NH_3)_4]SO_4$ и другие. Получение:- цинк добывают из полиметаллических руд, содержащих 1–4% Zn в виде сульфида, а также Cu, Pb, Ag, Au, Cd, Bi. Руды обогащают селективной флотацией, получая цинковые концентраты (50–60% Zn) и одновременно свинцовые, медные, а иногда также пиритные концентраты. Цинковые концентраты обжигают в печах в кипящем слое, переводя сульфид цинка в окись ZnO; образующийся при этом сернистый газ SO_2 расходуется на производство серной кислоты. От ZnO к Zn идут двумя путями. По пирометаллургическому (дистилляционному) способу, существующему издавна, обожжённый концентрат подвергают спеканию для придания зернистости и газопроницаемости, а затем восстанавливают углём или коксом при 1 200–1 300 °C:- $ZnO + C = Zn + CO$. Образующиеся при этом пары металла конденсируют и разливают в изложницы. Сначала восстановление проводили только в ретортах из обожжённой глины, обслуживаемых вручную, позднее стали применять вертикальные механизированные реторты из карборунда, затем – шахтные и дуговые электропечи; из свинцово-цинковых концентратов цинк получают в шахтных печах с дутьём. Производительность постепенно повышалась, но цинк содержал до 3% примесей, в том числе ценный кадмий. Дистилляционный цинк очищают ликвацией (то есть отстаиванием жидкого металла от железа и части свинца при 500 °C), достигая чистоты 98.7%. Применяющаяся иногда более сложная и дорогая очистка ректификацией даёт металл чистотой 99.995% и позволяет извлекать кадмий. Основной Способ Получения:- цинк – электролитический (гидрометаллургический). Обожжённые концентраты обрабатывают серной кислотой; получаемый сульфатный раствор очищают от примесей (осаждением их цинковой пылью) и подвергают электролизу в ваннах, плотно выложенных внутри свинцом или винипластом. Цинк осаждается на алюминиевых катодах, с которых его ежесуточно удаляют (сдирают) и плавят в индукционных печах. Обычно чистота электролитного цинка 99.95%, полнота извлечения его из концентрата (при учёте переработки отходов) 93–94%. Из отходов производства получают цинковый купорос, Pb, Cu, Cd, Au, Ag; иногда также In, Ga, Ge, Tl. Применение:- около половины производимого цинка расходуется на защиту стали от коррозии. Поскольку цинк в ряду напряжений стоит до железа, то при попадании оцинкованного железа в коррозионную среду разрушению подвергается цинк. Благодаря хорошим литейным качествам и низкой температуре плавления из цинка отливают под давлением различные мелкие детали самолётов и других машин. Сплавы меди с цинком – латунь, нейзильбер, а также цинк со свинцом и другими металлами широко применяются в технике. Цинк даёт с золотом и серебром интерметаллиды (нерастворимые в жидком свинце) и поэтому цинк применяется для рафинирования свинца от благородных металлов. В виде порошка цинк служит восстановителем в ряде химико-технологических процессов:- в производстве гидросульфита, при осаждении золота из промышленных цианистых растворов, меди и кадмия при очистке растворов цинкового купороса и другом. Многие соединения цинка являются люминофорами, например, три основных цвета на экране кинескопа зависят от ZnS·Ag (синий цвет), ZnSe·Ag (зелёный цвет) и $Zn_3(PO_4)_2$·Mn (красный цвет). Важными полупроводниковыми материалами служат соединения цинка типа $A^{II}B^{VI}$ – ZnS, ZnSe, ZnTe, ZnO. Магнитно-мягкими ферритами отечественных марок МН и НН являются соответственно марганец- и никель-цинковые шпинели. Наиболее распространённые химические источники тока (например, Лекланше элемент, окисно-ртутный элемент) имеют в качестве отрицательного электрода Цинк. Цинк, от Немецкого слова Zink (термин встречается в трудах учёных XVI–XVII веков), химический элемент, символ Zn (на Латинском языке Zincum), атомный номер 30, атомная масса 65.39. Цинк – металл синевато-белого цвета; плотность 7 130 кг/м^3; $t_{пл}$ 419.5 °C. В природе цинк широко распространён; важнейший минерал – сфалерит (цинковая обманка). Цинк применяется для покрытий, предохраняющих стальные изделия от коррозии (цинкование), и для изготовления многих сплавов, например, с медью (латунь). Соединения цинка используются для приготовления красок:- оксид ZnO – цинковых белил, сульфид ZnS – литопона, нетоксичных и обладающих хорошей кроющей способностью. ZnO применяют для получения фотокопировальной бумаги, как наполнитель резин, в фармацевтической промышленности, ZnS в смеси с CdS (люминесцентные свойства) – при изготовлении телевизионных трубок и экранов. Цинковые Руды:- основной минерал сфалерит, кроме того, каламин, смитсонит и другие. Цинковая руда является составной частью полиметаллических и медноколчеданных руд, реже образуют самостоятельные залежи. Главные добывающие страны:- Австралия, Канада, Перу, США, Япония. Мировое производство цинка в концентрате в 1982 составляло 4.8 миллиона тонн. Цинкование, нанесение слоя цинка или его сплава на поверхность металлических изделий или насыщение цинком поверхностных слоёв для защиты от коррозии. Цинкование:- (i) покрытие стальных и чугунных изделий слоем цинка для предохранения от коррозии, производится горячим способом (опусканием изделий в ванну с расплавленным цинком), электролитически, распылением расплавленного цинка; и (ii) диффузионное насыщение (также для предохранения от коррозии) цинком поверхностных слоёв стальных изделий.

ZINC DEFICIENCY = НЕДОСТАТОК ЦИНКА – Zinc Deficiency:- insufficient zinc in the plant tissue causes the midribs of the young rice leaves to become chlorotic especially at the base, brown blotches and streaks occur in the lower leaves, growth is stunted, tillering is reduced, leaf blade size is reduced, and uneven growth occurs. Zinc Deficiency may occur in association with bacterial stunt, lack of mycorrhiza or inadequate zinc in the soil. Plants are stunted, young leaves cup upwards and develop inter-veinal yellowing. Spots may also develop within the yellow areas. Zinc Deficiency is characterized by growth retardation, loss of appetite, and impaired immune function. In more severe cases, zinc deficiency causes hair loss, diarrhea, delayed sexual maturation, impotence, hypogonadism in males, and eye and skin lesions. Weight loss, delayed healing of wounds, taste abnormalities, and mental lethargy can also occur. Many of these symptoms are non-specific and often associated with other health conditions; therefore, a medical examination is necessary to ascertain whether a zinc deficiency is present. Zinc nutritional status is difficult to measure adequately using laboratory tests due to its distribution throughout the body as a component of various proteins and nucleic acids. Plasma or serum zinc levels are the most commonly used indices for evaluating zinc deficiency, but these levels do not necessarily reflect cellular zinc status due to tight homeostatic control mechanisms. Clinical effects of zinc deficiency can be present in the absence of abnormal laboratory indices. Clinicians consider risk factors (such as inadequate caloric intake, alcoholism, and digestive diseases) and symptoms of zinc deficiency (such as impaired growth in infants and children) when determining the need for zinc supplementation. / Недостаток Цинка может проявиться в связи с бактериальным воздействием, отсутствием микоризы или незначительного содержания цинка в почве. Растения становятся низкорослыми, молодые листья тянутся вверх и у них развивается междужильное пожелтение. Внутри жёлтых зон могут также возникнуть пятна. Недостаток Цинка:- среднее содержание цинка в живых организмах – тысячные доли процента. Недостаток цинка вызывает хлороз растений, розеточность листьев. Особенно чувствительны к недостатку цинка Плодовые культуры, Кукуруза, Сахарная Свёкла. На почвах, бедных цинком (карбонатных, переизвесткованных и других), применяют цинковые удобрения. В биогеохимических провинциях с недостатком цинка в рацион сельскохозяйственных животных включают сульфат цинка или сернокислый цинк ($ZnSO_4$; 0.15–0.25 мг цинка на 1 кг живой массы). Избыток фосфора препятствует поступлению цинка в растения и сопровождается симптомами недостатка цинка. Недостаток Цинка чаще наблюдается на щелочных почвах. Сахарная свекла менее чувствительна к этому элементу. Листья растений слабо развиваются, а хлороз обнаруживается на молодых центральных листочках. Жёлтые и белые пятна развиваются на верхней стороне листа между прожилками. Затем межпрожилковая поверхность листа высыхает, появляется некроз, хотя прожилки остаются зелеными и поднятыми. Внесение сульфата цинка на ранних стадиях дефицита способствует быстрому исчезновению пятнистости. При Недостатке Цинка у нижней части растений листья становятся серо-зелёными, затем бронзовыми или жёлто-коричневыми, края их буреют. Вдоль жилок образуются пятна, ткань разлагается. Молодые листья очень мелкие и покрыты жёлтыми точками или равномерно хлоротические. Затем появляется некроз, и листовая пластинка отмирает. Корневая система слаборазвита и буреет. Стебли тонкие и деревянистые. Недостаток цинка наиболее проявляется у тыквы, кабачка, патиссона. У томата образуются мелкие листья, они желтеют или покрываются мелкими пятнами. Все симптомы преимущественно проявляются на молодых листьях. Недостаток Цинка наблюдается на кислых почвах. При недостатке цинка наблюдаются пожелтение и пятнистость листьев, появляются бронзовые оттенки в окраске листьев, междоузлия становятся короткими а листья маленькими и толстыми. Признаки недостатка цинка появляются на всём растении или локализованы на старых нижних листьях. Вначале на листьях нижних и средних ярусов, а потом и на всех листьях растения, появляются пятна серо-бурого и бронзового цвета. Ткань таких участков как бы проваливается и затем отмирает. Молодые листья становятся мелкими и покрываются жёлтыми крапинками, края листьев могут закручиваться кверху. Пятна могут появлятся также на стержнях листьев и на стеблях. При таких признаках растение необходими подкормить микроудобрением, содержащим цинк (Zn). Источником цинка является микроудобрение сульфат цинка.

ZINC DIALKYL DITHIOPHOSPHATE = ДИАЛКИЛ ДИТИОФОСФАТ ЦИНКА – Zinc Dialkyl Dithiophosphate (ZDDP) is the most commonly used anti-wear additive in motor oils. It contains both zinc and phosphorus components that work together to provide anti-wear protection and minimize lubricant breakdown. ZDDP also exhibits mild extreme-pressure protection. Some motorists think that increased zinc content equals increased wear protection. Although somewhat true, the statement can be misleading. First, the mere presence of zinc doesn't mean it is in the form of ZDDP. In other forms, zinc offers additional oxidation protection but little wear protection. Second, other factors influence the oil's ability to control wear, such as its viscometrics and base stocks. While zinc is important in protecting against wear, the greatest concern should be in using a well-balanced oil that is designed for its intended application. How ZDDP Works:- as temperatures rise and surfaces come closer together, ZDDP decomposes, and the resulting chemistry protects critical metal surfaces. When parts move during operation, any sliding or rolling motion takes place on top of or within the ZDDP anti-wear film, which reduces metal-to-metal contact. This is especially important in modified engines with flat-tappet camshafts because the engine is creating more horsepower than it was designed for, which puts more stress on the engine. High-tension valve springs, often used in racing applications, also increase the potential for cam wear and require additional ZDDP. Negative Effects of ZDDP:- Since all engines benefit from oils with superior anti-wear properties, it seems obvious to formulate all motor oils with high levels of ZDDP. Generally, high levels of ZDDP result in volatile phosphorus being transferred from the combustion chamber to the catalytic converter. Phosphorus can blind over the catalytic reaction sites in the converter, making it less efficient in turning carbon monoxide (CO) into carbon dioxide (CO_2). The EPA mandates that catalytic converters operate as designed for more than 100 000 miles. As a result, phosphorus is limited for newer motor oil specifications. When the American Petroleum Institute (API) and the International Lubricants Standardization and Approval Committee (ILSAC) established phosphorus limits at 0.10 percent weight in 1996, motorists and enthusiasts wondered if it would negatively affect wear protection. The move to reduce phosphorus may not have taken into consideration high-performance and modified engines or engines that had yet to be broken in. The debate intensified in 2004 when the API and ILSAC further limited phosphorus to 0.08 percent, where it remains today. Despite the reduction, there is no evidence to suggest modern engines using today's lower-ZDDP oils are suffering widespread wear. A properly formulated oil that meets API SN and ILSAC GF-5 is capable of delivering reliable wear protection in stock engines. In fact, testing shows that AMSOIL Signature Series 5W-30 Synthetic Motor Oil (ASL) offers outstanding wear protection in the Four-Ball Wear Test (ASTM D4172 Mod.). When it comes to older engines – particularly those equipped with flat-tappet cams – and engines modified for increased performance, the challenges to delivering adequate wear protection become more pronounced. Flat-Tappet Cams:- the design of flat-tappet cams makes them especially vulnerable to wear. As the name indicates, the tappet – or lifter – is flat. During operation the surface of the cam lobe slides rapidly over the surface of the tappet, producing high friction and temperatures. The camshaft and lifters are responsible for triggering the precisely tuned movements of the valvetrain. Without the protective film barrier provided by ZDDP, the cams and lifters wear from the force of operation, negatively affecting cam and valve operation. Because most V-8 engines of the muscle car era came standard with flat-tappet cams, the problem is especially prevalent to classic-car and hot-rod owners. In these applications, modern oils, such as AMSOIL synthetic motor oils, are capable of providing adequate wear protection after the engine has been broken in. But due to variables like severity of service and level of modification, AMSOIL primarily recommends high-ZDDP oils in these applications, such as Z-ROD® Synthetic Motor Oil (ZRF, ZRT) or DOMINATOR® Synthetic Racing Oil (RD20, RD30, RD50, RD60). When breaking in a rebuilt or high-performance engine, AMSOIL recommends AMSOIL Break-In Oil (BRK), which contains high levels of ZDDP for added wear protection. Demand for High-ZDDP Oils:- as the debate over ZDDP levels and engine wear

continues, many enthusiasts and engine builders will continue to seek out high-ZDDP specialty oils. Zinc Dialkyl Dithiophosphate (ZDDP) is an antiwear additive found in many types of hydraulic and lubricating fluids. These additives are used by companies that manufacture lubricants and greases for use in industrial, professional and consumer applications. Formulated products containing ZDDP have a wide range of uses including initial-fill by original equipment manufacturers and service-fill for on-road and off-road vehicles. They are also used in industrial gear applications. Physical and Chemical Properties:- physical and chemical properties vary somewhat depending on the specific alkyl group(s). ZDDP additives are viscous liquids with molecular weights in the 400 to 2000 Dalton range. Their vapor pressures and fugacity are low. They are slightly-to-moderately soluble in water. Thermal stability, anti-wear protection, hydrolytic stability and cost performance vary depending on the type of ZDDP. Aryl type ZDDPs provide excellent thermal stability but are less effective in terms of antiwear protection and hydrolytic stability The secondary alkyl type provides the best antiwear protection and hydrolytic stability, but does not provide good thermal stability. Health Effects:- the health hazards of ZDDP additives have been well-studied in animals. The primary occupational concern during manufacture or formulation is eye and/or skin irritation or corrosion. ZDDPs exhibit low acute toxicity via oral, dermal, and inhalation routes of exposure and are not skin sensitizers. In oral gavage repeat dose studies, ZDDP causes effects only at high doses, primarily due to irritation. They do not cause effects on fertility or development at doses that are not maternally toxic. The weight-of-evidence of genotoxicity testing indicates that ZDDPs are not mutagenic and do not cause larger chromosomal effects. While ZDDPs have not been tested in carcinogenicity studies, genotoxicity studies and studies of formulated products indicate that they are not carcinogenic. Environmental Effects:- the environmental hazards of ZDDP additives have been well-studied in vertebrate and invertebrate species. Based on available environmental fate and ecotoxicological data for daphnids, fish, and algae, they are considered to be toxic to aquatic wildlife with long lasting effects. ZDDPs are not readily biodegradable. Regulatory Information:- ZDDP additives currently are subject to the European Commission REACH (Registration, Evaluation, Authorisation and Restriction of Chemical substances) regulation. The registration and Chemical Safety Reports for ZDDP substances subject to 2010 reporting have been submitted to the European Chemicals Agency (ECHA) by Lubrizol. As noted in Lubrizol safety data sheets, ZDDPs have gained acceptance in major industrialized countries through global notifications. Exposure Potential:- ZDDPs are sold to industrial customers who formulate lubricants and greases. Workers in these industrial exposure scenarios can be exposed to ZDDP via dermal and inhalation routes. Some operations are conducted under elevated temperatures that increase the potential for inhalation exposure. Because formulated products contain low levels of ZDDP, the exposure potential for professional workers and consumers generally is much lower. The extent of exposure varies depending on use conditions such as closed systems and the duration and frequency of use. Risk Management:- Information on the safe handling of these products is disseminated through material safety data sheets provided to workers who make the products and who formulate lubricants and greases. These documents provide a broad range of safety information including hazard warnings and risk management measures. They note engineering controls, work practices and personal protective equipment that are needed during manufacture and formulation to control exposures. Good industrial hygiene practices, training and gloves are used to avoid skin contact. Half mask respirators are recommended for certain operations. Control of spills and environmental releases is important. Conclusion:- ZDDPs are designed to meet a wide range of performance needs. Their excellent physical and functional properties make them ideal for use in lubricants and greases where controlling oxidation and corrosion is important. Exposure of workers to ZDDP can cause irritation or corrosion to the eyes and/or skin; release to the environment is toxic to aquatic organisms with potential long-lasting effects. However, the use of appropriate engineering controls, work practices, personal protective equipment, and environmental release controls and practices provides effective risk management. Zinc Dialkyl Dithiophosphate (ZDDP) is a lubricating oil additive of exceptionally high thermal and hydrolytic stability. It is generally used with detergent, dispersant and acid neutralizing additives in engine oils. This additive provides oxidation, copper-lead bearing corrosion and wear control in diesel and gasoline engines. It is particularly effective under the severe temperature and load conditions encountered in highly supercharged diesel engines. ZINC FINGER PROTEIN = ЦИНКОВЫЙ ПАЛЬЦЕВИДНЫЙ БЕЛОК – Zinc Finger Protein (ZFP):- protein molecules (transcription factors) bearing at least one 'finger shaped' molecular appurtenance which acts to either repress, or to activate transcription, i.e. of the gene the 'finger' touches within DNA molecule. For example, nuclear receptors contain two zinc fingers which target those receptors to hormone response elements, i.e. specific DNA sequences that initiate the activation of applicable gene(s) for that receptor. Thus, zinc finger proteins could potentially be utilized in Functional Genomics, i.e. to study the specific function of a given gene. Zinc finger DNA-binding proteins possess two domains:- (i) a 'DNA recognition domain' which locates and binds itself to a specific DNA sequence; (ii) a 'functional domain' which initiates (or inhibits) transcription. / Цинкосодержащий Пальцевидный Белок – белок, активирующий или тормозящий транскрипцию генов.

ZINC FORMALDEHYDE SULFOXYLATE = ФОРМАЛЬДЕГИД СУЛЬФОКСИЛАТ ЦИНКА – Zinc Formaldehyde Sulfoxylate is a Color Index Reducing Agent 6, used for discharge. This discharge agent works best in mildly acid conditions, so it is preferred, over sodium formaldehyde sulfoxylate, for work on wool. It is also often used in discharge screen printing of garments. / Формальдегид Сульфоксилат Цинка является Восстановителем № 6 Индекса По Цвету, используемый для обесцвечивания. Этот обесцвечивающий агент лучше всего работает в слабо кислых условиях, так что он более предпочтителен для работы по шерсти в сравнении с формальдегидом сульфоксилатом натрия (sodium formaldehyde sulfoxylate). Он также часто используется при обесцвечивании трафаретной (или экранной) печати на швейных изделиях.

ZIONISM = СИОНИЗМ – Zionism:- Jewish nationalist movement that has had as its goal the creation and support of a Jewish national state in Palestine, the ancient homeland of the Jews (Hebrew:- Eretz Yisraʾel, 'the Land of Israel'). Though Zionism originated in eastern and central Europe in the latter part of the XIX century, it is in many ways a continuation of the ancient nationalist attachment of the Jews and of the Jewish religion to the historical region of Palestine, where one of the hills of ancient Jerusalem was called Zion. In the XVI and XVII centuries a number of 'messiahs' came forward trying to persuade Jews to 'return' to Palestine. The Haskala ('Enlightenment') movement of the late XVIII century, however, urged Jews to assimilate into Western secular culture. In the early XIX century interest in a return of the Jews to Palestine was kept alive mostly by Christian millenarians. Despite the Haskala, eastern European Jews did not assimilate and in reaction to tsarist pogroms formed the Ḥovevei Ẓiyyon ('Lovers of Zion') to promote the settlement of Jewish farmers and artisans in Palestine. A political turn was given to Zionism by Theodor Herzl, an Austrian journalist who regarded assimilation as most desirable but, in view of anti-Semitism, impossible to realize. Thus, he argued, if Jews were forced by external pressure to form a nation, they could lead a normal existence only through concentration in one territory. In 1897 Herzl convened the first Zionist Congress at Basel, Switzerland, which drew up the Basel program of the movement, stating that 'Zionism strives to create for the Jewish people a home in Palestine secured by public law'. The center of the movement was established in Vienna, where Herzl published the official weekly Die Welt ('The World'). Zionist congresses met yearly until 1901 and then every two years. When the Ottoman government refused Herzl's request for Palestinian autonomy, he found support in Great Britain. In 1903 the British government offered 6 000 square miles (15 500 square km) of uninhabited Uganda for settlement, but the Zionists held out for Palestine. At the death of Herzl in 1904, the leadership moved from Vienna to Cologne, then to Berlin. Prior to World War I Zionism

represented only a minority of Jews, mostly from Russia but led by Austrians and Germans. It developed propaganda through orators and pamphlets, created its own newspapers, and gave an impetus to what was called a ‘Jewish Renaissance’ in letters and arts. The development of the Modern Hebrew language largely took place during this period. The failure of the Russian Revolution of 1905 and the wave of pogroms and repressions that followed caused growing numbers of Russian Jewish youth to emigrate to Palestine as pioneer settlers. By 1914 there were about 90 000 Jews in Palestine; 13 000 settlers lived in 43 Jewish agricultural settlements, many of them supported by the French Jewish philanthropist Baron Edmond de Rothschild. Upon the outbreak of World War I political Zionism reasserted itself, and its leadership passed to Russian Jews living in England. Two such Zionists, Chaim Weizmann and Nahum Sokolow, were instrumental in obtaining the Balfour Declaration from Great Britain (November 02, 1917), which promised British support for the creation of a Jewish national home in Palestine. The declaration was included in Britain’s League of Nations mandate over Palestine (1922). In the following years the Zionists built up the Jewish urban and rural settlements in Palestine, perfecting autonomous organizations and solidifying Jewish cultural life and Hebrew education. In March 1925 the Jewish population in Palestine was officially estimated at 108 000, and it had risen to about 238 000 (20 percent of the population) by 1933. Jewish immigration remained relatively slow, however, until the rise of Hitlerism in Europe. Nevertheless, the Arab population feared Palestine eventually would become a Jewish state and bitterly resisted Zionism and the British policy supporting it. Several Arab revolts, especially in 1929 and 1936–39, caused the British to devise schemes to reconcile the Arab and Zionist demands. Hitlerism and the large-scale extermination of European Jews led many Jews to seek refuge in Palestine and many others, especially in the United States, to embrace Zionism. As tensions grew among Arabs and Zionists, Britain submitted the Palestine problem first to Anglo-US discussion for solution and later to the United Nations, which on November 29, 1947, proposed partition of the country into separate Arab and Jewish states and the internationalization of Jerusalem. The creation of the State of Israel on May 14, 1948, brought about the Arab-Israeli war of 1948–49, in the course of which Israel obtained more land than had been provided by the UN resolution, and drove out 800 000 Arabs who became displaced persons known as Palestinians. Thus 50 years after the first Zionist congress and 30 years after the Balfour Declaration, Zionism achieved its aim of establishing a Jewish state in Palestine, but at the same time it became an armed camp surrounded by hostile Arab nations and Palestinian ‘liberation’ organizations engaged in terrorism in and outside of Israel. During the next two decades Zionist organizations in many countries continued to raise financial support for Israel and to encourage Jews to immigrate there. Most Jews, however, reject the view propagated by many very Orthodox Jews in Israel that the Jews outside Israel were living in ‘exile’ and could live a full life only in Israel. / Ротшильд. Сионизм, от названия холма Сион в Иерусалиме, реакционное националистическое течение, возникшее в конце XIX века в Европе среди Еврейской буржуазии, в основу которого был положен мифический тезис о ‘расовом’ превосходстве и ‘исключительности’ Евреев. После образования в 1948 государства Израиль сионизм является официальной идеологией и основой государственной политики Израиля. Основное содержание современного сионизма – воинствующий шовинизм и крайний национализм, антикоммунизм и антисоветизм. Идеология сионизма выражает интересы крупной Еврейской буржуазии, тесно связанной с монополистическими кругами империалистических держав. Сионизм проповедует несостоятельную в научном отношении концепцию ‘единой Еврейской нации’, якобы объединяющей всех Евреев вне зависимости от того, в какой стране они живут. Сионисты, скрывая проимпериалистическую буржуазно-реакционную сущность сионизма призывают к так называемому ‘классовому сотрудничеству’, стремясь тем самым отвлечь трудящихся Евреев от борьбы с буржуазией, противопоставляют Евреев другим народам. Стремясь привлечь на сторону сионизма и подчинить своему влиянию прогрессивно настроенных Евреев в Израиле и особенно в других капиталистических странах, сионисты пытаются придать своим идеям ‘социалистическую’ окраску и изображают сионизм как один из видов национально-освободительного движения. В действительности программа и практика сионизма основаны на сотрудничестве с империализмом, полностью подчинены планам международного империализма и экспансионистским целям правящих кругов Израиля. Сионистская пропаганда и деятельность направлены против социалистических государств, антиимпериалистической и национально-освободительной борьбы народов. В 1975 на XXX сессии Генеральной Ассамблеи Организации Объединённых Наций (ООН) сионизм признан формой расизма и расовой дискриминации. Сионизм – наиболее реакционная разновидность Еврейского буржуазного национализма, получившая значительное распространение в XX веке среди Еврейского населения капиталистических стран. Современный сионизм – националистическая идеология, разветвлённая система организаций и политика, выражающая интересы крупной Еврейской буржуазии, тесно связанной с монополистической буржуазией империалистических государств. Основное содержание современного сионизма – воинствующий шовинизм, расизм, антикоммунизм и антисоветизм. Как политическое течение сионизм возник в конце XIX века. Он был призван отвлечь Еврейские трудящиеся массы от революционной борьбы, сохранить господство буржуазии над трудящимися. Во исполнение этих целей идеологи сионизма выдвинули планы решения ‘Еврейского вопроса’ путём создания с помощью великих держав ‘Еврейского государства’. Эта идея была изложена, в частности, в книге одного из идеологов сионизма Австрийского журналиста Теодора Герцля ‘Еврейское Государство’ (1896). В 1897 в Базеле состоялся 1-й сионистский конгресс, на котором была основана Всемирная Сионистская Организация (ВСО), провозгласившая официальной целью сионизма ‘создание для Еврейского народа правоохраняемого убежища в Палестине’. Идеологическая доктрина сионизма весьма эклектична. Она активнейшим образом использует многие догмы иудаизма, а также включает в себя трансформированные идеологами сионизма теории буржуазного национализма, социал-шовинизма и другое. Её основные положения сводятся к следующему:- Евреи различных стран мира представляют экстерриториальную ‘единую всемирную Еврейскую нацию’; Евреи – ‘особый’, ‘исключительный’, ‘избранный богом’ народ; все народы, среди которых живут Евреи, так или иначе – антисемиты; антисемитизм – явление ‘извечное’; ассимиляция, то есть слияние Евреев с окружающими их народами, ‘противоестественна и греховна’, Евреи-де имеют ‘исторические права’ на ‘земли библейских предков’ (Палестину и прилегающие к ней области), на которых им и надлежит сконцентрироваться и построить ‘чисто Еврейское’ ‘эгалитарное государство’. Идеологи сионизма пытаются доказать ‘неразрывную связь Евреев во всём мире’ с сионизмом, которому, где бы они ни находились, должны подчинять свои интересы. Ополитизированные догматы иудаизма о ‘богоизбранности’ и мессианстве Евреев, а также мифический тезис об их ‘исключительности’ составляют одну из основ имманентно присущего идеологии и практике сионизма крайнего национализма, шовинизма и расизма. Идеологи сионизма утверждают, что ‘еврейский вопрос’ – ‘вечный’, ‘особый’ и надклассовый вопрос. Сионисты всячески пропагандируют лживую идею классового мира между трудящимися Евреями и Еврейской буржуазией (‘все Евреи – братья’). Все формы классовой борьбы среди Евреев объявляются идеологами сионизма национальным предательством. При помощи демагогии и тактических манёвров сионисты всегда стремились и пытаются ныне скрыть антинародную реакционную сущность сионизма, выдавая его за ‘национально-освободительное движение мирового Еврейского народа’. После образования в 1948 по решению ООН Государства Израиль (на части территории Палестины) сионизм стал официальной государственной идеологией Израиля. Главными целями сионизма провозглашаются безусловная поддержка этого государства Евреями всего мира, собирание в Израиле Евреев со всего мира, обработка в сионистском духе Еврейского населения различных стран. Сионизм ставит задачу расширения этого государства до границ так называемого ‘Великого Израиля’. Для решения этой задачи сионисты используют тезис о ‘вечном антисемитизме’ и вместе с тем нередко прибегают сами к его разжиганию. Сионизм лежит в основе официальной государственной политики Израиля. Государство Израиль объявлено сионистами

родиной всех Евреев, где бы они ни жили и как бы ни относились к сионизму. На 28-м Конгрессе ВСО (состоялся в 1972 в Иерусалиме) в нарушение норм международного права было принято ‘коллективное обязательство всех национальных (имеются в виду сионистские и просионистские) организаций помогать Еврейскому государству при любых обстоятельствах и условиях, даже если это будет наталкиваться на противодействие соответствующих властей’ стран, где имеется Еврейское население. Главной линией сионизма всегда была и есть открытая и тайная борьба против социализма, международных коммунистических и национально-освободительных движений, Союза Советских Социалистических Республик (СССР) и других социалистических стран. Сразу после победы Октябрьской Революции 1917 в России сионизм развернул активную борьбу против молодого Советского государства. После 2-й Мировой Войны 1939–45, в условиях дальнейшего углубления общего кризиса капитализма, антикоммунизм и антисоветизм международного сионизма приняли ещё более широкие масштабы. Общее изменение соотношения сил в мире в пользу социализма, успешное решение национального (в том числе Еврейского) вопроса в бывшем СССР, последовательная поддержка Советским Союзом национально-освободительной борьбы Арабских народов – всё это вызывает усиление антисоветской и антикоммунистической сионистской пропаганды и деятельности. Международный сионизм стремится подорвать морально-политическое единство народов социалистических стран, оторвать граждан Еврейской национальности от участия в строительстве социализма и коммунизма, ведёт подрывные действия против разрядки международной напряжённости, в частности против начавшейся нормализации Советско-Американских отношений. Являясь одним из ударных отрядов империализма, колониализма и неоколониализма, международный сионизм активно участвует в борьбе против национально-освободительного движения народов Африки, Азии, Латинской Америки. На Ближнем Востоке сионистские правящие круги Израиля проводят политику агрессии и постоянной территориальной экспансии за счёт Арабских народов, и прежде всего Арабского народа Палестины. Эта политика превратила Израиль в империалистического жандарма на Ближнем Востоке, была главной причиной Арабо-Израильских военных конфликтов в 1948–49, 1956, 1967, 1973. Сионизм стал одним из основных союзников империализма в его глобальной борьбе против мирового освободительного движения. Идеологические концепции и политические планы сионизма проводятся в жизнь широко разветвлённой и строго централизованной системой сионистских и просионистских организаций, руководящие центры которых находятся в США и Израиле. Основной руководящий и координирующий центр международного сионизма – система ВСО – Еврейское Агентство (ЕА) для Израиля. Последнее занимается главным образом вопросами иммиграции Евреев в Израиль и представляет ВСО в отношениях с Израильским правительством. Высшим органом ВСО юридически является Всемирный Сионистский Конгресс; главную роль в ВСО играет группа деятелей, имеющих тесные связи с определёнными империалистическими кругами США. Исполком ВСО состоит из двух отделений – в Нью Йорке и Иерусалиме. ВСО направляет и контролирует деятельность сионистских организаций в более чем 60 капиталистических странах. Крупнейшие:- Всемирная Женская Сионистская Организация, Всемирная Федерация Всеобщих Сионистов, Всемирное Сионистское Рабочее Движение, Американская Сионистская Организация. Фактически под контролем ВСО находится формально несионистский Всемирный Еврейский Конгресс (ВЕК, созданный в 1936), организации которого действуют в 67 капиталистических странах. К этим центрам прямо или косвенно примыкает множество местных сионистских и просионистских организаций, общественных комитетов и прочих, составляющих единую систему международного сионизма. ВСО обладает крупными финансовыми фондами, которые предоставляют ему главным образом Еврейские монополисты; часть средств собирается путём поборов, в том числе и принудительных, среди Еврейского населения. Под контролем или влиянием сионистских организаций находится значительная часть средств массовой информации:- в их руках находится большое число издательств, радио- и телекомпаний, кинокомпаний (в США, Западной Европе, в ряде стран Латинской Америки, Африки, в Австралии). Международный сионизм всегда включал и ныне включает ряд различных идеологических течений, политических фракций и группировок:- сионисты-‘социалисты’, ‘политические сионисты’, ‘духовные сионисты’, ‘религиозные сионисты’, ‘общие сионисты’, ‘сионисты-ревизионисты’ (ныне фашистская партия Херут и родственные ей группировки) и другие, что лишь отражает специфические интересы отдельных слоёв Еврейской буржуазии и нисколько не меняет, а только маскирует его проимпериалистическую сущность. Разногласия между различными направлениями в сионизме по существу не выходят за рамки споров по тактическим вопросам и часто являются отражением борьбы в сионистской верхушке за влиятельные посты. Марксисты всегда отвергали и отвергают теорию и практику сионизма. Владимир Ильич Ленин вскрыл реакционную сущность сионизма, подчеркнув, что его догмы реакционны и ложны по своей сущности, противоречат интересам Еврейского пролетариата. Он подверг критике тезисы сионистов об особом характере Еврейского народа, об отсутствии якобы классовых различий у Евреев и мнимой общности их интересов, разъясняя, что цель подобных утверждений состоит в том, чтобы увести трудящиеся массы Евреев в сторону от общей классовой борьбы пролетариата. Международное коммунистическое движение разоблачает антинародный реакционный характер сионизма и деятельность сионистов во всех странах. В документе, принятом международным Совещанием коммунистических и рабочих партий в 1969, содержится призыв ‘... развернуть самое широкое движение протеста ... против расовой и национальной дискриминации, сионизма и антисемитизма, которые разжигаются капиталистическими реакционными силами и используются ими для политической дезориентации масс’. Последовательную борьбу против сионизма ведёт, в частности, Коммунистическая Партия Израиля (КПИ). Она убедительно показывает, что сионизм всегда использовался силами крайней реакции и империализмом, что идеология и практика сионизма противоречат интересам Еврейских трудящихся во всём мире и национальным интересам народа Израиля, что борьба против сионизма – жизненная необходимость как народа Израиля, так и всех прогрессивных сил. КПИ разоблачает якобы ‘внеклассовый’ подход сионистов к ‘Еврейскому вопросу’, доказывает, что этот вопрос может быть решен лишь при условии победы демократии и социализма, о чём свидетельствует опыт СССР и других социалистических стран. КПИ выступает за братство и дружбу трудящихся всех стран, против антисоветской клеветнической пропаганды и подрывной деятельности сионистских лидеров и правителей Израиля. По мере углубления общего кризиса капитализма на современном этапе всё более очевидным становится и кризис идеологии сионизма, несостоятельность всех его концепций:- подавляющее большинство Евреев отвергает сионистские догмы. Еврейское население СССР (за редким исключением), как и все народы Советского Союза и прогрессивные силы мира, решительно осуждает агрессивный политический курс сионистской правящей верхушки Израиля. 30-я Сессия Генеральной Ассамблеи ООН (Ноябрь 1975) квалифицировала сионизм как форму расизма и расовой дискриминации. Во всём мире усиливается закономерный и объективный процесс ассимиляции Евреев. Не только в Еврейских общинах стран Запада, но и среди Израильского населения растёт понимание того, что сионистская политика правящих кругов Израиля может привести его население к подлинной национальной катастрофе.

ZIP = ZONE IMPROVEMENT PLAN

ZIPPER = ЗАСТЁЖКА МОЛНИЯ – Zipper is a device for binding the edges of an opening such as on a garment or a bag. A zipper consists of two strips of material with metal or plastic teeth along the edges, and a sliding piece that draws the teeth into interlocking position when moved in one direction and separates them again when moved in the opposite direction. The idea of a slide fastener was exhibited by Whitcomb L. Judson at the World’s Columbian Exposition of 1893 in Chicago. Judson’s fastener, called a Clasp Locker,

was an arrangement of hooks and eyes with a slide clasp for closing and opening. Gideon Sundbäck, a Swedish engineer working in the United States, substituted spring clips in place of hooks and eyes and in 1912 produced his Hookless #2. In the same year a similar device was patented in Europe by Catharina Kuhn-Moos. In 1917 the US Navy equipped windproof flying suits with slide fasteners. In the late 1920s and early 1930s they appeared on clothing for both men and women. In 1923 B.G. Work of the B.F. Goodrich Company gave the name zipper to the slide fastener that had just been adopted for closing overshoes. Also known as Slide Fastener. Zipper:- the physical parts of the zipper are:- scoop teeth, chain, lock, pull tape, and slider. Zippers used in industrial clothing are metal or brass. Plastic zippers are used typical apparel garments. Zippers are used as a closure in pants, skirts, and dresses. Zipper is a garment closure made of interlocking teeth attached to strips of fabric known as the Zipper Tape. Zippers were originally made of metal, but are now available with polyester or nylon molded teeth on a woven or knit polyester tape. Most zippers are attached to garments by stitching the zipper tape to the garment seam. Invisible zippers do not show once they are attached to the garment because the teeth of an invisible zipper are covered by the zipper tape and hidden in the seam of the garment. Zippers come in every size and color and can be used functionally or decoratively. Zip (Britian) or Zipper (USA) is a device for bringing together or separating two rows of metal or plastic teeth by means of a sliding tab, used for fastening clothing. Zipper is a plastic or metal teeth joined together by a plastic or metal piece with a handle attached. Closes jackets/bags/flies. / Найлан^{T3} (Nylon^{TM}). Хгидеон Сундбэк (Gideon Sundbäck). Наверняка у каждого из нас есть хотя бы одна ‘молния’ на одежде или на сумке. Она простая в использовании, хотя бывает, что заедает в самый неподходящий момент. Без неё нельзя представить нашу повседневную жизнь. Большинство исследователей считает, что застёжке-молнии уже как минимум 110 лет, а, может быть, и больше. Первое её упоминание относится к 1851, когда Американский изобретатель швейной машины Илайэс Хау (Elias Howe) получил патент на ‘автоматическую, непрерывную застёжку для одежды’. Но тогда его изобретение (как это часто бывает с техническими новшествами) было слишком революционным для одежды и не нашло своего применения. Только через 44 года застёжка-молния (clasp locker (застёжка-замочек), ставшая позже всемирно известной как ‘зиппер’) ещё раз была запатентована – Американским изобретателем пневматического трамвая Виткомом Эл. Дьжадсэном (Whitcomb L. Judson). Подтолкнуло его к неожиданному изобретению исключительно высокое чувство дружбы к близкому другу. Так и родилась застёжка для ботинок, с которой можно было справиться одной рукой. Изначально она состояла из двух цепочек, на каждой из которых чередовались крючки с дырочками, зацеплявшиеся друг за друга при помощи подвижной металлической скрепки – язычка. Технология изготовления ‘зиппера’ была слишком сложна, и поэтому стоил он поначалу в два раза дороже самих ботинок. Однако Шведский инженер Гхидеон Сундбэк (Gideon Sundbäck) в Декабре 1913 предложил принципиально новую практичную и удобную застёжку, которая без изменений существует и по сей день, и 90-летний юбилей которой мы отметили 29 Апреля 2003. Первоначально застёжка-молния так и использовалась исключительно в ботах и галошах. Само слово ‘зиппер’, которым на Западе до сих пор обозначают эту застёжку, возникло лишь в 1925. Считается, что его придумал Английский писатель Гилбёт Фрэнькау (Gilbert Frankau), подражая звуку застегивающегося механизма:- ‘Зип – и открыто, зип – и закрыто!’ В начале 1930-х Итальяно-Французский модельер Эльса Скиапарэлли (Elsa Schiaparelli) начала экспериментировать с ‘молнией’ на детских вещах, поскольку многие дети не умеют застёгивать пуговицы, то новая застёжка достаточно быстро прижилась. Но по-настоящему она ворвалась в нашу жизнь в 1937, когда истёк патент Сандбэка и использовать её в своих работах решил Французский модельер Жон-Клёд Житруа (Jean-Claude Jitrois). Исключительно для эпатажа он впервые поместил ‘зиппер’ на ширинку мужских брюк. Публика пришла в экстаз. Продажи рванулись вверх. И новая застёжка буквально захватила весь рынок одежды. В послевоенную эпоху ‘зиппер’ превратился в настоящий символ сексуальной революции и свободы! В 1953 вышел фильм ‘Дикарь’ (The Wild One), в котором главный герой в исполнении Американского актёра Малэна Брэндо (Marlon Brando) эффектно застёгивал и расстёгивал ‘молнии’ в самых неожиданных местах. Картина имела дикий успех. А на одном лишь звуковом эффекте от расстёгивания и застёгивания металлической ‘молнии’ зиждется самый сильный эротический эпизод в фильме Польского режиссёра Андржэя Вайды (Andrzej Wajda) ‘Охота на мух’ (Polowanie na muchy). Ясно, что после этого застёжка-молния (или ‘зиппер’) неизбежно должна была придти в женскую моду. Причём именно на женской одежде она обрела декоративные функции. ‘Молния’ позволяет сделать силуэт одежды более элегантным, а обтягивающие фигуру вещи с такой застежкой выглядят, словно вторая кожа. К тому же ‘зиппер’ дарит дамам самим моделировать одежду ‘под себя’. Например, вертикальная ‘змейка’ по всей длине юбки позволяет её владелице самой регулировать разрез, насколько хватает смелости. И всё же, наигравшись и натешившись техническим новшеством, большинство ведущих дизайнеров одежды ограничили применения новой застёжки исключительно утилитарными функциями. Лишь изредка ‘молния’ начинала жить своей особой жизнью, приобретая самостоятельное значение в мире высокой моды. Она редко выходила на самые верхние строчки в хит-параде актуальных деталей, но, появившись, не могла не привлечь к себе внимания. Так, Зимой 2007 классические маленькие чёрные платья от Гуччи (Gucci) были украшены многочисленными металлическими ‘молниями’ разной длины, создав совершенно новый силуэт. Сезон Весна-Лето/2003 также приветствует появление застёжки-молнии в качестве самостоятельного декоративного элемента. Причин тут несколько. Это и ориентир на подростковую моду в качестве примера для взрослых (а, как известно, подростки обожают ‘молнии’), и практичность самых хитовых вещей (в жаркую погоду так здорово одним движением расстегнуть стесняющий тебя комбинезончик или жакет), возвращение в моду байкерских тенденций. Как бы то ни было, в том сезоне ‘молнии’ появлялись на самых неожиданных вещах, в самых неожиданных местах и при использовании самых неожиданных материалов. У Прада (Prada) это парча, у Люи Вито (Louis Vuitton) – платья с бантиками в стиле 1960-х, у Томи Хилфигё (Tommy Hilfiger) – открытый топик с бретелями, у элегантного классического Эмпорио Армани (Emporio Armani) – тренч и укороченные спортивные жакеты с трикотажной отделкой, у Ацуро Таяма (Atsuro Tayama) – даже традиционное Восточное кимоно, у Ги Лярош (Guy Laroche) – несколько рядов параллельных молний на плаще и брюках, у Марка Дьжейкобза (Marc Jacobs), Мартин Сибо (Martine Sitbon), Ла Пэрла (La Perla), Мани (Marni) – комбинезоны, у Михэль Корс (Michael Kors) – чёрная с белыми молниями куртка в комплекте с мини-юбкой, которая также украшена декоративной застёжкой-молнией контрастного цвета. Молнии появляются в таких местах, куда их может забросить только настоящий взрыв буйной фантазии великого кутюрье. Например, в коллекции Moschino ‘молнии’ появилась даже на прозрачной вуалетке. А чисто декоративная ‘молния’ на сапогах от Этро (Etro) расположена на внутренней стороне обуви, где нам её привычнее видеть, а на внешней. На блузах, платьях, брюках и топиках застёжки-молнии сегодня выполняют и своеобразную творческую функцию, как раз помогая их владелицам самим моделировать силуэт. Длинные ‘молнии’ расположены так, что могут сделать больше или меньше разрез на юбке Йил Сандэр (Jil Sander), увеличить асимметрию подола Пол Смис (Paul Smith), уменьшить или увеличить глубину декольте на блузе Хэльмут Ланн (Helmut Lang), превратить брюки в штаны-‘бермуды’ или микро-шорты (Бобёри (Burbery)).

Z–MODEL = ЗИ.–МОДЕЛЬ (или МОДЕЛЬ ЗЭД.) – Z-Model:- the Z-score formula for predicting bankruptcy was published in 1968 by Edward I. Altman (New York University (NYU) Stern's Department of Finance Professor; Stern = Leonard N. Stern), who was, at the time, an Assistant Professor of Finance at New York University. The formula may be used to predict the probability that a firm will go into bankruptcy within two years. Z-scores are used to predict corporate defaults and an easy-to-calculate control measure for the financial distress status of companies in academic studies. The Z-score uses multiple corporate income and balance sheet values to measure the financial health of a company. Estimation of The Formula:- the Z-score is a linear combination of four or five common business ratios, weighted by coefficients. The coefficients were estimated by identifying a set of firms which had declared bankruptcy and then collecting a matched sample of firms which had survived, with matching by industry and approximate size (assets). Altman applied the statistical method of discriminant analysis to a dataset of publicly held manufacturers. The estimation was originally based on data from publicly held manufacturers, but has since been re-estimated based on other datasets for private manufacturing, non-manufacturing and service companies. The original data sample consisted of 66 firms, half of which had filed for bankruptcy under Chapter 7. All businesses in the database were manufacturers, and small firms with assets of < USD1 million were eliminated. The original Z-score formula was as follows:- $Z = 1.2T1 + 1.4T2 + 3.3T3 + 0.6T4 + 0.999T5$; where, T_1 = Working Capital / Total Assets:- measures liquid assets in relation to the size of the company; T_2 = Retained Earnings / Total Assets:- measures profitability that reflects the company's age and earning power; T_3 = Earnings Before Interest and Taxes / Total Assets:- measures operating efficiency apart from tax and leveraging factors. It recognizes operating earnings as being important to long-term viability; T_4 = Market Value of Equity / Book Value of Total Liabilities:- adds market dimension that can show up security price fluctuation as a possible red flag; and T_5 = Sales / Total Assets:- standard measure for total asset turnover (varies greatly from industry to industry). Altman found that the ratio profile for the bankrupt group fell at –0.25 avg, and for the non-bankrupt group at +4.48 avg. Precedents:- Altman's work built upon research by accounting researcher William Beaver and others. In the 1930s and on, Mervyn and others had collected matched samples and assessed that various accounting ratios appeared to be valuable in predicting bankruptcy. Altman's Z-score is a customized version of the discriminant analysis technique of Sir Ronald Aylmer Fisher (1936). William Beaver's work, published in 1966 and 1968, was the first to apply a statistical method, t-tests to predict bankruptcy for a pair-matched sample of firms. Beaver applied this method to evaluate the importance of each of several accounting ratios based on univariate analysis, using each accounting ratio one at a time. Altman's primary improvement was to apply a statistical method, discriminant analysis, which could take into account multiple variables simultaneously. Accuracy and Effectiveness:- in its initial test, the Altman Z-Score was found to be 72% accurate in predicting bankruptcy two years before the event, with a Type II error (false negatives) of 6% (Altman, 1968). In a series of subsequent tests covering three periods over the next 31 years (up until 1999), the model was found to be approximately 80–90% accurate in predicting bankruptcy one year before the event, with a Type II error (classifying the firm as bankrupt when it does not go bankrupt) of approximately 15–20% (Altman, 2000). From about 1985 onwards, the Z-scores gained wide acceptance by auditors, management accountants, courts, and database systems used for loan evaluation (Eidleman). The formula's approach has been used in a variety of contexts and countries, although it was designed originally for publicly held manufacturing companies with assets of more than USD1 million. Later variations by Altman were designed to be applicable to privately held companies (the Altman Z_1-Score) and non-manufacturing companies (the Altman Z_2-Score). Neither the Altman models nor other balance sheet-based models are recommended for use with financial companies. This is because of the opacity of financial companies' balance sheets and their frequent use of off-balance sheet items. There are market-based formulas used to predict the default of financial firms (such as the Merton Model), but these have limited predictive value because they rely on market data (fluctuations of share and options prices to imply fluctuations in asset values) to predict a market event (default, i.e. the decline in asset values below the value of a firm's liabilities). Original Z-Score Component Definitions Variable Definition Weighting Factor:- T_1 = Working Capital / Total Assets; T_2 = Retained Earnings / Total Assets; T_3 = Earnings Before Interest and Taxes / Total Assets; T_4 = Market Value of Equity / Total Liabilities; and T_5 = Sales / Total Assets. (1) Z_1-Score Estimated For Private Firms:- T_1 = (Current Assets − Current Liabilities) / Total Assets; T_2 = Retained Earnings / Total Assets; T_3 = Earnings Before Interest and Taxes / Total Assets; T_4 = Book Value of Equity / Total Liabilities; and T_5 = Sales/ Total Assets. Z_1 Score Bankruptcy Model:- $Z_1 = (0.717 \times T1) + (0.847 \times T2) + (3.107 \times T3) + (0.420 \times T4) + (0.998 \times T5)$. ZODIAC = ЗОДИАК – (1) Zodiac:- in astronomy and astrology, a belt around the heavens extending 9° on either side of the ecliptic, the plane of the earth's orbit and of the sun's apparent annual path. The orbits of the moon and of the principal planets (except Pluto) also lie entirely within the zodiac. The 12 astrological signs of the zodiac are each considered to occupy 1/12 (or 30°) of its great circle. These signs no longer correspond to the astronomical constellations in which the sun actually appears. The constellations are irregular in size and shape, and the sun regularly passes through one constellation (Ophiuchus) that is not considered a member of the zodiac. Because most of the constellations through which the ecliptic passes represent animals, the ancient Greeks called its zone Zōdiakos Kyklos, 'Circle of Animals', or Ta Zōdia, 'The Little Animals'. The size and number of zodiacal constellations varied in antiquity and became fixed only with the development of mathematical astronomy. The list below gives the constellations of the zodiac, with the dates of the sun's passage through them in the era when their boundaries were fixed. These dates are still used for the astrological signs, though precession of the equinoxes has shifted the constellations eastward, e.g., on January 01 the direction of the sun is now in Sagittarius instead of Capricornus. The history of the symbols is unknown; they seem to appear first in Greek manuscripts of the late Middle Ages. Название 'Зодиак' связано с тем, что большинство зодиакальных созвездий ещё с древних времён носит названия животных. Через зодиакальные созвездия проходит также видимый путь планет Солнечной системы и Луны. Ещё в Древней Греции зодиакальные созвездия были выделены в особую группу и каждому из них был присвоен свой астрономический знак. Знаками соответствующих созвездий были обозначены также и точки весеннего (созвездие Овна) и осеннего (Весы) равноденствий и точки летнего (Рак) и зимнего (Козерог) солнцестояний. Вследствие прецессии эти точки за прошедшие 2 000 лет переместились из упомянутых созвездий, однако присвоенные им древними Греками обозначения сохранились. Сохранились и названия:- тропик Рака (Северный тропик), тропик Козерога (Южный тропик), соответствующие летнему и зимнему солнцестояниям в ту эпоху. Созвездия Скорпиона и Стрельца видны в Южных районах бывшего Союза Советских Социалистических Республик (СССР), остальные – на всей его территории.

ZOI = ZONE OF INCORPORATION

ZOMBIE = ЗОМБИ – (1) Zombies are companies that earn just enough money to continue operating and service debt, but are unable to pay off their debt. Such companies, given that they just scrape by meeting overhead (wages, rent, interest payments on debt, for example), tend to be unable to invest to spur growth, are generally subject higher borrowing costs, and may be one event, market disruption or poor quarter away from insolvency or a bailout. As such, zombies are especially dependent on banks for financing, which may be viewed as a kind life support. Zombie companies are also known as the Living Dead or Zombie Stocks. Breaking Down Zombies:- Zombies often fail, falling victim to the high costs associated with debt or certain operations, such as research and development. They may lack the resources for capital investment, which would create growth. If a zombie company employed so many people that its failure would become a political issue, it may be deemed 'too big to fail'. Given that many analysts expect that zombies will eventually be unable to meet their financial obligations, such companies are considered riskier investments and will therefore see their share prices suppressed. Zombies were first spoken of in reference to companies in Japan during the country's 'Lost Decade' of the 1990s, following the bursting of its asset price bubble. During this perio companies were dependent on bank backing to remain in operation even though they were bloated, inefficient or failing. Economists argue that the economy would have been better served by allowing such poorly performing companies to fail. The term Zombies was picked up again in 2008 in response to US government bailouts that were part of the Troubled Asset Relief Program (TARP). Zombies:- What Creates Them? While the ranks of zombie companies are small, years of loose monetary policy highlighted by quantitative easing, high leverage and historically low interest rates have contributed to their growth. Economists argue that such policies preserve inefficiencies while stifling productivity, growth and innovation. When the market shifts, zombies will be the first to fall victim, unable to meet their basic obligations as rising interest rates make their debt more expensive to service. Meanwhile, successful companies, which were less able to build on their success because of tight credit, may feel any downturn more than they should. While keeping zombies on life support may preserve jobs, economists note that using such resources is misguided because it impedes growth at successful firms and therefore inhibits job creation. Zombies And Investing:- Because a zombie's life expectancy tends to be highly unpredictable, zombie stocks are extremely risky and are not suitable for all investors. For example, a small biotech firm may stretch its funds extremely thin by concentrating its efforts in research and development in the hope of creating a blockbuster drug. If the drug fails, the company can go bankrupt within days of the announcement. On the other hand, if the drug is successful, the company could profit and reduce its liabilities. In most cases, however, zombie stocks are unable to overcome the financial burdens of their high burn rates and most eventually go bankrupt. Given the lack of attention paid to this group, there can often be interesting opportunities for investors who have a high risk tolerance and are seeking speculative opportunities. Zombie:- companies that continue operation while they await merger or closure, even though they are insolvent and bankrupt. Zombie Company is a term used to describe an uncompetitive company that needs a bailout to successfully operate or an indebted company that is only able to repay interest on its debt (interest-coverage ratio of 1 or less). Zombie companies generate enough cash flow to only pay back the interest on the debt and are unable to reduce the actual principal amount. Therefore, zombie companies do not have excess cash or capacity and are stagnant, which means they are too weak to invest or grow. Zombie companies heavily depend on low interest rates to survive. Due to governments and central banks trying to stabilize their economies after a financial crisis, commercial banks are pressured to extend credit and use low interest rates. The Origin Of Zombie Companies:- The term Zombie Company originated in Japan to describe companies that were only generating enough cash to pay interest on their debts. After the collapse of the Japanese asset price bubble in late 1991, Japanese banks continued to support weak or failing firms instead of letting them go bankrupt. This contributed to what is known as the 'Lost Decade', a period of economic stagnation in Japan. In 2008, during the Global Financial Crisis, the term regained popularity and was used to describe companies that were bailed out by the US Troubled Asset Relief Program (TARP). External Risks To A Zombie Company:- A sudden change in the business or economic environment can kill zombie companies. If the economy strengthens, companies that are more successful can quickly take advantage of the opportunities and leave zombie companies behind. Unable to take advantage of these opportunities, consumer demand for their products or services will decrease and zombie companies will eventually encounter significant trouble competing with other companies. As the existence of zombie companies depends on creditors, a hike in interest rates will wipe out a significant number of zombie firms. The cost of debt will increase and the companies will be unable to meet their interest obligations. The Effect Of Zombie Companies On The Economy:- Zombie companies are seen as a barrier to productive growth as the survival of weak companies contribute to lowering the average overall productivity. Economists argue that zombie companies are detrimental to society as they take up market share and lock up talent ('scarce resources') that should be available to more successful and dynamic companies. Without cash to reinvest, a zombie company is unable to grow and is inefficient. Zombie companies are 'uncompetitive survivors' and contribute to lower productivity in the global economy. Although zombie companies adversely affect the economy, some companies play an important role in the economy. For example, a zombie company may be bailed out by the government simply because the company employs a large number of people. If the company were to go bankrupt, the massive job losses could cause a significant societal impact. Zombie Startups:- A zombie start-up is a company that receives initial funding but does not receive further investment from investors. A significant number of start-ups become zombie startups – unable to succeed past the early investments. These startup companies have a short-term plan to secure an early investment but lack a long-term plan for growth. As these companies mature, the lack of long-term planning becomes apparent and the performance of the company drops. Investors then do not see these startups as attractive and thus, do not allocate additional funds. The company becomes a zombie startup – a company that is still operating after the initial funding runs out but does not actually grow. / Компании, продолжающие осуществлять свои операции в то время, пока они ожидают поглощение или закрытие, хотя они на данный момент являются неплатёжеспособными или в стадии

банкротства. Зомби – компании, которые продолжают действовать, даже если они неплатёжеспособны или фактически банкроты. Например, в период массовой несостоятельности ссудо-сберегательных ассоциаций, когда многие из них понесли многомиллионные убытки из-за неудачных вложений в недвижимость, такие компании продолжали действовать, ожидая предложения слиться с другим финансовым институтом или закрытия по решению Корпорации по Разрешению Трастов (Resolution Trust Corporation). Такие компании помимо термина Зомби называются ещё и Живущим Мертвецом (Living Dead) или Разумным Мертвецом (Brain Dead).

(2) Zombie is a system that has been taken over using Remote Control Software. Zombies are often used to send spam or to attack remote servers with an overwhelming amount of traffic, a Distributed Denial-of-Service (DDoS) Attack. A collection of many zombies comprise a botnet. See also Bot. / Зомби это система, которая была поглощена с помощью Программного Продукта с Дистанционным Контролем (Remote Control Software). Зомби часто используются для рассылки бестолковых сообщений, так называемого спама, или для атаки на отдалённые серверы с целью подавления объёма обмена данными, так называемого трафика. Атаки последнего типа относятся к Атакам на Распространяемый Отказ в Обслуживании (Distributed Denial-of-Service (DDoS) Attack). Скопление большого количества зомби составляет повреждённую сеть (botnet). Зомби, или 'живые мертвецы', являются неотъемлемой частью жизни Карибской нации на Гаити. Последователи культа вуду считают зомби трупами, которых вернули к жизни с помощью чёрной магии. Труп будто бы оживает благодаря силе бога-змеи или входящего в него питона. Мертвец, теперь ставший зомби, все ещё считается человеческим существом однако лишён речи, воли и суждений. Тем не менее зомби способен к автоматическим действиям, может ходить и исполнять простые команды. Это состояние похоже на транс или на сон. Описания живых мертвецов весьма красочны. Иногда взломщики используют сеть компьютеров-зомби для атак на определённый вэб-сайт или сервер. Делается это очень просто:- злоумышленник приказывает всем компьютерам ботнета многократно обращаться к данному сайту, что приводит к резкому возрастанию нагрузки на сервер и замедляет открытие страниц для настоящих посетителей. Иногда трафик возрастает настолько, что сайт полностью отключается. Такая технология называется 'распределённые атаки типа 'отказ в обслуживании'' (Distributed Denial of Service, DDoS). Некоторые особенно хитрые ботнеты используют для атаки даже незаражённые компьютеры. Взломщик посылает команду к атаке своей армии зомби, а каждый из зомбированных компьютеров отправляет запрос на соединение незаражённому компьютеру-рефлектору. С точки зрения рефлектора, запрос отправляет не зомби, а компьютер конечной жертвы атаки. Рефлектор отправляет запрошенные данные целевому компьютеру, который в результате чего начинает работать гораздо медленнее или вообще отключается из-за многочисленных ответов на запросы, которых не посылал. С точки зрения жертвы, выглядит так, будто систему атакуют рефлекторы. С точки зрения рефлекторов, система-жертва сама запрашивает пакеты. Компьютеры-зомби при этом остаются в тени, не говоря уже о самом взломщике. Список пострадавших от DDoS-атак включает в себя немало громких имен – достаточно упомянуть корпорацию Microsoft, ставшую жертвой DDoS-атаки 'MyDoom'. Взломщики нападали и на другие ведущие Интернет-компании, в том числе, Эмэзэн (Amazon), Си.Эн.Эн. (CNN), Яху (Yahoo) и иБэй (eBay). Названия DDoS-атак варьируются от забавных до прямо-таки пугающих:- (i) Ping of Death (Ping смерти):- боты создают огромные пакеты данных и отправляют их жертвам; (ii) Mailbomb (Почтовая Бомба):- боты рассылают огромную массу электронных писем, обрушивая тем самым почтовые серверы; (iii) Smurf Attack (Отмывание):- боты отправляют сообщения ICMP (Internet Control Message Protocol – протокол управляющих сообщений Интернета) рефлекторам; и (iv) Teardrop (Слеза):- боты оправляют фрагменты недопустимого пакета, атакованная система пытается собрать их воедино, и это приводит к фатальному сбою. Если армия компьютеров-зомби начинает DDoS-атаку на систему, у её администратора почти не остаётся способов предотвратить катастрофу. Если ограничить количество трафика, допускаемого на сервер, это скажется не только на зомби, но и на рядовых пользователях. Обнаружив источник атаки, можно воспользоваться фильтрованием трафика, но поскольку многие компьютеры-зомби скрывают или подменяют свои адреса, сделать это очень нелегко.

ZONATE = ОКАЙМЛЁННОЕ (или ОПОЯСАННОЕ, или ПОЛОСАТОЕ, или ПОЛОСЧАТОЕ, или ЗОНИРОВАННОЕ) – Zonate:- in biology, having different colors, textures, or other patterns form a pattern of rings, bands, or stripes. In biology, having or appearing to have multiple zones, such as of color or texture. Zonate:- marked with zones, as of color or texture. Having concentric rings, like a target. Zonate:- having a zoned appearance, usually referring to a mushroom cap that has concentric color bands that give it a zoned appearance. Marked with or arranged in zones. / Имеющий концентрические круги как мишень. Маркированный или расположенный в зонах. Расположенный в один ряд.

ZONATUS = ЗОНАТУС (или ОПОЯСАННОЕ) – Zonatus:- with concentric markings. / с концентрическими расцветками. Видовое название Зонатус (Zonatus), происходит от Латинского аналога слова Полоса (Зона), и связано с наличием на боках самцов рыб характерных вертикальных полос в верхней части тела.

ZONE = ЗОНА – (1) Zone is area, belt or district extending about a certain point defined for transport and/or charge purpose. Zone is a distinct geographic region exhibiting characteristics distinct from neighbouring regions. / Под Зоной, от Греческого слова Zonē, означающее Пояс, понимается участок, область, пояс, полоса чего-либо, обладающие определённым качественным признаком (например, пограничная зона, зона молчания, зоны Френеля и другие). Под Зоной понимается площадь, пояс или округ, окружающий определённый пункт, установленный в целях перевозки и/или сборов. Полоса, пространство между какими-либо границами; территория, участок, характеризующийся определёнными признаками.

(2) Zones are locations in the warehouse where usage is determined by the characteristics of the product being stored such as special handling, or special inventory management requirements.

(3) Zone:- xxxxx. See also Empowerment Zone and Enterprise Community (EZ/EC) Program.

(4) Zone:- xxxxx. See also Control Zone.

ZONE CHARGE = ЗОНАЛЬНЫЙ СБОР – Zone Charge is an extra fee charged for crossing a predetermined boundary. / Зональный Сбор это сверх плата, взимаемая за пересечение предопределённой границы.

ZONED = ОПОЯСАННЫЙ – Botanical term Zoned, which is used in color variegation, is the same as ocellated, but the concentric bands more numerous. Ocellated:- a broad spot of some color has another spot of a different color within it. Leaf lower surface, Leaf upper surface (color variegation). Compare with Ocellated. / Ботанический термин, используемый в отношении цветовой окраски, означающий то же самое, что и глазчатый (ocellated), но концентрические полосы у которого более многочисленны. Глазчатый (или пятнистый):- широкое пятно одного цвета, которое имеет внутри себя другое пятно отличающегося цвета. Сравните с Глазчатое (Ocellated).

ZONE HAULAGE RATE = ЗОНАЛЬНАЯ СТАВКА ПОДВОЗА (или СТАВКА ЗОНЫ НАЗЕМНОЙ ДОСТАВКИ) – Zone Haulage Rate is the rate for which the carrier will undertake the haulage of goods or containers between either the place of delivery and the

carrier's appropriate terminal. Such haulage will be undertaken only subject to the terms and conditions of the tariff and of the carrier's Combined Transport Bill of Lading. / порядки и условия .

ZONE IMPROVEMENT PLAN = ПЛАН ЗОНАЛЬНОГО УСОВЕРШЕНСТВОВАНИЯ – Zone Improvement Plan (ZIP) is a system to simplify sorting and delivery of mail, consisting of a number of five digits (the so-called ZIP-Code) for identification of the state, city or district, and the postal zone in the USA delivery areas. In 1943, the US Post Office Department implemented a system of postal zoning that was used until the debut of the new ZIP Code system in 1963. Pre-1960's Zoning:- The concept of postal zoning, or assigning numbers based on geographic regions, was not new to the 1960's ZIP Code campaign. The basic idea of postal zoning came into being in 1943, in the midst of World War II. At this time, US annual mail volume was growing steadily (the years between 1940 and 1943 saw an increase from about 28 billion pieces of mail to about 33 billion pieces of mail). In addition, post offices across the country were forced to hire inexperienced clerks as more experienced staff members went off to serve in the war. The creation of a postal zone system was deemed necessary in order to improve the accuracy and efficiency of mail sorting and delivery. Zone numbers were implemented in 124 of the country's largest urban areas, and individual delivery districts within these areas were given one or two digit codes, to be written as part of the address after the city name. These early postal zone codes faced little opposition and caught on quickly with businesses and the American public. The Need For ZIP Code, An Improved Zoning System:- The Postal Delivery Zone System that was implemented in 1943 was utilized in mail sorting and delivery until the early 1960's. In 1962, the Postmaster General of the United States, James Edward Day, declared that the system was outdated and outmatched by the nation's rapid urban expansion and climbing mail volume. Between 1943 and 1962, annual mail volume doubled, growing from 33 billion pieces of mail to 66.5 billion. Business growth accompanied urban expansion, bringing new and large volume mailings of advertisements and periodicals. The old zoning system of could not move the mail efficiently in the face of this type of rapid growth. In addition, the development of suburban communities and greater geographic dispersion of the country's population made mail delivery more complicated. In order to keep the mail moving as smoothly as possible, the Postmaster General proclaimed an urgent need for a more effective postal zoning system. And in the summer of 1963, the Zone Improvement Plan (ZIP Code) began was introduced to the public. Xxxxx. ZIP Code, in full Zone Improvement Plan Code, system of zone coding introduced by the US Post Office Department (now the US Postal Service) in 1963 to facilitate the sorting and delivery of mail. After an extensive publicity campaign, the department finally succeeded in eliciting from the public a widespread acceptance of the ZIP code. Users of the mails were requested to include in all addresses a five-number code, of which the first three digits identified the section of the country to which the item was destined and the last two digits the specific post office or zone of the addressee. The primary purpose of the zone coding system was to fully exploit the capabilities of electronic reading and sorting equipment. The US Postal Service introduced a nine-digit ZIP Code in 1983. The new code, composed of the original five digits plus a hyphen and four additional numbers, was designed to speed up automated sorting operations. The first two of the four extra digits specify a particular sector, such as a group of streets or cluster of large buildings. The last two digits of the expanded code represent an even smaller area called a Segment, which may consist of one side of a city block, a single floor in a large building, or a group of post office boxes.

ZONE OF RATE FLEXIBILITY = ЗОНА ГИБКОСТИ СТАВОК – Zone Of Rate Flexibility:- in the United States, railroads may raise rates by a percentage increase in the railroad cost index that the ICC (short for the US Interstate Commerce Commission; it was eliminated in 1994; Effective 1996-January-01, the US Department of Transportation (DOT) assumed the Interstate Commerce Commission's (ICC) remaining responsibilities for administering trucking regulations) determines; the railroads could raise rates by 6 percent per year through 1984 and 4 percent thereafter.

ZONE OF RATE FREEDOM = ЗОНА СВОБОДЫ СТАВОК – In the United States, the commission shall establish annually a 'Zone Of Rate Freedom' which will provide for a maximum permitted percentage adjustment to any rate, fare or charge for regular route autobus service. The commission shall promulgate this percentage within 60 days after the effective date of this act for the time remaining in the 1984 calendar year, and shall thereafter promulgate a percentage for each calendar year 60 days prior to the commencement of the calendar year. The commission shall consider all relevant factors, including but not limited to the availability of alternative modes of transportation, increases or decreases of the costs of bus operations, the interests of the consumers or users of bus services, and the rates, fares and charges prevailing in the bus industry, as well as in other related transportation services, such as rail services, in establishing the 'zone of rate freedom' for each period. A Zone Of Rate Freedom (ZORF) is a zone within which a carrier can raise or lower rates without regulatory or other administrative action. Motor carriers may raise or lower rates by 10 percent in one year without ICC (short for the US Interstate Commerce Commission; it was eliminated in 1994; Effective 1996-January-01, the US Department of Transportation (DOT) assumed the Interstate Commerce Commission's (ICC) remaining responsibilities for administering trucking regulations) interference; if the rate change is within the zone of freedom, the rate is presumed to be reasonable. / В Соединённых Штатах Америки автоперевозчики могут повысить или понизить ставки на 10% за год без вмешательства Межштатовской Комиссии США по Вопросам Коммерции (МКВК; the US Interstate Commerce Commission (ICC)). Если ставка находится в пределах зоны свободы, то предполагается, что она является обусловленной и недорогой.

ZONE OF REASONABLENESS = ЗОНА ПРИЕМЛЕМОСТИ – In the United States, the law authorized truckers to price freely within a 'Zone of Reasonableness', meaning that truckers could increase or decrease rates from current levels by 15 percent without challenge, and encouraged them to make independent rate filings with even larger price changes. Zone Of Reasonableness (ZOR) is a zone or limit within which air carriers may change rates without regulatory scrutiny; if the rate change is within the zone, the new rate is presumed to be reasonable. Zone Of Reasonableness, in general, a rate or division of a motor carrier for service in noncontiguous domestic trade or water carrier for port-to-port service in that trade is reasonable if the aggregate of increases and decreases in any such rate or division is not more than 7.5 percent above, or more than 10 percent below, the rate or division in effect 1 year before the effective date of the proposed rate or division.

ZONE PICKING = ЗОНОВОЕ КОМПЛЕКТОВАНИЕ (или ЗОНАЛЬНАЯ КОМПЛЕКТАЦИЯ, или ЗОНОВЫЙ ОТБОР) – Zone Picking:- a method of order picking where the warehouse is divided into pick zones. Items are picked from each zone and then transferred on a conveyer system from one zone to the next. Zone Picking involves combining groups of customer orders into a master batch, so that multiple orders are picked at the same time. Doing so vastly reduces the travel time required to pick goods for orders. Inventory pickers then forward their picked items to a central location in the warehouse, where the items are separated and matched to specific customer orders. Not only does this approach reduce travel time, but it also reduces the number of inventory transactions to be recorded, since picks are being conducted for multiple units at the same time. Zone picking creates the largest number of efficiencies when there are many customer orders, but is much less effective when customer orders arrive relatively infrequently. Additional efficiencies associated with zone picking are:- (i) Familiarity:- a picker assigned to a specific part of the warehouse will become very familiar with the locations of the items in his or her area, and so will be better able to pick, both more accurately and at a higher rate of speed; (ii) Traffic Interference:- there are no problems with stock pickers blocking aisles and getting in the way of other pickers, since there is no reason for anyone to stray outside of their assigned area; and (iii) Location Changes:- pickers will become so familiar with usage patterns in their assigned areas that they may reshuffle bin locations to locate high-frequency items where they can be more

easily picked. Problems with Zone Picking:- despite the significant advantages of zone picking, there are also a few issues to consider, such as:- (i) Central Picking Area:- there must be a method for efficiently reshuffling picked items into their designated customer orders, which may represent a level of organization that does not currently existing within the company; (ii) Responsibility:- it can be difficult to track down the reason for a picking error, since a large number of pickers may be involved in each order; and (iii) Lumpy Demand:- the content of customer orders may change over time, resulting in some pickers being intensely busy and others looking for work to do. This issue can be mitigated by periodically rebalancing work loads in the warehouse, based on picking frequencies.

ZONE PRICE = ЗОНАЛЬНАЯ ЦЕНА – Zone Price is the constant price of a product at all geographic locations within a zone. / Зональная Цена является постоянной ценой продукта во всех географических пунктах внутри конкретной зоны. Под Зональной Ценой понимается вид регулируемых цен, которые дифференцированы по географическому принципу. В пределах одной зоны уровень цены фиксирован и, за редким исключением, распространяется на продукцию одного вида не зависимо от того, кем она производится.

ZONE PRICING = ЗОНАЛЬНОЕ ЦЕНООБРАЗОВАНИЕ – Zone Pricing is the process of setting prices for goods or services based on the location where they will be offered for sale to consumers. In using a zone pricing strategy, a company typically keeps its prices to distributors consistent within a particular zone but will usually raise its prices within zones that are further away from its manufacturing facilities to help account for higher transport costs. Zone Pricing is a geographic pricing strategy in which a firm groups its customers in zones (groups of cities, regions, or countries) and applies different pricing formulas to each zone. Zone Pricing:- prices increase as shipping distances increase. This is sometimes done by drawing concentric circles on a map with the plant or warehouse at the center and each circle defining the boundary of a price zone. Instead of using circles, irregularly shaped price boundaries can be drawn that reflect geography, population density, transportation infrastructure, and shipping cost. (The term 'Zone Pricing' can also refer to the practice of setting prices that reflect local competitive conditions, i.e. the market forces of supply and demand, rather than actual cost of transportation.) Zone pricing, as practiced in the gasoline industry in the United States, is the pricing of gasoline based on a complex and secret weighting of factors, such as the number of competing stations, number of vehicles, average traffic flow, population density, and geographic characteristics. This can result in two branded gas stations only a few miles apart selling gasoline at a price differential of as much as USD0.50 per gallon. Many businesspeople and economists state that gasoline zone pricing merely reflects the costs of doing business in a complex and volatile marketplace. Critics contend that industry monopoly and the ability to control not only industry-owned 'corporate' stations, but locally owned or franchise stations, make zone pricing into an excuse to raise gasoline prices virtually at will. Oil industry representatives contend that while they set wholesale and dealer tank wagon prices, individual dealers are free to see whatever prices they wish and that this practice in itself causes widespread price variations outside industry control. Zone Pricing is a strategy of setting selling prices according to the geographic area (zone) in which the product will be sold, allowing for the costs of product shipping and handling to the zone. Zone pricing provides a uniform delivered price to all buyers within a geographic area. However, selling prices are incrementally higher as the zones get further away from the place of product manufacture. Zone Pricing is a pricing method in which all customers within a defined zone or region are charged the same price. And more distant customers pay a higher price than those closer to the company's dispatch point. It is also called Multiple Zone Pricing. Prices increase as shipping distances increase. This is sometimes done by drawing concentric circles on a map with the plant or warehouse at the center and each circle defining the boundary of a price zone. Instead of using circles, irregularly shaped price boundaries can be drawn that reflect geography, population density, transportation infrastructure, and shipping cost. The term Zone Pricing can also refer to the practice of setting prices that reflect local competitive conditions, i.e. the market forces of supply and demand, rather than actual cost of transportation. / Под Зональным Ценообразованием понимается разделение единого рынка на зоны (районы) и установление различных цен и тарифов. Все покупатели в пределах одной зоны платят одну и ту же цену.

ZONING = ЗОНИРОВАНИЕ (или РАЙОНИРОВАНИЕ) – Zoning is the legislative method of controlling land use by regulating such considerations as the type of buildings (e.g., commercial or residential) that may be erected and the population density. Applied primarily to urban areas, it is accomplished by dividing land area into zoning districts, each having specific conditions under which land and buildings may be legally developed and used. In combination with other city-planning techniques, zoning is a major instrument for gaining greater physical order in cities. The earliest form of zoning was inspired by architectural and urban-design controls introduced in European cities toward the end of the XIX century. In accordance with long-established municipal powers, German and Swedish cities applied zoning regulations about 1875 to new land being urbanized around the older city cores as a way of controlling the heights and concentrations of buildings and avoiding problems of congestion. Much of the orderliness of German and Swedish cities and the consistent quality of building line and height is due to the early establishment of detailed zoning regulations and their widespread application at the time of major building activity growing out of the Industrial Revolution. Zoning in the United States (US), in contrast, has been more concerned with the social and economic function for which land is used rather than with architectural and site-planning criteria. The earliest US zoning ordinances – around the turn of the XX century – were motivated by the need for regulating the location of commercial and industrial activities. See also Agricultural Zoning. Zoning is the process in physical planning, or the results thereof, in which specific functions or uses are assigned to certain areas, for example, industrial zones, residential areas. Zoning:- the separation or division of a municipality into districts, the regulation of buildings and structures in such districts in accordance with their construction and the nature and extent of their use, and the dedication of such districts to particular uses designed to serve the General Welfare. Zoning, the regulation of the use of real property by local government, restricts a particular territory to residential, commercial, industrial, or other uses. The local governing body considers the character of the property as well as its fitness for particular uses. It must enact the regulations in accordance with a well-considered and comprehensive plan intended to avoid Arbitrary exercise of government power. A comprehensive plan is a general design to control the use of properties in the entire municipality, or at least in a large portion of it. Individual pieces of property should not be singled out for special treatment. For example, one or two lots may not be placed in a separate zone and subjected to restrictions that do not apply to similar adjoining lands. Zoning ordinances divide a town, city, village, or county into separate residential, commercial, and industrial districts, thereby preserving the desirable characteristics of each type of setting. These laws generally limit dimensions in each zone. Many regulations require certain building features and limit the number and location of parking and loading areas and the use of signs. Other regulations provide space for schools, parks, or other public facilities. Zoning helps city planners bring about orderly growth and change. It controls population density and helps create attractive, healthful residential areas. In addition, zoning helps assure property owners and residents that the characteristics of nearby areas will remain stable. In some states a municipality has the right to be heard on proposed zoning in an adjoining community. Courts have upheld this so-called Extraterritorial Zoning as an exercise of the Police Power of the state, with the goal of serving the general welfare of both communities and creating harmony among the uses of a given area, without regard to political boundaries. Following the lead of New York City, which passed the first major zoning ordinance in 1916, most urban communities throughout the country have enacted zoning regulations. Zoning is not merely the division of a city into districts and the regulation of the structural and architectural designs of buildings within each district. It also requires consideration of future growth and development, adequacy of drainage and storm sewers, public streets, pedestrian walkways, density of population, and many other factors that are within legislative competence. Building Codes, which govern the safety and structure of buildings, do not contradict zoning ordinances, but

exist side by side with them. Both rest on the police power:- zoning stabilizes the use of property, and building codes ensure the safety and structure of buildings. Zoning is intended to have a relative permanency, whereas building codes are much more flexible because they must keep abreast of new materials and other technological advances. Municipalities have power to zone property only if a state grants it by statute or it is derived from constitutional provisions. Zoning ordinances must be reasonable because by their nature they restrain the use of property that the owners could otherwise use as they chose. The landowner cannot complain as long as the power to zone is used in the public interest and for the general welfare of the community impartially and without compensation. The regulations must meet the demands of the constitutional prohibition against taking private property for public use without just compensation as mandated by the Fifth and Fourteenth Amendments to the US Constitution as well as by the constitutions of the states. The US Supreme Court decided three cases that have had considerable impact in this area:- Lucas v. South Carolina Coastal Council, 505 US 1003, 112 S. Ct. 2886, 120 L. Ed. 2d 798 (1992), Lujan v. National Wildlife Federation, 497 US 871, 110 S. Ct. 3177, 111 L. Ed. 2d 695 (1990), and Dolan v. City of Tigard, 512 US 374, 114 S. Ct. 2309, 129 L. Ed. 2d 304 (1994). The decisions made it more difficult for municipalities to require that land developers give up part of their property for public purposes, such as access to lake shores, sidewalks, access roads, and parks. If the government needs the land, it must compensate the owner by exercising its power of Eminent Domain and condemning the property. Courts have held that a zoning regulation is legal or valid if it is reasonable and not arbitrary and bears a reasonable and substantial relation to the public health, safety, comfort, morals, and general welfare and if the means employed are reasonably necessary for the accomplishment of its purpose. An ordinance is invalid if its enforcement will preclude use of the property for any purpose to which it is reasonably adapted. In determining whether a regulation is reasonable, no single factor is controlling. Those factors normally considered are need for the adoption, the purpose, location, size, and physical characteristics of the land, and the character of the neighborhood. Also considered are the effect on the value of property, the amount by which property values are decreased, the notion of the general welfare (that is, what is best for the community at large), and the density, population, and aesthetics of the area. Traffic, use of nearby land, and length of time the property has been vacant are also relevant. An ordinance that is reasonable when enacted may prove to be unreasonable, and hence may be set aside by a court, if circumstances have changed. Zoning regulations must promote the good of all the people in the community rather than further the desires of a particular group, and the power cannot be invoked to further private interests that conflict with the rights of the public. Restrictions based solely on race or occupancy of property within certain districts are invalid. A classification that discriminates against a racial or religious group can only be upheld if the state demonstrates an overwhelming interest that can be served no other way. The regulation must be clear and specific. It must describe districts with certainty, and if maps are necessary, it should include references to them. The standards governing conduct of the administrator must be clear. The fact that regulations have not been enforced does not prevent their enforcement. Only persons whose rights are injured by regulations may attack them. An invalid enactment is without effect and confers no rights and imposes no duties. Regulations must be in accordance with a comprehensive plan, which may be separate or part of the zoning regulation. Spot zoning of individual parcels of property in a manner different from that of surrounding property, primarily for the private interests of the owner of the property so zoned, may be improper but not illegal in all cases. Spot zoning disregards the requirement that zoning be in accordance with a comprehensive plan. It may be valid if there is a reasonable basis for distinguishing the parcel from surrounding parcels. Zoning regulations may validly prescribe a type of building, location of utility lines, restrictions on accessory buildings or structures, and preservation of historical areas and buildings. General rules of construction apply to restrictions affecting architectural and structural design of buildings and open spaces. Such rules apply to building setbacks from the streets and other boundaries, size and height of buildings, number of rooms, floor space or area and cubic feet, and minimum cost of buildings. They also apply to frontage of lots, minimum lot area, front, rear, and side yards, off-street parking, the number of buildings on a lot, and the number of dwelling units in a certain area. Regulations may restrict areas to single-family homes or to multifamily dwellings or townhouses. An ordinance may permit the construction of a building intended for nonresidential use, such as a school, church, hospital, or charitable institution, in a residential district. Municipalities have gained some flexibility in their regulations by authorizing special use permits in certain districts. This gives them the power to impose restrictions and requirements that might not otherwise be possible under the strict classification of the district. It is also possible to create a unit development in an entire district or a large part of one, with plans and restrictions governing the entire project. This arrangement may mix some commercial and residential uses and ‘clustering’ of certain properties, leaving room for green spaces and parkways. A municipality may use broad discretion to fix the location and boundaries of business, commercial, and industrial districts and has the power to review and periodically update zoning regulations. This should be done whenever growth and progress require. Failure or refusal to make a change in regulations when they are clearly appropriate in view of development may be regarded as unreasonable, arbitrary conduct. Only the legislative body empowered to enact zoning regulations has the power to amend them. This must be done with the same formality, including required notices and hearings, as the original enactment. Neither the courts nor boards of zoning appeals should undertake such amendment, regardless of how archaic the regulations may be. Zoning ordinances may permit or prohibit certain uses and may create whole districts devoted only to residence, commerce, or industry. When a structure’s use does not conform to a zoning ordinance but the structure existed before the adoption or amendment of the ordinance, the structure has nonconforming use status, sometimes called Legal Nonconforming Use. A vested legal nonconforming use is safeguarded by the Constitution unless it is abandoned or terminated. It is a property right that cannot be taken away without just compensation. However, the nonconforming use structure may not be expanded, its use may not be changed, and, under many laws, if it is destroyed by fire or other cause, it may not be rebuilt. Zoning regulations are subject to interpretation by the courts where their meaning is unclear. Because such laws are in derogation of the Common Law, they are to be construed strictly, but they should receive a reasonable and fair construction in the light of the public good they propose to serve. Boards of zoning appeals are created by statutes. They are Quasi-Judicial bodies because they conduct hearings with sworn testimony by witnesses and a transcript is made, which courts may review. Municipalities generally require permits for building or remodeling and certificates of occupancy after inspection discloses conformity with applicable codes. An owner without legal training who contests a zoning requirement would be ill-advised to try to argue his case alone because the members of the board, the municipal attorney, and the planning official have long experience, knowledge of the law, and a built-in tendency to favor their interpretations of the ordinances. Where full compliance with the strict letter of the ordinance works a hardship on the owner, the board of appeals or governing body may grant a variance, which is toleration of a slight violation of the ordinance. The owner, however, may not create her own hardship by willfully violating the law. Zoning regulations may be enforced by Mandamus, an action that results in a judgment of a court compelling the appropriate public officers to carry out their duty; by Injunction, which results in a court order forbidding the use or structure that is in violation; and by civil Forfeiture actions or criminal prosecutions. Adjoining owners or citizens at large may have standing to enforce the ordinances where the municipal officers fail to do so. Some ordinances provide for a certain sum to be paid to the municipality for each day of violation. Some courts enforce these penalties strictly, whereas others are more lenient, as long as compliance with the ordinances is achieved in a reasonable time. Zoning is the division of a city or county into areas (zones) specifying the uses allowable for the real property in these areas. (1) Zoning (retailing definition) is the regulation of the construction and use of buildings in certain areas of a municipality. (2) Zoning (sales definition) is the method for scheduling sales calls that divides a territory into areas or zones. The salesperson then makes calls in each zone for a prespecified length of time. See also Agricultural Zoning. / Лукас (Lucas) Люхан (Lujan) Долэн (Dolan). В градостроительстве под

Зонированием территории понимается деление городской территории на зоны главным образом по функциональному признаку (жилая зона, промышленная зона и так далее) и установление градостроительных регламентов.

ZONING LAWS = ЗАКОНЫ О ЗОНИРОВАНИИ – Zoning Laws:- local zoning ordinances and regulations are important considerations when choosing your business location. Zoning laws impact several critical business decisions such as purchasing property or making improvements to your existing property, so it is important to understand the laws before you commit to anything. Property is zoned into commercial and residential uses, so a commercial building cannot be built in a residential neighborhood and vice versa, unless there is a change in zoning ordinances. Other considerations also come into play such as how you intend to use your facility, the nature of any renovations, and so on. Finding out How Property is Zoned:- you can find out how property is zoned by contacting your local planning agency. One way to determine your local planning agency is to perform an Internet search using the name of your community or city, your state, and the term 'Planning'. Before getting too involved in a zoning issue, consider hiring a local land use attorney to help you through the process and ensure you are compliant. Zoning regulations affect not only what land uses are permitted on a property but also what can be built as well as provides other regulations such as lot size, type of buildings, etc. / наём (hiring). Законы О Зонировании:- законодательные положения о разделении города на зоны. Постановления муниципалитета о разделении города на административные зоны (округа) и установлении границ этих зон. Такое разделение вводится для облегчения управления и контроля за использованием муниципальной собственности, зданий и сооружений.

ZOOM = ФОКУСИРОВАТЬ – Zoom expands or shrinks forms displayed in the working area for readability and is only available in the forms mode or when you are using the Split View. To change the form size, on the view menu click Zoom. In the Zoom to dialog box, click the new form size, and then click OK. / Устанавливать Фокус:- регулировать оптическую систему – фотоаппарата, телескопа и тому подобного – с целью получения чёткого изображения.

ZOONOSES = ЗООНОЗЫ – Zoonoses are the diseases that are communicable from animals to humans. Examples would include the diseases anthrax (caused by Bacillus Anthracis), tularemia (caused by Francisella Tularensis), etc. See also Zoonotic Diseases. Zoonosis is the name given to diseases or infections that can be transmitted between humans and animals. Many people interact with animals during their daily lives, and millions of households in the United States have pets. Other people come into contact with animals through their work, such as farming, or in the wild. What Is Zoonosis? Zoonosis refers to diseases that can be passed from animals to humans. They are sometimes called zoonotic diseases. Animals can carry harmful germs, such as bacteria, fungi, parasites, and viruses. These are then shared with humans and cause illness. Zoonotic diseases range from mild to severe, and some can even be fatal. Zoonotic diseases are widespread both in the United States and worldwide. The World Health Organization (WHO) estimates that 61 percent of all human diseases are zoonotic in origin, while 75 percent of new diseases discovered in the last decade are zoonotic. Before the introduction of new hygiene regulations around 100 years ago, zoonotic diseases such as bovine tuberculosis, bubonic plague, and glanders caused millions of deaths. They are still a major problem in developing countries. / Под Зоонозами (Zoonoses), от Греческих слов Zōōn, означающее Животное, и Nósos, означающее Болезнь, понимаются инфекционные и инвазионные болезни, свойственные только животным, например, контагиозная плевропневмония крупного рогатого скота, некробактериоз, чума свиней, мыт, чума крупного рогатого скота. Зоонозы, заразные болезни, возбудители которых в процессе эволюции приспособились к паразитированию в организме определённых видов животных. К зоонозам относят чуму рогатого скота, чуму свиней, пастереллёз и другие. При определённых санитарно-экономических условиях, благоприятствующих тому или иному механизму передачи возбудителя, возможно возникновение зоонозов среди людей. Но циркулировать в коллективах людей возбудители зоонозов не могут (в отличие от Зооантропонозов), так как человек для них является биологическим тупиком, не включается в течение эпизоотического процесса и не участвует в эволюции возбудителя как паразитического вида. Зооноз – заболевание, передающееся от животных человеку.

ZOONOTIC = ЗООНОТИЧЕСКОЕ – Zoonotic:- pertaining to a zoonosis:- a disease that can be transmitted from animals to people or, more specifically, a disease that normally exists in animals but that can infect humans. There are multitudes of zoonotic diseases. Some examples include:- anthrax, ascariasis, brucellosis, plague, echinococcosis, Lassa fever, listeriosis, Lyme disease, monkeypox, psittacosis, rabies, salmonellosis, trichinosis, toxoplasmosis, typhus and West Nile fever. Zoonoses may appear suddenly and be relatively virulent, as illustrated by HIV (short for the Human Immunodeficiency Virus) which ignited the AIDS (short for the Acquired Immunodeficiency Syndrome) epidemic and the coronavirus responsible for the outbreak of SARS (short for the Severe Acute Respiratory Syndrome). See also Zoonoses. / Зоонотическое:- .

ZOONOTIC DISEASES = ЗООНОТИЧЕСКИЕ БОЛЕЗНИ (или ЗООНОТИЧЕСКИЕ ЗАБОЛЕВАНИЯ) – Zoonotic Diseases (also known as Zoonoses) are caused by infections that are shared between animals and people. Every year, tens of thousands of Americans will get sick from diseases spread between animals and people. These are known as Zoonotic Diseases. Zoonotic means infectious diseases that are spread between animals and people. Because these diseases can cause sickness or death in people, the US Centers for Disease Control and Prevention (CDC) is always tracking and reporting them. Animals provide many benefits to people. Many people interact with animals in their daily lives, both at home and away from home. Pets offer companionship and entertainment, with millions of households having one or more pets. We might come into close contact with animals at a county fair or petting zoo, or encounter wildlife while enjoying outdoor activities. Also, animals are an important food source and provide meat, dairy, and eggs. However, some animals can carry harmful germs that can be shared with people and cause illness – these are known as Zoonotic Diseases or Zoonoses. Zoonotic diseases are caused by harmful germs like viruses, bacterial, parasites, and fungi. These germs can cause many different types of illnesses in people and animals ranging from mild to serious illness and even death. Some animals can appear healthy even when they are carrying germs that can make people sick. Zoonotic diseases are very common, both in the United States and around the world. Scientists estimate that more than 6 out of every 10 known infectious diseases in people are spread from animals, and 3 out of every 4 new or emerging infectious diseases in people are spread from animals. Every year, tens of thousands of Americans will get sick from harmful germs spread between animals and people. Because of this, CDC works 24/7 to protect people from zoonotic diseases. How Do Germs Spread Between Animals And People? Because of the close connection between people and animals, it's important to be aware of the common ways people can get infected with germs that can cause zoonotic diseases. These can include:- (i) Direct Contact:- Coming into contact with the saliva, blood, urine, mucous, feces, or other body fluids of an infected animal. Examples include petting or touching animals, and bites or scratches. (ii) Indirect Contact:- Coming into contact with areas where animals live and roam, or objects or surfaces that have been contaminated with germs. Examples include aquarium tank water, pet habitats, chicken coops, plants, and soil, as well as pet food and water dishes. (iii) Vector-Borne:- Being bitten by a tick, or an insect like a mosquito or a flea. (iv) Foodborne:- Each year, 1 in 6 Americans get sick from eating contaminated food. Eating or drinking something unsafe (such as unpasteurized milk, undercooked meat or eggs, or raw fruits and vegetables that are contaminated with feces from an infected animal). Who Is At A Higher Risk Of Serious Illness From Zoonotic Diseases? Anyone can become sick from a zoonotic disease, including healthy people. However, some people may be more at risk than others and should take steps to protect themselves or family members. These people are more likely than others to get really sick, and even die, from infection with certain diseases. These groups of people include:- (i) children younger than 5; (ii) adults older than 65; and (iii) people with weakened immune

systems. What Can You Do To Protect Yourself And Your Family From Zoonotic Diseases? People can come into contact with animals in many places. This includes at home and away from home, in places like petting zoos, fairs, schools, stores, and parks. Insects, like mosquitoes and fleas, and ticks bite people and animals day and night. Thankfully, there are things you can do to protect yourself and your family from zoonotic diseases. (i) Keep Hands Clean:- Washing your hands right after being around animals, even if you didn't touch any animals, is one of the most important steps you can take to avoid getting sick and spreading germs to others. (a) Always wash your hands after being around animals, even if you didn't touch the animals. (b) Many germs are spread by not washing hands with soap and clean, running water. (c) If clean, running water is not accessible, use soap and available water. (d) If soap and water are unavailable, use an alcohol-based hand sanitizer that contains at least 60% alcohol to clean hands. Because hand sanitizers do not eliminate all types of germs, it is important to wash your hands as soon as soap and water are available. (ii) Know the simple things you can do to stay safe around your pets. (iii) Prevent bites from mosquitoes, ticks, and fleas. (iv) Learn more about ways to handle food safely – whether it's for yourself or your family, your pet, or other animals. (v) Be aware of zoonotic diseases both at home, away from home (such as at petting zoos or other animal exhibits), in child care settings or schools and when you travel. (vi) Avoid bites and scratches from animals. Zoonotic Diseases are the diseases that, under natural conditions, are communicable from animals to humans. Included among these are brucellosis (undulant fever), salmonellosis (salmonella poisoning), leptospirosis (Weil's disease), anthrax (woolsorter's disease), and tetanus (tetanus or lockjaw). See also Zoonoses. Zoonotic Diseases:- diseases that are naturally transmitted from warm-blooded animals to humans are called Zoonoses. In Europe zoonoses originating from wildlife sources and transmitted by arthropods are considered to become increasingly important in the future. Climate and ecological changes may favour already existing arthropods to expand to other regions and thus new pathogens can be introduced in Europe. In the Netherlands zoonoses are of major importance because it is a densely populated country with high numbers of livestock and pet animals and human activities favours close contact with wildlife such as migrating waterfowl, deer and fox populations. Recent zoonotic outbreaks of importance are avian influenza in poultry in 2003 and Q fever epidemic in 2007–10. Besides the threat for outbreaks, endemic zoonoses still need attention. Zoonotic diseases affect and are carried by domestic animals, farm animals, wild animals or rodents such as mice and rats. Humans are frequently exposed to zoonotic organisms since they can also spread into the environment, such as children's sandpits, water and food. Some diseases are transmitted by insect or tick bites. The insect or tick is then termed a 'Vector' (from the Latin word for Carrier). One Health Approach:- RIVM (short for the Dutch name of Rijksinstituut voor Volksgezondheid en Milieu; in English the National Institute for Public Health and the Environment; headquartered in Bilthoven, The Netherlands) coordinates national activities on the signalling and response of zoonoses together with key partners in the veterinary field. Monthly meetings are being organised to discuss the zoonotic signals between veterinary and (regional) public health partners. Strategic focus of research activities in the field of zoonoses are livestock-, wildlife- and vector borne zoonoses on the animal-human interface. RIVM has unique expertise in the field of parasitic zoonoses and advices national authorities. Examples of research activities include Livestock Farming and Neighbouring Residents' Health, Lyme disease and other tick-borne diseases, Q fever, parasitic zoonoses in wildlife and livestock and rodent borne diseases. International Context:- Zoonoses are important to signal and control in international context. RIVM collaborates in many international activities, coordinates international projects related to zoonoses and advices international bodies such as European Food Safety Authorithy (EFSA), European Centre for Disease Prevention and Control (ECDC), World Health Organization (WHO) and Food and Agriculture Organization of the United Nations (FAO) related topics on zoonoses. Zoonotic Diseases are diseases that are transmitted between animals and humans. They include all diseases that people can contract from animals such as wildlife, domestic animals, insects, primates, and birds. Some important zoonotic diseases of New Mexico include Hantavirus Pulmonary Syndrome, Plague, Rabies, West Nile Virus, and Zika Virus. / Зоонотические Заболевания, которые могут передаваться от животных к человеку являются реальной проблемой. После утверждения в 1975 доклада Объединённого Комитета Экспертов ФАО/ВОЗ (сокращения для Продовольственной и Сельскохозяйственной Организации Объединённых Наций, более известной по Англоязычной аббревиатуре FAO (ФАО), и Всемирной Организации Здравоохранения) по ветеринарной санитарии, новым возникающим и вновь возникающим зоонотическим болезням (например, лихорадка Рифтовой долины и энцефалит), включая болезни пищевого происхождения (например, вызываемые Salmonella Enteritidis, резистентной к многолекарственной терапии – Salmonella Typhimurium DT 104 и Escherichia Coli O157:H7, и губчатая энцефалопатия крупного рогатого скота) приобрели глобальное значение для здоровья человека. Эти события потребовали быстрых ответных мер со стороны врачей-ветеринаров и биологов, а также совместной работы и сотрудничества между ними. Хотя такие зоонотические болезни, как бешенство, бруцеллёз и туберкулез крупного рогатого скота (вызываемый Mycobacterium Bovis) были взяты под контроль или ликвидированы в ряде промышленных стран, они остаются эндемическими в развивающихся регионах. Кроме того, связанные с животными инфекции (например, вызываемые Toxoplasma Gondii, Listeria Monocytogenes) отмечались у людей повышенного риска, в связи с недостаточностью нормальной иммунной реакции и в результате употребления иммуносупрессивных лекарственных средств, рака или ВИЧ-инфекции. Факторы, которые способствовали усугублению таких тенденций, включали, среди прочих, изменяющиеся структуры популяций диких животных, интенсивную практику животноводства и глобализацию пищевой промышленности, сопровождающуюся изменением структуры производства, хранения и распределения продовольствия. Эти события требуют более высокого уровня эпидемиологического надзора и готовности, а также новаторских подходов к борьбе и профилактике. Главная задача большинства организаций и служб ветеринарной санитарии – это оценка связанных с животными рисков для здоровья населения и управление ими, а также информирование об этих рисках соответствующих сторон.

ZOOPHILOUS = ЗООФИЛЬНОЕ – Zoophilous:- pollinated by animals, especially other than insects, e.g., bats. / Под Зоофильным понимается растение, опыляемое животными, нежели насекомыми, например, летучими мышами. Под Зоофилией, от Греческих слов Zōon, означающее Живое Существо или Животное, и Philéō, означающее Люблю, понимается:- (i) разновидность полового извращения:- половое влечение направлено на животных; известна также как Содомия; или (ii) перекрёстное опыление растений с помощью животных; наибольшее число видов растений опыляется насекомыми (которые питаются пыльцой, нектаром и тому подобным), меньшее – птицами и млекопитающими.

ZOOPLANKTON = ЗООПЛАНКТОН – Zooplankton are the heterotrophic (sometimes detritivorous) type of plankton. Plankton are organisms drifting in the water column of oceans, seas, and bodies of fresh water. The name of zooplankton is derived from the Greek zoon, meaning 'animal', and planktos, meaning 'wanderer' or 'drifter'. Many zooplankton are too small to be seen individually with the naked eye. Zooplankton is tiny aquatic animals eaten by fish. Zooplankton is small floating or weakly swimming organisms that drift with water currents and, with phytoplankton, make up the planktonic food supply upon which almost all oceanic organisms are ultimately dependent. Many animals, from single-celled Radiolaria to the eggs or larvae of herrings, crabs, and lobsters, are found among the zooplankton. Permanent plankton, or holoplankton, such as protozoa and copepods (an important food for larger animals), spend their lives as plankton. Temporary plankton, or meroplankton, such as young starfish, clams, worms, and other bottom-dwelling animals, live and feed as plankton until they leave to become adults in their proper habitats. Zooplankton is an animal plankton. Plankton is composed of the phytoplankton ('the plants of the sea') and zooplankton (zoh-plankton) which are typically the tiny animals found near the surface in aquatic environments. Like phytoplankton, zooplankton are usually weak swimmers and usually just drift

along with the currents. Plankton are comprised of two main groups, permanent members of the plankton, called Holoplankton (such as diatoms, radiolarians, dinoflagellates, foraminifera, amphipods, krill, copepods, salps, etc), and temporary members (such as most larval forms of sea urchins, sea stars, crustaceans, marine worms, some marine snails, most fish, etc), which are called Meroplankton. Along with phytoplankton, zooplankton are key components of marine ecosystems forming the base of most marine food webs. / Под Зоопланктоном понимается совокупность животных, обитающих в толще воды морских и пресных водоёмов и не способных противостоять переносу течениями; составная часть планктона. Наибольшая биомасса зоопланктона в тропических водах (до 200–500 мг/м^3 и выше). Смотрите также Планктон (Plankton). Зоопланктон – разнообразное, утончённое и часто очень красивое сообщество животных, обитающих в толще воды. Термин Планктон предложил известный Немецкий учёный Виктор Гэнзэн в конце XIX века. В переводе с Греческого языка планктон означает блуждающий или свободно парящий. Зоопланктон нельзя полностью отделить от другого пелагического сообщества животных – нектона, которое представлено активно плавающим сообществом рыб, кальмаров, черепах и так далее. Однако зоопланктон, в отличие от нектона, не может сопротивляться течениям, а переносится вместе с ними. Для того, чтобы ‘парить’ в толще воды, у планктонных животных есть разнообразные приспособления:- у одних – плотность тела меньше, чем плотностью воды, у других – поверхность позволяет планировать в воде. Зоопланктон является центральным компонентом морской системы. Многие зоопланктонные животные питаются фитопланктоном, а ими, в свою очередь, питаются личинки рыб. Таким образом, зоопланктон осуществляет связь между первичной продукцией фитопланктона и рыбами. Изменение численности зоопланктона – важный фактор, влияющий на запасы рыб. Зоопланктон характеризуется огромным диапазоном размеров тела, составляющих его животных. Размеры зоопланктонных организмов могут варьировать от нескольких микрон (например, некоторые инфузории) до 0.5 м и более. Разделение зоопланктона на размерные группы:- (i) микрозоопланктон – инфузории, коловратки – менее 0.2 мм; (ii) мезозоопланктон – копеподы, кладоцеры, некоторые коловратки, личинки полихет и моллюсков – 0.2–20 мм; (iii) макропланктон – личинки рыб, гребневики, некоторые медузы более 20 мм; и (iv) мегапланктон – медузы – могут достигать 20 см и более.

ZOOT = СТИЛЯЖНЫЙ (или ЗУТ) – Zoot:- suit a severely cut suit consisting of a thigh-length jacket with wide padded shoulders and peg pants with narrow cuffs. A Zoot Suit (occasionally spelled Zuit Suit) is a men’s suit with high-waisted, wide-legged, tight-cuffed, pegged trousers, and a long coat with wide lapels and wide padded shoulders. This style of clothing, popular among the African American population of the time, would soon be adopted by Chicano and Italian American communities during the 1940s. In Britain the bright-coloured suits with velvet lapels worn by Teddy Boys bore a slight resemblance to zoot suits in the length of the jacket. The zoot suit was originally associated with Afro-American musicians and their sub-culture. According to the Oxford English Dictionary, the word zoot probably comes from a reduplication of suit. The creation and naming of the zoot suit have been variously attributed to Harold C. Fox, a Chicago clothier and big-band trumpeter; Louis Lettes, a Memphis tailor; and Nathan (Toddy) Elkus, a Detroit retailer. Anti-Mexican youth riots in Los Angeles during World War II are known as the Zoot Suit Riots. In time, zoot suits were prohibited for the duration of the war, ostensibly because they used too much cloth. Zoot suiters often wear a fedora or pork pie hat color-coordinated with the suit, occasionally with a long feather as decoration, and pointy, French-style shoes. A young Malcolm X described the zoot suit as:- ‘a killer-diller coat with a drape shape, reet pleats and shoulders padded like a lunatic’s cell’. Zoot suits usually featured a watch chain dangling from the belt to the knee or below, then back to a side pocket. Zoot suit wearers’ dates often wore flared skirts and long coats. The amount of material and tailoring required made them luxury items, so much so that the US War Production Board said that they wasted materials that should be devoted to the World War II war effort. When Life published photographs of zoot suiters in 1942, the magazine joked that they were ‘solid arguments for lowering the Army draft age to include 18 year olds’. This extravagance, which many considered unpatriotic in wartime, was a factor in the Zoot Suit Riots. Wearing the oversized suit was a declaration of freedom and self-determination, even rebelliousness. / Хэролд Си. Фокс (Harold C. Fox); Луи Лэтэз (Louis Lettes); и Нэйсэн Тади Элкас (Nathan (Toddy) Elkus).

ZOOTOXIN = ЗООТОКСИН – Zootoxin is any toxin of animal origin, as a snake or scorpion venom, or serum produced by means of such toxin. / Зоотоксин – яд животного происхождения.

ZOO VIRUS = ЗОО ВИРУС (или ЗООЛОГИЧЕСКИЙ ВИРУС) – Zoo Virus is a virus found only in virus laboratories that has not moved into general circulation. / Зоо Вирус или Зоологический Вирус (Zoo Virus) – вирус, существующий только в антивирусных лабораториях, в коллекциях исследователей вирусов и не встречается в ‘дикой природе’.

ZOR = ZONE OF REASONABLENESS

ZORF = ZONE OF RATE FREEDOM

ZORI = ЗОРИ (или ПЛЕТЁНЫЕ САНДАЛИИ) – Zori is a flat thonged sandal usually made of straw, cloth, leather, or rubber. Zori are flat and thonged Japanese sandals made of rice straw or other plant fibers, cloth, lacquered wood, leather, rubber, or – increasingly – synthetic materials. Zori are quite similar to flip-flops, which first appeared in New Zealand and the United States sometime around World War II as rubber imitations of the wooden thong sandals long worn in Japan. / Зори – плоские сандалии на ремешке, сделанные из соломы, полотна, кожи или каучука. В Японии сандалии Зори обычно надевают по особым случаям, вместе с кимоно, однако такая обувь настолько удобна (мягкая, упругая подошва напоминает татами), что её можно прекрасно использовать в качестве домашних тапочек или прогулочных шлёпанцев.

ZOSTER = ОПОЯСЫВАЮЩЕЕ (или ОПОЯСЫВАЮЩИЙ ГЕРПЕС) – Zoster:- Shingles, also known as Herpes Zoster, is a viral disease characterized by a painful skin rash with blisters in a localized area. Typically the rash occurs in a single, wide stripe either on the left or right side of the body or face. Two to four days before the rash occurs there may be tingling or local pain in the area. Otherwise there are typically few symptoms though some may have fever, headache, or feel tired. The rash usually heals within two to four weeks; however, some people develop ongoing nerve pain which can last for months or years, a condition called Postherpetic Neuralgia. In those with poor immune function the rash may occur widely. If the rash involves the eye, vision loss may occur. Shingles is due to a reactivation of Varicella Zoster Virus (VZV) within a person’s body. The disease chickenpox is caused by the initial infection with VZV. Once chickenpox has resolved, the virus may remain inactive in nerve cells. When it reactivates, it travels from the nerve body to the endings in the skin, producing blisters. Risk factors for reactivation include old age, poor immune function, and having had chickenpox before 18 months of age. How the virus remains in the body or subsequently re-activates is not well understood. Exposure to the virus in the blisters can cause chickenpox in someone who has not had it, but will not trigger shingles. Diagnosis is typically based on a person’s signs and symptoms. Varicella Zoster Virus is not the same as herpes simplex virus; however, they belong to the same family of viruses. The shingles vaccine reduces the risk of shingles by 50 to 90% depending on the vaccine used. It also decreases rates of postherpetic neuralgia, and if shingles occurs, its severity. If shingles develops, antiviral medications such as acyclovir can reduce the severity and duration of disease if started within 72 hours of the appearance of the rash. Evidence does not show a significant effect of antivirals or steroids on rates of postherpetic neuralgia. Paracetamol, NSAIDs, or opioids may be used to help with the acute pain. It is estimated that about a third of people develop shingles at some point in their life. While more common

among older people, children may also get the disease. The number of new cases per year ranges from 1.2–3.4 per 1 000 person-years among healthy individuals to 3.9–11.8 per 1 000 person-years among those older than 65 years of age. About half of those living to age 85 will have at least one attack, and less than 5% will have more than one attack. The disease has been recognized since ancient times. / Опоясывающий Герпес:- Опоясывающий Лишай (Herpes Zoster) (синоним:- Опоясывающий Герпес) – заболевание вирусной природы, характеризующееся односторонними герпетиформными высыпаниями на коже с сильным болевым синдромом. Возбудитель – Вирус Ветряной Оспы (Varicella Zoster) Семейства Герпесвирусов, при первой встрече с организмом (чаще в молодом возрасте) вызывает типичную ветряную оспу. У детей, переболевших ветрянкой, вирус переходит в латентное состояние, скрываясь в нервных клетках задних рогов спинного мозга, черепных нервах или ганглиях автономной нервной системы, реже – в клетках нейроглии, и не вызывает каких-либо симптомов. Спустя десятилетия после первичного попадания вируса в организм, происходит его активизация с выходом из нервных клеток и продвижением вдоль по их аксонам. Достигнув окончания нерва, вирус вызывает инфекцию кожи того региона, который иннервируется данным нервом, заболевание сопровождается сильным зудом, болями и высыпаниями. Самоисцеление наступает чаще всего через 2–4 недели, однако у некоторых больных боли и зуд могут сохраняться месяцы и годы, состояние называемое ‘Постгерпетическая Невралгия’. Детальные механизмы того, как вирус ветряной оспы переходит в спящее состояние, а затем реактивируется, остаются неизученными.

ZOUAVE = ЗУАВ – Zouave:- was the title given to certain light infantry regiments in the French Army, normally serving in French North Africa between 1831 and 1962. The name was also adopted during the XIX century by units in other armies, especially volunteer regiments raised for service in the American Civil War. The characteristic zouave uniform included short open-fronted jackets, baggy trousers and often sashes and oriental headgear. / Под Зуавами, от Французского слова Zouaves, от Арабского слова Zyaya, означающее название одного из Кабильских племён в Алжире, понимается вид лёгкой пехоты во Французских колониальных войсках XIX–XX веков; формировались из жителей Северной Африки из Французов-добровольцев, проживавших там же; с начала XX века – на основе воинской повинности. Первые 2 батальона Зуавов были созданы в Алжире в 1830 для ведения колониальной войны в Северной Африке. В середине XIX века было сформировано 3, а затем 4 (1914) и 6 (1939) полков. Зуавы участвовали в различных войнах, которые вела Франция в XIX–XX веках, в том числе в Крымской Войне 1853–56, в Франко-Прусской Войне 1870–71, 1-й и 2-й Мировых Войнах. Имели особую форму (куртка, жилет, шаровары с широким поясом, феска или чалма). Зуавами назывались также наёмные стрелковые части в армии султанской Турции; в начале XX века имелась 1 бригада Зуавов. Во время Польского восстания 1863–64 в рядах повстанцев существовали отряды зуавов (жуавов) смерти, состоявшие из храбрецов-смертников.

Z–SCORE = ПОКАЗАТЕЛЬ ЗИ. (или ПОКАЗАТЕЛЬ ЗЭД.) – (1) The Z-Score formula for Predicting Bankruptcy of Dr. Edward I. Altman (New York University (NYU) Stern’s Department of Finance Professor; Stern = Leonard N. Stern) is a multivariate formula for a measurement of the financial health of a company and a powerful diagnostic tool that forecasts the probability of a company entering bankruptcy within a 2 year period. Studies measuring the effectiveness of the Z-Score have shown the model is often accurate in predicting bankruptcy (72–80% reliability). The Z-Score was developed in 1968 by Dr. Edward I. Altman, Ph.D., a financial economist and professor at New York University’s Stern School of Business. The Z-Score bankruptcy predictor combines five common business ratios, using a weighting system calculated by Altman to determine the likelihood of a company going bankrupt. It was derived based on data from manufacturing firms, but has since proven to be effective as well (with some modifications) in determining the risk a service firm will go bankrupt. How should the results be judged? It depends:- (i) Original Z-SCORE (For Public Manufacturer) If the score is 3.0 or above – bankruptcy is not likely. If the Score is 1.8 or less – bankruptcy is likely. A score between 1.8 and 3.0 is the gray area. Probabilities of bankruptcy within the above ranges are 95% for one year and 70% within two years. Obviously, a higher score is desirable. (ii) Model A Z-Score (For Private Manufacturer) Model A of Altman’s Z-Score is appropriate for a private manufacturing firm. Model A should not be applied to other companies. A score of 2.90 or above indicates that bankruptcy is not likely, but a score of 1.23 or below is a strong indicator that bankruptcy is likely. Probabilities of bankruptcy in the above ranges are 95% for one year and 70% within two years. Obviously, a higher score is desirable. (iii) Model B Z-Score (For Private General Firm) Edward Altman developed this version of the Altman Z-Score to predict the likelihood of a privately owned non-manufacturing company going bankrupt within one or two years. Model B is appropriate for a private general (non-manufacturing) firm. Model B should not be applied to other companies. A score of 1.10 or lower indicates that bankruptcy is likely, while a score of 2.60 or above can be an indicator that bankruptcy is not likely. A score between the two is the gray area. Probabilities of bankruptcy in the above ranges are 95% for one year and 70% within two years. Again, obviously, a higher score is desirable. See also Z-Model. Z-Score is a statistical measure that quantifies the distance (measured in standard deviations) a data point is from the mean of a data set. Separately, Z-Score is the output from a credit-strength test that gauges the likelihood of bankruptcy. Also known as the Altman Z-Score. Z-Score was developed by Edward Altman. Originally, he developed the Altman Z-Score by examining 85 manufacturing companies. Later, additional ‘Z-Scores’ were developed for private manufacturing companies (Z-Score – Model A) and another for general/service firms (Z-Score – Model B). VentureLine selects the ‘Z-Score’ appropriate for each firm based upon the questionnaire input from the listing company. A ‘Z-Score’ is only as valid as the data from which it was derived, i.e. if a company has altered or falsified their financial records/books, a ‘Z-Score’ derived from those ‘cooked books’ is of highly suspect value. Altman Z-Score reliably predicts whether or not a company is likely to enter into bankruptcy within one or two years:- (i) if the Z-Score is 3.0 or above – bankruptcy is not likely; (ii) if the Z-Score is 1.8 or less – bankruptcy is likely. A Z-Score between 1.8 and 3.0 is the gray area, i.e. a high degree of caution should be used. Probabilities of bankruptcy within the above ranges are 95% for one year and 70% within two years. Obviously a higher Z-Score is desirable. It is best to assess each individual company’s Z-Score against that of the industry. In low margin industries it is possible for Z-Scores to fall below the above. In such cases a trend comparison to the industry over consecutive time periods may be a better indicator. It should be remembered that a Z-Score is only as valid as the data from which it was derived, i.e. if a company has altered or falsified their

financial records/books, a Z-Score derived from those 'cooked books' is of lesser use. Z Score is a statistical measure that quantifies the distance (measured in standard deviations) a data point is from the mean of a data set. In statistics, a standard score indicates how many standard deviations an observation or datum is above or below the mean. It is a dimensionless quantity derived by subtracting the population mean from an individual raw score and then dividing the difference by the population standard deviation. This conversion process is called Standardizing or Normalizing; however, 'normalizing' can refer to many types of ratios. The standard deviation is the unit of measurement of the Z-score. It allows comparison of observations from different normal distributions, which is done frequently in research. Standard scores are also called Z-Values, Z-Scores, Normal Scores, and Standardized Variables; the use of 'Z' is because the normal distribution is also known as the 'Z Distribution'. They are most frequently used to compare a sample to a standard normal deviate (standard normal distribution, with $\mu = 0$ and $\sigma = 1$), though they can be defined without assumptions of normality. The Z-score is only defined if one knows the population parameters, as in standardized testing; if one only has a sample set, then the analogous computation with sample mean and sample standard deviation yields the Student's t-statistic. The standard score is not the same as the Z-factor used in the analysis of high-throughput screening data, but is sometimes confused with it. Z-Score is a spread-based measure of whether a bond is rich or cheap; Z-score is calculated by taking the difference between a bond's current spread and it's 3-month average spread and then dividing by its 3-month standard deviation. The Altman Z-Score is a measure of a company's financial strength that uses a weighted sum of several factors. Although it is sometimes referred to simply as z-score, this is can be ambiguous. It was devised by Edward I. Altman. Although many measures of financial strength exist the z-score is different to most in that it combines multiple factors, and has been proved to be successful as a predictor of bankruptcy. The weightings used for each factor have changed significantly since they were first estimated in 1968. The original model was:- $Z = 1.2X_1 + 1.4X_2 + 3.3X_3 + 0.6X_4 + X_5$; where:- X_1 is working capital / total assets; X_2 is retained earnings (profit) / total assets; X_3 is EBIT / total assets; X_4 is market value of equity / book value of debt; and X_5 is sales / total assets. This is slightly different from the z-score as it appears in Altman's original paper because it uses fractions rather than percentages for each number:- e.g., 0.2 rather than 20 for a ratio that is usually expressed as a percentage. The spurious accuracy of multiplying X_5 by 0.999 instead of leaving it at one has also been omitted. A more recent estimate by Altman (in 2000) is significantly different:- $Z = 0.72X_1 + 0.85X_2 + 3.1X_3 + 0.42X_4 + X_5$. Once again, this has been rounded to two significant figures. Altman's 2000 paper revisits the z-score and his proprietary zeta model. Other single number measures of financial strength exist, including Piotroski's F-score. A 'Z-Score' is only as valid as the data from which it was derived, i.e. if a company has altered or falsified their financial records/books, a 'Z-Score' derived from those 'cooked books' is of highly suspect value. Altman Z-Score:- the output of a credit-strength test that gauges a publicly traded manufacturing company's likelihood of bankruptcy. The Altman Z-score, is based on five financial ratios that can be calculated from data found on a company's annual 10K report. The Altman Z-score is calculated as follows:- Z-Score = (1.2 x A) + (1.4 x B) + (3.3 x C) + (0.6 x D) + (1.0 x E); where:- A = Working Capital / Total Assets; B = Retained Earnings / Total Assets; C = Earnings Before Interest & Tax / Total Assets; D = Market Value of Equity / Total Liabilities; and E = Sales / Total Assets. A score below 1.8 means the company is probably headed for bankruptcy, while companies with scores above 3.0 are not likely to go bankrupt. The lower/higher the score, the lower/higher the likelihood of bankruptcy. NYU Stern Finance Professor, Edward Altman, developed the Altman Z-score formula in 1967. In 2012, he released an updated version called the Altman Z-score Plus, that can be used to evaluate both public and private companies, both manufacturing and nonmanufacturing companies and both US and non-US companies. Investors can use Altman Z-scores to help determine whether they should buy or sell a particular stock if they're concerned about the underlying company's financial strength. The Altman Z-score Plus can be used to evaluate corporate credit risk. Z Score (Altman's Z Score):- a statistic, devised by Edward I. Altman (1941–) in 1968, that attempts to measure the susceptibility of a business to failure. It is computed by applying Beta coefficients to a number of selected ratios taken from an organization's final accounts using the technique of multiple discriminant analysis. A UK-based version was introduced by Richard J. Taffler in 1983. The Z score is now often included in software used to decide whether or not a business loan should be approved. The Z-Score (sometimes called the Standard Score) is a statistical calculation. Formula:- Z-Score = (N * (R – 0.5) – X) / ((X * (X – N)) / (N – 1))^(1/2); where, N – the total number of trades in the sequence, R – the total number of runs in the sequence, X = 2 * W * L, W – the total number of winning trades in the sequence, and L – the total number of losing trades in the sequence. What It Means:- The Z Score is the result of the runs test and will tell us if our system has more (or fewer) streaks of consecutive wins and losses than a random distribution. The Z Score shows us how many standard deviations we are away from the mean of a distribution. What we are trying to answer is how many streaks of wins (losses) can we expect from a given system? Are the win (loss) streaks of the system we are testing in line with what we could expect? If not, is there a high enough confidence limit that we can assume dependency exists between trades, i.e. is the outcome of a trade dependent on the outcome of previous trades? The Z Score only takes into account the dependency from the point of view of whether the last trade was a winner or a loser. It does not take into account the size of each winner or loser. For that we use the Serial Correlation. How Can We Profit From It? The Z Score tells the trader the tendency for a system to win or lose in streaks. Streaks are defined by the times a system shifts between losing or winning trades. The Z score is calculated by comparing the number of streaks there are in a set of trades with the number of streaks that could be expected randomly. We can then transform this number into another value called the confidence level which gives us a good idea of the relationship between wins and losses. Use this table to translate the absolute Z Score to the confidence level (Z-Score – Confidence Limit):- 3.00 – 99.73%, 2.58 – 99.00%, 2.33 – 98.00%, 2.17 – 97.00%, 2.05 – 96%, 2.00 – 95.45%, 1.96 – 95%, 1.64 – 90%. A confidence level of 95% or above is needed to exploit (for extra profit) the apparent non-randomness of streaks in a system so based on this table we're looking for Z scores of above 1.96 and below –1.96. A negative Z score means that there are fewer streaks in the trading system than would be expected statistically. This means that winning trades tend to follow winning trades and that losing trades tend to follower losers. A positive Z score means that there are more streaks in the trading system than would be expected. This means that winners tend to follow losers and vice versa. If you discover that the system that you have back tested or the system that you are currently trading has a reasonable Z score then it is possible to exploit the system for extra profit using money management techniques. / Профессор Финансов из США Эдвод Ай. (2) Z-Score:- sometimes data for a variable will include one or more values that appear unusually large or small and out of place when compared with the other data values. These values are known as Outliers and often have been erroneously included in the data set. Experienced statisticians take steps to identify outliers and then review each one carefully for accuracy and the appropriateness of its inclusion in the data set. If an error has been made, corrective action, such as rejecting the data value in question, can be taken. The mean and standard deviation are used to identify outliers. A z-score can be computed for each data value. With x representing the data value, x' the sample mean, and s the sample standard deviation, the z-score is given by $z = (x – x') / s$. The z-score represents the relative position of the data value by indicating the number of standard deviations it is from the mean. A rule of thumb is that any value with a z-score less than −3 or greater than +3 should be considered an outlier. / Показатель Зи. (в США) или Показатель Зэд. (в

Z–SPREAD = КУРСОВАЯ РАЗНИЦА ЗИ. (или ЗЭД.–СПРЭД) – The Z-Spread is conceptually closely related to Yield to Maturity (YTM). It is a more accurate definition of spread than the simple difference between two numbers, for the same reasons that YTM is a more accurate measure than flat yield:- particularly changes in rates over time. The z-spread is the amount by which the discount rate would need to exceed the return of risk free bonds in order for the present value to equal the market price. Looking at this another way, the z-spread is an Internal Rate of Return (IRR). However, rather than discounting each cash flow (coupon payment) at the same rate, each is discounted by the rate over that term (i.e. read off the yield curve) plus the z-spread. The calculation, assuming annual ocupon payments, is:- $P = C_0 + C_1 / (1 + r_1 + z) + C_2 / (1 + r_2 + z)^2 + C_3 / (1 + r_3 + z)^3 ... T (1 + r_n + z)^n$. Where P is the dirty price of the bond; C_1 is the first coupon payment, C_1 the second etc; r_1 is the risk free rate over the next year, r_2 over the next two years, etc; T is the terminal value – the total payments in the year the bond matures; and z is the z-spread. The z-spread needs to be calculated starting from a guess that is progressively improved, using the same procedure as for IRR. Zero-Volatility Spread or Z-Spread is the constant spread that will make the price of a security equal to the present value of its cash flows when added to the yield at each point on the spot rate Treasury curve where a cash flow is received. In other words, each cash flow is discounted at the appropriate Treasury spot rate plus the Z-spread. The Z-spread is also known as a Static Spread. A Z-spread calculation is different than a nominal spread calculation. A nominal spread calculation uses one point on the Treasury yield curve (not the spot rate Treasury yield curve) to determine the spread at a single point that will equal the present value of the security's cash flows to its price. A Z-Spread, or Zero-Volatility Spread, is the spread where the security's discounted cash flows equal its present value on a spot yield curve. Its primary purpose for investors or traders is to measure the spread that can be captured over the yield curve if the security is held until maturity. It is a useful tool for analyzing a non-treasury security, as it measures its credit, liquidity and option risks. Z-spreads can also be used as an economic indicator, where a negative Z-spread often indicates a recession is on its way. Calculating the Z-spread requires trial and error to find the correct spread, using basis points so that the present value of cash flows and the bond's price are the same. Calculating the Z-spread begins with adding basis points to each rate on the spot curve. For example, if the two-year rate on the spot curve is 4% with 50 basis points to be added, the rate would be 4.50%. An analyst can use this rate to calculate the present value of each cash flow and then add all of the cash flows together. The grand total of the cash flows should equal the security's price. If these two numbers do not match, recalculations will need to be made using different spreads, or basis points, until the present value of the cash flows is the same as the bond's price. Advantages of a Z-spread include its ability to be independent of other points on the yield curve. Unlike the nominal spread, the Z-spread is not dependent on only one point of the yield curve, which allows it to be trusted by investors or traders. While Z-spreads are most commonly used by investors and traders, it is sometimes used as an indicator of the health of the economy. For example, a negative Z-spread can point to a looming recession. Measuring the Z-spread is not limited to any one spot rate curve, so calculations should clearly indicate which spot rate curve was used. For instance, a Z-spread can use the security issuer's benchmark spot rate curve to measure liquidity and option risk of this particular instrument. Short-term and high-rated debt will have little or no difference between the Z-spread and its asset-swap spread. If there is a difference between these two spreads for this type of debt, then it can be safe to assume that the market has not priced this security accurately and adjustments will be seen shortly.

Z Table is a mortality table showing ultimate experience on insured lives computed from the experienced mortality on Life policies issued by major companies from 1925 to 1934. The Z Table was a step in the development of the Commissioners' Standard Ordinary (CSO) Table of Mortality. Mortality Table is a table showing the incidence of death at specified ages. It shows the number of persons in each age group that die, expressed in terms of deaths per thousand, and based on the deaths in a population of a million persons. Mortality table is a statistical table showing the death rate (probability of death) at each age. American Experience Table of Mortality is a statement of expected mortality rates based upon data accumulated in 1868 from a large number of insured persons. This table was widely used by life insurers until the 1950s to establish rates. A mortality table which was published in 1928 for use in determining rates for group annuities. / Таблица Зи. Таблица смертности, представляющая окончательные итоги по застрахованным жизням, подсчитанные исходя из практической смертности застрахованных полисами страхования жизни, выпущенных крупными страховыми компаниями в период между 1925 и 1934. Таблица Зи. стала шагом в развитии Комиссарской Стандартной Ординарной (КСО) Таблицы Смертности. Смертность, демографический показатель, характеризующий состояние здоровья населения:- количество смертей на 1 000 населения за 1 год. Страхование может увеличить ожидаемую полезность для лица, подвергающегося риску случайных потерь. Основой простых моделей для страховых договоров, заключённых на один временной период, являются бернуллиевские случайные величины, отражающие наступление или ненаступление страхового случая. Наступление страхового случая в некоторых примерах приводит к другому случайному процессу, определяющему величину потерь. Существуют модели страховых систем, предназначенных для работы со случайными потерями, в которых случайность связана с тем, насколько долго будет жить некое лицо. Основным структурным элементом подобных моделей является случайная величина, называемая продолжительностью предстоящей жизни (временем дожития) и обозначаемая через T(x). Существует ряд идей, которые позволят описывать и использовать распределение как этой случайной величины, так и соответствующего ей возраста в момент смерти X. Как распределение случайной величины 'возраст в момент смерти' можно представить посредством таблицы смертности? Таблицы смертности полезны во многих областях знания. Поэтому в каждой из этих разнообразных областей, где используются таблицы смертности, была разработана свои терминология и обозначения. Например, инженеры используют таблицы смертности для изучения надежности сложных механических и электронных систем. В биостатистике таблицы смертности используются для сравнения эффективности различных методов лечения серьёзных заболеваний. Демографы используют таблицы смертности как средство популяционного проектирования. Страховые компании используют таблицы смертности для построения моделей страховых систем, призванных содействовать людям, находящимся перед лицом неопределённости, связанной с моментом наступления их смерти. В страховании жизни:- таблица смертности, основанная на данных только о тех лицах, которые приобрели полисы по страхованию жизни в относительно недавний срок. Практика показывает, что для этих лиц характерен более низкий коэффициент смертности в годы, непосредственно следующие за приобретением страхования, по сравнению с теми, кто был застрахован уже давно, возможно, не только потому, что данные лица моложе последних, но и потому, что были обеспечены более высоким уровнем медицинского обслуживания.

(2) Z Table:- in statistics, the values inside the given table represent the areas under the standard normal curve for values between 0 and the relative z-score. For example, to determine the area under the curve between 0 and 2.36, look in the intersecting cell for the row labeled 2.30 and the column labeled 0.06. The area under the curve is .4909.

Z–TWIST = КРУТКА Z (или ПРАВАЯ КРУТКА) – Z Twist:- in yarn and rope production, process that binds fibers or yarns together in a continuous strand, accomplished in spinning or playing operations. The direction of the twist may be to the right, described as Z twist, or to the left, described as S twist. See also Direction Of Twist. Z-Twist:- spinning counterclockwise. Traditionally, the direction 'plied' yarns are spun. Z-Twist conforms with the spiral portion of the letter Z. It was known formerly as Right Twist. See also S-Twist, and Twist. Z-Twist is a right-hand twisted yarn. Z Twist is a direction of the twist in yarns, from top right to bottom left, resembling the long stroke of the letter Z. Z Twist is a direction of yarn twist which gives a 'Z' like appearance to the yarn. Positive twist, or right-hand twist. / Правое направление крутки пряжи или слева вверх направо. В зависимости от направления вращения веретена крутка волокнистых материалов может быть двух разных направлений. Если смотреть на веретено сверху, то есть со стороны поступающей на веретено нити, то направление вращения веретена определит знак или направление крутки на этом участке продукта. При вращении веретена по часовой стрелке получается крутка, которую принято называть круткой Z, так как направление витков в скрученном продукте здесь будет совпадать с направлением средней части этой буквы. Иногда крутку Z называют правой круткой. В практике прядильного производства крутка S применяется редко:- ровница – всегда, а пряжа – в большинстве случаев изготовляется с круткой Z. Пряжа с круткой Z необходима в тех случаях, когда рисунок переплетения в ткани должен быть отчётливо заметен, необходимо основным и уточным нитям дать крутку одного знака – обычно Z. По направлению крутки пряжа бывает:- (i) правой крутки, которую обозначают буквой Z, и (ii) левой крутки, обозначаемой буквой S. При правой крутке витки на пряже идут слева снизу вверх направо, а при левой крутке – справа снизу вверх налево. Правую крутку обычно применяют при кручении одиночной пряжи, левую – при кручении пряжи в два сложения и более. Кручёная пряжа может быть разных видов круток. Например:- Z/S, Z/Z/S, Z/S/Z, S/Z/S и тому подобное.

ZUCCHETTO = ЗУККЕТТО (или СКУФЬЯ, или КАМИЛАВКА) – Zucchetto is a small round skullcap worn by Roman Catholic ecclesiastics in colors that vary according to the rank of the wearer. The scull cap worn by Catholic clergy is called the Zucchetto. It is similar in appearance, but not identical, to the yarmulke, which Jewish men are required to wear during any sacred ceremonies or in a sacred place. Current use is governed by a Motu Proprio of Pope Paul VI in 1968, who made the zucchetto obligatory only for members of the hierarchy. Other clerics may use it. Previously, a seminarian became a cleric on the assumption of celibacy which occurred with sub-diaconate. Since that stage leading to Sacred Orders was abolished for the Latin-Rite, a man becomes a cleric with ordination to the diaconate. (1) White – Pope. This use developed in the 1500s. Previously the popes had their own distinctive cap, called a Camauro. White became the papal color with the ascension of Pope Pius V, a Dominican, to the chair of Peter. He retained his Dominican habit. Religious orders whose habit is white, like the Dominicans and Norbertines, may also wear a white zucchetto. (2) Red – Cardinals. Pope Pius II decreed this color for cardinals in 1464. (3) Amaranth Red – Patriarchs, Archbishops, Bishops. This violet color has only been the official episcopal color since 1867, when Pius IX replaced the black zucchetto of bishops, the color previously common to all clerics below the rank of Cardinal. (4) Black – lower clergy. All priests and deacons may wear the black zucchetto, though it has fallen out of use, except in some monasteries. Noonan mentions that only Roman supply houses seem to know how to make zucchettos properly so that they hug the skull in the unique way proper to them. Other sources end up with a yarmulke-like cap (the Jewish cap), rather than the Roman zucchetto. When the zucchetto is worn it is worn outdoors, indoors and, if a bishop, in the liturgy. Other clerics are supposed to leave them in the sacristy. Within the liturgy if the prelate is not celebrating it is removed briefly when reverencing the altar. It is removed at the Sanctus and restored before the Our Father, during which it is worn. Noonan notes that some prelates have started removing them during the Gospel and Our Father, but this is against long-standing custom and law. The zucchetto is removed in the presence of the exposed Blessed Sacrament, in procession of the Blessed Sacrament and during veneration of, or blessing with, a relic of the True Cross. They are also removed in the presence of the Holy Father, except during the liturgy, when it is worn as previously stated. However, it is briefly removed as a reverential acknowledgement when addressing the Holy Father or referring to him in a liturgical or other public discourse at which he is present. / Зуккетто – маленькая круглая .

ZULU = ЗУЛУ – Zulu (pronunciation:- ZOO-loo) or Z is international nautical signal flag meaning:- I require a tug. 20% Scoring Penalty (Sailing Regatta). Meaning:- to be used to address or call shore stations. I require a tug. With one or more numerals, Zulu (GMT) time. When flown by fishing vessels:- 'I am shooting nets'.

ZULU TIME = ВРЕМЯ ЗУЛУ (или ЗУЛУССКОЕ ВРЕМЯ) – Zulu Time:- the world is divided into 24 time zones. For easy reference in communications, a letter of the alphabet has been assigned to each time zone (no letter I or O as they can be confused with numbers). The 'clock' at Greenwich, England is used as the standard clock for international reference of time in communications, military, maritime and other activities that cross time zones. The letter designator for this clock is Z. Times are usually written in military time or 24 hour format such as 1830Z (06:30 pm). To pronounce this, the phonetic alphabet is used for the letter Z, or Zulu. This time is sometimes referred to as Zulu Time because of its assigned letter. It's official name is Coordinated Universal Time or (UTC). Previously it had been known as Greenwich Mean Time or GMT but this has been replaced with UTC. Zulu +three hours is the time in Moscow, Russia. Zulu Time is the time based on Greenwich Mean Time. Zulu is a nation of Nguni-speaking people in KwaZulu/Natal province, South Africa. They are a branch of the southern Bantu and have close ethnic, linguistic, and cultural ties with the Swazi and Xhosa. The Zulu are the single largest black ethnic group in South Africa and numbered about 9 million in the late XX century. Zulu is astronautical slang for Greenwich Mean Time (GMT). / коммуникация (communication, от Латинского слова Communicare, означающее Совещаться С Кем-Либо). Время Зулу или Зулусское Время:- наша планета Земля разделёна на 24 часовых пояса или временных зоны (time zones). В средствах связи для удобства справки каждому часовому поясу предписана своя буква Английского алфавита, за исключением букв Ай. (I) и Оу. (O), дабы не возникло путаницы их с цифрами. Часы в Гринвиче, Англия используются в качестве стандартных часов для международной справки о времени в средствах связи, вооружённых силах, морском деле и прочих видах деятельности, предполагающих пересечение часовых поясов. Так получилось, что на это время была предписана буква Зэд. (Z). Разное время суток обычно прописываются во времени в вооружённых силах или 24-часовом формате следующим образом 1830Z (06:30 пп). Чтобы произнести это фонетический алфавит использует букву Зэд. (Z) или слово Зулу (Zulu). Это время иногда ещё называют как Время Зулу вследствие предписанной ему буквы. Хотя его официальным названием в настоящее время является Универсальное Координированное Время (УКВ; Coordinated Universal Time (UTC)). Раньше оно было известно как Гринвичское Среднее Время (ГСВ; Greenwich Mean Time (GMT)), но оно было заменено УКВ. Зулу +три часа является временем в Москве, Россия. Зулусское Время или Время Зулу это время, основанное на Гринвичском Среднем Времени (ГСВ; Greenwich Mean Time). Термин Зулу в данном контексте является астрономическим жаргонным термином для обозначения Гринвичского Среднего Времени (ГСВ; Greenwich Mean Time). Зулу – это народность, говорящая на языке Нгуни (Nguni) и проживающая главным образом в Провинции КваЗулу/Наталь (KwaZulu/Natal Province) Южной Африки. Эта народность является ветвью Южной Банту (Bantu) и имеет тесные этнические, лингвистические и культурные узы со Свази (Swazi) и Клхоса или Коса (Xhosa). Зулу являются

единственной крупнейшей в Южной Африке этнической группой с чёрным цветом кожи, насчитывавшей в конце XX столетия приблизительно 9 миллионов человек.

ZYGOMORPHIC = ЗИГОМОРФНОЕ – Zygomorphic is bilaterally symmetrical. Relating to a flower that can be divided into equal halves along only one line; bilaterally symmetrical. The flowers of the iris and the snapdragon are zygomorphic. Compare Actinomorphic. Zygomorphic:- the concept of symmetry is applied in botany. A flower is considered symmetrical when each whorl consists of an equal number of parts or when the parts of any one whorl are multiples of that preceding it. Thus, a symmetrical flower may have five sepals, five petals, five stamens, and five carpels, or the number of any of these parts may be a multiple of five. When the different members of each whorl are alike, the flower is regular and is referred to as Actinomorphic, or Radially Symmetrical, as in the petunia, buttercup, and wild rose. Differences in size or shape of the parts of a whorl make the flower irregular (as in the canna and Asiatic dayflower). When a flower can be divided by a single plane into two equal parts, it is zygomorphic, or bilaterally symmetrical, as in the snapdragon, orchid, and sweet pea. Zygomorphic said of a flower which can be bisected only in one plane in similar halves. Zygomorphic (Yoke Shaped, and Bilateral) flowers can be divided by only a single plane into two mirror-image halves, much like a yoke or a person's face. Examples are orchids and the flowers of most members of the Lamiales, e.g., Scrophulariaceae and Gesneriaceae. Zygomorphic flowers generally have petals of two more different shapes, sizes, and colors. Least commonly, flowers may be asymmetrical; they cannot be divided into two identical or mirror-image halves on any plane. Such flowers are typical of most members of the Zingiberales, such as cannas and various gingers. In most cases, different kinds of floral symmetry are linked to particular pollinators. Actinomorphic flowers are a basal angiosperm character; zygomorphic flowers are a derived character that has evolved many times. Some familiar and seemingly actinomorphic flowers, such as those of daisies and dandelions (Asteraceae), are actually clusters of tiny zygomorphic flowers arranged into a radially symmetric inflorescence. Most flowers are actinomorphic (Star Shaped, and Radial), meaning they can be divided into symmetrical halves by more than one longitudinal plane passing through the axis, much as a pie can be cut into several equal and identical pieces. In these flowers, the petals are usually similar in shape, size, and color. Such flowers are also called Radially Symmetrical or Regular Flowers. Examples of actinomorphic flowers are the lily (Lilium, Liliaceae) and the buttercup (Ranunculus, Ranunculaceae). See also Flower. / Смотрите также Цветок (Flower). Зигоморфный Цветок, цветок, через ось которого можно провести только одну плоскость симметрии, например, у Бобовых, Губоцветных, Орхидных. В отличие от актиноморфного цветка, имеющего не менее двух плоскостей симметрии, например, у Вишни или Мака. Под Зигоморфным Цветком, от Греческих слов Zygón, означающее Пара или Ярмо, и Morphē, означающее Форма, понимается цветок, через который можно провести лишь одну плоскость симметрии, делящую его на две части. Симметричность устанавливают по околоцветнику без учёта расположения внутренних его частей. Различают типично зигоморфный цветок (плоскость симметрии проходит через цветоножку и ось соцветия, то есть совпадает с медианной плоскостью, например, у Бобовых, Губоцветных); поперечно-зигоморфные (плоскость симметрии перпендикулярна медианной, например, у Хохлатки, Дымянки) и косозигоморфные (плоскость симметрии расположена под острым углом к медианной плоскости, например у Конского Каштана). Появление зигоморфного цветка – результат приспособления растений к опылению их определёнными насекомыми, которые проникают в цветок только из одной позиции и при этом обязательно задевают тычинки и рыльце пестика. Зигоморфный Цветок:- цветок, околоцветник которого имеет одну плоскость симметрии. Обычно эта плоскость проходит через середину прицветника, цветоножку и ось соцветия, то есть совпадает с медианной плоскостью цветка (Бобовые, Губоцветные, Орхидные); редко встречаются цветки, у которых плоскость симметрии перпендикулярна медианной плоскости (Хохлатка, Дымянка). Появление зигоморфного цветка – результат приспособления к опылению Насекомыми, которые могут проникать в цветок единственным путём.

ZYGOTE = ЗИГОТА – Zygote is a fertilized reproductive cell formed by the merging of two gametes, before any cell division occurs. Zygote is a fertilized egg formed as a result of the union of the male (sperm) and female (egg) sex cells. The zygote gives rise to the placenta (lining of the uterus) in addition to growing into (adult organism) body. Zygote is a cell formed by the union of two gametes and the individual developing from this cell. A Zygote (from Greek Zygōtos = Joined or Yoked, from Zygoun = To Join or To Yoke), is the initial cell formed when two gamete cells are joined by means of sexual reproduction. In multicellular organisms, it is the earliest developmental stage of the embryo. In single-celled organisms, the zygote divides to produce offspring, usually through meiosis. Meiosis is the formation of gametes. Mitosis is the process of cell division. A zygote is always synthesized from the union of two gametes, and constitutes the first stage in a unique organism's development. Zygotes are usually produced by a fertilization event between two haploid cells – an ovum (female gamete) and a sperm cell (male gamete) – which combine to form the single diploid cell. Such zygotes contain DNA derived from both parents, and this provides all the genetic information necessary to form a new individual. Plants:- in land plants, the zygote is formed within a chamber called the Archegonium. In seedless plants, the archegonium is usually flask-shaped, with a long hollow neck through which the sperm cell enters. As the zygote divides and grows, it does so inside the archegonium. Zygote is formed due to fusion of sperm and ovum in oviduct. Zygote is morula a mass of cells, then it undergo mitosis and cell divides and form blastocyst. Zygote undergo divisions for four days and on fifth day it forms a blastocyst. Animals:- in animal development, the term zygote is also used more loosely to refer to the group of cells formed by the first few cell divisions, although this is properly referred to as a Morula. In mammalian reproduction, after fertilization has taken place the zygote travels down the fallopian tube, while dividing to form more cells without the zygote actually increasing in size. This cell division is mitotic, and is known as Cleavage. All mammals go through the zygote stage of life. Mammalian zygotes eventually develop into a blastocyst, after which they are more generally termed an embryo, and then a fetus. A human zygote exists as a single cell before undergoing cleavage, forming blastomeres, and becomes a blastocyst on the fifth day. In other species:- a biparental zygote is a Chlamydomonas (a kind of Algae) zygote that contains chloroplast DNA (cpDNA) from both parents. / Хламидомонада (вид). Под Зиготой, от Греческого слова Zygōtós, означающее Соединённый Вместе, понимается оплодотворённое яйцо; диплоидная клетка, образующаяся у животных и растений в результате слияния двух – мужских (сперматозоиды) и женских (яйца) – половых клеток (гамет (gametes)), развивающаяся индивидуально из этой клетки и дающая начало развитию нового организма; начальная стадия развития зародыша. Как правило, имеет двойной, диплоидный (2 n) набор хромосом – один материнский и один – отцовский. Под Зиготой понимается клетка, образующаяся в результате слияния гамет. Термин Зигота ввёл в обращение Немецкий ботаник Эдвад Адольф Штрасбурга (Eduard Adolf Strasburger; 1844–1912). В отличие от гамет, зигота имеет диплоидный (двойной) набор хромосом. Зигота приступает к развитию непосредственно после оплодотворения или (у многих Водорослей и Грибов) одевается плотной оболочкой и на некоторое время превращается в покоящуюся спору, часто называемую Зигоспорой. Зигота – диплоидная клетка, образовавшаяся в результате слияния женской и мужской гамет.

ZYLON® = ЗАЙЛОН® – Zylon® fiber:- PBO (short for the Poly (p-phenylene-2,6-benzobisoxazole)) fiber is a super fiber with strength and modulus that almost doubles p-Aramid fiber. Zylon® has superior creep resistant to p-Aramid fibers and is very heat resistant, with a decomposition Temperature of 650 °C (1 202 °F) and has extremely high flame resistance. Zylon® is not light resistant and shows a

decrease in strength with exposure to sunlight. Zylon® products for outdoor use have to be protected by convering materials. Zylon® Fiber Properties:- (i) highest tensile strength and tensile modulus among high-performance fibers; (ii) creep resistant; (iii) extremely heat and flame resistant; (iv) decomposition temperature of 1 202 °F; (v) low shrinkage in hot air; (vi) strength decreases in conditions of high humidity; (vii) strength decrease with exposure to ultraviolet light and visible light; (viii) stable with most organic mediums (methanol, gasoline, brake fluid, etc); and (ix) strength decreases in exposure to strong acids. Zylon® Fiber Applications:- (i) tethers; (ii) aerospace tethers; (iii) Formula One tethers; (iv) standard rigging; (v) industrial rope and cord; and (vi) military applications. Zylon® (IUPAC name:- poly (p-phenylene-2,6-benzobisoxazole)) is a trademarked name for a range of thermoset liquid-crystalline polyoxazole. This synthetic polymer material was invented and developed by the Stanford Research Institute International (SRI International; an American nonprofit research institute headquartered in Menlo Park, State of California) in the 1980s and is manufactured by the Toyobo Co., Ltd (Osaka, Japan). In generic usage, the fiber is referred to as PBO. Zylon® has 5.8 GPa of tensile strength, which is 1.6 times that of Kevlar. Like Kevlar, Zylon® is used in a number of applications that require very high strength with excellent thermal stability. Tennis racquets, table-tennis blades, snowboards, various medical applications, and some of the Martian rovers are some of the better-known instances. / и изготавливаемое компанией Тойобо Ко., Лтд (Toyobo Co., Ltd; Осака, Япония). Кэвла®, или Кевлар® (Kevlar®), . Зайлон® представляет собой синтетический материал, весьма редко используемый в швейной промышленности. Созданный в 1980-е, Зайлон® является смесью синтетических полимеров на основе полиуретана, которая используется в тех местах, где требуется термическая стабильность и прочность. Самое известное использование (среди большинства людей) Зайлона® – изготовление ракеток для тенниса. Уникальная температурная стабильность, прочность и долговечность волокон зайлоновой нити используются в изготовлении проводящих тканей. Зайлоновые нити обшиваются проводящими металлами и вплетаются в проводящую ткань. В недавнем прошлом зайлон использовался в качестве материала для производства недорогих бронежилетов, которые часто носили сотрудники правоохранительных органов. Однако, как оказалось с течением времени, эффективность бронежилетов, сконструированных из зайлона, быстро шла на спад, и это привело к постепенному выходу из обихода жилетов из данного материала. Зайлон® – это синтетический полимер с уникальными свойствами, прочность которого в почти два раза выше чем у парарамидного волокна (Кэвла® или Кевлар®). Прочность на разрыв 1 квадратного миллиметра составляет 591 кг/мм. Волокна после производства получаются очень мягкими позволяя сплетать Зайлон® в нити и пучки. В последствии из которых можно изготовить сверхпрочный бронежилет, неразрушимый трос да и ещё много чего. На данный момент его используют в качестве армирующих нитей в ремнях ГРМ, лентах гусенечных снегоходов, а также в космической промышленности и так далее. Этот материал применяется даже в Формуле 1. Чтобы колёса болида далеко не улетели при жёсткой аварии, ступицы колёс скрепляют с монококом, прочными тросами из материала Зайлон®. Прочность это не самое интересное свойство этого уникального материала. Интересен тот факт что Зайлон® расширяется вдоль волокон при снижении температуры. Причем это свойство сохраняется вплоть до температуры жидкого гелия (–240 °C). Температурная стойкость также на высоте. Деградация волокон наступает только при нагреве его свыше 780 °C. Используя это свойство, можно шить несгораемые защитные костюмы. Естественно существует и ахелесова пята, не будь которой, материал получил бы более широкое распространение нежели сейчас, так как изобретён довольно давно, в далёких 1980-х. Суть проблемы заключается в том, что Зайлон® довольно быстро разлагается под воздействием ультрафиолетовых лучей, которых предостаточно в солнечном свете. Это накладывает некоторые ограничения на его использование. А именно:- либо использовать не долго, либо защищать от воздействия ультрафиолета. Хотя Зайлон® и обладает сверх высокой прочностной и температурной стойкостью, он довольно дёшев в производстве, что позволяет использовать его, даже в строительстве домов. Нитями Зайлон® армируют бетонные блоки, получая невероятную прочность, позволяющую строить высотные здания 500+ метров.

ZYME SYSTEM = СИСТЕМА ФЕРМЕНТОВ (или СИСТЕМА ЭНЗИМОВ) – Zyme System:- chemical reactions characterized by the presence of an inactive precursor of an enzyme. The enzyme is activated via another enzyme that normally removes an extra piece of peptide chain at a physiologically appropriate time and place. / :- химические реакции, характеризующиеся наличием неактивного предшественника фермента (или энзима). Фермент активируется через другой фермент, который обычно removes an extra piece пептидной цепи в физиологически отведённое время и место. Система Ферментов – химические реакции, характеризующиеся присутствием неактивных ферментов, приходящих в активное состояние продуктом предыдущей реакции.

ZYMOGEN = ЗИМОГЕН – Zymogen is any of a group of proteins that display no catalytic activity but are transformed within an organism into enzymes, especially those that catalyze reactions involving the breakdown of proteins. Trypsinogen and chymotrypsinogen, zymogens secreted by the pancreas, are activated in the intestinal tract to trypsin and chymotrypsin. Activation is effected by the cleavage of one or more peptide bonds of the zymogen molecule and may be catalyzed by a separate enzyme – e.g., enterokinase converts trypsinogen to trypsin – or by the active form itself – trypsin also converts trypsinogen to more trypsin. Zymogenic cells synthesize and store zymogens in inactive form. Also known as Proenzyme. Zymogens are the enzymatically inactive precursors of certain proteolytic enzymes. The enzymes are inactive because they contain an extra piece of peptide chain. When this peptide is hydrolyzed (clipped away) by another proteolytic enzyme the zymogen is converted into the normal, active enzyme. Zymogens are sometimes referred to as Proenzymes. / Известен также как Проэнзим (Proenzyme). Зимогены являются ферментативно неактивными предшественниками некоторых протеолитических ферментов. Ферменты неактивны, поскольку они содержат сверх кусок пептидной цепи. Когда этот пептид гидролизуется (отщипывается) другим протеолитическим ферментом, зимоген превращается в нормальный, активный фермент. Зимогены упоминаются иногда как Проферменты (Proenzymes). Под Зимогенами, от Греческих слов Zýme, означающее Закваска, и Genes, означающее Рождающий или Рождённый, понимаются непосредственные предшественники ферментов (энзимов), их неактивная форма; то же, что Проферменты. Зимоген – неактивный предшественник фермента, активизирующийся после появления продукта предыдущей реакции.

ZYMOGENOUS RICE BLAST = ЗИМОГЕНОВЫЙ ПИРИКУЛЯРИОЗ РИСА (или ЗИМОГЕННЫЙ ПИРИКУЛЯРИОЗ РИСА) – Zymogenous Rice Blast is a fungal disease of Rice which is characterized by the presence of spindle-shaped lesions. The lesion develops a grayish center and a brownish margin. See also Rice Blast. Blast – blighted, withered plant parts. Rice Blast:- disease. Pathogen:- Magnaporthe Oryzae (anamorph:- Pyricularia Oryzae). Hosts:- Rice (Oryza Sativa). Hundreds of millions of people world-wide depend on Rice as a staple food. A crop failure, for any reason, poses a real threat of starvation. Rice blast, caused by a Fungus, causes lesions to form on leaves, stems, peduncles, panicles, seeds, and even roots. So great is the potential threat for crop failure from this disease that it has been ranked among the most important plant diseases of them all. Other grasses, including crabgrass, are infected with closely related Fungi (Magnaporthe Grisea, Magnaporthe Poae, Magnaporthe Rhizophila and Magnaporthe Salvinii), which cause nearly identical symptoms on their respective hosts. Symptoms And Signs:- The symptoms of Rice blast include lesions that can be found on all parts of the plant, including leaves, leaf collars, necks, panicles, pedicels, and seeds. A recent report shows that even roots can become infected. However, the most common and diagnostic symptom, diamond shaped lesions, of Rice blast occur on the leaves, whereas lesions on the sheaths are relatively rare. Rice Leaves:- The symptoms on leaves may vary according to the environmental conditions, the age of the plant, and the levels of resistance of the host Cultivars. On susceptible Cultivars, lesions

may initially appear gray-green and water-soaked with a darker green border and they expand rapidly to several centimeters in length. On susceptible Cultivars, older lesions often become light tan in color with necrotic borders. On resistant cultivars, lesions often remain small in size (1–2 mm) and brown to dark brown in color. Rice Collars:- The collar of a Rice Plant refers to the junction of the leaf and the stem sheath. Symptoms of infection of the collars consist of a general area of necrosis at the union of the two tissues. Collar infections can kill the entire leaf and may extend a few millimeters into and around the sheath. The Fungus may produce spores on these lesions. Rice Necks And Panicles:- The neck of the Rice Plant refers to that portion of the stem that rises above the leaves and supports the seed head or panicle. Necks are often infected at the node by the Rice blast Fungus and infection leads to a condition called Rotten Neck or Neck Blast. Infection of the necks can be very destructive, causing failure of the seeds to fill (a condition called Blanking) or causing the entire panicle to fall over as if rotted. The Rice blast Fungus can also infect the panicles as the seeds form. Lesions can be found on the panicle branches, spikes, and spikelets. The lesions are often gray brown discolorations of the branches of the panicle, and, over time, the branches may break at the lesion. Rice Seeds:- The Fungus has often been isolated from the pedicels of the seeds. Seeds are not produced when pedicels become infected, a condition called Blanking. Symptoms of Rice blast on seeds themselves consist of brown spots, blotches, and occasionally the classic diamond-shaped lesion often seen on leaves. The process and the time during which infection of seeds by spores of the pathogen occurs has not been fully described but recent information shows that the Fungus can infect seeds by infecting the florets as they mature into seeds, and it is believed that this is the main way seed infection develops. Pathogen Biology:- The Fungus that causes Rice blast is called Magnaporthe Oryzae (formerly Magnaporthe Grisea). It is an ascomycete because it produces sexual spores (ascospores) in structures called Asci, and is classified in the newly erected Family Magnaporthaceae. The asci are found within specialized structures called Perithecia. The mycelium of Magnaporthe Oryzae is septate and the nuclei within the mycelium and spores of this Fungus are haploid. Sexual Reproduction:- The sexual, or teleomorphic, stage of the Rice blast pathogen can be produced in the laboratory if isolates of opposite mating type are paired, but has not been found in the field in the United States. As an ascomycete, it produces hyaline, fusiform shaped (spindle-shaped with tapering ends) ascospores with three septa. The asci are unitunicate. This Fungus is considered to be heterothallic with a bipolar mating system (mating controlled by two different alleles at a single locus) with additional genes controlling the sexual cycle. Based on recent phylogenetic, molecular and morphological data, isolates of the Fungus from Rice and closely related isolates from other grasses like Eragrostris Curvula, Eleusine Coracana, Lolium Perenne, and Setaria Spp. are taxonomically described as Magnaporthe Oryzae, while isolates from Digitaria Sanguinalis (Crabgrass) are distinct and should be described as Magnaporthe Grisea. Asexual Reproduction:- The asexual stage of Magnaporthe Oryzae is described by the name Pyricularia Oryzae (formerly called Pyricularia Grisea) and it is the most common spore form of the fungus in the USA. These spores, called Conidia, are produced abundantly on lesions and in culture on specialized stalks, called Conidiophores. The conidia are usually three-celled, and produced on the apex of a conidiophore. Sporulating colonies on agar plates may take on a fleecy grayish appearance. Under favorable conditions, the Fungus sporulates in the center of the lesions on susceptible cultivars. It can also sporulate on seed lesions. It rarely sporulates on the most resistant Cultivars. Spores are produced on infected leaf, collar, panicle, and seed, on conidiophores that extend beyond lesion surfaces; the conidiophores and spores en-masse may give the lesions a dusty gray appearance. Conidia are produced after several hours of high humidity and are easily released or liberated near mid-day, especially under windy conditions. The Infection Process:- Infection of Rice occurs when conidia are deposited on Rice tissues, and germinate by producing a germ tube and an appressorium. The appressorium is a melanized structure, and from it develops an infection peg which penetrates the tissue. After penetration, the primary infection hypha grows rapidly and ramifies within susceptible tissues. Growth within tissues of resistant cultivars is often inhibited. Disease Cycle And Epidemiology:- Plant diseases are often severe during periods of warm temperatures and high moisture. In the United States, Rice is grown in Arkansas, California, Florida, Louisiana, Mississippi, Missouri, and Texas. In the United States, Rice is planted mechanically as seed, while in many other countries, Rice seedlings are grown in beds and transplanted manually or by machine. Throughout the world, Rice is normally grown partially submerged in water in paddies, although in some regions Rice is grown as upland rice in much the same way as wheat. Generally, rice blast is favored by moderate temperatures (24 °C) and periods of high moisture that are 12 hours or longer, conditions readily attainable in flooded Rice fields. The overwintering sources of spores that comprise the primary inoculum consist of grasses, volunteer plants, infested refuse, and infested seed on the soil surface after mechanical planting. Infested seeds left on the soil surface can readily produce spores of Pyricularia Oryzae for more than several weeks after planting, well after seedlings have emerged. In the greenhouse, the Fungus also sporulates on the dead or dying coleoptiles of plants grown from infected seeds. Spores produced as the primary inoculum on the overwintering tissues produce the initial infections on young seedlings when the spores that are deposited on leaves, germinate and invade leaf tissues. Disease severity is often correlated with the amount of infested material. For example, in Arkansas, the first visible lesions often appear approximately 45 to 55 days after planting, but the disease is much more severe in plots receiving the highest amounts of primary inoculum found on infested seeds. Lesions on the young seedlings appear within a few days after infection. These secondary lesions produce more spores and these spores are readily wind disseminated to nearby healthy leaf tissues. The secondary cycles can be repeated many times during the growing season, with the potential for very high amounts of disease within the crop. The number of cycles and the number of spores that are produced on each individual lesion can be influenced by many factors, including the temperature, rainfall, the depth of the water in the paddy, the amount of nitrogen used to fertilize the Rice, and the level of genetic resistance in the cultivar that is infected. Generally, the leaf phase of the disease is most severe when daily temperatures are moderate, and when Rice is over-fertilized, or if it is being grown in flood waters below the recommended depths. Under these conditions conducive to disease, very high incidences of disease have been recorded on susceptible cultivars such as Newbonnet and RT7015 in comparison to cultivars genetically resistant to the Fungus. The amount of disease at the end of the vegetative phase of the growing season influences the amount of disease during the reproductive phase. Spores produced near the end of the growing season may infect the collar of the flag leaf producing symptoms called Collar Rot. They may also infect the neck when it emerges from the infected collar upon which the head will be supported to produce a condition called Rotten Neck or Neck Blast. Yield losses are significantly correlated with the extent of rotten neck. Research has shown a 0.5% loss in yield for every 1% of rotten neck. Infections of the neck are generally considered the most deleterious phase of the disease because infection at this location can reduce seed set on the entire panicle. In addition, the fungus can infect the panicle, the branches on the panicle, and the peduncles upon which the seeds are carried on these branches. Finally, new information shows that the seed also can be infected. Infections of the neck, panicle and branches of the panicle are usually relatively nondescript grayish discolorations of the tissues. Disease Management:- The successful management of Rice blast results from a comprehensive series of recommendations that employ several different management strategies involving techniques within each strategy as outlined below. Cultural strategies to manage this disease include useful techniques that Rice producers are urged to follow. Crop rotation is one simple and effective technique that is highly recommended simply because it provides a mechanism that separates viable spores in crop residue from the newly emerging seedlings. A second technique that Rice producers are urged to consider is to fertilize each of the different cultivars properly. Overuse of nitrogen fertilizers, as shown above, increases the amount of Rice blast in their fields while often failing to significantly increase yields. A third technique that is often overlooked or difficult to employ in some fields is maintaining a proper flood level for the Rice to grow. Rice blast is known to be more severe in fields or parts of fields in which the water in paddies falls below recommended levels.

Thus, Rice blast is often severe in fields that were not rotated, are under-irrigated, and are over-fertilized. Finally, using high quality and disease-free seed is always highly recommended because infested seeds left on the soil surface provide inoculum from which epidemics develop. Genetic resistance is a strategy that has long been the mainstay of successful rice production in the United States, even though the Fungus has shown genetic variability for virulence. In the United States, many Rice Cultivars contain genes that confer resistance to one or more of the individual Races of the Fungus found regionally, and many also contain a high level of resistance to the Fungus that is conferred by many other genes. The major difficulty in controlling Rice blast with genetic resistance is that there are many Races of the pathogen, and Cultivars containing a single gene conferring resistance to a specific race of the pathogen often become susceptible over time with the development of new races that can infect plants with that specific resistance gene. For example, a mutation of an 'avirulence' gene in the blast Fungus that produces an elicitor that induced the expression of resistance in the host with the Pi-ta gene for resistance has led to the formation of a new race capable of infecting plants that carry that important resistance gene, simply because the plant did not recognize the new race of the pathogen. In this way, the new race of the Fungus has eluded resistance, which means that the cultivars containing this important resistance gene are very susceptible to the new race, even though they remain resistant to the other races of the Fungus. A third strategy that has long been viewed as a last resort for Rice blast is the use of chemical fungicides to control the disease. There are two basic techniques that can be used to manage diseases with the chemical fungicide strategy. The first technique uses seed treatments to prevent infection of the seedlings after germination. The second technique uses fungicides to prevent infection of leaves and panicles during the growing season by making one or two applications of fungicides to the foliage to protect the panicles when they are emerging from the boot. This technique attempts to reduce the incidence of Rice blast on the panicle necks and panicles. Both techniques have been used to manage rice blast but neither one is considered to be highly successful. In addition, the use of foliar fungicides applied by airplanes can be very expensive. Managing Rice blast requires vigilance and careful integration of many strategies and techniques learned in all parts of the world by the individual Rice producer. A single mistake can result in crop failure from this one important plant disease. Significance Of The Disease:- Rice is the staple food crop for a large part of the human population in the world today. Rice blast is by far the most important disease of the many diseases that attack Rice. It is found wherever Rice is grown, it is always important, and it is always a threat. Failures of entire rice crops have resulted directly from rice blast epidemics. The challenge for research continues to be to produce high quality food, in ever-increasing amounts at a lower costs, all while in the presence of an unforgiving and unrelenting pathogen. All of the plant disease management strategies and techniques that have been generated through research have been brought to bear against Rice blast, but often with limited success. Rice blast has never been eliminated from a region in which Rice is grown, and a single change in the way in which Rice is grown or in the way resistance genes are deployed can result in significant disease losses even after years of successful management. This disease is a model that demonstrates the seriousness, elusiveness, and longevity of some plant diseases. Rice blast has been widely studied throughout the world. Many investigators have considered it to be a model disease for the study of genetics, epidemiology, molecular pathology of host parasite interactions and biology. Recent advances in understanding the genes that govern the avirulence (resistance) and virulence (susceptibility) interactions have been made with Rice blast, and each advance has helped us to understand how other plant diseases work. It is also important to note that the entire genomes of the Rice blast Fungus and Rice have been sequenced and that M. Oryzae is the first plant pathogenic Fungus to have its genome sequenced and released to the public. / Зимогенный Пирикуляриоз Риса – это грибковая болезнь Риса, которая характеризуется наличием поражений веретеноподобной формы. Поражение проявляется в виде сероватого центра и буроватых краёв (переферии). Смотрите также Пирикуляриоз Риса (Rice Blast). Пирикуляриоз – поражённые, засохшие части растения. Запал, гниль узла метёлки. Под Пирикуляриозом Риса понимается болезнь, вызываемая паразитическими Грибами. На листьях, стеблях, метёлках и семенах пятна различной формы и окраски. Стебли ломаются, семена щуплые. Пирикуляриоз Риса – опасное заболевание Риса, вызываемое несовершенным Грибом Piricularia Oryzae. Распространён во всех рисосеющих районах мира. Проявляется образованием пятен различной формы и окраски на листьях, листовых влагалищах, стеблевых узлах, метёлках и семенах. Поражённые листья отмирают, стебли ломаются, метёлки преждевременно засыхают или образуют щуплые семена. Наибольший вред приносит пирикуляриоз Риса во время колошения-цветения. Потери урожая 15–40%. Значительно снижается и качество зерна. При эпифитотии растения гибнут. Возбудитель болезни в период вегетации имеет несколько поколений, распространяется с помощью конидий, зимует в форме мицелия на послеуборочных остатках (1–3 года) и в семенах. Развитие пирикуляриоза Риса происходит при высокой влажности воздуха (не ниже 88%) и температуре 15–35 °С. Возможна передача инфекции с поливной водой. Резерватором возбудителя пирикуляриоза Риса могут быть также дикие формы Риса и другие Злаки. Меры борьбы:- возделывание устойчивых Сортов; запашка пожнивных остатков; сжигание стерни на участках с сильным развитием болезни; обработка заражённых посевов и протравливание семян Риса фунгицидами. Другой Класс составляют Зимогенные Бактерии, они вызывают различные процессы брожения.

PREFACE TO ALPHABETICAL INDEX

The following alphabetical index contains Russian terms to be found in the main text of the glossary beside the corresponding English keywords.

Where the Russian term is a translation of more than one English term, the English terms will be separated by a semi-colon. English terms separated by a slash are single entries in the main text.

ПРЕДИСЛОВИЕ К АЛФАВИТНОМУ УКАЗАТЕЛЮ

Приводимый алфавитный указатель содержит Русскоязычные термины, которые должны быть найдены в основном тексте этого толкового словаря рядом с соответствующими Англоязычными ключевыми словами.

Там, где Русскоязычный термин является переводом более одного Англоязычного термина, Англоязычные термины будут приводиться на новой строке с отделением полу-колонкой (отступом). Англоязычные термины, отделённые друг от друга дробью, являются единственными вставками в основном тексте.

На дату публикации данный указатель находится в стадии наполнения в качестве частичного примера того, что будет в готовой книге.
